McArdle's disease – is the most common form of these disorders. Deficiency of myophosphorylase results in failure of breakdown of glycogen to glucose in muscle. Severe myalgia with cramp develops soon after start of exercise, but the patient may notice easing of symptoms as exercise continues ('second-wind' phenomenon), as alternative energy sources are mobilised. The disease can be diagnosed from absent phosphorylase on muscle biochemistry.

Mitochondrial disorders – can affect muscle specifically or as part of multisystem disease, typically involving the CNS. Large deletions of mitochondrial DNA commonly underline Kearns-Sayre syndrome and chronic progressive ophthalmoplegia. Point mutations cause a variety of syndromes including mitochondrial encephalopathy, lactic acidosis and strokes (MELAS) and myoclonus, epilepsy and ragged red fibres (MERRF). Diagnosis by demonstration of:

- Increased blood plasma lactate and CSF lactate
- Inappropriately large increase in plasma lactate on exercise testing
- Typical histochemical features (e.g. ragged red fibres and cytochrome - negative fibres on muscle biopsy).

OTHER DISORDERS

Malignant hyperthermia characterized by hyperpyrexia, rhabdomyolysis and severe acidosis induced by inhaled anaesthetic agents (halothane) or muscle relaxant (succinylcholine) is relatively common and genetically heterogeneous. Other manifestations include muscle rigidity, cardiac arrhythmia, hypotension and cyanosis. Complications – Pulmonary oedema, DIC, acute kidney failure, swelling of skeletal muscles (Refer Tropical disease section). Mutations at one malignant hyperthermia locus on 19q13.1 (ryanodine receptor) also determines a congenital myopathy (*central core disease*).

King syndrome – is an AR form of malignant hyperthermia associated with congenital defects such as short stature, webbed neck, kyphosis, low-set ears, antimongoloid obliquity of palpebral fissures of eyes and winged scapulae.

ACQUIRED MYOPATHIES

Inflammatory Myopathies

Inflammatory myopathy can result from a variety of acute infections, including HIV, but the idiopathic forms of polymyositis and dermatomyositis are most common.

Polymyositis typically presents with symmetrical proximal weakness, often associated with myalgia and muscle tenderness. Progression may be rapid, but more indolent forms may occur, particularly in older women.

Investigations – CK is usually raised. EMG shows a mixed picture of increased insertional and spontaneous activity ('myogenic denervation') and 'myopathic' changes (rapid recruitment of small amplitude, polyphasic potentials on contraction). Muscle biopsy typically shows lymphocytic infiltration of muscle connective tissues, with fibre necrosis, degeneration and regeneration, but the process is patchy and inflammation may be inconspicuous. Demonstration of HLA class antigens on fibres by immunohistochemistry, indicative of an immune reaction, is then invaluable for diagnosis.

Dermatomyositis is essentially an immune-mediated microangiopathy affecting principally skin and muscle, though childhood dermatomyositis can include gut involvement, resulting in GI hemorrhage. Skin lesions are diagnostic – erythema affecting light-exposed areas such as the supraorbital ridges, eyelids and malar areas, chest, knuckles, knees and elbows. Skin lesions may sometimes occur without muscle weakness, but careful investigation

usually confirms muscle involvement. There is an association between dermatomyositis and underlying malignancy and this should be of consideration in men with dermatomyositis presenting over age of 55 years.

Management – Treatment begins with i.v. immunoglobulin 0.4 g/kg/day for 5 days, followed by high oral dose corticosteroids 1 mg/kg p.o., with azathioprine 1–2 mg/kg. Dose of corticosteroid should be tapered reasonably rapidly, depending on clinical response and serial CK measurements, and switched to alternate-day regimen after about one month. Use of etidronate with calcium supplements can help prevent corticosteroid-induced osteoporosis. Avascular necrosis of femoral head is a rare complication.

Inclusion body myositis – is the most common cause of acquired myopathy in those over age of 50. It has many common features with polymyositis, but tends to be indolent in progression, is not associated with myalgia and causes marked muscle wasting, particularly distally. *Muscle biopsy* is diagnostic. Up to 10% fibres show ‘rimmed vacuoles’ – areas of probable nuclear dissolution containing a number of aberrant proteins, including β -amyloid and hyperphosphorylated tau protein, strikingly reminiscent of changes in the brain in Alzheimer's disease. Response to immunosuppressive treatment is usually minimal and progression is inevitable.

Myopathies in systemic disease – Muscle can be involved directly as in infectious diseases, or indirectly through the effects of metabolic derangements or immune responses. Myopathy can be a feature of any endocrine disorder and can be affected by a variety of drugs.

Specific congenital myopathies – are rare disorders which present with undue floppiness in infancy – (1) *Central core disease* – is characterised by presence of one or more cores which run axially along the fibres. The disease is compatible with a normal ambulant life. Risk of developing malignant hyperpyrexia. (2) *Nemaline myopathy* – runs a benign course in childhood but may later progress. Skeletal abnormalities such as scoliosis, high arched palate, arachnodactyly.

METABOLIC MYOPATHIES

Clinical Patterns

1. **Infantile hypotonia** (Floppy infant syndrome) due to acid maltase deficiency.
 - (a) *Infantile form* – Heart, liver and muscles involved with failure to thrive and death within first year.

- (b) *Childhood and adult varieties* – Glycogen accumulation only in skeletal muscle. Slowly progressive limb-girdle syndrome, often with hypertrophy of lower limbs. Respiratory muscle involvement in 50%, and often causes death.
2. **Limb-girdle myopathies** – Relatively late-onset myopathy.
 - (a) *Benign acid maltase deficiency* – with glycogen storage in childhood, adolescence or early adulthood.
 - (b) *Carnitine deficiency* – (i) Systemic deficiency – Intermittent attacks of hepatic enlargement and insufficiency, associated with hypoglycemia and encephalopathy. Pre-myopathic phase of 2–10 years before onset of muscle weakness. (ii) Muscle carnitine deficiency – Presents as limb-girdle syndrome in childhood or early adult life, and is progressive. Cardiac involvement is cause of death in later stages.
 - (c) *Mitochondrial disorders* – usually result of disorders of respiratory chain function. Late-onset limb girdle myopathy sometimes accompanied by prolonged paralytic attacks (at times involving bulbar and ventilatory functions) and precipitated by exercise, exposure to cold or excessive alcohol intake. ‘Ragged red’ fibre appearance on muscle biopsy.
 3. **Exercise-induced cramps with myoglobinuria** – at rest or on exertion. *Types* – (i) Myophosphorylase deficiency with defect in glycolysis (McArdle's disease). Cramping pains on exercise. (ii) Carnitine palmitoyl transferases (CPTI and II deficiency) – causing defective fatty acid oxidation. Late onset cramps (more than 3 hours after exercise). (iii) AMP deaminase deficiency – Disorder of purine nucleotide metabolism. Occasional cases (including families).
 4. **Chronic progressive ophthalmoplegia plus (CPEC+)** – Most disorders associated with ‘mosaic’ cytochrome oxidase deficiency. Generalized disorder with involvement of extra-ocular muscles and limb girdles (mildly). Mitochondrial cytopathy is common to all clinical syndromes.

ENDOCRINE MYOPATHIES

1. **Acromegaly** – A mild myopathy may develop in long-standing cases.
2. **Hyperthyroidism** – (a) Proximal myopathy common. (b) Myasthenia gravis is an uncommon complication. (c) Chronic thyrotoxic myopathy is associated

Table 72: Muscle cramps or pain on exercise

- Disorders of glycogenolysis or glycolysis (e.g. McArdle's disease).
- Mitochondrial myopathies, including zidovudine toxicity.
- Toxic myopathy caused by drugs.
- Dermatomyositis.
- Myopathy caused by deficiency of carnitine palmitoyl transferase.
- Hypothyroid myopathy.

Table 74: Early or prominent bulbar muscle weakness

- Mitochondrial myopathies – external ophthalmoplegias.
- Oculopharyngeal dystrophy – blepharoptosis, EOP, dysphagia.
- Myotonic dystrophy – temporal m. wasting, facial diplegia, blepharoptosis.

Table 76: Respiratory insufficiency

- Adult-onset maltase deficiency.
- Acute myopathy after high-dose corticosteroids and muscle paralyzing agent.
- Myotonic dystrophy.
- Nemaline myopathy.
- Myopathy with cytoplasmic bodies.

with fasciculations and hyperactive tendon reflexes. (d) Attacks of hyperkalaemic periodic paralysis may occur.

Primary hyperparathyroid myopathy is limb girdle muscle disease in patients with muscle weakness and exaggerated reflexes. It is completely reversible with surgery of parathyroid adenoma

3. *Hypothyroidism* – may be associated with mild proximal weakness, muscle cramp, slowness of contraction, myoedema and delayed tendon reflexes.
4. *Cushing's syndrome and steroid myopathy* – present with proximal weakness, often confined to lower limbs.
5. *Primary hyperaldosteronism* – Episodes of prolonged and severe weakness associated with hypokalaemia.

TOXIC MYOPATHIES

1. Alcohol – (a) *Acute alcoholic myopathy* – induced by heavy drinking in chronic alcoholics. Presents with acute muscle pain, tenderness and weakness, sometimes associated with myoglobinuria, hyperkalaemia and renal impairment. (b) *Subacute alcoholic myopathy* – presents insidiously with proximal weakness often confined to lower limbs.

Table 73: Myoglobinuria

- Disorders of glycolysis or glycogenolysis.
- Carnitine-palmitoyl transferase deficiency.
- Malignant hyperthermia crisis.
- DMD after anaesthetic exposure.
- Acute alcoholic myopathy.
- Acute viral myositis.

Table 75: Clinical myotonia

- Myotonic dystrophy (adults).
- Myotonia congenita.
- Paramyotonia congenita.
- Myxoedema myopathy.

2. Drug-induced myopathies – (a) *Mechanism unknown* – Heroin, amphetamine, clofibrate, chloroquine, aminocaproic acid, vincristine, cimetidine, isoetharine, statins, steroids, phencyclidine. (b) *Due to marked hypokalaemia* – Diuretics, purgatives, liquorice, carbenoxolone, amphotericin B.

Distinguishing clinical features of common myopathies (Tables 72 to 76).

Investigations

1. *Serum creatine kinase (SCK)* – if elevated indicates muscle damage or necrosis. Very high values in DMD dysferlinopathy and some metabolic myopathies (malignant hyperthermia, acute alcoholic myopathies).
2. *EMG and nerve conduction studies* – confirm the diagnosis of either a myopathy and/or neuropathy.
3. *Muscle biopsy* – provides conclusive evidence.
4. *Molecular genetic analysis* – can diagnose symptomatic and presymptomatic hereditary diseases. It can also detect carriers and be suitable for prenatal diagnosis.
5. *Muscle imaging by CT or MRI* – can establish the distribution and degree of involvement in individual muscles. This may be diagnostically helpful or indicate a suitable site for biopsy. In vivo ³²P or proton-based magnetic resonance spectroscopy are particularly useful to differentiate some cases of metabolic myopathies from chronic fatigue syndrome and fibromyalgia.
6. *Miscellaneous tests* – Biochemical methods to analyse deficiency states (e.g. glycogenolytic enzyme defects, carnitine deficiency). Immunological and serological studies for investigating inflammatory myopathies or retroviral diseases.

Management

1. *Treatment of cause where possible* – e.g. cessation or reduction of corticosteroids together with high protein diet in steroid myopathy, correction of endocrinopathy.
2. *Drug therapy* – In DMD, muscle destruction can be slowed and clinical course stabilised by oral prednisolone or deflazacort 0.75 mg/kg/day. Mexiletine controls myotonia in myotonia congenita and paramyotonia congenita.

Acetazolamide or spironolactone for preventing acute attacks of hyperkalaemic periodic paralysis. Dantrolene for prevention and treatment of malignant hyperthermia crisis. Some mitochondrial myopathies respond to graded muscle conditioning aided by oral dichloroacetate.

MYOTONIC DISORDERS

Failure of voluntary muscle to relax immediately innervation ceases.

1. *Myotonic Dystrophy* (Dystrophia myotonica):
 - (i) *Onset* – Most patients present in adult life with distal weakness and wasting in upper or lower limbs.
 - (ii) Muscle weakness/wasting:
 - (a) Myopathic facies – Ptosis, hanging jaw, haggard appearance, temporal wasting.
 - (b) Weakness of neck flexion, wasting of sternomastoids.
 - (c) Distal limb weakness with wasted brachioradialis.
2. Frontal baldness. Hyperostosis frontalis interna.
3. Cataracts (post. subcapsular)
4. Cardiac conduction defects (Heart block, atrial arrhythmias) Cardiomyopathy.
5. Hypoventilation, post-anaesthetic respiratory failure.
6. Hypersomnolence, mental retardation.
7. Hypogammaglobulinaemia.
8. End-organ resistance to insulin (impaired glucose tolerance).
9. Dysphagia, oesophageal dilatation.

Investigations – (a) CPK - Normal or slightly elevated. (b) EMG - Characteristic myopathic picture with myotonic discharges. (c) Muscle biopsy - Chains of central nuclei, marked variation of fibre size and selective atrophy of type I fibres.

Treatment – Quality of speech may be improved by procainamide 250 mg t.d.s. or phenytoin 100 mg t.d.s.

1. *Myotonia congenita* – (i) *Thomsen's disease* (AD) – begins in infancy and affects entire voluntary musculature giving rise to generalised muscular stiffness. (ii) *Becker's Disease* (AR) – usually begins later in childhood and is characterized by striking muscular hypertrophy giving the patient a *Herculean appearance*. 'Startle' myotonia may often be present.
2. *Congenital myotonic dystrophy* – can occur in an infant born of a mother with myotonic dystrophy. Features are marked hypotonia, feeding difficulties, areflexia and respiratory insufficiency. About half die in infancy, and those who survive show classical picture of myotonic dystrophy before age of 10.
3. *Paramyotonia congenita* – Generalised myotonia accentuated by cold and accompanied by episodes of weakness related to disturbance of potassium metabolism.

23. MYASTHENIA GRAVIS

Myasthenia gravis is an autoimmune disease in which antibodies are directed against muscle acetylcholine receptors (AChRs) on the postsynaptic membrane of the neuromuscular junction.

CLASSIFICATION

Myasthenia gravis patients can be divided into antibody-positive and antibody-negative, and into four subgroups that may be useful in determining treatment:

- An early onset group (age <40 years) with hyperplasia of the thymus. HLA B8 and DR3 association and 4:1 female:male ratio
- A late-onset group without thymic hyperplasia, HLA B7 and DR2 association and 1:2 female:male ratio
- Patients with thymoma, who have no HLA association and 1:1 sex ratio
- Patients with ocular myasthenia gravis

PATHOGENESIS

Up to 70% of AChR negative myasthenia patients (seronegative myasthenia gravis) have antibodies to muscle tyrosine kinase MUSK in 85% of patients with generalized disease and in 50% of those with isolated ocular symptoms. Binding leads to down-regulation of AChRs via cross-linking, complement-mediated lysis and possibly direct blockade of AChR function. It is the reduction of functional AChRs that is responsible for the clinical picture.

Transient neonatal myasthenia caused by placental transfer of AChR antibodies occurs in 8% of babies born to mothers with myasthenia gravis.

The thymus gland is thought to have an important role in the pathogenesis. The normal thymus is a source of AChR, and expression may be up-regulated in patients with thymoma. The thymus is also thought to be involved in deleting autoreactive T cells specific for cell antigens, and therefore any disruption of function would allow escape of such cells. In addition, the hyperplastic thymus may be a site of anti-AChR antibody production.

Penicillamine treatment is a rare cause of myasthenia gravis seen in rheumatoid arthritis, and usually resolves on drug withdrawal.

CLINICAL FEATURES

- Ocular muscles - Patients typically present with weakness of ocular muscles causing variable ptosis and diplopia. Up to 20% of cases involve ocular muscles only (ocular myasthenia).
- Fatiguability - Increase in weakness on repeated use of muscles, worsening of weakness towards the end of the day. Improvement in muscle strength after rest are characteristic features.
- Limb weakness - In generalized disease, weakness of the limbs affecting proximal muscles, elbow extension and finger extension is common.
- Facial involvement may cause difficulty with eye closure and a snarling smile, and weakness of jaw muscles difficulty in chewing.
- Trunk involvement can occur.
- Respiratory muscle involvement can be life-threatening. Shortness of breath, particularly on lying flat (diaphragmatic weakness) is common. Reduced arterial oxygen capacity is a late sign of respiratory failure.
- Bulbar symptoms, e.g. nasal speech and nasal regurgitation may occur. Severe dysphagia may necessitate tube feeding.
- Weakness of neck muscles may cause head dropping. Muscle wasting is not a feature, tendon reflexes are well retained.
- Slow ventilatory recovery from general anaesthesia following use of curare-like muscle relaxants can be a first presentation.

Myasthenic crisis. It is characterized by weakness of intercostal and other respiratory muscles. The crisis because of acute respiratory failure.

Precipitating Causes - Intercurrent infection, physical fatigue, emotional stress, pregnancy, use of aminoglycosides, anaesthetic agents causing muscular paralysis.

Diff. Diag. TB syndrome, acute poliomyelitis, other hypercapnia syndromes (if respiratory muscles are chiefly involved, botulism, snake poisoning (krait, cobra bite) acute tubular acidosis (due to severe hypokalaemia), familial periodic paralysis.

Management. Intubation and ventilation, also use of pyridostigmine, steroids, immunoglobulins and even plasmapheresis.

INVESTIGATIONS

Anti-AChR antibodies are detectable in the serum of most patients. A negative result does not exclude the diagnosis, and is common in the pure ocular form.

RNS (Repetitive Nerve Stimulation) - shows decreasing muscle action potential with rapid stimulation. Increased jitter and blocking is found on single-fibre EMG. Abnormal single fibre EMG can be found in motor neuron disease and some myopathies.

Prostigmine test - 1-1.5 mg of prostigmine by IM injection. Improvement in muscle power in 15-30 mts, if patient myasthenic.

Serum AChR antibodies are most commonly associated with thymoma.

Autoantibodies to acetylcholine receptors are positive.

Chest CT/mRI to identify any associated thymoma (Figs. 62 and 63).

Differential diagnosis - Difficulties arise in patients who are antibody negative. (a) Lambert-Eaton myas-

Fig. 62: CECT axial view showing thymoma (arrow)

Fig. 63: CECT coronal view showing thymoma (arrow)

thenic syndrome (*see further*). (b) Congenital myasthenic syndromes – should be considered in early-onset cases, particularly those with family history of similar disease. (They do not respond to immunotherapies). (c) Chronic progressive external ophthalmoplegia can mimic ocular symptoms of myasthenia, though fatigue is not typical.

Plus minus lid syndrome with ataxia. It is an acquired neurological abnormality of eyelid position with unilateral ptosis and contralateral eyelid retraction. This association has been described in ocular myasthenia, after lesions of oculomotor nerve, ocular myositis and paramedian mesencephalic diencephalic lesions

MANAGEMENT

Drug Therapy

Anticholinesterase – first line treatment – Pyridostigmine 60 mg qds or Neostigmine 30 mg qds. Cholinergic side-effects (abdominal cramps, diarrhoea) can be controlled with probanthine bromide 15 mg tds. A pyridostigmine replacement of more than 90 mg qds indicates need for immuno-suppression.

Corticosteroids: Prednisolone dose – (a) For myasthenia of ocular muscles 10 mg on alternate days initial, increase by 5 mg every 5 days to dose of 1 mg/kg body weight (b) Azathioprine for steroid sparing effect. Dose 50 mg/d, increased every 2 week by 50 mg till total dose of 2.5 mg/kg. Blood counts and LFTs should be checked once in 2 weeks because of its adverse effects. It takes about 6 months for Azathioprine.

Once there is remission of myasthenia, prednisolone is slowly reduced to 5 mg per dose every month till dose

of 20 mg on alternate days, subsequently dose is further reduced by 1 mg per dose every month till the drug is stopped and continue Azathioprine only if possible.

Other drug therapies – if patient responds inadequately to above regimen – (a) *Cytotoxic agents* such as cyclosporine or methotrexate. (b) *Plasma exchange* – 3–5 daily exchanges of 2–3 litres. (c) IV *immunoglobulin* 0.4 g/kg/day for 5 days in myasthenic crisis.

Mycophenolate mofetil, azathioprine, cyclosporine, tacrolimus, rituximab and occasionally cyclophosphamide are effective in many patients, either alone or in various combinations.

Thymectomy

Indications – Patients <40 years of age who have strongly positive antibody test (i.e. high titre of antibodies to acetylcholine receptors) and have thymic hyperplasia on imaging studies. Thymoma is an indication for surgery with or without postoperative radiotherapy to treat the tumour. Thymectomy should be carried out in all patients with generalized MG who are between the ages of puberty and at least 55 years.

LAMBERT-EATON MYASTHENIC SYNDROME

LEMS is an autoimmune disorder of the presynaptic neuro-muscular junction caused by antibodies to the voltage-gated calcium channels situated at the nerve terminus.

Aetiology and pathogenesis – LEMS is more common after age of 50; 60% cases are associated with small cell lung cancer. A predisposition to other autoimmune diseases is also seen.

Antibodies to P/Q-type voltage-gated calcium channels on the presynaptic membrane of the neuromuscular junction are detectable by radioimmunoprecipitation assay in 95% of patients. Association with small lung cell cancer is thought to result from crossreactivity of autoantibodies to voltage-gated calcium channels on the malignant cells with those situated at the neuromuscular junction.

Clinical features – (a) Proximal muscle weakness is the most common presentation. It may be followed by upper limb weakness. (b) Autonomic symptoms – Dry mouth, constipation, impotence. (c) Diplopia is uncommon and tendon reflexes tend to be exaggerated particularly in lower limbs in contrast to myasthenia gravis.

Investigations – Highly specific voltage-gated calcium channel antibodies are detectable in the serum in most patients. Compound action muscle potentials are reduced and increase by more than 100% after high-frequency nerve stimulation or maximal voluntary contraction. (c) Chest CT for small lung cancer.

Management – 3,4-diaminopyridine (3,4-DAP) qds. usually improves symptoms in most patients. Immunosuppression is effective in non-cancer LEMS. Azathioprine is contraindicated in presence of malignancy. Treatment of the tumour can lead to resolution of LEMS. Plasma exchange and immunoglobulin can be useful in treatment of severe symptoms, but the effect wears off after a few weeks.

24. MUSCULAR WASTING

Table 77 lists the causes of muscle wasting.

INVESTIGATION OF A CASE OF MUSCULAR WASTING

I. History

- Family history** – in Autosomal dominant disease, e.g. HMSN.
- Age of onset** – Muscular dystrophy, poliomyelitis and diphtheritic paralysis in infancy and childhood; motor neuron disease in second half of life, peroneal muscular atrophy and wasting of cervical rib presents in early adult life, cervical spondylosis usually after 45.
- Mode of onset** – Rapid in poliomyelitis and acute radiculitis. More gradual in diphtheritic paralysis, cervical spondylosis or tumour, and infective polyneuritis. In spinal lesions, atrophy usually precedes weakness, in polyneuritis, weakness precedes atrophy.
- Symmetry** – Symmetric and proximal in muscular dystrophies, symmetric and distal in axonal neuropathies.
- Asymmetry** – in MND, benign focal amyotrophy, radiculopathy.
- Progressive** – Muscular dystrophies, MND, hereditary neuropathies.
- Static** (following an initial progression) – Axonal GBS, monomelic amyotrophy.
- Associated discomfort** – Muscle pain – at rest can occur in polymyositis, polymyalgia rheumatica, acute myoglobinuric myopathy and in myopathies of metabolic bone disease. Episodic pain, which may at times be associated with weakness, suggests a metabolic

Table 77: Causes of muscle wasting

A. Neuromuscular causes

1. Primary muscular diseases

- Muscular dystrophies (LGMD, DMD, BMD, myotonic dystrophy).
- Inflammatory muscle diseases – Polymyositis, dermatomyositis.

2. Anterior horn cell diseases

- Motor neuron disease (ALS, progressive muscular atrophy).
- Benign focal amyotrophy (monomelic amyotrophy), spinal muscular atrophy (Werdnig- Hofmann, Welander, Adult SMA, bulbospinal atrophy).
- Infection like poliomyelitis, West Nile fever.

3. Root lesions – Radiculopathies due to spondylosis, spinal neoplasms.

4. Plexopathies – Idiopathic brachial plexopathy (Parsonage Turner syndrome), radiation plexopathy, diabetic lumbosacral plexopathy (diabetic amyotrophy).

5. Neuropathies

- Axonal neuropathies, e.g. HMSN 2, Axonal GBS.
- Compression neuropathies, e.g. carpal tunnel syndrome leads to ulnar wasting, ulnar neuropathy at elbow leads to hypothenar and interossei wasting, common peroneal neuropathy at fibular head (peroneal muscle wasting).
- Infection like leprosy leads to wasting in distribution of affected nerve.

6. Myoneural junction disorder – Myasthenia gravis (muscular wasting very rare).

B. Disuse atrophy

- In UMN lesions, e.g. strokes, cerebral neoplasms.
- Due to pain as in arthritis, following fracture.

C. Systemic generalized wasting – HIV, malignancy, thyrotoxicosis, TB.

disorder. Pain that develops during exercise is considered to be characteristic of McArdle's disease, though it can occur in other metabolic myopathies (e.g. mitochondrial myopathies). Pain that follows exercise by a few hours usually occurs in disorders of lipid metabolism.

II. Examination

1. Distribution of wasting:

- Proximal wasting** – Muscular dystrophies, lumbosacral plexopathy, brachial plexopathy.
- Symmetric distal wasting** – Calf, hand and forearm wasting in axonal neuropathies.
- Wasting of small muscles of hand** – C8 to T1 radiculopathy, syringomyelia, lower cervical cord tumors, onset of MND, distal muscular dystrophies, carpal tunnel syndrome (wasting of thenar muscles), ulnar neuropathies (wasting of interossei and lumbricals III and IV), multifocal motor neuropathy with conduction block. Lower brachial plexus lesions (radiation or tumors).

- (d) *Wasting of legs* - Peroneal muscle wasting in pseudoneuritic presentation of MND, common peroneal neuropathy, HMSN, cauda lesions, L5-S1 radiculopathy.
- (e) *Cranial muscle atrophy* - FSHD, oculopharyngeal muscular dystrophy, MD.
- Pseudohypertrophy** - BMD, DMD, myotonia congenita.
 - Muscle tenderness** - None in dystrophy, motor neuron disease, and syringomyelia. In arthritic atrophy and cervical rib pressure, affected muscles are tender to pressure while the wasting process is active. In carpal tunnel syndrome production of typical symptoms by digital compression of median nerve in region of transverse carpal ligament or by forcible flexion of the wrist for one or two minutes.
 - Fasciculations** - Absent in MND, monomelic amyotrophy, syringomyelia, radiculopathy. Fasciculatory tremors in neuropathies.
 - Myotonia** - in myotonic dystrophy. In longstanding cases however, grip myotonia may not be evident because of progressive wasting.
 - Evidence of other signs of diseases in the nervous system** - (i) Monoplegia or hemiplegia in disuse or post-paralytic atrophy. (ii) Bulbar paralysis in motor neuron disease. (iii) Pain in neck and shoulder in radiculitis. (iv) CSF changes in spinal block. (v) Treponemal antibodies in syphilitic amyotrophy. (vi) Blue line on gums, and anemia in lead poisoning.
 - Thickening of peripheral nerves** - (a) Single nerve thickening in neoplastic process, e.g. neurofibroma, Schwannoma, malignant nerve sheath tumour, localized peripheral hypertrophic neuropathy. (b) Generalized thickened nerves - Leprosy, acromegaly, neurofibromatosis, amyloidosis, chronic inflammatory demyelinating polyradiculoneuropathy, peroneal muscular atrophy, lymphoma infiltration, Refsum's disease.
 - Sensory loss** - Glove and stocking in axonal neuropathy, radicular distribution in radiculopathies, in nerve distribution in ulnar, median, common peroneal neuropathies. Dissociated sensory loss in syringomyelia. No sensory loss in ALS.
 - Reflexes** - Absent or depressed reflexes in upper limbs and present in lower limbs in syringomyelia. Exacerbated in presence of wasting in ALS. Absent in radiculopathies in the involved segment. Absent ankle reflex in axonal neuropathies.

III. Investigations

- Haematological and biochemical** - to demonstrate nature of primary disorder to which muscular wasting is secondary in case of systemic, inflammatory or metabolic disease.
- Serum creatine kinase (CK)** - Very high levels in Duchenne and Becker dystrophies, acute polymyositis, and acute myoglobinuric myopathies. In other myopathies it may be normal or only moderately raised.
- EMG** - Large, wide polyphasic motor unit potentials in neuropathic wasting; small, short, polyphasic potentials in myopathic wasting.
- NCS** - Small compound muscle action potential amplitude in axonal neuropathies. Normal in myopathies.
- Muscle biopsy and immunochemistry** - Normal in muscular dystrophies, polymyositis, dermatomyositis. Neurogenic atrophy can be confirmed in case of doubt.

25. PERIPHERAL NEUROPATHY

PATHOPHYSIOLOGY

A peripheral nerve comprises about six fascicles, each containing many myelinated and unmyelinated axons. Each fascicle has small nutrient blood vessels integral to the function of the nerve. Disorders of peripheral nerves can primarily damage myelin (e.g. Guillain-Barre syndrome) or the axons (e.g. vincristine, other drugs), or interfere with blood supply of the nerve leading to areas of necrosis in the distribution of small nutrient vessels (e.g. polyarteritis nodosa), vasculitis.

Many toxic processes that produce slowly progressive damage to nerve cell bodies lead to a 'dying-back' type of neuropathy, in which the longest axons show damage initially and neuropathic symptoms ascend from the feet, i.e. distal to proximal progression.

Some pathological processes selectively affect small unmyelinated nerves (e.g. alcohol, amyloid), leading to characteristic autonomic disturbances and pain seen in these neuropathies. Vasculitic disorders often lead to multiple, random pathologic lesions within the nerve (mononeuritis multiplex).

CLASSIFICATION

Peripheral nerve disease can be classified according to -

- Clinical classification,
- Generalized neuropathy, whether pathological process is axonal or demyelinating,
- Predominantly sensory or predominantly motor forms.

A. Clinical Classification

1. **Mononeuropathy or focal neuropathy** – Single nerve involved.

(a) Compression – e.g. compression of radial nerve against humerus (Saturday night palsy).

(b) Entrapment.

Carpal tunnel syndrome – Compression of median nerve as it passes through the carpal tunnel in the flexor retinaculum at the wrist. *Causes* – (i) Wrist fracture. (ii) Arthritis of the wrist particularly RA. (iii) Soft tissue thickening in myxoedema and acromegaly. (iv) Oedema, notably associated with pregnancy. Obesity. (v) No obvious cause. More common in women. *Symptoms* – Pain, numbness and paraesthesiae in the hand. Pain may radiate through forearm and occasionally involve the whole arm. Typically pain is most troublesome at night or first thing in morning. *Signs* – Weakness of abductor pollicis brevis, with or without wasting, and also weakness of opponens. Sensory impairment – of median distribution. Positive Tinel sign – Gentle tapping over carpal tunnel causes paraesthesiae in part of the cutaneous distribution of the nerve. Phalen's sign – Carpal tunnel symptoms on holding wrist flexed at 90° for one minute.

Treatment – (i) Mild case – Wrist splint, diuretics and injection of hydrocortisone into carpal tunnel may give temporary relief. (ii) In severe case – Surgical decompression of carpal tunnel.

Common peroneal nerve palsy – The common peroneal nerve at the fibula head is a common site of entrapment. *Causes* – Focal presentation of more generalized neuropathy, individuals who have sat with their legs crossed for a long period (e.g. during airline flight), or sitting from a kneeling position. *Clinical features* – Patient develops foot drop and variable sensory loss in outer border of the foot and lateral aspect of lower leg. *Management* – If the disorder is confined to a demyelinating lesion, recovery occurs within 1 or 2 weeks. Continued pressure on the nerve leads to axonal damage, recovery may take several months. Surgery is seldom of benefit.

(c) Other causes – Trauma, fractures, operations, penetrating injuries, lacerations and injections.

2. **Multifocal neuropathy** – More than one and at times many individual nerves affected in a patchy asymmetric distribution – mononeuritis multiplex.

Causes

(a) **Vascular** – Diabetes, rheumatoid arthritis, polyarteritis nodosa, SLE, Wegener's granulomatosis, non-systemic vasculitis, Lyme disease.

(b) **Infections** – Leprosy, HIV.

(c) **Physical injury** – Repeated flexion extension of wrist (while typing), due to hand held vibrating instruments.

(d) **Inflammation** – Sarcoidosis.

(e) **Demyelination** – Multifocal motor neuropathy with conduction block (MMN), multifocal acquired demyelinating sensory and motor neuropathy (MADSAM).

(f) **Familial disposition** – to entrapment neuropathy (tomaculous neuropathy).

Generalized Neuropathy

Diffuse symmetrical involvement of peripheral nerves. Some diseases, e.g. diabetes, may also produce a multifocal neuropathy. Some neuropathies also affect spinal roots (polyradiculoneuropathy). Common causes are – Leprosy, diabetes mellitus, chronic kidney failure, G-B syndrome, INH toxicity (Table 78).

Table 78: Causes of peripheral neuropathy

1. Toxins	
– Alcohol.	
– Heavy metals and industrial agents – Arsenic, lead, mercury, thallium, gold, acrylamide, n-hexane, methyl n-butyl ketone, tri-orthocresyl phosphate, carbon disulphide.	
– Drugs	Amiodarone
Isoniazid	Metronidazole
Nitrofurantoin	Lithium
Vincristine	Cyclosporine
Dapsone	Gold
Chloroquine	Stavudine
Statins	Didanosine
2. Avitaminosis – Beriberi, pellagra, vitamin B ₁₂ deficiency, burning feet syndrome, vitamin E deficiency.	
3. Metabolic and endocrine disorders – Diabetes, gout, myxoedema, acromegaly, amyloid disease, uraemia, porphyria, copper deficiency.	
4. Infections	
(a) <i>Systemic</i> – (i) <i>As a complication</i> – Diphtheria, tetanus, typhoid, parainfectious, mumps, staphylococcal septicaemia, measles, influenza, tuberculosis, meningitis, infectious mononucleosis, brucellosis, HIV. (ii) <i>As the main symptom</i> – Acute inflammatory polyneuropathy, 'rheumatic' polyneuritis, brachial neuritis, polyneuritis with parotitis and iridocyclitis.	
(b) <i>Local infections of nerves</i> – Leprosy.	
5. Collagen and allied disorders – Polyarteritis nodosa, sarcoidosis, disseminated lupus erythematosus, rheumatoid polyneuritis.	

Contd...

Contd...

6. **Malignancy** – Carcinoma especially of lung, lymphoma, leukaemia. Malignant inflammatory sensory polyganglionopathy. Paraneoplastic vasculitic neuropathy.
7. **Paraproteinaemias and dysproteinaemias** – Multiple myeloma, cryoglobulinaemia, benign monoclonal gammopathy, primary amyloidosis (AL and AF).
8. **Hereditary** – Charcot-Marie-Tooth (CMT) disease, Peroneal muscular atrophy (HMSN type I, II, III, IV), Friedreich's ataxia, familial dysautonomia (Riley-Day), metachromatic leucodystrophy, Fabry's disease (Angiokeratoma corporis diffusum). Hypertrophic neuropathy (Dejerine-Sottas disease), hereditary sensory neuropathy, hereditary ataxic neuropathy (Refsum's syndrome), abetalipoproteinaemia.
9. **Polyneuritis of obscure origin (cryptogenic neuropathy):** Recurrent polyneuritis.

Symptoms

1. **Sensory** – (a) *Subjective disturbances* – Numbness, tingling, feelings of pins and needles in hands and feet, burning sensations, pain in the extremities, sensation of walking on cotton wool or band-like constrictions around wrist or ankles, unsteadiness on the feet and tumbling (ataxia). (b) *Objective sensory loss* – Bilaterally symmetrical, impairment of all forms of sensation; glove and stocking type of anaesthesia. Preceding the anaesthesia, there is hyperaesthesia. Tenderness of calf muscles and sometimes nerves.
2. **Motor** – Major symptom is weakness. Wasting and weakness most marked initially in the limbs, involving lower limbs before upper. Predominantly proximal weakness as in Guillain-Barre syndrome. Fasciculations may be seen, usually in patients with rapidly progressive denervation.
3. **Autonomic disturbances** – Dryness or excessive sweating of the extremities, postural hypotension, impotence and sphincter disturbances, diarrhoea and constipation.
4. **Bulbar dysfunction** – can follow cranial nerve involvement in some peripheral neuropathies. Double vision, respiratory problems and difficulties with swallowing and speech may occur.

Signs

- Wasting and weakness – in distal muscles of hand and feet.
- Absent or reduced reflexes
- Signs of autonomic disturbance (e.g. postural hypotension)

Table 79: Causes of demyelinating neuropathy

Acute

- Guillain-Barre syndrome

Chronic

Hereditary

- Hereditary motor and sensory neuropathy types I, III, IV
- Refsum's syndrome
- Metachromatic leucodystrophy
- Cockayne's syndrome

Paraproteinemia

- Myeloma
- Waldenstrom's macroglobulinemia
- Monoclonal gammopathy of undetermined significance

Drugs

- Amiodarone
- Perhexiline

Chronic inflammatory demyelinating neuropathy

- Sensory loss – Small fibre type involving pain and heat sensation, or large-fibre type with loss of fine touch or pin-prick sensation or two point discrimination.
- Cranial nerve examination may reveal facial weakness and ptosis
- Vital capacity may be reduced
- Trophic changes – Skin glossy, furrowing and falling off of nails, cold extremities

C. Demyelinating Neuropathy

Table 79 for the causes of demyelinating neuropathy.

D. Axonal Neuropathy

Table 80 for the causes of axonal neuropathy.

Table 81 gives the differentiating features between demyelinating and axonal neuropathy.

Table 82 for the clinical types of neuropathies.

INVESTIGATIONS

Nerve conduction studies – determine whether the process is axonal or demyelinating and whether there is conduction block. Conduction block is characteristic of chronic inflammatory demyelinating polyneuropathy (CIDP) and multifocal motor neuropathy. Nerve conduction studies also provide information on whether the process is generalized or focal, and may reveal specific site of damage in focal entrapment neuropathies (Table 83).

Nerve biopsy – Sural nerve (or radial nerve) biopsy is usually helpful in leprosy, giant axonal neuropathy. Nerve biopsy is also indicated in suspected vasculitic neuropathies or in the diagnosis of amyloid (AL and AF).

Table 80: Causes of axonal neuropathy

<i>Acute</i>	
• Toxins	
• Porphyria	
• Vasculitic disease (SLE, PAN)	
<i>Chronic</i>	
<i>Metabolic</i>	<i>Autoimmune diseases</i>
• Diabetes	• RA
• Uraemia	• SLE
<i>Deficiencies</i>	<i>Hereditary</i>
• Vitamin B ₁₂	• Hereditary motor and sensory neuropathy type II
• Thiamine	
• Vitamin E	
• Nicotinamide	• Giant axonal neuropathy
<i>Toxic</i>	• Hereditary ataxias
• Alcohol	
• Drugs	
<i>Leprosy</i>	
<i>Paraneoplastic</i>	<i>Miscellaneous</i>
• Lymphoma	• Chronic obstructive airway disease
• Carcinoma of lung	
• Polycythemia rubra vera	• Primary amyloid
	• Sarcoid

Other investigations – should include:

- Blood glucose, glucose tolerance test
- Vitamin B₁₂
- ESR
- Full blood count
- Serum protein electrophoresis (to exclude myeloma and other paraprotein-associated neuropathies)
- Chest radiograph (neoplasm)

MANAGEMENT

1. *General* – (i) Elimination of possible toxic or infectious cause. (ii) Control of any existing metabolic or nutritional deficiencies – correction of anaemia with iron or vitamin B₁₂, high protein diet, multivitamins.
2. *Local measures* – Occupational therapy helps maintain full use of weak muscles. Physiotherapy helps stimulate recovery and maximum gain of function. Foot deformity requires attention to footwear and appropriate orthotic aids.

Table 81: Differentiation between demyelinating and axonal neuropathy

<i>Features</i>	<i>Demyelinating neuropathy</i>	<i>Axonal neuropathy</i>
Onset	Acute or insidious	Insidious
Sensory loss	Minimal	Glove and stocking anaesthesia
Deep reflexes	All DTRs loss	Loss of only ankle reflexes
Progress	Recovery within few weeks	Recovery, if at all over months or years
Central involvement	Rare	Can occur
Nerve conduction	Increased	Normal

Table 82: Clinical types of neuropathies

<i>Acute onset</i>	
• Guillain-Barre	• Serum sickness
• Porphyria	• (Post-vaccinal)
• Diphtheria	• Malignancy
• Toxic	• Critical illness polyneuropathy
<i>Predominantly motor</i>	
• Guillain-Barre	• Lead
• Porphyria	• Botulism
• Diphtheria	• Charcot-Marie-Tooth disease
<i>Predominantly sensory</i>	
• Leprosy	• Hereditary sensory neuropathies (HSAN)
• Diabetes	
• Vitamin B ₁₂ or B ₁ deficiency	
• Malignancy	• Uraemia (early stages)
	• Amyloid disease
	• Lyme disease.
<i>Painful neuropathies</i>	
• Alcohol, nutritional deficiencies	• Thallium poisoning
• Diabetic neuropathy	• Cryoglobulinemia
	• Lyme disease
• Hereditary sensory neuropathy	• AIDS-related neuropathy
• Drug-induced	
<i>Predominant upper limb involvement</i>	
Diphtheria	
Porphyria	

Contd...

Contd...

Lead
MMN
<i>With associated hypertension</i>
GB syndrome
Polyarteritis nodosa. Lead poisoning
Porphyria (acute intermittent)
<i>Cr. nerve involvement in peripheral neuropathy</i>
Guillain Barre (VI, VII)
Miller-Fisher variant (III, IV, VI)
Diabetes (III, VI)
Sarcoidosis (VII).
Leprosy [VII, V (sensory)]

3. *Specific* – e.g. vitamin B₁ for thiamine deficiency, adequate control of diabetes, etc. Corticosteroids may be helpful in chronic relapsing demyelinating neuropathies and some patients may respond to immunosuppressive and cytotoxic drugs and to plasmapheresis.

INHERITED NEUROPATHIES

Peroneal Muscular Atrophy

(Charcot-Marie-Tooth disease, CMT)

Most common hereditary motor and sensory neuropathy. Types I and II are most common varieties.

CMT type I – is a demyelinating usually autosomal dominant neuropathy. At least 70% of cases are caused by duplication of a stretch of DNA on chromosome 17 encoding a myelin protein (PMP22). It characteristically presents with foot drop in early childhood and weakness of the legs, some develop mild weakness in the hands. Sensory loss is mild. Nerve conduction studies show severely reduced peripheral conduction.

CMT type II – is an axonal disease dominant or recessive. Presentation is similar to type I, though the disorder may produce more extensive wasting.

INFLAMMATORY DEMYELINATING POLYNEUROPATHIES

Acute Inflammatory Demyelinating Polyradiculoneuropathy (AIDP) (Guillain-Barre Syndrome)

Guillain-Barre syndrome is an acute, predominantly motor neuropathy, which progresses to its peak in less

Table 83: NCV and EMG studies in demyelinating vs axonal neuropathy

	<i>Axonal segmental degeneration</i>	<i>Segmental degeneration demyelination</i>
<i>Motor nerve conduction studies</i>		
CMAP amplitude	Decreased	Normal

SNAP amplitude	Decreased	Normal or decreased
Distal latency	Normal	Prolonged
Conduction velocity	Normal	Slow
<i>Needle EMG</i>		
Spontaneous activity		
Fibrillations	Present	Absent
Fasciculations	Present	Absent
<i>Motor unit potential</i>		
Recruitment	Decreased	Decreased
Morphology	Long duration/polyphasic	Normal

than 4 weeks. It is a clinical syndrome with a number of subtypes:

- Guillain-Barre syndrome
 - Acute inflammatory demyelinating polyneuropathy
 - Acute motor axonal neuropathy
 - Acute motor and sensory axonal neuropathy
- Miller-Fischer syndrome
 - Subacute inflammatory demyelinating neuropathy
 - Chronic inflammatory demyelinating neuropathy (CIDP)

Patient with progressive neuropathy over 8 weeks have CIDP.

Aetiology – Age – usually 15–40 years. Sex – Male female ratio 1.5:1. **Antecedent infection** – usually upper respiratory tract infection or GI illness in about 70%. Infectious agents commonly identified are *Campylobacter jejuni* and cytomegalovirus.

Pathogenesis – Probably a cell-mediated immune response to preceding infection.

Clinical Features

Prodromal stage – Headache, vomiting, slight fever, pain in back and limbs.

Latent period – Few days to several weeks; may be absent.

Stage of paralysis – Patient may come in this stage, the initial stage being absent. Alarming clinical picture with motor weakness progressing to paralysis and various sensory disturbances.

Diagnosis

A. Clinical

- Motor symptoms** – Onset of paralysis sudden or gradual. Proximal weakness is more than distal. Headache and fever. All four limbs may be paralysed simultaneously or first lower and then upper. Proximal and distal segment muscles affected equally. Involvement of muscles of neck and trunk. Dysphagia and ophthalmoplegia. Loss of superficial and deep reflexes.
- Sensory symptoms** – Pain, radicular involving most commonly the proximal portions of the limbs, numbness and tingling of limbs. Sensations may be impaired at the periphery, and muscles may be tender.
- Cranial nerve paralysis** – Facial, neck and bulbar muscle paralysis common, and weakness of extraocular muscles may also occur.
- Reflexes** – usually depressed or absent.
- Sphincters** – rarely involved.
- Symptoms of toxæmia** – Fever, rash, leucocytosis, are usually absent.

B. CSF

Protein levels usually increased (sometimes up to 6 g/litre). Some patients may have normal levels in the first week,

C. Nerve conduction velocity studies

Typical early findings are prolonged distal motor latencies in either upper or lower limbs, prolonged F wave latencies and low muscle action potential amplitudes (CMAP). Slowing of nerve conduction indicating demyelination is seen late.

Diagnostic Criteria

Table 84 for the Asbury's criteria and Table 85 for the Brighton criteria.

Management

Respiratory Care

- Monitor vital capacity (not peak flow) 4-hourly.
- If <1 litre, check accuracy (ensure air is not escaping because of facial weakness, check patient technique). If accurate consider urgent ventilation
- If < 1.5 litre but falling, shift to ICU
- Positive pressure ventilation and chest physiotherapy

Cardiac Care

Institute cardiac monitoring – if evidence of bradycardia (heart rate < 50), particularly following tracheal suction, consider temporary cardiac pacing.

Table 84: Asbury's criteria for Guillain-Barre syndrome

A. Features required for diagnosis

1. Progressive motor weakness of more than one limb (can progress to total paralysis of all four extremities).
2. Areflexia

B. Features strongly supporting the diagnosis

- (a) *Clinical features.*
 1. Progression of symptoms and signs over days up to 4 weeks.
 2. Relative symmetry of symptoms.
 3. Mild sensory symptoms or signs.
 4. Cranial nerve involvement, especially facial diplegia.
 5. Recovery beginning 2–4 weeks after progression ceases.
 6. Autonomic dysfunction.
 7. Absence of fever at onset of illness

(b) CSF picture

1. Elevated CSF protein after one week of symptoms.
2. Cell counts of >10 mononuclear leucocytes per cmm of CSF.

(c) Electrodiagnostic studies

Evidence of nerve conduction slowing or block.

C. Features making the diagnosis doubtful

1. Marked persistent asymmetry of weakness.
2. Marked bladder or bowel dysfunction at onset or its persistence thereon.
3. Presence of polymorphonuclear leucocytes or >50 mononuclear leucocytes per cmm of CSF.
4. Sharp sensory level.

D. Features excluding the diagnosis

1. Diagnosis of acute intermittent porphyria or recent diphtheria infection.
2. Diagnosis of botulism, poliomyelitis, hysterical paralysis, toxic neuropathy.
3. Purely sensory syndrome.

Table 85: Brighton criteria for diagnosis of Guillain-Barre syndrome (GBS) and Miller-Fisher syndrome**Clinical case definitions for diagnosis of GBS***Level 1 of diagnostic certainty*

Bilateral AND flaccid weakness of the limbs

AND

Decreased or absent deep tendon reflexes in weak limbs

AND

Monophasic illness pattern and interval between onset and nadir of weakness between 12 h and 28 days and subsequent clinical plateau

AND

Electrophysiologic findings consistent with GBS

AND

Cytoalbuminologic dissociation (i.e. elevation of CSF protein level above laboratory normal value AND CSF total white cell count <50 cells/ μ L)

AND

Absence of an identified alternative diagnosis for weakness

Level 2 of diagnostic certainty

Bilateral AND flaccid weakness of the limbs

AND

Decreased or absent deep tendon reflexes in weak limbs

AND

Monophasic illness pattern and interval between onset and nadir of weakness between 12 h and 28 days and subsequent clinical plateau

AND

CSF total white cell count <50 cells/ μ L (with or without CSF protein elevation above laboratory normal value)

OR

If CSF not collected or results not available, electrophysiologic studies consistent with GBS

AND

Absence of identified alternative diagnosis for weakness

Level 3 of diagnostic certainty

Bilateral and flaccid weakness of the limbs

AND

Decreased or absent deep tendon reflexes in weak limbs

AND

Monophasic illness pattern and interval between onset and nadir of weakness between 12 h and 28 days and subsequent clinical plateau

No alterations in consciousness or corticospinal tract signs

AND

Absence of identified alternative diagnosis

Course – Within a period of 3 weeks, it progresses to maximum disability, often with complete quadriplegia and respiratory paralysis. Recovery without significant disability occurs in about 80%, subsequent relapses occur in about 5% of patients.

Prevention of Thrombosis and Limb Deformity

Give subcutaneous heparin and apply anti-embolism stockings.

Pay special attention to position of limbs.

Active Treatment

- Intravenous human immunoglobulin 0.4 g/kg/day for 5 days
- If deterioration continues, consider further IV immunoglobulin or
- Plasma exchange (50 mL/kg on five occasions over 7–10 days)

Miller-Fisher syndrome – Triad of ophthalmoplegia, ataxia and areflexia without weakness. It is considered to be a variant of GB syndrome. Antibodies to ganglioside GB are seen in 90% of patients. Recurrences are rare.

Chronic inflammatory demyelinating polyneuropathy (CIDP) – is a subacute or chronic progressive demyelinating neuropathy.

Progression over 2 months distinguishes it from G-B syndrome. The disorder is associated with increased frequency of HLA DR3, indicating that the disease may result from an aberrant immune response leading to a chronic form of G-B syndrome.

Management of CIDP and Miller-Fisher syndrome – Corticosteroids, plasma exchange and IV IG in combination are effective. Azathioprine and other immunosuppressive agents are usually needed as corticosteroid-sparing agents.

Vasculitic neuropathies – in systemic disorders such as RA and PAN which produce a number of different lesions within the nerve and are hence termed multifocal. Because of the multifocal onset, the combination of individual peripheral nerve involvement is called ‘mononeuritis multiplex’. *Diagnosis* – High ESR or positive antinuclear

factor or antinuclear cytoplasmic antibody. Nerve biopsy reveals patchy multifocal process with inflammatory cells.

Multifocal motor neuropathy – resembles CIDP, but does not respond well to steroids. It has considerable similarities to LMN form of MND, especially because of marked fasciculations. Disorder is suspected in patients that present with asymmetrical upper limb weakness in absence of sensory disturbance. *Diagnosis* – Evidence of conduction block often between supraclavicular fossa and axilla.

Diabetic neuropathy – may be distal predominantly sensory neuropathy, neuropathy with some autonomic involvement, isolated cranial neuropathies (e.g. IIIrd nerve palsy), femoral neuropathy and a focal, predominantly motor neuropathy affecting the shoulder or lumbar plexus (diabetic amyotrophy).

Multiple myeloma. Neuropathy occurs in about 5% of patients (particularly those with disease of osteosclerotic type) and is usually of mixed sensory and motor type. Neuropathies that occur with solitary plasmacytomas often respond to radiation or removal of primary lesion.

Benign monoclonal gammopathy may be associated with demyelinating polyneuropathy. This usually has a slow course, and immunocytochemistry may show binding of IgM to, and widening of the interperiod line within myelin. Has similarity to CIDP.

Neuropathies associated with solid malignancies – *Subacute sensory neuropathy* is the most common type. It is typically associated with ataxia and may precede the detection of the tumour (usually in the lung) by several years.

Autonomic Peripheral Neuropathy

Autonomic neuropathy is the term used to describe autonomic disturbances resulting from diseases of peripheral ANS. Table 86 lists the causes of autonomic neuropathy.

Table 87 gives clinical features of autonomic disturbances in a case of autonomic neuropathy.

Investigations in Autonomic Neuropathy

- Chemistry, haematology, pathology:
 - Complete blood count
 - Blood glucose
 - HIV testing
 - Immunoelectrophoresis of blood and urine
 - Plasma norepinephrine (supine and standing)
 - Urinary porphyrin concentration
 - Genetic testing for inherited neuropathies
 - Fat aspirate, rectal or gingival biopsy for amyloid

Table 86: Causes of autonomic neuropathy

- *Immune mediated:* Acute pandysautonomia, GBS, paraneoplastic, Lambert-Eaton syn., postural orthostatic tachycardia syn., inflammatory bowel disorder related causes, chronic inflammatory demyelinating polyneuropathy.
- *Related to systemic disease:* Diabetic neuropathy, acquired amyloid neuropathy, uremic neuropathy.
- *Infections:* Botulism, HIV, Chaga's disease, diphtheria.
- *Toxic:* Alcohol, heavy metals, organic solvents, hexacarbons.
- *Drug-induced:* Vincristine, cisplatin, amiodarone, taxols, pyridoxine.
- *Hereditary:* Hereditary sensory and autonomic neuropathy (HSAN), Fabry disease, Tangier's disease, familial dysautonomia.
- *Idiopathic neuropathy:* Idiopathic distal small fibre, chronic idiopathic anhidrosis.

- Autoantibody assessment
 - Antinuclear antibody
 - Rheumatoid factor
 - Anti-Ro/SS-A, Anti-La/SS-B
 - Antibodies to P/Q-type calcium channel
 - Paraneoplastic antibodies
- Electrophysiological studies: Nerve conduction studies (including repetitive stimulation). Quantitative sensory testing.

26. ROOT AND PLEXUS SYNDROMES

RADICULOPATHY

1. Cervical spondylosis –

Symptoms and signs

- Radicular symptoms** – due to compression of one or more nerve roots. In acute disc protrusion sudden severe pain in neck and referred in the distribution of the compressed nerve. Neck held rigid and sometimes flexed towards side of lesion. If insidious onset burning or tingling sensation sometimes accompanied by pain radiating down the upper limb. Motor symptoms usually slight or absent. Usually some diminution of appreciation of light touch and pinprick within the dermatomes corresponding to the affected radicular nerve. Tendon reflexes innervated by affected segments likely to be diminished or lost.
- Symptoms of cord compression due to cervical myelopathy** – Main initial symptoms are dysaesthesiae in the hands, weakness and clumsiness

Table 87: Autonomic disturbances in a case of autonomic neuropathy

- *CVS:* Orthostatic hypotension, labile hypertension, brady and tachyarrhythmias.
- *GI:* Dysphagia, constipation, episodic diarrhoea, faecal incontinence, gastroparesis (persistent fullness and subsequent abdominal pain and vomiting), early satiety, abdominal bloating.
- *Urogenital:* Urinary retention or incontinence, bladder urgency, frequency, nocturia, incomplete bladder voiding, impotence, loss of ejaculation, vaginal dryness.
- *Thermoregulatory:* Hypothermia, hyperpyrexia.
- *Secretomotor:* Anhidrosis or hypohidrosis (mainly in feet), hyperhidrosis (in feet/hand/head), gustatory sweating, dryness of mouth/eyes, excessive salivation.
- *Pupillomotor:* Abnormalities of size (presents with blurred vision, difficulty in focussing, poor night vision).
- *Skin and joints:* Feeling of coldness, acrocyanosis, pallor, mottling or redness (vasomotor changes). Loss of hair, nail thickening/discoloration. Charcot's joints.

of the hands and spastic weakness of the lower limbs. When as is commonly the case, the cervical enlargement (C_5 , C_6 and C_7) is involved, there is a combination of diminution of some tendon reflexes with exaggeration of others. The triceps jerk is most commonly diminished or lost. There may be some impairment of appreciation of light touch and pinprick over some or all the digits.

- Pain in the neck** – Acute disc protrusion is likely to be associated with severe pain, muscular spasm and rigidity of the neck muscles. In chronic cervical spondylosis pain is usually comparatively mild and tends to be more severe in the morning.
- Headache** – Characteristically occipital and often described as spreading up over the back of the head to the frontal region. Usually worse in morning.
- Vertebrobasilar ischemia** – Often rotation to one or other side or extension of the neck and, less frequently flexion may precipitate a brief attack of giddiness or a drop attack. Probably pressure on the vertebral arteries with consequent impairment of the blood supply of the hindbrain.

Radiological changes – (a) Reduction of one or more disc spaces. (b) Changes in the normal curve of the spine. (c) Formation of osteophytes. (d) Sclerosis of parts of the vertebrae adjacent to the damaged discs. (e) MRI usually shows exact site of mechanical compression.

Management – (a) *Conservative* – Bed rest and analgesics in acute painful stage. Cervical collar may be used day and night to start with, and gradually let off as symptoms improve. As pain subsides active exercises for neck and shoulders combined with heat treatment. Head traction may be tried provided there are no signs of cord compression. (b) *Surgery* – When cervical movement is limited over three or four segments, laminectomy and decompression may be indicated. Anterior discectomy and fusion may be advisable in presence of excessive mobility of cervical spine.

2. **Acute cervical disc herniation** – Often associated with trauma. Posterolateral prolapse results in neck stiffness, pain and radiculopathy. In general cervical disc lesions respond rapidly to immobilization.

3. **Lesions of brachial plexus:**

(a) **Lesions of upper part of brachial plexus** – Lesions are usually traumatic. Rucksack palsy is due to traction on upper part of brachial plexus from heavy rucksacks.

(b) **Lesions of lower part of brachial plexus**

Thoracic outlet syndrome – In this condition, the lower trunk of the brachial plexus may be angulated over a cervical rib, together with the subclavian artery.

Clinical features:

Sensory – Loss in C₈-T₁ distribution.

Motor – Wasted interossei.

Vascular – (a) Arterial – (i) Arm claudication. Arm abduction (to 90°) and external rotation leads to reproduction of symptoms, fall in systolic BP in arm by more than 15 mm Hg, loss or diminution of radial pulse. (ii) Arm pallor, cyanosis, oedema. (iii) Supraclavicular bruit. (b) Venous – Dilated venous collaterals, axillary thrombosis.

Investigations – (a) X-ray – of the root of the neck may reveal an enlarged transverse process or cervical rib. (b) Electromyography may demonstrate involvement of the medial cord of the plexus. (c) Doppler ultrasonic angiography to show involvement of subclavian artery, and digital subclavian to outline the vessels in more detail.

Management – Minor symptoms can be relieved by appropriate physiotherapy, but progressive neurological deficit calls for surgical interference.

Malignant infiltration – of brachial plexus may result from either upward extension of apical lung carcinoma, or local metastatic spread from mammary carcinoma. Pain and sensory loss in medial aspect of

forearm and slowly progressive weakness which starts in the small hand muscles.

Brachial neuralgia (Neuralgic amyotrophy) – may follow injury, operation, inoculation or specific fever. Pain is usually the first symptom, often severe and of sudden onset, followed after several days or few weeks by weakness and wasting of muscles, especially those innervated by C5 and C6 cord segments. Sensory loss is mild or absent and there are usually few or no constitutional symptoms. Recovery is slow.

4. **Fibrositis, peri-arthritis and arthritis of the shoulder** – Diseases of shoulder joint and its surrounding structures should be considered. Pain referred to the shoulder, to arm, or to region of elbow, associated with loss of range of movement or pain on movement.

Treatment – None specific. In acute stage arm should be supported in a sling. Physiotherapy as soon as pain subsides.

5. **Lesions of median nerve** – Carpal tunnel syndrome (Refer).

6. **Vascular conditions** – Those producing sensory disturbances in arm include occlusion of brachial artery due to embolus, or ischemia from polyarteritis nodosa, scleroderma and other conditions grouped under the term Raynaud's phenomenon. Inspection of the skin, changes in temperature and colour of the limb, and inadequate pulse at the wrist facilitate diagnosis. Coronary insufficiency may be responsible for pain in the ulnar aspect of arm and forearm.

LUMBOSACRAL PLEXUS

Sciatica

Pain in the distribution of the sciatic nerve or its component nerve roots (L5, S1). The syndrome is now accepted as being caused by lumbar disc prolapse. However, sciatic nerve lesions can occur due to pressure in the buttock or upper part of thigh.

Causes

- I. *True sciatic neuritis* – Polyarteritis nodosa, nerve injury due to injections or trauma, post-herpetic neuralgia.
- II. *Mechanical pressure on nerves or roots or referred pain*–
 1. *In the spinal cord* – Tumours of cauda equina, arachnoiditis, rarely thrombosis, haemorrhage or infection irritating meninges of the cord.
 2. *In the cord space* – Protruded intervertebral disc, extramedullary tumours.

3. *In the vertebral column* – Arthritis, tuberculosis, spondylolisthesis, ankylosing spondylitis, primary bone tumours, secondary carcinoma.
4. *In the back* – Fibrositis of posterior sacral ligaments. Compression where the nerve leaves the pelvis in those who lie immobile on a hard surface for long time (a form of Saturday night palsy).
5. *In the thigh and buttock* – Fibrositis, sacrosciatic band, hip joint or sacroiliac joint disease, neurofibroma, haemorrhage within or adjacent to nerve sheath in blood dyscrasias and anticoagulant therapy, misplaced therapeutic injection.
6. *In the pelvis* – Sacroiliac arthritis or strain, hip disease, infection of prostate or female genital tract, rectal impactions, tumors of lumbosacral plexus.
7. *Lumbosacral spondylosis* is a common cause.

Investigation of a Case of Sciatica

History: Of trauma, exposure to damp or cold, sphincter control and history of previous attacks. Type of radiation whether nerve root type or vaguely localised deep aching pain. Paraesthesia will occur in pain from sensory pathways but not in referred pain. Pain down the leg on coughing in root lesions and also acute extraneural disease of spine, pelvis and sacroiliac joints.

Physical examination

1. *Lumbar spine* – Shape, mobility, muscle spasm, list to one or other side on standing (sciatic scoliosis), local tenderness and presence of trigger points in back and limbs. Sciatica may be the first symptom of spinal caries.
2. *Special signs* –
 - (i) *SLR test* – Restriction of straight leg raising is usually much more marked in lesions affecting the nerve roots than in purely skeletal affections. SLR test gives a useful indication of the severity of the sciatica, and increased capacity for painless SLR is objective measure of improvement.
 - (ii) *Tenderness of nerves* – *Tinel's sign*.
 - (iii) *Intensification of pain in back and leg* during rotatory extension of lumbar spine very suggestive of ruptured disc.
 - (iv) *Popliteal compression* – Radiating pain can often be aggravated by pressure over the course of the tibial nerve through the popliteal fossa. It is an additional finding in favour of root compression.
 - (v) *Testing of the sacroiliac joints* – by pressure on the two anterior superior iliac spines.

- (vi) *Estimation of range and painlessness* or otherwise of hip joint by passive stretching.
 - (vii) *Muscle power* in the lower limb tested against resistance.
 - (viii) *Knee and ankle jerks* – When L4 root is involved knee jerk is depressed and there is likely weakness of tibialis anterior muscle. L5 root lesions, both knee and ankle jerks usually normal but there is weakness of dorsiflexion of the toes particularly of extensor hallucis longus. S1 root ankle jerk lost and weakness, when present involves the calf muscles.
 - (ix) *Tone and size of gluteal muscles* judged by asking patient to contract both buttocks; in upper sacral root lesions marked wasting may be clearly visible.
3. *Sensations* – Impairment of perception of pin-prick commonly found on dorsum of foot, if implication of 5th lumbar and 1st sacral nerve roots.
 4. *Presence of tender nodules* – in paraspinal muscles and along iliac crest may be found in sciatica due to inflammation of muscular and fascial structures.
 5. *Rectal examination* – in older patients.

Investigations

1. *Imaging of spine* – (a) Straight X-rays – for detecting disc narrowing in lumbar spine, or lesion of sacroiliac or hip joint. (b) MRI of lumbosacral spine.
2. *CSF* – may show increased protein with normal cell count in large protruded intervertebral disc.
3. *EMG* – may be used to confirm presence of denervation in affected muscles.
4. *Procaine injection test* – for diagnosis of fibrositic pain; contact with needle aggravates local pain and elicits referred pain; procaine suppresses both, and freedom of leg and spine movement is restored.

Differential Diagnosis of Conditions Causing Sciatica

1. **Disc lesion** – Recurrent bouts of lower back pain (lumbago) followed by unilateral sciatica, or pain first in calf or thigh or both without any lumbar symptoms. SLR limited. Neurological signs absent, if small protrusion, present if large displacement compressing the root severely. A huge herniation may squeeze the root so hard that it becomes anaesthetic from ischemia and the pain ceases; SLR becomes once again of full range at the same time as cutaneous analgesia and loss of power and reflexes supervene.

2. **Spondylolisthesis** – Signs of disc lesion together with lumbar deformity. When spondylolisthesis causes intrinsic symptoms: backache after prolonged standing, or bilateral sciatica. X-ray taken with the patient standing diagnostic.
3. **Attrition of disc** – Full approximation of the vertebral bodies following attrition of disc allows posterior longitudinal ligament to be unduly long. Sciatica caused by standing due to compression causing posterior bulge of the disintegrated disc which is pushed back into position when posterior longitudinal ligament is tightened by lying down. X-ray – Diminished joint space with marked anterior beaking at the affected level.
4. **Sacroiliac arthritis** – Alternation of pain significant, i.e., pain comes in one buttock and posterior thigh, then it transfers itself to the other side. Signs of involvement of 1st and 2nd sacral segments. No lumbar signs. Pressure on anterior iliac spines provokes pain in the buttock. SLR normal.
5. **Secondary deposits in spine** – Gradually increasing central backache, tendency to radiate to lower limb, soon to both. Marked limitation of movements at lumbar spine. SLR of full range though painful at the extreme. Multiradicular signs in lower limbs. Muscle weakness bilateral, unequal and marked. Spinal tenderness.
6. **Benign spinal tumour** – Progressive increase in symptoms. Neurological signs more severe and progressive than in disc lesion. If radiograph shows erosion of bone and induction of epidural anaesthesia does not cause disappearance of pain for the time being, a tumour is very probably present.
7. **Major lesions in the buttock** – such as acute osteomyelitis of ilium or upper femur, ischio-rectal abscess pointing into buttock, septic gluteal bursitis. Straight leg raising and hip flexion both very painful. (In sciatica due to disc lesion hip flexion is not limited.)
8. **Arthritis of the hip** – Hip movements restricted and pain provoked by passive movements. Radiograph of pelvis diagnostic.
9. **Intermittent claudication** – When internal iliac artery is affected alone, claudication in gluteus maximus on walking may be the only symptom. Diagnostic signs – Patient lies prone and his hip is extended passively; this causes no pain. He is then asked to keep the leg extended for a minute, this brings on the claudication.
Spinal claudication – Pins and needles in both lower limbs on walking a certain distance. All arteries of the

lower limbs patent on examination. Cause is intraspinal ischemia of the nerve-roots compressed by a disc lesion or involved in arachnoiditis.

10. **Dissecting aneurysm** – A rare cause of sciatica is a slowly expanding aneurysm at the bifurcation of aorta compressing 3rd and 4th LNs. causing local pain and accompanied by paraesthesia and weakness in left lower limb. Severe backache. Aortography diagnostic.

Management

A. Symptomatic sciatica

1. **Acute stage** – (i) Rest in bed with boards under the mattress to support the back. (ii) Analgesics as required. (iii) Heat. (iv) Injection of 2% procaine or of lignocaine into the sciatic nerve or epidural space or tender spots in the sacroiliac region may give dramatic relief.
2. **Chronic stage** – Management will depend on cause. Conservative management – (a) High sciatica – (i) Injection of tender spots with 5% procaine. (ii) Counter-irritation, heat and massage. (iii) Epidural injection – 10 mL of 2% novocaine, followed by 80 to 100 mL of normal saline; repeated once a week. Many patients with sciatica due to extradural adhesions may be benefited by injection of 30 mL 1% procaine hydrochloride mixed with 125 mg. hydrocortisone injected into the epidural space. Three injections are given on consecutive or alternate days. This should be followed by active and passive exercises carried out to limit of tolerance. (b) Low sciatica – Stretching of sciatic nerve, and injection of novocaine into, or as near as possible to the sheath of the nerve.

B. Sciatica due to herniated intervertebral disc

1. **Conservative treatment** – Complete rest in bed in supine position with only one pillow for 3–6 weeks. When pain is relieved, plaster jacket to immobilise the lumbar spine completely for 3–6 months. After this the jacket is removed, and a lumbar corset worn at all times during the day.
2. **Operative treatment** – Indications – (i) Acute and incapacitating symptoms not relieved by rest in bed or even immobilisation in plaster jacket. (ii) Quick recurrence of symptoms. (iii) Evidence of large prolapse causing pressure on cauda equina, or clinical evidence of severe root compressions shown by marked motor and sensory changes. Operation consists of hemilaminectomy, removal of the protrusion, and curetting out nuclear material from the central part of the disc.

C. Sciatica due to inflammation of muscular and fascial structures

Rest, local application of heat, and massage. If tender nodules, injection with 2% procaine solution. Treatment of sepsis.

Miscellaneous

Neurological aspects of pregnancy

Eclampsia - Neurological symptoms may include headache, visual disturbances, seizures and later coma. Cerebral infarction and hemorrhage may supervene. The precise pathophysiological mechanisms are poorly understood. Posterior reversible encephalopathy syndrome (PRESS).

Stroke occurs in the last trimester, but is uncommon. It is usually caused by middle cerebral artery occlusion, but occasionally results from a secondary hemorrhage caused by eclampsia. Intracranial venous thrombosis (commonly presenting with headache, seizures and focal neurological signs) occurs most commonly in the last trimester.

Peripheral nerve disorders

- Carpal tunnel syndrome often develops, possibly through fluid retention
- Bell's palsy. The incidence is about three times more than in non-pregnant women. If the condition is severe, a short course of prednisolone started within 2 days of the onset may be helpful.

Epilepsy. Frequency of seizures may increase or decrease during pregnancy, partly as a result of changes such as altered plasma protein binding, dilutional effects, changes in absorption, and sometimes poor compliance. When medication must be continued, it should be limited to monotherapy and as low a dose as possible. Folic acid 5 mg should be taken for 3 months before pregnancy and throughout the first trimester.

BENIGN INTRACRANIAL HYPERTENSION

- Iatrogenic cause
- Tetracycline
- Oral contraceptive
- Corticosteroids
- Nitrofurantoin
- Nalidixic acid
- Vit A toxicity

Pisa syndrome - Refers to axial dystonia with severe tonic lateral flexion of the trunk. Disproportionate torticollis often seen as chin on chest, whereas flexion attitude of rest of the body is normal.

Triad of normal pressure hydrocephalus

- Gait disorders
- Urinary incontinence
- Dementia

Multiple CNS defects. Causes

- Multiple sclerosis
- Multiple infarcts
- Multiple metastasis
- Meningeal carcinomatosis
- Meningovascular syphilis
- Vasculitis, e.g. PAN

Cerebral autosomal dominant arteriopathy with subcervical infarcts (ADASI) - It is a hereditary AD cause of early recurrent strokes, dementia. Migraine with atypical aura and mood disorders. The underlying lesion is widespread vacuolopathy distinct from generally affecting leptomeningeal and perforating arteries of the brain. MRI shows hypertense signal in subcortical white matter and basal ganglia.

Renal Disorders

1. INVESTIGATIONS IN RENAL DISEASE

URINE

General Characters

- A. **Volume:** Varies with amount of fluids ingested, perspiration, etc. Normal average for adult 1,200–1,500 mL (40–50 oz)

Polyuria

a. Transient polyuria

- Induced or therapeutic* (a) Ingestion of large amounts of fluids. (b) Alcohol, tea, coffee, acidifying salts like citrates or tartrates, spices, large amounts of sugar. (c) Diuretics. (d) High protein diet.
- Spontaneous* (a) Due to nervousness or after a nervous attack, e.g. examination, neurasthenia, after an attack of epilepsy, migraine, asthma, angina pectoris or paroxysmal tachycardia. (b) Hydronephrosis with periodic emptying of renal sac. (c) Attack of malaria, during the cold stage. (d) During convalescence from fevers like enteric. (e) Diminution or disappearance of oedema, e.g. recovery from acute nephritis, cirrhosis of liver. (f) Post-anuric diuresis. (g) Crisis of chronic nephrosis.

b. Continued polyuria

- Cranial diabetes insipidus*
- Nephrogenic diabetes insipidus*
- Primary polydipsia*

Oliguria Diarrhoea, fever, decompensated heart disease, glomerulonephritis, during accumulation of fluid in serous cavities, uraemia.

Nocturia

- Prostatism*
- Oedematous states*

- Polyuric states* - Diabetes mellitus/insipidus, primary polydipsia, Post-ATN.
- Salt-losing nephropathies* - Analgesic nephropathy, medullary sponge kidneys, sickle cell diseases.
- Bladder disease* - Tumour, infection (TB, fungal, schistosoma), loss of reflex inhibition (e.g. MS), vesicoureteric reflux (double micturition) in children.
- Transparency** - Freshly passed normal urine is clear with a faint yellow type due to urochromes.

Cloudiness - (a) Amorphous phosphates - form a white sediment in neutral or alkaline urine which disappears on addition of acid. (b) Amorphous urates - White or pink cloud which disappears on heating. (c) Blood - Bright red blood from lower urinary tract, dark red or brown from upper tract. Dipstick testing for haemoglobin is a sensitive method of detecting significant microscopic hematuria particularly when the specific gravity of urine specimen is low. (d) Bacteria - Uniform cloud or opalescence. (e) Chyluria or milky urine - due to blocking of thoracic duct by filaria or inflammatory or neoplastic conditions, with consequent rupture of lymphatics of the bladder. (f) Spermatozoa and prostatic fluid.

- Colour** - Depends on volume of urine voided and varies roughly with specific gravity. (1) *Colourless* - in polyuria and diabetes insipidus. (2) *Dark colour* - concentration as in fevers. (3) *Dark yellow* - bile, riboflavin, carotene containing foods. (4) *Red* - Drugs: (a) Excretion products - Rifampicin, metronidazole, sulphasalazine, doxorubicin, desferrioxamine. (b) Drug toxicity - Barbiturates (acute intermittent porphyria), clofibrate, heroin (rhabdomyolysis), warfarin, urokinase (hematuria) (ii) Beeturia. (iii) Favism. (5) *Red brown* - Urates, porphyria, myoglobinuria. (6) *Dark brown to black* - Alkaptonuria, tyrosinosis, melanosis. (7) *Green to greenish blue* - Methylene blue, Ps. aeruginosa infection, indigo compounds. (8) *Cloudy* - Leucocytes, bacteria, urates (acid urine), oxalates (alkaline urine), (9) *Smoky* - Trace of erythrocytes. (10) *Bloody* - Frank hematuria.

- D. **Odor** - Characteristic "aromatic" odour most marked in concentrated urine. Odour becomes *ammoniacal* during decomposition; a cloudy urine with an ammoniacal odour suggests cystitis or pyelitis, usually with obstruction in the urinary tract. Fruity odour in diabetes. Urine containing cystine may develop odour of sulphuretted hydrogen during decomposition. Articles of diet and drugs impart peculiar odour, e.g. asparagus and turpentine.
- E. **Reaction** - of fresh urine usually acidic (blue litmus paper turns red) with an average pH about 6.0. pH paper range is from 4.5 to 7.
- F. **Specific gravity** - Generally varies with quantity of urine. Normal range 1.017 to 1.020. Diseased kidneys lose partially or completely their ability to respond to the need of the body with the result that the urine has about the same specific gravity throughout the day (isosthenuria).

Chemical Examination

1. **Proteins** - Urine may contain mostly albumin (*selective proteinuria*) or may contain larger molecules as well (*non-selective proteinuria*). Excretion mainly of albumin signifies a glomerular lesion.

Causes of Proteinuria

1. **Physiological** - Amount of protein excreted is small and the condition is temporary. (a) Orthostatic benign - usually in older children and adolescence. (i) Urine sample passed on waking is negative for proteinuria while urine passed after 2 hours ambulation is positive. Usually increased by exercise. (ii) Proteinuria 'tubular' in character i.e. it contains small molecular weight proteins which normally pass through the glomerulus and are reabsorbed by the proximal tubule. (iii) <1 g/day. No increase with time. (b) Prolonged exposure to cold. (c) After a meal rich in proteins (alimentary proteinuria). (d) Pregnancy. (e) Pre-menstrual. (f) During first 10 days after birth.
2. **Pathological**
- a. *Glomerular lesion* - (i) Primary glomerular disease - Minimal change disease, mesangial proliferative GN, focal and segmental GN, membranous GN, mesangiocapillary GN, crescentic GN. (ii) Secondary glomerular disease - Diabetes, collagen vascular disease, amyloidosis, drugs (gold, penicillamine, mercury).
- b. *Overflow proteinuria* - Multiple myeloma, amyloidosis, myoglobinuria, haemoglobinuria.
- c. *Tissue proteinuria* - Acute inflammation of urinary tract.

Quantitative analysis of proteinuria

The following types of proteinuria are distinguished by mg of protein measured during a 24-hour urine collection:

Microalbuminuria	30-300 mg
Mild	150-500 mg
Moderate	500-1000 mg
Heavy	1000-3000 mg
Macroalbuminuria	300-3500 mg
Nephrotic range	3500 mg

Detection of protein in urine is done with either dipstick method or by using sulfoosalicylic acid or trichloroacetic acid. Dipstick method is easy to perform but detects only albumin, so proteinuria not due to albumin can be missed like Bence-Jones protein in multiple myeloma.

Quantification of albuminuria can be done with 24 hour urine collection (mg/24 hr) which is cumbersome or albumin-creatinine ratio on spot urine sample which is equally reliable with range of values same as 24-hour urine collection (mg/24 hr) but measured in (mg/g)

Microalbuminuria is defined as the excretion of 30-300 mg albumin/day. Because the albumin particle is relatively small, it is often among the first proteins to enter the urine after the kidney is damaged. Screening for and monitoring the level of albuminuria has been shown to be of importance in the following conditions:

- Diabetes mellitus
- Hypertension
- Myocardial infarction
- Stroke
- Pregnancy

Systemic diseases that may present as asymptomatic albuminuria - Diabetes mellitus, amyloidosis, hypertension, gout, SLE.

Mucin - Traces in normal urine. Increased amounts in irritation and inflammation of urinary tract or vagina.

Bence-Jones protein - may be found in multiple myeloma, chronic leukaemia, osteomalacia. It precipitates on warming the urine to 40° to 60°C but dissolves almost completely when the temperature is increased to 100°C.

Principal solutes in normal urine

Organic	Concentration (g)
Urea	25
Creatinine	1.5
Uric acid	0.8
Hippuric acid	0.7
Indican	0.01
Ketone bodies	0.04

Other substances	2.9
<i>Inorganic</i>	
Sodium chloride	15
Potassium	3.3
Magnesium	0.1
Calcium	0.3
Sulphate	2.5
Phosphate	2.5
Ammonium	0.7

2. **Sugars** - *Glycosuria without hyperglycaemia* - Renal glycosuria, alimentary glycosuria after ingestion of considerable amounts of carbohydrate, glycosuria of pregnancy. *Glycosuria with hyperglycaemia* - Hyperthyroidism, emotional glycosuria, increased intracranial pressure, thiazide diuretics, ether anaesthesia.

Non-glucose sugars

Lactose: May be present normally. It is present in lactating women.

Fructose: in liver disorders

Pentose: due to drug therapy or hereditary conditions

3. **Acetone bodies** (Ketonuria) - (a) Diabetes mellitus - in which normal carbohydrate catabolism is lacking. (b) Starvation in which a deficient carbohydrate diet is the cause of abnormal fat consumption.

4. Pigments

- a. *Bile pigments* - (i) *Bilirubin* - Detection of small amounts of bile of value as one of the earliest signs of acute viral hepatitis. Small amounts transiently in acute cholecystitis or cholelithiasis without obvious jaundice. (ii) *Urobilinogen* - Increased urobilinogen is found in haemolytic anaemia and liver cell dysfunction.
- b. *Haemoglobin* - Haemoglobinuria occurs in extensive burns, poisoning by mushrooms and potassium chlorate, blackwater fever, symptomatic haemolytic anaemias, and paroxysmal haemoglobinurias.
- c. *Haemosiderin* - Dark yellow pigment containing iron, occurs in haemochromatosis and pernicious anaemia.
- d. *Porphyrin* - in congenital or acquired porphyria.
- e. *Melanin* - in most cases of melanotic tumours.
- f. *Alkapton bodies* - In alkaptonuria, urine turns reddish brown to brownish black on standing and strongly reduces copper.
5. **Drugs** - Most poisons are eliminated in urine and their detection is useful in toxicology, e.g. lead, mercury, quinine.

6. **Myoglobinuria** - *Causes* - (a) Muscle crush injury. (b) Malignant hyperthermia. (c) Polymyositis. (d) McArdle's syndrome. (e) Acute alcoholic intoxication. (f) Heroin. (g) Rare diseases - Meyer-Betz. *Diagnosis* - (a) Acute oliguric renal failure. (b) Initial severe hypoglycaemia followed by rebound hypercalcaemia. (c) Red urine. (d) No red cells on microscopy. (e) Raised serum potassium, phosphate, urate.

2. Microscopic Examination

Crystals

In acid urine

Uric acid - Rosette-like clusters of prism and whet stone and rhombic plates. Of no significance unless in fresh urine. Their presence suggests stone in kidney or bladder or abnormal uric acid metabolism as in gout.

Amorphous urates - common in fevers. Fine yellowish or colourless granules or rarely slender prisms.

Calcium oxalate - "Envelope" crystals. Causes - Ingestion of vegetables rich in oxalic acids, such as tomatoes, spinach, asparagus and rhubarb; digestive disturbance with fermentation of carbohydrates, neurasthenia. Their presence in fresh urine, especially if they are clumped in small masses, is suspicious of calculi.

Leucine and tyrosine - indicate autolysis of tissue proteins. Clinically most frequent in acute yellow atrophy or phosphorous poisoning.

Cystine - Colourless refractile hexagonal plates with well-defined edges. Traces in normal urine. Cystinuria is due to obscure abnormality of protein metabolism and strongly predisposes to renal or cystine calculi.

Sulphonamides - Crystal forms of certain derivatives of sulphonamide may precipitate out from the urine.

Fat globules - After ingestion of large quantities of cod liver oil or other fats, phosphorus poisoning.

In alkaline urine

Phosphates - Amorphous phosphates, triple phosphates in osteitis fibrosa cystica, administration of parathyroid hormone, alkalosis, compensatory measure in acidosis to help maintain acid base balance. Magnesium ammonium phosphate "coffin-lid" crystals.

Calcium carbonate - as amorphous granules, or rarely as colourless spheres and dumb-bells.

Ammonium biurate - "Thorn apple" crystals.

Blood

RBCs lyse on the indicator pad of the dipstick, which detects haemoglobin. False-positive results occur in haemoglobinuria and myoglobinuria and may occur in

presence of oxidizing agents or large number of bacteria in the urine. Also in patients who ingest large amounts of vitamin C.

RBCs – On microscopy, glomerular and non-glomerular RBCs may be distinguished in fresh urine sample. Glomerular RBCs vary in size and shape and are often crenated in appearance; non-glomerular RBCs are uniformly round. When RBCs occur with significant proteinuria, they can be attributed to a renal rather than lower urinary tract source.

Leucocytes

Normally, 2 or 3 pus cells are present per HPF. If more than 5, it indicates urinary infection or noninfective conditions such as fever, stress, dehydration, urethral or bladder irritation.

Casts

Casts are cylinders of material that have been extruded from the renal tubule.

- Hyaline casts contain physiologically secreted tubular proteins and are not pathological.
- Granular casts indicate renal disease but are nonspecific, they are common in acute tubular necrosis.
- Casts comprising RBCs indicate significant glomerular inflammation and bleeding, they must be distinguished from granular casts with a few adherent RBCs on the surface.
- Waxy–Advanced stages of glomerulonephritis and renal amyloid disease.
- Malignant cells – may be visible as syncytia with prominent nuclei in stained filter preparations.
- “Telescoped urinary sediment” – Presence of more than 2 types of casts in a single urinary specimen together with leucocytes and erythrocytes usually implies lupus nephritis.

‘Telescoped’ urinary sediment

(Red cells, white cells, casts, tubular epithelial cells, fat globules) occur in collagen vascular disease especially SLE and PAN.

- WBC cast is seen in interstitial nephritis, pyelonephritis and allograft rejection.
- Eosinophiluria is seen allergic interstitial nephritis, atheroembolic disease.
- Renal tubular epithelial cells and cast is seen in acute tubular necrosis and tubulointerstitial nephritis.

Bacteriological Examination

Bacteria – most commonly found are *E. coli*, *Pseudomonas pyocyaneus*, *Staphylococcus aureus*, *Proteus vulgaris*,

Klebsiella pneumoniae and *Streptococcus faecalis*. A clear relationship has been demonstrated between in vitro sensitivity of the organism and the outcome of treatment, and laboratory control of chemotherapy improves the chances of successful treatment.

Spirochetes – *Leptospira icterohaemorrhagica*.

Ova and parasites – *Trichomonas vaginalis* and ova of *Oxyuris vermicularis* and of *Schistosoma haematobium*. Larvae of filaria. Scolices and hooklets of hydatid cysts.

Spermatozoa – sometimes found following nocturnal emissions, convulsions or prostatic massage.

Special

Pregnancy test – Concentration of human chorionic gonadotrophin (HCG) increased (1–5 IU/mL) within one week after the first missed period.

Urinary free cortisol, catecholamines, etc.

ASSESSMENT OF RENAL FUNCTION

Indications

1. *Renal disease* – (a) Detection. (b) Evaluating its severity. (c) Following its progress. 2. *Evaluation of safety and effectiveness of drugs excreted by the kidneys.*

Tests and interpretation of results

- Urine examination** and usually a quantitative measurement of proteinuria.
- Glomerular filtration rate (GFR)** is the most widely used test of renal function.

Normal GFR is about 130 mL/minute (180 litres/day, or 2 mL/second)

Measurement of Clearance

Concept of ‘clearance’ – The renal excretion of any substance per unit time is equivalent to its urinary concentration (U) multiplied by the volume of urine produced per unit time (V). The rate of renal excretion must equal that of removal of solute from the blood, which may be expressed as $P \times C$, P (plasma concentration) and C (clearance) is the virtual volume of blood that is completely cleared by the kidney of solute per unit time termed the ‘renal clearance’. Thus, $UV = PC$, and $C = UV/P$.

Following filtration, water and solutes are variably reabsorbed and secreted in the tubules. Hence, tubular function, as well as glomerular filtration governs excretion, but GFR can be estimated measuring the clearance of a solute that is filtered but neither secreted nor reabsorbed in the tubule, Inulin has this property so used for estimation for

GFR. Urea and creatinine are used as surrogate measures of renal function. However, urea undergoes passive tubular reabsorption and creatinine is actively secreted in the proximal tubule; hence urea clearance underestimates GFR and creatinine reabsorption clearance overestimates it.

Inulin clearance – involves infusion of inulin to produce a steady-state concentration; urinary excretion, which requires accurately timed urine collection, is then measured, allowing calculation of inulin clearance. Alternatively, a single bolus injection of inulin followed by sequential measurements of its disappearance from the plasma may be used. The method is now seldom performed.

Other Clearance Methods

Isotope methods – A single bolus injection of ^{51}Cr -EDTA with subsequent blood sampling. Disadvantages include radiation exposure and high cost.

Dynamic renography – An estimate of GFR can be obtained from a dynamic renogram (^{99}Tc -DPTA or ^{99}Tc -MAG3), but this method is less accurate than EDTA unless it is combined with blood sampling.

Iohexol – A low osmolality, non-ionic contrast medium is non-radioactive and can be measured by high performance liquid chromatography. Iohexol clearance is a simple, reliable and accurate method of estimating GFR.

Cystatin C is an endogenous cysteine protease inhibitor. It is a low molecular weight protein that is freely filtered by the glomerulus and is produced at a relatively constant rate. Its levels are independent of tubular function, and are therefore closely related with GFR.

Creatinine clearance – Creatinine production is relatively stable and therefore creatinine clearance is commonly used as an estimate of GFR. Urine collection should begin on an empty bladder. Patient should note the time and collect all the urine in next 24 hours, ending with complete emptying of the bladder at the same time on the following day.

Creatinine clearance gives a good approximation of glomerular filtration at high GFR. At lower GFR, however the contribution from tubular secretion becomes more important and creatinine clearance tends to overestimate GFR by 10–20%. In addition some creatinine is lost through the bowel. Patients with creatinine clearance < 15 ml/minute must be considered for dialysis.

Estimation of creatinine clearance (Cockcroft-Gault equation)

Men

Creatinine clearance =

$$\frac{(140 - \text{age}) \times (\text{wt. in kg})}{72 \times \text{Serum creatinine (mg/dL)}}$$

Women: For women, above formula is multiplied by 0.85

Note: The formula should not be used in patients below age or 18 years, those grossly obese, oedematous or cachectic, or with ascites, or when muscle mass is reduced (e.g. paraplegias), or in pregnant women.

Serum urea and creatinine concentrations – are the simplest monitors of renal function. The level of urea or creatinine depends not only on the glomerular filtration but also on the rate of production of the solute (Table 1).

At times, there may be certain substances in blood that interfere with creatinine measurement (Table 2).

Reciprocal creatinine plots – A single measure of plasma glomerular filtration does not provide a reliable indicator of GFR. However, the rate of production of

Table 1: Causes of abnormal creatinine and urea in blood

Creatinine	
<i>Raised</i>	
<ul style="list-style-type: none"> • Large muscle bulk • Acute rhabdomyolysis • Reduced tubular secretion (trimethoprim, potassium-sparing diuretics, probenecid, triamterene) 	
<i>Reduced</i>	
<ul style="list-style-type: none"> • Small muscle mass • Pregnancy • Raised antidiuretic hormone 	
Urea	
<i>Raised</i>	
<ul style="list-style-type: none"> • Reduced GFR (including dehydration) • GI bleeding • Corticosteroids/tetracycline • Catabolic state • High-protein diet 	
<i>Reduced</i>	
<ul style="list-style-type: none"> • Liver disease • Starvation/anabolic state • Pregnancy • Raised antidiuretic state 	

Table 2: Substances that interfere with creatinine measurement

Endogenous substances	Common drugs
Protein	Cephalosporins
Ketones	5-fluorocytosine
Glucose	Methanol
Bilirubin	Metabolites
Fatty acids	
Urate	
Urea	

creatinine is more constant than that of urea. There is a relationship between creatinine and GFR, by which creatinine is proportional to the reciprocal of creatinine clearance ($P = UV/C$). At high levels of GFR, even large changes in renal function can lead to minor alterations in serum creatinine. Conversely, at low levels of GFR a large change in creatinine can arise from small changes in renal function.

In many forms of CRF, decrease in GFR occurs at a constant rate, and a plot of the reciprocal creatinine level against time should therefore give a straight line. Any deviation from the predicted plot may give an early indication of an intercurrent additional renal insult.

Cystatin C is a biomarker for kidney function. If kidney function and GFR decreases, cystatin C level rises. It is a better test for kidney function than creatinine (Table 3). Cystatin C levels are altered in patients with cancer, impaired thyroid function

Differential renal function – In some situations (particularly when planning surgery), it is important to know the relative contribution of each kidney to overall renal function. This can be determined using ^{99}Tc -DMSA, which localizes in the proximal tubular cells. Using a gamma camera, activity-time curves are generated for each kidney. Uptake of activity by each kidney can then be used to determine the relative contribution to overall GFR. The error with this technique lies in the difference in depth of the two kidneys; each 1 cm difference accounts for a 10% difference in activity count.

TESTS OF TUBULAR FUNCTION

1. **Urinary concentration and dilution** – Inability to concentrate the urine to more than 600 mOsmol/litre indicates diabetes insipidus. Cranial diabetes insipidus can be distinguished from nephrogenic diabetes insipidus by subsequent response to ADH.

The ability to dilute urine to achieve maximum free water clearance is also often impaired in patients with CRF. It can be assessed by administering 1000–1500 mL water (12 mL/kg body wt). More than 75% of the water load should be excreted within 3 hours and urinary osmolality fall below 100 mOsmol/kg.

Table 3: Cystatin C levels and GFR

Cystatin C level	Interpretation
0.5–6.9	Normal GFR
1–1.2	Mild decrease
1.3–1.9	Moderate decrease
2–3	Severe decrease
> 3.5	End-stage kidney disease

2. **Urinary acidification tests** – In distal type I and type II renal tubular acidosis (RTA), patients are unable to generate an acid urine ($\text{pH} < 5.5$). Diagnosis is confirmed if low urine pH is not achieved in presence of systemic acidosis. Oral acidification tests (usually with ammonium chloride) are indicated only in partial RTA, in which patients are hypocalcaemia but not acidotic as a result of increased excretion of hydrogen ions with ammonia. In the proximal type II RTA, bicarbonate resorption is defective; the urine may still be acidic if bicarbonate entry to the tubule is reduced by severe systemic acidosis and/or low GFR.

3. **Urinary electrolytes and other tests of tubular function** – Measurement of 24-hour sodium output is at times helpful in managing patients with salt-losing nephropathy. Low urinary sodium ($< 10 \text{ mm}$) is associated with prerenal failure but this measurement should not determine management because a higher sodium level will not respond to appropriate filling. Tests of proximal tubular function may be required in the investigation of Fanconi's syndrome or isolated proximal tubular defects (e.g. urate clearance). Bicarbonate, glucose, phosphate and amino acids are normally reabsorbed in the proximal tubule, their presence in the urine is abnormal.

RENAL IMAGING

Ultrasonography – has largely replaced IVU as the first-line investigation of renal disease. The bladder should be imaged full, to allow optimal assessment of wall thickness, masses and calculi. Post-micturition volume can be assessed. Indications for renal system ultrasonography are given in Table 4.

Doppler ultrasonography – Using colour Doppler, vessel patency, direction of flow and abnormal vascularity can be determined.

Plain abdominal radiography – of kidneys, ureters and bladder (KUB). Renal outline can be defined, calcification may be detected in renal areas, ureters, bladder and urethra. Common causes of renal tract calcification are urinary calculi, and nephrocalcinosis, focal calcification (e.g. tuberculosis, tumour) is also seen.

Intravenous urography (IVU) – gives excellent anatomical information and some indication of function, but diagnostic IVU may be difficult to perform in patients with renal impairment. A 1-minute film after IV injection of contrast medium, coned to renal area, coincides with highest concentration of contrast medium in the nephrons and this 'nephrogram' can be used to assess renal size and outline. A 5-minute film shows the pelvicalyceal system,

Table 4: Indications for renal system ultrasonography**Paediatrics**

- Renal masses – hydronephrosis, tumours, cystic disease
- Bladder dysfunction

Renal failure

- Obstruction – Pelvicalyceal dilatation
- Kidney size, cortical thickness and scars

Renal masses

- Differentiation of simple cystic and solid lesions and abscesses
- Tumour extension into renal vein

Calculi

- Detection of radiolucent stones
- Demonstration of site of stone impaction

Renal transplantation

- Complications – obstruction and vascular patency, perirenal collections (e.g. lymphocoele, urinoma)

Bladder

- Post-micturition volume combined with flow rate

Renal Doppler

- Renal artery stenosis
- Venous patency
- Vascularity of renal masses

Intervention

- Renal biopsy
- Nephrostomy
- Cyst aspiration
- Drain insertion

Prostate

- Transrectal ultrasonography
- Prostatic biopsy

detecting abnormal filling defects. Further films show ureters and bladder. A post-micturition film is looked at for bladder emptying, intravesical abnormalities and obstruction. The IVU films series should be inspected for:

Kidneys

- Kidney length is about 3 lumbar vertebrae. The left kidney is slightly higher and larger than the right.
- Renal outline should be smooth. Patients with renal masses may have associated calyceal distortion.
- Calyceal dilatation may be caused by obstruction or by disease of the papilla (papillary necrosis, pyelonephritis, reflux nephropathy).
- The renal pelves are inspected for filling defects (e.g. tumour, stones, blood clot, sloughed papilla).

Ureters – Opacification of the whole ureter suggests distal obstruction. Displacement occurs in retroperitoneal pathology (e.g. retroperitoneal fibrosis).

Bladder – Contour should be smooth and no post-micturition residual volume should be seen.

CT – provides excellent anatomical and functional information on renal perfusion and filtration. Using fast spiral CT, kidneys can be imaged initially in the parenchymal phase, followed by the pyelogram phase (analogous to IVU).

Indications

- Renal trauma
- Staging and assessing response to therapy in renal (Figs. 1A and B), bladder (Fig. 2), prostatic and testicular carcinoma
- Investigation of renal masses when ultrasonography is equivocal or tumour is small

Figs. 1A and B: CECT (A) axial and (B) coronal image showing left renal mass at lower pole (arrow)

Fig. 2: CECT showing carcinoma of bladder (arrow)

Fig. 3: CT coronal view showing left renal calculus (black arrow) with emphysematous pyelonephritis (white arrow)

Fig. 4: Angiography showing right renal artery stenosis (arrow)

- To distinguish stones (Fig. 3) from transitional cell carcinomas when a pelvicalyceal defect is seen on IVU or ultrasonography
- Detection of ureteric calculi
- Retroperitoneal fibrosis and masses

Spiral CT angiography demonstrates the renal vasculature, this is useful in renal artery stenosis (Fig. 4), and shows the relationship of renal arteries to aortic aneurysms.

MRI - is used principally in the staging of pelvic, prostatic and renal tumours, as an alternative to CT. Renal cell carcinoma, angiomyolipoma and simple and complex cysts can be readily distinguished by MRI, which is an excellent means of imaging thrombus, tumour in the renal veins. It is useful in those who are intolerant of iodinated agents because of allergy or nephrotoxicity and in pregnancy.

Magnetic resonance urography (MRU) is used in patients with chronic urolithiasis or ureteric tumour, and in paediatric urology. It can be performed in two ways:

- Excretory MRU is analogous to IVU.
- In static-fluid MRU, non-enhanced T₂-weighted sequences produce excellent images of markedly dilated urinary tract, even in patients with markedly impaired renal function.

Magnetic resonance angiography is the most common form of renal MRI. The renal artery can be studied with or without contrast, though the use of IV gadolinium considerably improves sensitivity and specificity. The sensitivity is comparable to that of angiography or multislice CT in determination of renal artery stenosis.

Interventional magnetic resonance procedures—Open- access scanners can be used to perform nephrostomy and take biopsies.

Nuclear medicine

Static renal scanning uses ^{99m}Tcdimercapto-succinic acid (^{99m}Tc-DMSA), which binds to the proximal renal tubules. The kidneys are imaged 3 hours post-injection, when about 15% of the tracer has been excreted. About 20% is retained in each kidney. It is used mainly in children to identify renal scarring.

Dynamic renography uses radiolabelled tracers that are excreted rapidly by the kidneys, their arrival, uptake and elimination are imaged using a gamma-camera.

Uses

1. Venography gives useful information on degree of obstruction, relative renal function and renal artery stenosis.
2. Assessment of renal transplants, in terms of perfusion, filtration and drainage.
3. In obstruction, frusemide may be given IV at 15 minutes post-tracer injection and the amount of washout calculated; this is useful to confirm pelviureteric junction obstruction.
4. In children vesicoureteric reflux (indirect radionuclide cystography) should be sought during micturition. In significant renal artery stenosis, tracer uptake is decreased after administration of captopril, reflecting reduced blood flow and renal function.

Direct radionuclide cystography – ^{99m}Tc is instilled to maximum bladder capacity. The kidneys and ureters are imaged continually during this procedure and subsequent micturition views are assessed for reflux.

Special techniques

Ureterography is used to identify urethral strictures or injuries in men.

Micturating cystography – Contrast medium introduced via a catheter fills the bladder to capacity; the catheter is removed and films are taken during voiding with the patient upright using fluoroscopy. It is used to look for vesicoureteric reflux, structural bladder and urethral abnormalities (urethral valves, bladder diverticula) and micturition dysfunction.

Antegrade pyelography is used to identify the precise level in upper renal tract. A needle is inserted into a dilated pelvicalyceal system under ultrasound or fluoroscopic guidance. The initial urine sample is sent for culture and cytology. Contrast medium is then used to opacify the urinary tract and identify the level of obstruction. This can be undertaken as a prelude to nephrostomy.

Retrograde pyelography is now seldom performed but is indicated in suspected transitional cell carcinoma of the upper renal tract. The ureters are catheterised retrograde and contrast is introduced to opacify the upper tracts.

Angiography – Its use has declined since the introduction of CT and ultrasonography. It is usually performed using DSA.

Indications –

1. In live transplant donors to document the number and pattern of renal arteries and to confirm the normality of the other kidney.
2. As a part of embolization procedure for AV malformations, in fistulas and as palliative embolization therapy for renal tumours.
3. As a diagnostic and therapeutic tool in renal vascular abnormalities such as renal artery stenosis and fibromuscular dysplasia, and angioplasty can be performed at the same time.

Venography can be performed to demonstrate renal venous patency as part of varicocele embolization and detection of undescended testis.

Interventional uroradiology – Nephrostomy (insertion of a catheter into the pelvicalyceal system) is a common urinary tract intervention. It is indicated in obstruction to prevent loss of renal function, in presence of pyonephrosis and for pain relief. Percutaneous nephrolithotomy may be performed to extract calculi from renal pelvis. Other procedures that can be performed subcutaneously include biopsy, pyelolysis in PUJ obstruction, ureterolithotomy, antegrade stent insertion, and cyst and abscess aspiration.

KIDNEY BIOPSY**Indications**

1. **Asymptomatic proteinuria** – Patients with normal renal function but persistent proteinuria of 2 g or more/24 hrs. Biopsy may demonstrate a treatable condition such as SLE, membranous nephropathy.
2. **Nephrotic syndrome** – (Proteinuria >3 g/24 hours, plasma albumin <35 g/litre and oedema) in patients under 1 year or over 10 years of age require renal biopsy. In 1–5 years old, likelihood of minimal change nephropathy is more than 90%; this responds to corticosteroid treatment. Therapeutic trials of high dose corticosteroids can be avoided.
3. **Persistent proteinuria and hematuria** – associated with renal impairment measured by GFR.
4. **Acute renal failure** – The most common finding is vasculitis. This is usually seen as vasculitic GN, in which destruction of varying amounts of the glomerular tuft occurs in varying numbers of glomeruli. Other common findings are acute interstitial nephritis, small vessel vasculopathy of the type seen in scleroderma, accelerated hypertension or haemolytic uraemic syndrome, myeloma kidney and acute post-infective GN. In all these causes of ARF, the tubules are abnormal and acutely damaged. If acute tubular damage is the only finding, it suggests a likely cause (e.g. the effects of gentamicin).

5. **Chronic kidney failure with normal-sized kidneys** – An accurate histological diagnosis may help determine prognosis and plan treatment. Biopsy may be useful in diagnosis of paraprotein-associated disease, in which the outlook for the patient may be limited, and focal segmental glomerulosclerosis, in which transplantation is associated with a significant risk of disease recurrence.
6. **Renal allograft dysfunction** – Biopsy is used to determine whether an immune response against the transplanted kidney (rejection) is present. Acute rejection occurs soon after transplantation and often takes the form of acute cellular rejection. Acute vascular rejection is less common. Many grafts develop slow narrowing of the arteries leading to ischaemia, loss of tubules and decline in function (chronic vascular rejection).
7. **Systemic disorders** – Associated with hematuria, proteinuria or impaired renal function. Biopsy important for determining diagnosis and prognosis. Severity of renal lesion may influence nature of therapy, e.g. in SLE, serial biopsies may be useful in judging response to treatment.

Contraindications

1. Single kidney or severe malfunction of one kidney.
2. Uncontrollable bleeding diathesis.
3. Small, shrunken kidneys (difficult to locate, and information obtained usually non-specific).
4. Asymmetrical kidneys with significant discrepancy in split function (measured by isotope technique).

Table 5: Complications of renal biopsy

• Hematoma <ul style="list-style-type: none"> – Occult (visible by CT) – Clinically significant
• A-V fistula <ul style="list-style-type: none"> – Occult (demonstrable by angiography) – Clinically significant
• Macroscopic hematuria (Microscopic hematuria occurs in most patients)
• Blood loss requiring transfusion
• Infection
• Surgical intervention required post-biopsy
• Loss of kidney
• Inadvertent biopsy of other organs (e.g. liver, spleen, pancreas, intestine, gallbladder, adrenal glands)

5. Reflux nephropathy.
6. Acute urinary infection

In patients with a coagulation defect, transjugular renal biopsy may be used.

Preparation – Investigations required are FBC, electrolytes, urea and creatinine, LFTs, clotting screen, group and store serum for blood crossmatching, and ultrasound measurement of the size and symmetry of the kidneys. Serology for anti-GM antibodies if required. Premedication and IV line. Diastolic B.P. should be controlled at less than 90 mm Hg. If creatinine is > 400 µmol/L, DDAVP may be given parenterally to reduce risk of bleeding.

Technique

Localization of the kidney – (a) *Native renal biopsy* – Lateral border of lower pole of kidney is the safest area to biopsy. Ultrasound is the preferred imaging technique to mark the position of the kidney. It is particularly preferred in patients with impaired function as it avoids use of contrast media. (b) *Allograft biopsy* – Safest area is generally the lateral border of the more accessible pole.

Biopsy needle – Disposable needles of the Tru-cut type or newer, automatic systems, in which the core of tissue is taken automatically by rapid opening and closing of the needle using a spring mechanism. Spring-loaded techniques require fewer passes to obtain tissue and allow use of finger gauge needles.

Complications – Complications of renal biopsy are listed in Table 5.

2. HEMATURIA

Causes of hematuria are listed in Table 6.

Table 6: Causes of haematuria

In the urinary tract

Kidney

- Congenital anomalies—Polycystic disease, angioma.
- Calculus.
- Mobile kidney.
- Infections – Pyelonephritis, tuberculosis, glomerulonephritis.
- Neoplasms – Renal carcinoma, Wilm's tumour.
- Drugs – Sulphonamides, anticoagulants.
- Trauma – Ruptured kidney.
- Oxaluria.
- Post-operative – After nephro- or pyelolithotomy or partial nephrectomy.

Contd...

Contd...

- Radiation damage.
- Hereditary nephritis – Airport's syndrome, familial recurrent haematuria.
- Renal embolization/infarction.
- Analgesic nephropathy.
- Unknown origin – Essential haematuria ("renal epistaxis"). Loin pain/haematuria syndrome.

Ureter

- Trauma.
- Calculi.
- Infection.
- Tumours – Papilloma, carcinoma.

Prostate

- Benign hypertrophy
- Carcinoma.

Bladder

- Diverticulum.
- Trauma – following prostatectomy or other operations or instrumental.
- Calculus or foreign body.
- Tuberculosis.
- Tumours – Simple, papilloma, carcinoma.
- Ulcers.
- Chemical cystitis – e.g. after cyclophosphamide.
- Parasitic – Schistosomiasis, bancroftian filariasis.

Urethra

- Malformations.
- Injuries.
- Calculus or foreign body.
- Infections.
- Tumours.
- Naevus.

Systemic causes

- Bleeding diathesis.
- Collagen disorders – SLE, PAN.
- Subacute infective endocarditis.
- Cryoglobulinaemias.
- Amyloidosis.
- Acute fevers – Malignant malaria.
- Tuberous sclerosis (associated angiomyolipomata).
- Severe exertion (e.g. jogging).

Investigation of a Case of Haematuria**History**

1. *Age* – Newborn – Haemorrhagic disease due to deficiency of vitamin K. Child – Acute nephritis, acute leukaemia, acute infectious fevers, scurvy, haemophilia, bladder stone, meatal ulcer. Young adults – Renal calculus or tuberculosis, gonococcal urethritis. Middle or old age – Bladder tumours, congenital cystic kidneys, calculus, hypernephroma and other malignant tumours, hypertension, enlarged prostate.
2. *Sex* – Bladder stone almost always in males.
3. *Family history* – of polycystic kidneys or urinary calculi.
4. *Drugs* – History of taking anticoagulants, sulphonamides or large doses of aspirin.
5. *Previous history* – of pulmonary or bone and joint tuberculosis.
6. *Quantity of blood* – Profuse in tumours of kidney or bladder injury with rupture of kidney. Rarely tuberculosis and enlarged prostate.
7. *Precipitating cause* – Trauma, jolting or exercise in renal calculus. Instrumentation. Intercourse.
8. *Timing of bleeding in relation to urinary stream* – Terminal haematuria preceded by clear urine suggests source in bladder, initial haematuria followed by clear urine is indicative usually of lesion in urethra. Haematuria equally distributed throughout the urinary flow is characteristic of renal and ureteric lesions, but may occur in bleeding from the bladder.
9. *Pain* – (i) Colicky in stone. (ii) Loin pain suggests renal cause. (iii) Pain at tip of penis especially after micturition indicates irritation of trigone. (iv) Pain in perineal area – malignant disease of bladder or prostate. (v) Hypogastric pain in cystitis. (vi) In Dietl's crisis, severe pain but haematuria rare. Haematuria precedes pain in tuberculosis and new growth of kidney; follows pain in renal stone.
10. *Absence of pain* – Enlarged congested prostate, early stage of malignant disease of bladder, renal neoplasms, congenital cystic kidneys, tuberculosis and systemic causes. Painless, periodic, progressive and profuse haematuria in simple papilloma.
11. *Increased frequency of micturition* – Local causes in bladder, tuberculosis or pyelitis.
12. *Constitutional symptoms* – Fever in pyelitis and cystitis. Rash or eruption in acute fevers.
13. *Haemorrhage elsewhere in the body* – in purpura, haemophilia, fevers, hypertension.

Physical Examination

- a. *Local examination:*
 1. Palpation of kidneys - (i) Unilateral tumour - in tuberculosis, hypernephroma, hydro- or pyonephrosis. (ii) Bilateral in polycystic disease.
 2. Bladder tumour is occasionally palpable.
 3. Inspection of external genitals and urinary meatus for local causes.
 4. Examination of testis and epididymis for evidence of tuberculosis.
 5. Rectal examination - Enlarged prostate, stone in bladder in children.
 6. Vaginal examination - pelvic tumour, e.g. malignancy of uterus.
- b. *General examination* - Examination of heart for SBE. Blood pressure. Signs of anaemia. Bruising or other evidence of haemostatic defect. Abdominal palpation for splenomegaly, enlarged kidneys or distended bladder.

Investigations

1. *Urine* - (i) Excess of crystals of uric acid, oxalates, etc., may indicate presence of stones. (ii) Albuminuria and epithelial cells in acute nephritis. (iii) Pus cells in pyelitis and tuberculosis. (iv) Red cells - In glomerular bleeding there is great variation in size and many cells show loss of normal haemoglobin pigment. In non-glomerular bleeding the cells are uniform in appearance and usually have normal haemoglobin content (except in acid urine). (v) Renal tubular epithelial cells - A sharp rise in these cells may be produced by certain drugs. The number of these cells is greatly increased in acute tubular necrosis. (vi) Casts - Red cell casts or casts containing red cells imply glomerular disease. Granular casts, oval fat bodies and broad, waxy casts imply an underlying renal lesion. (vii) Culture - Pyuria with no growth on urine culture occurs with tuberculosis, tumours of urinary tract and analgesic nephropathy. (viii) Cytology - when urothelial neoplasm is suspected.
2. *Blood examination* - for evidence of hypoprothrombinaemia, purpura or haemophilia.
3. *Chest radiograph* - for evidence of malignancy or tuberculosis.
4. *Cystoscopy* - If IVU and urine culture are normal. Upper urinary tract bleeding is usually unilateral. Bladder tumours and pre-malignant papillomata can be diagnosed by cystoscopy, with biopsy when necessary.
5. *Renal imaging.*
6. *Additional investigations:*
 - a. *Serum calcium and phosphorus* - to exclude hyperparathyroidism with urinary calculi.
 - b. *Serum acid phosphatase* - Elevated in carcinoma of prostate associated with metastases.
 - c. *Prostatic biopsy* - when prostatic carcinoma is suspected.
 - d. *Prostatic exfoliative cytology* - Examination of prostatic fluid obtained by prostatic massage may show malignant cells.
 - e. *Kidney biopsy* - in patients with recurrent haematuria in whom IVU and cystoscopy are normal and urine shows proteinuria, red cell casts and impaired renal function and raised serum IgA concentration.

3. GLOMERULAR DISEASES

A group of diverse entities, including, but not limited to glomerular inflammation (glomerulonephritis). Structural, functional and clinical similarities exist within the group because of the limited ways a tissue can respond to injury, and these injuries manifest as symptoms and signs.

Mechanism of glomerular injury - Many glomerular diseases, whether occurring in isolation or as part of multisystem diseases, are associated with demonstrable immunological abnormalities. There are two possible mechanisms:

1. **Antigen in kidney** - (in situ complex formation) - Antigen may be an intrinsic part of the glomerulus, or derived from other parts of the body and deposited in the glomerulus. Thus formation of antigen-antibody complex can occur if an appropriate antibody is generated.
2. **Antigen remote from the kidney** - (Antigen either endogenous or exogenous from other sources than the kidney) - When the antigen-antibody complex gains access to, or is produced in the circulation, it can be deposited in the kidneys, where it activates mediators of inflammation. The production of glomerular injury is complex and probably depends on linked cellular and non-cellular mechanisms. Immunohistopathological study of renal tissue from renal biopsies reveals antibody (IgG, IgM or IgA) and complement components. Also the common finding of monocytes, macrophages (producers of TNF-alpha and interleukin-1) and T helper lymphocytes (producers of interleukin-2) suggests a role for these cells and cytokines in pathogenesis.

Table 7: Causes of glomerular disease

1. Hereditary disorders –
– Alport's syndrome – Progressive nephritis and sensorineural hearing loss. Characteristic 'basket-weave' appearance of glomerular basement membrane.
– Thin membrane basement disease – presents as recurrent hematuria.
– Familial clusters – Some conditions like minimal change nephropathy, focal and segmental glomerulosclerosis have been reported in familial clusters.
2. Systemic disease in which glomerulonephritis may feature
– Connective tissue diseases, particularly SLE
– Systemic vasculitis
– Infective endocarditis
– Other infections including Staph. aureus, malaria, hepatitis B, HIV
– Drug reactions (NSAIDs, gold, penicillamine), carcinoma, lymphoma, myeloma
3. Idiopathic

CAUSES OF GLOMERULAR DISEASE

These are listed in Table 7.

PRESENTATION OF PRIMARY GLOMERULAR DISEASE

- Asymptomatic proteinuria
- Nephrotic syndrome
- Nephritic syndrome
- Microscopic hematuria (occasionally macroscopic particularly after intercurrent infections in IgA nephropathy)
- Hypertension
- Rapidly progressive glomerulonephritis

ACUTE GLOMERULONEPHRITIS

A disease most common in children, characterised pathologically by diffuse inflammatory changes in the glomeruli and clinically by usually abrupt onset of macroscopic hematuria, proteinuria (usually moderate), oedema, hypertension and impaired kidney function with or without oliguria. Not all features may be present at the same time.

Pathogenesis of GN – Immune reactions underlying GN: There are contributions from cellular immunity (T lymphocytes, macrophages), humoral immunity (antibodies,

immune complexes, complement), and other inflammatory mediators (including the coagulation cascade). In some cases, the target of immune response is known (e.g. when GN complicates infections or tumour). In many cases, the target is unknown and an autoimmune aetiology is suspected.

As in other autoimmune conditions, primary GN is considered to result from an interaction between genetic susceptibility and an environmental precipitant. Genetic factors are typically genes involved in control of the immune response, particularly major histocompatibility complex and HLA genes. Environmental precipitant may be drugs, chemicals or infectious agents. The role of immune mechanisms in the pathogenesis of GN is indicated by the presence of circulating autoantibodies and/or abnormalities of serum complement, and glomerular deposition of antibodies, immune complexes, complement and fibrin.

Clinical Features

Modes of onset – (a) Oedema – puffiness of face. (b) Urinary symptoms – Scanty and smoky or frank bloody urine. (c) Symptoms of acute infection – Fever, bodyache, vomiting. (d) Cerebral symptoms – Headache, convulsions. (e) Insidious onset – Weakness, pallor, loss of appetite. (f) Accidental discovery – on routine urine examination.

Symptoms and Signs

1. *Oedema* – may come on suddenly or gradually. Puffiness of face and whitish pallor constitute “nephritic facies”, swelling of face usually in morning. Generalized anasarca may occur. Oedema may be absent in mild cases and also in very severe cases.
2. *Hypertension* – occurs in majority of cases, the diastolic pressure being 90 to 120 mm usually, and as a rule persists for at least one week, returning to normal a few days after patient has had diuresis. In 5 to 10% cent cases hypertensive encephalopathy develops. The rise of pressure may give rise to pulmonary oedema. JVP is commonly elevated and with peripheral oedema presents a picture of CHF. Renal retention of salt and water is responsible for the circulatory disturbance.
3. *Impaired renal function* – Oliguria. Acute renal failure develops in some.

Laboratory Tests

1. *Urine* – Volume reduced, dark in colour or smoky when fresh, tea-coloured after haemolysis. Proteinuria variable, rarely more than 2.5 g per day. Red cells and red cell casts. Also white cells, white cell casts and granular casts.

2. *Evidence of streptococcal infection* – in post streptococcal GN. Demonstration of presence of A beta-haemolytic streptococcus of nephritogenic M - protein type in throat or skin lesion, and of an immune response to one or more of streptococcal exoenzymes.
3. *Haematology* – Polymorphonuclear leucocytosis, raised ESR.
4. *Osmolality* – of diagnostic help because osmolality of urine is often appreciably higher than that of plasma in acute nephritis in contrast to other forms of acute renal failure.
5. *Renal biopsy* – Indications – (i) Unusually protracted course, especially if accompanied by kidney failure. (ii) Suspicion of multisystem disease. (iii) Transition to nephrotic phase. (iv) Persistent hypocomplementaemia.

Tests to Exclude a Systemic Disorder Underlying GN

- Chest radiography (plus more detailed screening for malignancy if suspected)
- Microbiological tests (e.g. blood culture, viral serology)
- Lupus serology (particularly anti-DNA antibodies)
- Serum complement levels (low C3 and/or C4 common in acute lupus, systemic infections, immune complex disease)
- Antineutrophil cytoplasmic antibody (if systemic vasculitis is suspected)
- Myeloma screen (serum immunoglobulin electrophoresis urine test for Bence-Jones protein)

Course – Complete recovery occurs in majority of children and in about 50 % of adults. Even when acute renal failure develops the patient may recover despite oliguria lasting for several weeks. Haematuria, which is often exacerbated by exertion, commonly persists for 6–12 months before complete recovery. Slight proteinuria persists for many months before returning to normal.

Complications – (a) Acute renal failure. (b) Acute heart failure with pulmonary oedema. (c) Hypertensive encephalopathy. (d) Urinary tract infection especially if oliguria is prolonged. (e) Renal or urinary tract pain occasionally as a result of clot colic. (f) Arthritis occurs rarely and suggests multisystem disease.

Management

1. *Rest in bed* – diminishes risk of pulmonary oedema and hypertensive crises. In a mild case, 3 weeks, in more severe cases it must at least be 3 months. Persistence of microscopic haematuria, or proteinuria under 1 g day does not justify prolonged bed rest. Patient should

be allowed to be up and about once urinary findings have become stationary. Bowels should be kept open.

2. *Restricted fluids* – (Fruit juices contain potassium and should be used with caution in oliguric patients). First 24–28 hours only 500 mL of water and glucose or barley water. After that if urine volume in 24 hours is less than 400 mL, treat as for acute renal failure. If urine volume is more than 400 mL limit intake of fluid to 500 mL plus a volume equal to that passed in preceding 24 hours; low salt, low protein diet can be started.
3. *Diet* – Low protein diet. If patient is oedematous or has engorged neck veins, the diet should contain very little sodium.
4. *Antibiotics* – Benzathine penicillin G 500,000 units IM 6-hourly to destroy any residual haemolytic streptococci. Erythromycin 250 mg qds if penicillin is not tolerated.
5. *Management of complications* – (i) Convulsions – IV Diazepam 10 mg slowly, if fits recur phenytoin sodium 100 mg bd IM (ii) Hypertension – ACE inhibitors or angiotensin II receptor antagonists. (iii) Acute renal failure – See renal failure.
6. *Dialysis* – if unconscious, twitching or deteriorating patient, rapidly rising blood urea or rising serum potassium. In children peritoneal dialysis is preferred to haemodialysis.
7. *Transplantation* for those who progress to ESKF. Some forms of GN tend to occur in transplanted kidneys.

Subtypes of GN – Using histological analysis, it is possible to identify subtypes of GN with particular pattern of glomerular injury. Although there is some overlap in presentation treatment and prognosis, these subtypes have certain distinguishing features.

Following are types of glomerulonephritis which presents with acute nephritic syndrome:

IgA nephropathy – is the most common type of GN. It presents with hematuria, which may be macroscopic, particularly after recurrent infections. Prognosis is generally good if no associated proteinuria, hypertension or impairment of excretory renal function. If proteinuria is more than 1 g/24 hours, risk of eventual ESRF is about 25%.

Renal biopsy – Deposition of polymeric IgA in the glomerulus, usually associated with proliferation of intrinsic glomerular cells is pathognomonic. Aetiology is unknown, but there is evidence that primary abnormality is in the IgA system rather than in the kidney. An identical glomerular lesion is seen in Henoch-Schonlein purpura.

Management – There is no proven treatment. Fish oils may protect renal function in poor prognosis subgroups. ACE inhibitors are antihypertensive agents of choice. In

case of rapidly progressive glomerulonephritis, steroid and plasmapheresis should be considered.

Mesangiocapillary GN (MCGN, membranoproliferative GN) – is uncommon. There are three subtypes, with indistinguishable clinical presentations (proteinuria, hematuria, hypertension, impaired renal function) and findings on histology. The subtypes are defined according to appearances on electron microscopy, and probably have different pathogenesis. MCGN is associated with activation of the complement cascade – the classical pathway in type I MCGN, alternative pathway in type II and terminal pathway in type III. Types II and III MPGN are usually idiopathic, except in patients with complement factor H deficiency, in the presence of C3 nephritic factor and/or in partial lipodystrophy producing type II disease or complement receptor deficiency in type III disease.

Type II MCGN may be associated with partial lipodystrophy in which selective loss of fat cells in the face and upper trunk occur giving patients a characteristic cadaveric appearance. Secondary forms of MCGN are usually of type I pattern and result from chronic infections (e.g. infective endocarditis, visceral abscesses, infected prosthetic materials) or cryoglobulinaemia (which may complicate infections particularly hepatitis C).

On renal biopsy: 1. Type I MPGN, there is mesangial proliferation with lobular segmentation and mesangial interposition between the capillary basement membrane and endothelial cells, producing a double contour sometimes, called “tram-tracking”. 2. Type II MPGN, biopsy shows a dense thickening of the GBM containing ribbons of dense deposits and C3, sometimes called “dense deposit disease.” 3. In Type III MPGN, proliferation is less common than the other two types and is often focal; mesangial interposition is rare and subepithelial deposits can occur along widened segments of the GBM that appear laminated and disrupted.

All types of MCGN tend to have a progressive course; up to 50% develop chronic renal failure within 10 years.

Management – Control BP with ACE inhibitors and treat other complications (e.g. hypercholesterolaemia). High-dose corticosteroids are not always effective. Therapy aimed at blocking complement activity may be useful. In secondary MPGN, treating underlying condition is important.

Focal necrotizing GN – FNGN is the renal lesion associated with the clinical syndrome of rapidly progressive GN (RPGN) and is a medical emergency. Severe acute inflammation occurs in the glomerulus, sometimes with formation of ‘crescents’ when the glomerulus is squashed

by cells that fill Bowman’s space; these cells are a mixture of infiltrating inflammatory cells and proliferating resident cells. ARF can occur without crescents if glomerular necrosis is sufficiently severe.

If antibodies to glomerular basement membrane (GBM) are present, the glomerulus shows linear deposition of IgG. More commonly there is no immunoglobulin in the glomerulus and the condition is termed (pauci-immune FNGN); these patients typically exhibit circulating antineutrophil cytoplasmic antibodies (ANCA).

Anti-GBM disease is the only form of GN in which the pathogenesis is fully understood and treatment rational (plasma exchange to remove circulating antibody, corticosteroids to suppress inflammation, cyclophosphamide to suppress further antibody synthesis).

Small vessel vasculitis – Wegener’s granulomatosis, Churg-Strauss syndrome and microscopic polyangiitis are small vessel vasculitides usually associated with ANCA. The renal manifestations in all three diseases are hematuria and proteinuria, often with rapid deterioration of excretory renal function. Focal segmental necrosis of glomerular capillaries with crescent formation but without immune deposits (segmental necrotizing glomerulonephritis), is characteristic on kidney histology. On biopsy, Wegener’s granulomatosis is differentiated from other small vessel vasculitis by presence of noncaseating granuloma. Diagnosis is confirmed by detection of ANCA by indirect immunofluorescence or enzyme-linked immunosorbent assay.

Management – Initial therapy (remission induction) requires high-dose cyclophosphamide and corticosteroids. Plasma exchange results in significant improvement. In those with less advanced renal involvement (creatinine < 5.6 mg/100 ml). Prednisolone 1 mg/kg/day PO to maximum of 80 mg/day; dose reduced to 12.5-15 mg/day by 3 months plus Cyclophosphamide 2.5 mg/day. During cyclophosphamide therapy, cotrimoxazole 480 mg 3 times per week for prophylaxis of *Pneumocystis jiroveci*, *Nocardia* and nasal streptococcus aureus infections. WBC count is monitored weekly. Cyclophosphamide should be continued for up to 3 months. If clinical remission is achieved, cyclophosphamide is replaced with azathioprine 2-3 mg/day initially, reduced to 1.5 mg/kg/day by the end of the first year. Later, if patient is both clinically in remission and ANCA negative, both azathioprine and prednisolone are slowly reduced and then stopped.

In patients intolerant to azathioprine, mycophenolate mofetil may be tried starting at 250 mg PO b.d. and increasing to 1 g b.d. over 3-4 weeks.

Post-infectious GN – Proliferative GN is seen in association with certain infections particularly streptococcal throat infections, also staphylococcus, influenza B, certain parasites. Usual presentation is with *acute nephritic syndrome*. (Refer to Acute GN).

Causes

1. **Primary renal disease** – Idiopathic, immune complex, anti-GBM nephritis.
2. **Secondary extrarenal disease** – (a) Infections – PSGN, infective endocarditis, shunt nephritis, visceral sepsis, hepatitis. (b) Multisystem disease – SLE, Henoch-Schonlein purpura, Wegener's granulomatosis, polyarteritis nodosa, disseminated intravascular coagulation, accelerated hypertension.

Clinical features

Hypertension, oedema, proteinuria and microscopic haematuria continue till the patient dies of renal failure or hypertension in 6–18 months after initial attack. Death from uraemia occurs in about 1½–2 years of onset.

Renal biopsy — Demonstrates hypercellularity of mesangial and endothelial cells, glomerular infiltrates of polymorphonuclear leukocytes, granular subendothelial immune deposits of IgG, IgM, C3, C4 and C5-9 and subepithelial deposits (which appear as “humps”). In endocarditis related glomerulonephritis, foci of necrosis is seen.

Treatment

Plasma exchange (2–4 litres of plasmapheresis daily) combined with corticosteroids and cyclophosphamide in patients with diffuse crescentic glomerulonephritis. Also anticoagulants, like heparin and warfarin and antithrombotic agent such as clopidogrel because of involvement of coagulation process in crescent formation. Table 8 lists renal diseases requiring plasmapheresis.

Nephrotic Syndrome (NS)

A clinical condition in which there is oedema, proteinuria and hypoproteinaemia and hyperlipidaemia irrespective of aetiology or any other additional abnormal clinical features. Over 80% of patients with nephrotic syndrome have idiopathic glomerular lesions.

Causes

1. **Primary glomerular diseases**
 - Minimal change nephropathy.
 - Mesangiol proliferative glomerulonephritis.
 - Membranous nephropathy.

Table 8: Indications of plasmapheresis in renal disease

Anti-GBM nephritis.
Rapidly progressive GN.
Goodpasture's syndrome.
Polyarteritis nodosa and other vasculitides
Systemic lupus erythematosus.
Thrombotic thrombocytopenic purpura.
Haemolytic-uraemic syndrome.
Scleroderma.
Acute renal allograft rejection.

- Focal and segmental glomerulosclerosis.
 - Crescentic glomerulonephritis.
2. **Idiopathic**
 3. **Secondary to other diseases**
 - **Infections** – Malaria, hepatitis B, herpes zoster, streptococcal and staphylococcal infections, syphilis, leprosy, schistosomiasis.
 - **Drugs** – NSAIDs. Heavy metals such as gold, anti-convulsants (especially phenytoin and troxidone), penicillamine, ACE inhibitors, heroin, rifampicin, tolbutamide and probenecid.
 - **Malignancy** – Hodgkin's disease and other lymphomas.
 - **Systemic diseases** – Diabetes mellitus, amyloidosis, SLE, Henoch-Schonlein purpura, cryoglobulinaemia, polyarteritis nodosa.
 - **Familial disorders** – Congenital (neonatal) nephrotic syndrome, Airport's syndrome, Fabry's disease.
 - **Miscellaneous conditions** – Reflux nephropathy, renal vein thrombosis, toxemia of pregnancy, allergic reactions to insect bites, pollens and vaccines, renal artery stenosis.

Minimal change nephropathy (MCN)

It is a most common cause of nephrotic syndrome in children. It can be primary or secondary to other diseases like Hodgkin's lymphoma. On renal biopsy, under light microscopy it doesn't show abnormal lesion; hence it is also called “Nil lesion”. Under electron microscope effacement foot processes of podocytes is seen.

Treatment

Steroids (Prednisone) is mainstay of treatment. Among these patients few become steroid dependent and relapse on steroid tapering. In case of non responders or steroid resistance diagnosis of FSGS is considered and repeat biopsy done to confirm diagnosis.

Focal segmental glomerulosclerosis (FSGS) – typically presents with nephrotic syndrome, and is more likely than minimal change nephropathy to be associated with hypertension, microscopic hematuria, impaired excretory renal function and/or corticosteroid resistance. It tends to recur after renal transplantation; there is evidence for a circulating permeability factor in these cases, removal of which by plasmapheresis leads to temporary reduction in proteinuria.

Histology – Areas of scarring in glomeruli; the sclerotic changes are focal (affecting some glomeruli) and segmental (affecting only parts of each glomerulus). Similar glomerular changes are seen as a secondary phenomenon when the number of functioning nephrons is reduced (e.g. as a result of nephrectomy, ischaemia or another primary renal disease), leading to the hypothesis that FSGS results from ‘overloading’ of the remaining nephrons. Similar changes may be seen in association with extreme obesity. A variant of FSGS has been recognized in association with HIV infection – the so-called ‘collapsing’ FSGS, the glomerulus collapses as a result of proliferation of surrounding epithelial cells, filling Bowman’s space. Other variants are endocapillary hypercellularity and glomerular tip lesion.

Management – In primary FSGS, prolonged courses of high dose corticosteroids is used to induce remission of nephrotic syndrome. Cyclosporine 3-5 mg/kg/day for 4–12 months, may induce remission. An ACE inhibitor to reduce proteinuria and statins for hyperlipidaemia should also be given. Disease often progresses; ESRF develops within 10 years in about 50% of patients.

In secondary FSGS, management is treating underlying cause and there is no role of steroids and immunosuppressant.

Membranous nephropathy (MN) – typically presents with proteinuria, which may be asymptomatic or severe enough to cause nephrotic syndrome. Microscopic hematuria, hypertension and/or impaired excretory renal function may be associated. Identical glomerular histology is seen in the primary (idiopathic) form, and when MN is secondary to drugs (particularly NSAIDs, gold, penicillamine), solid organ tumours particularly carcinoma of bronchus or breast, infection (particularly hepatitis B) or hypothyroidism and rheumatological diseases like lupus. Susceptibility to idiopathic MN and to some forms of secondary MN is closely linked to the MHC allele DR3, strongly suggesting that shared immunological mechanisms are operating.

On renal biopsy, it shows uniform thickening of the basement membrane along the peripheral capillary loops

under light microscopy; this thickening needs to be distinguished from that seen in diabetes and amyloidosis. Immunofluorescence demonstrates diffuse granular deposits of IgG and C3 and electron microscopy typically reveals electron-dense subepithelial deposits. Degree of tubular atrophy and interstitial fibrosis are predictive of progression of disease.

Management – If MN is secondary to drugs, complete resolution is expected when the same is withdrawn. Treatment is reserved for those with poor prognostic signs (deteriorating excretory renal function and/or severe nephrotic syndrome). Combination of prednisolone and chlorambucil in alternating monthly cycles for a total of 6 months. Cyclophosphamide, mycophenolate mofetil and cyclosporine can be used. In cases, that relapse or fail to respond Rituximab (anti-CD20 antibody) can be used. ACE inhibitors reduce proteinuria and may slow progress of renal insufficiency. Nephrotic syndrome caused by membranous GN is associated with risk of thrombotic complications and anticoagulants may be prescribed.

Pathology – The kidneys are large, pale and soft. Biopsy studies show a wide variety of histopathological changes – (a) Minimal change nephropathy is common in very young children. (b) Focal glomerulosclerosis. (c) Membranous nephropathy. (d) Proliferative glomerulosclerosis – accounts probably for the largest group of adults with idiopathic nephrotic syndrome.

Clinical Features

1. **Age and sex** – Two to three times more common in childhood with peak incidence at 2–3 years. In this age group, there is a male: female ratio of 2.5: 1, in adults, sex incidence is equal.
2. **Oedema** – is peripheral involving the limbs, particularly lower limbs. In children, oedema may be more obvious in the face and abdomen. Usually massive generalized anasarca, the patient almost weighing double his true weight. Intense oedema of the scrotum or vulva may occur. There may be bilateral hydrothorax. Oedema may persist for many weeks or months. Spontaneous subsidence with diuresis (nephrotic crisis) may occur, to be followed again by increase of oedema.
3. **GI symptoms** – Anorexia causes severe malnutrition. Diarrhoea and vomiting due to oedema of intestinal wall.
4. **General symptoms** – Prolonged protein loss causes anorexia, lethargy, tiredness, frequent infections and muscle wasting. Dyspnoea may occur if there is fluid in the pleural cavity.

- Blood pressure* - There may be periods of hypertension; ultimately with development of chronic nephritis permanent hypertension may develop.

Laboratory Findings

- Urine* - (i) Oliguria while oedema is forming, diuresis or normal amount of urine during period of subsidence of oedema. (ii) Proteinuria - Massive, usually more than 5 g/day though variable from time to time; urine becomes almost solid on boiling. Daily loss of protein may be 20-50 g. (iii) Red blood cells absent or few. (iv) Casts - Fatty casts, tubular cells, oval fat bodies, doubly refractile bodies.
- Blood* - (i) Anaemia - Slight, normochromic. (ii) Hypoalbuminaemia - Serum albumin usually less than 3 g/100 mL. Total serum globulin concentration frequently lowered with often elevation of α_2 and β globulins. (iii) Hyperlipoproteinaemia (LDL level in particular) and hyperfibrinogenaemia (contributing to raised ESR).
- Renal biopsy* - is normal on light microscopy but electron microscopy shows typical abnormalities (effacement of epithelial cell foot processes).

Differential Diagnosis

- From acute nephritic syndrome* Table 9 lists the differences between acute nephritic syndrome and nephrotic syndrome
- Of conditions causing nephrotic syndrome* - Cases due to diabetes, anaphylactoid purpura, drug therapy or irradiation of the kidneys can be diagnosed from the history or other typical findings. Amyloid disease - history of chronic suppuration; positive liver or gum biopsy or renal biopsy. In thrombosis of renal vein, there is evidence of inferior vena caval thrombosis or presence of only one kidney. Polyarteritis can be diagnosed from other characteristic features like fever, peripheral neuritis etc., or positive muscle biopsy. Disseminated lupus - Anti-dsDNA and anti-SM antibodies.
- Of generalized anasarca.*

Complications

- Protein malnutrition* - Wasting, striae, osteoporosis, poor wound healing.
- Hypercoagulability* - Spontaneous venous and arterial thrombosis due to rise of many clotting factors in plasma including fibrinogen and factor VIII.
- Impaired resistance to infection* - Cellulitis, primary peritonitis with pneumococci, urinary tract infection.

Table 9: Differences between acute nephritic syndrome and nephrotic syndrome

	<i>Acute nephritic syndrome</i>	<i>Nephrotic syndrome</i>
Previous illness	Preceding streptococcal infection	No previous illness
Age	Predominantly school-going child	Most often seen in pre-school child
Onset	Sudden	Insidious
Oedema	Rarely severe	Presenting feature and rapidly becomes massive
Hypertension	Invariably present	Usually absent
Urine	Many red cells	Few red cells
Azotaemia	Present	Absent
Recovery	In 90%	May occur
Death	Due to uraemia or left ventricular failure.	Uraemia may develop after months or years. Secondary infections common.

- Acute hypovolaemia* - may occasionally be severe enough to precipitate renal failure.

- Hyperlipidaemia* - probably increased atherogenesis.

Prognosis - With minimal lesion nephrotic syndrome, about 90% of children respond to prednisolone. In adults the response rate is about 60%. Relapse rate is high, particularly in children and constant steroid administration may be necessary to prevent relapses. The long-term prognosis for renal function is excellent. Progression to renal failure does not occur unless the morphology alters and progressive lesions of focal and segmental hyalinosis and sclerosis develop. This is uncommon in those who show an initial response to corticosteroids, it is much more likely among non-responders. Prolonged heavy proteinuria may be one of the factors responsible for the progressive glomerular lesion.

Management

Corticosteroids - produce rapid and complete remission with clearing of proteinuria in 90% cases. Dose - Prednisolone 1 mg/kg/day, maximum 80 mg/day. Remission usually occurs between days 7 and 14, though some patients need up to 16 weeks therapy to achieve complete remission. After disappearance of proteinuria, or one week after remission, prednisolone dose is reduced to 0.5 mg/kg/day and then tapered slowly. An attempt to stop

treatment should be made after 8 weeks. In patients who relapse, course of prednisolone should be repeated.

Immunosuppressive drugs – In steroid-resistant patients, or in those in whom remission can only be maintained by heavy doses of steroids, cyclophosphamide 1.5–2 mg/kg/day for 8–12 weeks with concomitant prednisolone 7.5–15 mg/day. The neutrophil count must be checked every 2 weeks and cyclophosphamide stopped if it falls below $2 \times 10^3/\text{mm}^3$.

Cyclosporine 3–5 mg/kg/day is effective in some corticosteroid resistant or dependent patients.

Prednisolone 7.5–15 mg/day is also given.

Levamisole – In corticosteroid dependent children 2.5 mg/kg to maximum 150 mg on alternate days is useful in maintenance of remission.

4. ACUTE RENAL FAILURE (ARF)

ARF may be defined as any sudden fall in GFR sufficient to cause uraemia. Oliguria (< 15 mL/hour) is a feature in many patients. 'Non-oliguric' renal failure is seen, particularly in patients with severe burns, nephrotoxic damage (particularly due to aminoglycosides, and radiographic contrast media), oliguric renal failure that may be converted to non-oliguric failure by aggressive management with fluids, diuretics and other agents.

PATHOPHYSIOLOGY

Pre-renal ARF is an appropriate physiological response to effective or true hypovolaemia, resulting in intense renal conservation of sodium and water at the expense of decreased GRF. Urea clearance decreases more than creatinine clearance as a result of action of ADH. Renal function returns rapidly to normal once the underlying cause is corrected. Reduction in renal arterial perfusion pressure below the level at which autoregulation of GRF occurs is an important contributor. However, in hypovolaemic or septic patients, pre-renal ARF may still occur as a result of intra-renal vasoconstriction.

Acute tubular necrosis (ATN) results from the insults that cause pre-renal ARF, but lasting long enough to cause ischaemic injury to renal tubules. This results in long-lasting reduction in GFR. This is caused by a combination of:

- Persistent, intense intra-renal vasoconstriction caused by endothelin, other autocrine mediators and increased intracellular calcium.
- Loss of polarity of tubular cells, leading to loss of function

- Loss of adherence of tubular cells, leading to desquamation into the tubular lumen
- Formation of tubular casts, blocking the lumen and preventing urine flow
- Tubuloglomerular feedback (reflex reduction of glomerular filtration due to high sodium concentration in distal tubule)
- Back-leak of tubular filtrate as a result of loss of tubular viability and obstructing casts
- Reperfusion injury, causing oxidant stress

Intrinsic renal disease. The diseases listed as causes, cause ARF by numerous mechanisms, including:

- Destruction of glomeruli
- Renal arterial vasoconstriction (e.g. contrast nephropathy)
- Ischaemic damage resulting in ATN
- Direct tubular toxicity, resulting in an ATN-like syndrome

Post-renal ARF. Increased pressure within the renal collecting systems results in reduced GRF, reduced tubular reabsorption of sodium and water, and acquired renal tubular acidosis, phosphaturia and other abnormalities of tubular function. In addition, obstruction leads to tubulointerstitial inflammation, caused by infiltrating macrophages and T lymphocytes and followed by fibrosis, resulting in incomplete recovery of renal function if obstruction is not rapidly relieved.

AETIOLOGY

Causes of acute renal failure are listed in Table 10.

Causes of acute renal failure in tropical and developing countries

- Diarrhoeal illness
- *Shigella dysenteriae* type 1, *Salmonella typhi* and other infections. Haemolytic-uraemic syndrome
- *G-6-PD deficiency and drugs*: Massive intravascular haemolysis and haemoglobinuria
- Snake bite: Direct nephrotoxicity, myoglobinuria, haemolysis, DIC
- *Plasmodium falciparum* malaria: Intravascular haemolysis, intravascular sequestration of parasitized RBCs
- Herbal remedies (e.g. djenkol bean, marking nut tree): Acute tubular necrosis
- Paraquat and copper sulphate poisoning
- Melioidosis: Haemolysis, direct nephrotoxicity

Table 10: Causes of acute renal failure**Hypovolaemia**

- Haemorrhage
- Volume depletion (vomiting, diarrhoea, inappropriate diuresis, burns)

Renal hypoperfusion

- NSAIDs, cyclooxygenase 2 inhibitors
- Angiotensin converting enzyme inhibitors/angiotensin II receptor antagonists
- Abdominal aortic aneurysm
- Renal artery stenosis/occlusion
- Hepatorenal syndrome

Hypotension

- Cardiogenic shock
- Distributive shock (Sepsis, anaphylaxis)

Oedematous states

- Cardiac failure
- Hepatic cirrhosis
- Nephrotic syndrome

'Intrinsic' renal failure**Glomerular disease**

- Inflammatory – Post-infectious GN, cryoglobulinaemia, Henoch-Schonlein purpura, SLE, antineutrophil cytoplasmic antibody associated GN, anti-glomerular basement membrane disease
- Thrombosis – DIC, thrombotic microangiopathy

Interstitial nephritis

- Drug-induced – NSAIDs, antibiotics
- Infiltrative – Lymphoma
- Granulomatous – Sarcoidosis, tuberculosis
- Infection related – Post-infective, pyelonephritis

Tubular injury

- Ischaemia – Prolonged renal hypoperfusion
- Toxins – Drugs e.g. aminoglycosides, radiocontrast media, pigments (such as myoglobin), heavy metal (e.g. cisplatin)
- Metabolic – Hypercalcaemia, immunoglobulin light chains
- Crystals – Urate, oxalate

Vascular

- Vasculitis (usually associated with antineutrophil cytoplasmic antibody)
- Cryoglobulinaemia
- Polyarteritis nodosa
- Thrombotic microangiopathy
- Cholesterol emboli
- Renal artery or renal vein thrombosis
- Malignant hypertension

Post-renal**Intrinsic**

- Intra-luminal – Stone, blood clot, papillary necrosis
- Intra-mural – Urethral stricture, prostatic hypertrophy or malignancy, bladder tumour, radiation fibrosis

Extrinsic

- Pelvic malignancy
- Retroperitoneal fibrosis

- *Leptospira interrogans*: Acute interstitial nephritis, acute tubular necrosis
- *Ischistosoma haematobium*: Ureteral stenosis with obstructive nephropathy
- Heat stroke: Rhabdomyolysis and DIC

Pre-renal ARF is defined as a reduction in GFR caused by impaired renal perfusion as a result of hypotension or hypovolaemia or renal artery stenosis that is rapidly reversed by correction of underlying cause.

CLINICAL FEATURES – STAGES

Early or pre-oliguric stage

This is overshadowed by symptoms of the primary cause. Symptoms like lethargy, nausea, headache, are indicative of overhydration and should arouse suspicion of impending renal insufficiency. Restoration of renal perfusion leads to rapid recovery of renal function.

Oliguric stage

- Oliguria* – (less than 400 mL urine in 24 hours in adults) sets in majority within 24–48 hours. The duration varies, average being 4–10 days. Complete anuria is rare and indicates either a severe renal catastrophe or obstructive aetiology.
- Gastrointestinal* – Anorexia, nausea, vomiting; at times diarrhoea, mouth ulceration, dynamic ileus or pseudo-peritonitis if these are related to uncontrolled uraemia, they disappear after dialysis.
- Circulatory* – Hypertension is common in acute glomerulonephritis, renal infarct and cortical necrosis and when ARF results from intoxication by organic solvents. Severe hypertension is usual in malignant nephrosclerosis or thrombotic microangiopathy. Pericarditis is uncommon.
- Respiratory* – Dyspnoea is related to metabolic acidosis, to pulmonary infection or oedema.
- Neuromuscular* – Drowsiness, confusion and agitation occur in advanced uraemia and may indicate water or drug intoxication. Convulsions, coma or focal neurological signs may also be observed. Muscular twitching or cramps are uncommon in absence of plasma electrolyte disorders.
- Infection* – Secondary sepsis is a major risk in patients with ARF.

Diuretic stage

This phase of the disease is ushered in by increase in urinary output to about 1000 mL in 24 hours; this

may progress to polyuria. Febrile reaction is common and uraemic symptoms may be aggravated and lead to coma. With profound diuresis dehydration may set in.

DISTINGUISHING ARF FROM CKD

Renal Ultrasonography

- Reduced renal volume, length or cortical thickness, together with increased echogenicity, is a feature of many types of CRF, through renal size may remain normal in CRF (e.g. diabetic nephropathy, amyloidosis).
- Renal swelling is only seen in ARF.
- Renal size is normal in most patients with ARF.

Anaemia is a feature of CRF

Bone disease. Radiological evidence of hyperparathyroidism, very high PTH levels is diagnostic of CRF, but hypocalcaemia and hyperphosphataemia may occur in both ARF and CRF.

Investigations

Table 11 enumerates the investigation that can be done in acute renal failure.

MANAGEMENT

Early Management

1. **Restoration of fluid and electrolyte balance** -There are two good physical signs of volume depletion - (a) Low jugular venous pressure. (b) Postural drop in BP. Blood pressure, for example, 120-80 may be regarded as unremarkable in recumbent position; significant volume depletion may be recognized only when BP falls substantially as the patient sits or stands. Intravascular volume depletion should be corrected rapidly. If large veins in forearms or antecubital fossa are not available, access should be established through femoral vein.

Table 11: Investigation in acute renal failure

Test	Comment
Urinalysis	
Dipstick for blood, protein, or both Microscopy for cells, casts, crystals	Suggests a renal inflammatory process Red cell casts diagnostic in glomerulonephritis
Biochemistry	
Serial urea, creatinine, electrolytes metabolic Blood gas analysis, serum bicarbonate Creatine kinase, myoglobinuria rhabdomyolysis C-reactive protein Serum immunoglobulins, serum protein and electrophoresis, Bence-Jones proteinuria	Important metabolic consequences of ARF include hyperkalaemia, Acidosis, hypocalcaemia, hyperphosphataemia Markedly elevated creatine kinase and myoglobinuria suggests Non-specific marker of infection or inflammation Immune paresis, monoclonal band on serum protein electrophoresis, Bence-Jones proteinuria suggests myeloma
Haematology	
Full blood count, blood film embolisation, microangiopathy Coagulation studies	Eosinophilia may be present in acute interstitial nephritis, cholesterol or vasculitis Thrombocytopenia red cell fragments suggest thrombotic Disseminated intravascular coagulation associated with sepsis
Immunology	
Antinuclear antibody (ANA) Anti-double stranded (ds) DNA antibodies Antineutrophil cytoplasmic antibody (ANCA), Antiproteinase 3 (PR3) antibodies, Antimyeloperoxidase (MPO) antibodies Complement concentrations Antiglomerular basement membrane antibodies Antistreptolysin O and anti-DNAse B titres Virology Hepatitis B and C; HIV Radiology	ANA positive in SLE and other autoimmune disorders; anti-dsDNA antibodies more specific of SLE Associated with systemic vasculitis; c-ANCA and anti-PR3 antibodies associated with Wegener's granulomatosis; p-ANACA and anti-MPO antibodies present in microscopic polyangiitis Low in SLE, acute postinfectious glomerulonephritis, cryoglobulinaemia Present in Goodpasture's disease High after streptococcal infection Important implications for infection control within dialysis area Renal size, symmetry, evidence of obstruction
Kidney biopsy antibodies,	If clinical suspicion of PRGN (e.g. positive antineutrophil cytoplasm hematuria and proteinuria, raised C-reactive protein)
Differentiating features between pre-renal and renal causes of ARF in an oliguric patient are given in Table 12.	

Table 12: Differentiating features between pre-renal and renal causes of ARF in an oliguric patient

	Pre-renal	Renal
Identifiable causes (shock, hypovolaemia)	Yes	No
Urine		
Protein	0-1	1-4
RBCs	0	1-3
WBCs	0	1-3
Casts	0-1	1-3
Osmolality	> 500	< 400
Sodium	< 20	> 35
Urine/urea ratio	> 18	< 3
Urea/creatinine ratio	> 40	< 20
Fractional excretion of sodium	< 1%	> 1%

2. **Other measures** - If oliguria persists after adequate circulation is established in order to increase renal tubular flow and promote glomerular vasodilatation. Fluids restricted to previous 24-hr urine volume plus other losses. Sodium and potassium restricted to <80 mmol/day and 60 mmol/day respectively:

- Mannitol** - 100-150 mL of 10% solution or 50 mL of 20% solution (maximal dose 50 g/24 hours), after shock and/or fluid depletion has been treated and urinary obstruction excluded. If urine flow exceeds 50 mL/hour, further doses should be given 3 or 4 hours later to maintain an output of about 100 mL/hour. Mannitol can also be used to determine whether renal failure is due to dehydration. Infusion of 100 mL 20% mannitol over 15 minutes should result in a diuresis of 100 mL in the next 2 hours in the presence of dehydration but not if there is renal impairment.
- Frusemide** - in large doses is equally effective. Shock, hypotension or fluid depletion must be excluded or corrected first. A first dose of 100-200 mg IV (or 250-500 mg by mouth) is followed every 3-4 hours by equal doses if urine flow increases. Urinary losses of water, electrolytes must be replaced by 5% dextrose containing 4-6 g. litre NaCl and 1-1.6 g/litre KCl, adjusted to the actual urinary output.
- Dopamine** - 2.5 µg/kg/minute, if oliguria persists after adequate circulation has been established.

Management of Established ARF

1. Recognition and treatment of life-threatening complications

Hyperkalaemia - can cause cardiac arrest, the risk of which can be judged by ECG manifestations (no P waves, widened QRS complexes and tenting of T waves) requires immediate treatment:

- IV calcium (10% calcium gluconate, 10 mL over }1 minute given immediately and repeated until ECG improves), this acts instantly to 'stabilize' the cardiac membranes, but does not alter serum potassium level.
- IV insulin and glucose (rapidly acting insulin 10 U, with 50% glucose, 50 mL over 5-10 minutes, after IV calcium). This reduces serum concentration by 1-2 mmol/l over 1/2-1 hour.
- If rapid recovery does not occur, hyperkalaemia will recur and further treatment is required:
- Haemodialysis/haemofiltration
- Cation exchange resins (sodium or calcium polystyrene sulphonate 15 g PO q6h or 15-30 g p.r. 6-hourly). These require 4 hours for effect and lead to severe constipation if taken without laxatives (e.g. lactulose 10-15 mL)

Pulmonary oedema - is the most serious complication of salt and water overload when IV fluids are administered to patients with oliguric renal failure.

- Fluid and electrolytes** - After initial resuscitation, fluid and electrolyte input depends on output. A satisfactory regimen is to give in 24 hours a volume equal to total fluid output from the kidneys and GI tract in previous 24 hours with additional 500-1000 mL for insensible loss. Alternate administration of 0.9% saline and 5% dextrose provide sufficient sodium in most patients. Potassium supplement is seldom required and must be monitored.
- Nutrition** - Adequate caloric intake to minimise endogenous protein catabolism and acidosis. (i) If ARF not severe - 30 kcal/kg/day and 0.5 g/kg/day of protein (2,000 kcal and 30 g protein/day for an adult). If anorexia is pronounced feeding can be done through a gastric tube. (ii) If ARF is severe - (e.g. post-traumatic or surgical), 50 kcal/kg/day and 1 g/kg/day of protein may be required to obtain a positive nitrogen balance. Since fluid must be restricted, parenteral fluid using dextrose-rich solutions and amino-acid mixtures is often indicated.

According to the Kidney Disease Improving Global Outcomes (KDIGO) guidelines, patients with AKI should achieve a total energy intake of 20-30 kcal/kg per day. Protein intake should vary depending on the severity of AKI: 0.8-1.0 g/kg per day in noncatabolic AKI without the need for dialysis; 1.0-1.5 g/kg per day in patients on dialysis and up to a maximum of 1.7 g/kg per day if hypercatabolic and receiving continuous renal replacement therapy.

4. **Antibiotics** – because infection is a major complication. Aminoglycosides, tetracyclines (except doxycycline), cephaloridine and cephalexin, and amphotericin B must be avoided. Unexplained fever, particularly if accompanied by toxic manifestations, is highly suggestive of undetected abscess which requires drainage.
5. **Other measures** – (i) For nausea and vomiting – Domperidone 10 mg IM. (ii) For sedation and fits – Diazepam. (iii) Anaemia – Packed red blood cells. (iv) H₂-receptor antagonists or sucralfate – for preventing bleeding from stress ulcers especially in post-trauma and surgical patients.
6. **Monitoring** – Daily monitoring of body weight, fluid balance, urea, electrolytes, creatinine. Full blood count and culture of all secretions and wounds, and twice weekly calcium, phosphate and LFTs.
7. **Watch for complications** – of the causative condition (particularly persisting sepsis, fungal superinfection, muscle compartment syndromes) and for complications of treatment (line sepsis, antibiotic colitis, metabolic complications of parenteral nutrition). Hypercatabolism is an important clue to occult infection if other causes (GI bleeding, inadequate nutrition, injured or necrotic tissue, drugs such as corticosteroids and tetracycline) have been excluded. Febrile patients require chest radiographs, measurement of C-reactive protein (>100 mg/L is suggestive of septicaemia) and cultures of sputum, urine, blood and operative wound sites. Abdominal ultrasound and CT scan may be required to detect intra-abdominal infection.
8. **Renal replacement therapy (RRT)** – is urgently required if there is hyperkalaemia, rapidly increasing serum creatinine, oliguria (particularly in those with impending or established pulmonary oedema) and severe metabolic acidosis.

Options are usually continuous haemofiltration (more commonly used in ICUs) and intermittent haemodialysis. Peritoneal dialysis is often complicated by fluid leaks, difficulty in achieving satisfactory fluid balance, and infection. Haemodialysis using biocompatible membranes and highly purified water for dialysate preparation gives better outcomes than conventional dialysis.

Management of Diuretic Phase

Fluid and electrolyte replacement during this stage must be based more on clinical observation such as general condition, pulse, blood pressure and thirst, and biochemical observations rather than on quantitative and qualitative loss of water and electrolytes in urine. Intravenous therapy is stopped and the patient encouraged to take a high potassium, high salt diet and liberal intake of water

(about 3000 mL). Infection remains a problem during this phase. Dialysis should be continued until there is a spontaneous drop in creatinine and urea. Early ambulation and return to normal dietary habits should be allowed as soon as possible.

5. CHRONIC KIDNEY DISEASE (CKD)

CKD: Stages (NKF/K/DOQI) Classification:

Stage GFR

1. > 90 mL/min → Kidney damage with N or ↑ GFR
2. 60–89 mL/min → Kidney damage with mild ↓ GFR
3. 30–59 mL/min – Moderate ↓ GFR
4. 15–29 mL/min – Severe ↓ GFR
5. 15 mL/min – Dialysis required

CAUSES

Common

- Glomerulonephritis
- Diabetic nephropathy
- Hypertensive renal disease

Uncommon

- Renovascular disease (especially in elderly)
- Acute interstitial nephritis and other drug reactions
- Vasculitis in the kidney (e.g. Wegener's granulomatosis, microscopic polyangiitis)
- Obstructive uropathy
Congenital lesions and reflux nephropathy in children
Prostatic obstruction in elderly

Pathogenesis – of clinical syndrome of CKD:

1. **Uraemic toxins** – Fall in glomerular filtration rate and reduction in renal tubular secretory capacity prevent certain substances from being excreted by the kidney and these probably produce their adverse effects on every organ of the body. However, studies of the effects of dialysis, dietary modifications and transplantation have not identified the toxins involved.
2. **Electrolyte and water excretion** – Limited ability of diseased kidney to manipulate electrolyte and water excretion appropriately may lead to either salt and water retention with oedema and circulatory congestion, or to salt depletion.
3. **Erythropoietin and 25-hydroxy-cholecalciferol** – There is impaired production of erythropoietin and reduced hydroxylation of 25-hydroxy-cholecalciferol to 1,25 dihydroxycholecalciferol, the most active metabolite of vitamin D, a step which normally occurs in the kidney.

4. *Renin* - Impaired perfusion of remaining renal tissue may stimulate the inappropriate release of renin.
5. *PTH* - One of the principal disturbances of endocrine function in CKF is marked hyperplasia of parathyroid glands with very high levels of PTH. This contributes to renal osteodystrophy, soft tissue calcification and bone necrosis in CKF and also probably to pruritus, anaemia, hyperlipidaemia, neurological disturbances and sexual dysfunction. However, patients with primary hyperparathyroidism manifest few of these disturbances and the role of PTH in uraemic toxicity is still uncertain.
6. '*Middle molecules*' - The middle molecule hypothesis is based on the apparent absence of neuropathy in patients on chronic peritoneal dialysis (which is less efficient than haemodialysis in removing small molecules, but more efficient for middle molecules), and the high risk of neuropathy in patients treated with small surface area dialysers. Also the observation that when weekly haemodialysis time was markedly reduced, neuropathy did not appear, provided a membrane highly permeable to middle molecules was used. While the identity of uraemic toxins is largely unknown, it is suggested that some dialysis schedules permit accumulation in body fluids of molecules in the range 1,000 to 2,000 daltons, and these cause some of the uraemic problems encountered by patients on regular dialysis.

STAGES

Chronic progressive renal disease has four stages:

1. *Diminished renal reserve* - About 50-70% of kidney function has to be lost before the effect on blood chemistry becomes readily detectable, e.g. by rise of blood urea.
2. *Renal insufficiency* - from loss of further kidney function. There is moderate nitrogen retention (blood urea 50-100 mg/100 mL, plasma creatinine 1.5-2.5 mg/100 mL) and mild acidosis may occur. Usually no symptoms except nocturia. Hypertension may dominate the clinical picture.
3. *CKF* - As renal function declines, a broader range of biochemical abnormalities develop. However symptoms may be absent or slight. Patients often have hyperphosphataemia and hypocalcaemia, because GFR, renal tubular responses and hormonal action are not capable of maintaining homeostasis. Anaemia is common, but because the main underlying process involves decreased production of RBCs, the anaemia is typically characterised by normal RBC indices.
4. *ESKF* - is typified by uraemia and various symptoms.

CLINICAL FEATURES

Clinical features of advanced or end-stage kidney failure are listed in Table 13.

Table 13: Clinical features of advanced or end-stage kidney failure

System	Symptoms	Signs
Genitourinary	Nocturia	Proteinuria
	Thirst	Abnormal urinary sediment
Cardio-vascular	Fatigue	Hypertension
	Dyspnoea	Pericarditis
	Orthopnoea	Circulatory overload
	Chest pain	Blood volume depletion
Gastro-intestinal	Oedema	
	Anorexia	Foetor
	Nausea	Oral and buccal ulceration
	Vomiting	Parotitis
	Hiccoughs	
Neuromuscular	Diarrhoea	
	Cramps	Tremor
	Weakness	Flap (asterixis)
	Drowsiness	Hyper-reflexia going on to loss of tendon jerks
	Hallucinations	Loss of vibration sense and light touch
	Fits	
	Stupor. Coma	
Cutaneous	Itching	Dry skin
		Pigmentation
		Scratch marks
		White bands on nails
Haematological	Bruising	Anaemia
	Epistaxis	Bruises
	Dyspnoea	Microangiopathic haemolytic anaemia
	Fatigue	
Ocular	Sore eyes	Congested eyes
	Failing vision	Corneal calcification
		Retinopathy
		Retinal detachment
Skeletal	Bone pain	Deformities or rickets in children

MANAGEMENT

Indications for Initiation of Therapy in ESRD

- Hyperkalaemia resistant to medical therapy
- Metabolic acidosis resistant to medical therapy
- CKF resistant to medical therapy
- Uraemic symptoms
- Uncontrollable hypertension
- Pericarditis
- Neuropathy
- Encephalopathy
- Uraemic coagulopathy

COMPLICATIONS AND CONSEQUENCES OF CKF

Cardiovascular disease – incidence is 3–5 fold greater, and even microalbuminuria significantly increases cardiovascular risk. Explanations include high prevalence of diabetes, hypertension, dyslipidaemia and LV hypertrophy and other factors such as hyperhomocysteinaemia, increased oxidative stress, progressive malnutrition and ‘micro-inflammation’.

Anaemia is common resulting from a reduction in circulating erythropoietin and some bone marrow resistance to its action. There is high chance of bleeding in these patients.

Bleeding in Uraemia

Mechanisms

1. Increased prostacyclin production by the endothelium and reduced biosynthesis of thromboxane.
2. Accumulation of waste products (urea and its metabolite guanidinosuccinic acid) in uraemic plasma may lead to smaller platelet size, reduced platelet coagulant activity (platelet factor III), decreased platelet adhesion, defects in cytoplasmic calcium mobilization, decreased expression of fibrinogen receptors and impaired platelet aggregation, and consequently prolonged bleeding time.
3. Anaemia may contribute to reduced adhesion in vivo, and consequently, abnormal bleeding time.

Renal bone disease is a composite of high and low bone turnover disease. Patients with uraemia exhibit skeletal resistance to the action of circulating parathyroid hormone, and often incipient vitamin D deficiency. Early symptoms are uncommon, so biochemical and radiological analysis are required.

Malnutrition is common, particularly as renal function deteriorates to GFR 10–20 ml/minute. Fluid retention may mask loss of muscle, so body weight may change little.

Endocrine abnormalities include dysregulation of vitamin D and lack of erythropoietin. Increased reverse free triiodothyroxine conversion is also seen. Reduced insulin degradation by renal tubules is a feature of GRF < 40 mL/minute. Testosterone levels are often low in male dialysis patients, and prolactin elevation can contribute to gynaecomastia. Erectile dysfunction is common.

Infection rates and immune system function are often abnormal. Infection is a common cause of death.

Malignancy is more common and on dialysis. This is partly explained by presence of multicystic kidneys, but increased incidence of primary liver and thyroid cancer and lymphoma are reported. This may relate to impaired immune surveillance and T cell function.

Psychiatric problems are common in CKF and dialysis patients and may range from depression, anxiety and phobias to full-blown psychosis.

Neuromuscular problems are peripheral and autonomic neuropathy. Peripheral neuropathy usually becomes clinically evident after the patient reaches stage 4 CKD. “Restless leg syndrome” is seen. It is characterized by ill-defined sensations of sometimes debilitating discomfort in the legs and feet relieved by frequent leg movement.

Dermatological complication: Apart from pruritus another complication is nephrogenic fibrosing dermopathy consists of progressive subcutaneous induration, especially on the arms and legs. The condition is similar to scleromyxedema and is seen very rarely in patients with CKD who have been exposed to the magnetic resonance contrast agent gadolinium.

Management to Retard/Prevent Progression of CKF

Blood pressure control. ACE inhibitors reduce risk of ESKF by about 30%. Calcium channel blockers when used together with ACE inhibitors/ARBs are highly effective and confer nephroprotection. BP targets of 130/80 mm Hg for all renal patients are widely accepted.

Lipid-lowering therapy with statins for all patients with cardiovascular history or diabetes.

Cardiovascular Diseases in Uraemia

Uraemic vasculopathy – Loss of vascular elasticity due to thickening of arterial wall contributes to higher systolic and lower diastolic pressure. An unusual feature of uraemic vasculopathy is the extent of calcium deposition both in intimal layer of the artery, but also in the media.

Uraemic cardiomyopathy – Severe myocardial disease may manifest as both impaired myocardial contractility which leads to both systolic and diastolic dysfunction. Clinical features are of CHF, and arrhythmias, and patients with end-stage cardiomyopathy often become hypotensive.

Possible cardiovascular risk factors in uraemia and its management are given in Table 14.

Anaemia – Factors contributing to anaemia in CKD are listed in Table 15. Anaemia of CKD is normochromic and normocytic and hypoproliferative. Reticulocyte count is inappropriately low for the degree of anaemia, but the peripheral blood film often looks normal except for occasional fragmented cells (burr cells).

Management

Erythropoietin therapy – Erythropoietin is a large glycoprotein containing 165 amino acids. Usual starting dose is 2000 units 2–3 times per week s.c. A reticulocyte response is obtained within 3–4 days, and haemoglobin

concentration usually begins to increase from 2 weeks onwards. Erythropoietin therapy should be commenced once Hb concentration falls below 10g/dl, and the recommended target of Hb concentration in dialysis patients is 11–12 g/dL.

Efficacy – Erythropoietin therapy is effective in correcting the anaemia in 90–95% patients, and has secondary benefits, such as reduction in high cardiac output, increased peripheral vascular resistance, improvement in myocardial ischaemia and reduced LV mass.

Side effects – Most common is hypertension. Others include an increased risk of stroke in those with type 2 diabetes and increase in thromboembolic events, perhaps a faster progression to the need for dialysis, thrombosis of vascular access, clotting of dialysis lines, hyperkalaemia, flu-like symptoms and skin irritation around injection site. A serious side effect reported is red cell aplasia with anti-erythropoietin antibodies.

Darbepoetin alpha is a second generation erythropoietic agent which has longer circulating half-life, and hence has to be given less frequently (once weekly or every other week). The conversion factor is about 200 units of erythropoietin to 1µg of darbepoetin alpha.

Epoetin beta can be self-administered s.c. by the patient by use of a pen. Dose 3 × 20 IU/kg body wt/week initially. May be increased every 4 weeks, but maximum dose should not exceed 720/IU/kg week.

Renal osteodystrophy – The term generally encompasses four major histological types of bone disease:

- Secondary hyperparathyroidism
- Osteomalacia
- Mixed renal osteodystrophy
- Adynamic bone disease

Biochemical disturbances and radiological features of renal osteodystrophy are listed in Table 16.

Other skeletal complications of renal failure include osteoporosis, dialysis-associated amyloid and metastatic calcification. Patients with a GFR of 60 mL/minute/1.73 m² are at risk and should be evaluated for bone disease.

Table 14: Possible cardiovascular risk factors in uraemia and its management

Uraemic vasculopathy

- Smoking
- Diabetes mellitus
- Hypertension
- Dyslipidaemia
- Hyperhomocysteinaemia
- Increased oxidative stress
- Elevated calcium phosphate product
- Inflammation

Uraemic cardiomyopathy

- Hypertension
- Anaemia
- Volume overload
- Diabetes mellitus
- A-V fistulas

Management

- Cessation of smoking and healthy lifestyle modifications
- Treatment of hypertension
- Treatment of lipid abnormalities
- Treatment of anaemia
- Adequate glycaemic control in DM
- Control of plasma calcium and phosphate levels
- Reduction in homocysteine levels
- Antioxidant therapies
- Anti-inflammatory drugs (e.g. aspirin)

Table 15: Factors contributing to renal anaemia

- Relative deficiency of erythropoietin
- Shortened RBC survival (haemolysis or hypersplenism)
- 'Uraemic inhibitors' of erythropoiesis
- Hyperparathyroidism with marrow fibrosis
- Aluminum toxicity
- Blood loss (mainly GI tract)
- Chronic inflammation
- Iron, folate and vitamin B₁₂ deficiency

Mixed renal osteodystrophy – Mineralization time can be measured by giving patients tetracycline before renal biopsy. Increased osteoid may be caused by increased production (in hyperparathyroidism) or reduced mineralization (osteomalacia). Mixed renal dystrophy is said to occur when both abnormalities are found on bone biopsy.

In addition, strong epidemiological evidence indicates an association between hyperphosphataemia and increased calcium phosphate product, and coronary artery calcification and death.

Another complication of mineral metabolism is “calciophylaxis”. Calciophylaxis (calcific uremic arteriopathy) is a devastating condition seen almost exclusively in patients with advanced CKD. It is heralded by livedo reticularis and advances to patches of ischemic necrosis, especially on the legs, thighs, abdomen and breasts. Pathologically, there is evidence of vascular occlusion in association with extensive vascular and soft tissue calcification. Originally it was ascribed to severe abnormalities in calcium and phosphorus control in dialysis patients, usually associated with advanced hyperparathyroidism. However, more recently, calciophylaxis has been seen with increasing frequency in the absence of severe hyperparathyroidism. Other etiologies have been suggested, including the increased use of oral calcium as a phosphate binder and warfarin, which is commonly used in hemodialysis patients and one of the effects of warfarin therapy is to decrease the vitamin K dependent regeneration of matrix GLA protein. This latter protein is important in preventing vascular calcification.

Clinical features – (a) Cutaneous manifestations – Pruritus and conjunctival calcification resulting in acute infection (‘red eye’ syndrome of renal failure) and rarely calciophylaxis. (b) Growth and skeletal maturation stunted in children. (c) Osteomalacia associated with bone pain, skeletal deformity and waddling gait.

Treatment – should be started early when creatinine clearance falls to about 40 mL/minute. (a) Phosphate binders – As renal failure advances, dietary reduction of phosphate may not suffice. Calcium carbonate or acetate 2–8 g/day with meals. In some patients if serum phosphate is not controlled, aluminium phosphate binders (at the lowest effective dose) must be used. Sevelamer hydrochloride (a non-absorbable polymeric phosphate binder) is a newer effective agent. (b) Suppression of PTH – Treatment with oral calcitriol should aim to maintain levels at 1.5–3 times normal. Dose ranges from 0.25 µg on alternate days to 1 µg/day. Calcitriol ‘pulse therapy’ in which higher doses (2–4 µg) are given three times weekly PO or IV is also effective.

Table 16: Biochemical disturbances and radiological features of renal osteodystrophy

Type of bone disease	Biochemical features	Radiological characteristics
<i>Hyperparathyroid</i>	Early low calcium, high-normal phosphate, raised calcium phosphate product PTH > 3 times normal Serum phosphate, alkaline phosphatase and PTH rising with increasing severity Hypercalcaemia with tertiary hyperparathyroidism	Osteopaenia and areas of sclerosis (‘Rugger-Jersey spine’), ‘pepper-pot skull’ Subperiosteal erosions first seen in phalanges Metastatic calcification Reduced bone mineral density on DXA
<i>Osteomalacia</i>	Tendency to lower serum phosphate levels, more severe acidosis, lower serum calcitriol levels, low or only slightly elevated PTH Elevated serum aluminium may be the cause	Osteopaenia, Looser’s zones particularly in ribs, scapulae and pelvis, skeletal deformity, vertebral compression Reduced bone density on DXA
<i>Adynamic bone disease</i>	Tendency to hypercalcaemia, particularly in patients given calcitriol Normal serum alkaline phosphatase Low PTH	Osteopaenia Reduced bone mineral density on DXA

Combined use of calcium salts and calcitriol increase the risk of hypercalcaemia and regular blood monitoring is required. (c) Parathyroidectomy is occasionally required.

Control of aluminium – Development of hypercalcaemia with small doses of calcitriol should suggest aluminium toxicity or adynamic bone disease. Serum aluminium levels should be checked periodically and should be less than 50 µg/L. Desferrioxamine can be used in provocative tests to determine the body burden of aluminium, and in treatment to remove aluminium by chelation.

MANAGEMENT OF END-STAGE KIDNEY FAILURE

Renal replacement therapy (RRT)

Typically renal replacement therapy is initiated in patients with creatinine clearance less than 10 mL/minute, or less optimally when uraemic symptoms are present. Dialysis attempts to replace the excretory functions of the kidney.

Haemodialysis

Principles

Diffusive and convective mass transfer across a semipermeable membrane, allowing changes in the composition of body fluids.

- Diffusive transport depends on solute molecular weight and charge, transmembrane concentration gradients, blood and dialysis flow rates and membrane characteristics. Small molecules (e.g. urea) are cleared well.
- Convection is the bulk movement of solvent and dissolved solute across the membrane, down a transmembrane hydrostatic pressure gradient. Convection improves the clearance of poorly diffusible middle molecule (e.g. b_2 microglobulin). Ultrafiltration is convective movement of water across the membrane.

Haemodialysis techniques

- Conventional haemodialysis uses low-flux, regenerated cellulose dialysers, allowing diffusive but little convective solute removal. Middle molecule clearance is poor.
- Haemofiltration is a convective treatment. Clearance of middle molecules is greatly improved, but that of small molecules is poor. This technique is unsuitable for maintenance therapy of ERKF.
- High flux haemodialysis uses biocompatible membranes with high ultrafiltration coefficients, allowing convective and diffusive solute removal.
- Haemodiafiltration adds a greater convective component to high-flux haemodialysis. Middle molecule clearance is excellent.

Managing Dialysis

Adequate dialysis and duration – Optimal dialysis dose is defined in terms of normalized urea clearance, Kt/V (where K is the dialyser urea clearance duration of dialysis in minutes, and V the urea distribution volume estimated as total body water from anthropomorphic data). Kt/V of > 1.05 or > 1.2 per session is a minimum threshold for well-nourished patients dialysed three times per week.

Vascular access – Obtaining and maintaining reliable venous access monitoring can pre-empt problems. Fistula flow assessment by ultrasound is probably the method of choice.

Acute Complications

- Dialysis disequilibrium syndrome is caused by rapid reductions in serum osmolality and paradoxical CSF acidosis, producing cerebral oedema. It presents with

restlessness, headache, tremors, and occasionally, fits and coma. It occurs in severely uraemic patients subjected to over-aggressive initiation of dialysis.

- Symptomatic hypotension, causing nausea, vomiting, dizziness and syncope, is a consequence of excessive ultrafiltration, particularly in patients with cardiovascular compromise or those on anti-hypertensive medication.
- Anaphylactoid reactions occur in first 20 minutes. They may be caused by ethylene oxide sensitivity and complement activation by bio-incompatible membranes.
- Pyrexia is often caused by central venous catheter-related sepsis.
- Pyrogen reactions are uncommon if ultrapure water is used.
- Other complications (e.g. air emboli, circuit disconnection) are with modern fail-safe machines.

Dialysis-related amyloidosis usually presents as carpal tunnel syndrome and destructive arthropathy. Amyloid deposits contain b_2 -microglobulin which is renally excreted, accumulates in patients with ESKF, and is not cleared by low-flux membranes.

Other chronic complications – Anaemia is largely attributed to erythropoietin deficiency, though repeated blood loss and, in high flux treatments, vitamin B_{12} and folate loss may contribute. Phosphate retention (often aggravated by short dialysis duration), hypocalcaemia and deficiency of calcitriol contribute to secondary hyperparathyroidism.

Peritoneal Dialysis

Peritoneal dialysis is a form of renal replacement therapy which enables removal of nitrogenous waste products from the body, using peritoneal dialysis fluid (PDF) instilled via a catheter into the peritoneal cavity.

Peritoneal Dialysis Regimens

Continuous ambulatory peritoneal dialysis (CAPD) uses the smallest volume of dialysate possible to prevent uraemia (8–10 litres daily) with four daily exchanges of 0.5–3.0 litres.

Automated peritoneal dialysis refers to all forms of peritoneal dialysis using a mechanical device (cycler) to assist in the delivery and drainage of dialysate. Regimens are – (a) continuous cyclic peritoneal dialysis, (b) nightly intermittent peritoneal dialysis, and (c) tidal peritoneal dialysis. Main advantage of automated peritoneal dialysis is that it eliminates the need for intensive manual involvement. Most dialysis occurs at night during sleep. However,

daytime exchanges may be necessary to achieve solute and fluid removal targets.

Advantages and Disadvantages of Peritoneal Dialysis

Advantages of peritoneal dialysis over haemodialysis:

- Peritoneal dialysis is a technically simple procedure. Hence, it can be safely performed at home or at work by patients who have completed a brief training course. Little or no special equipment is required.
- Peritoneal dialysis provides continuous excretory function with steady-state biochemistry. Therefore, patients experience few of the cyclical symptoms associated with haemodialysis-induced fluid and electrolyte shifts.

Disadvantages

- Peritoneal dialysis is less efficient than haemodialysis, and adequate excretory function often depends on patient's residual renal function.
- The presence of peritoneal dialysis catheters may cause body image or psychosexual problems.
- Successful peritoneal dialysis relies on the efficiency of the peritoneal membrane, which is often damaged by peritonitis, thereby rendering it technically impossible.

Medical Contraindications to Peritoneal Dialysis

Relative

- Large muscle mass – potentially inadequate dialysis
- Obesity – difficulty with catheter insertion
- Intestinal disease – potential to initiate peritonitis
- Respiratory disease – intolerance of splinting of diaphragm by intraperitoneal fluid
- Hernia – exacerbated by peritoneal dialysis fluid if not surgically correctable

Absolute

- Abdominal wall stoma – high risk of peritonitis
- Diaphragmatic fluid leak – peritoneal fluid leak causes pleural effusions
- Adhesions – hinder flow of peritoneal dialysis fluid
- Loss of peritoneal function or integrity – peritoneal dialysis not technically possible

Complications of Peritoneal Dialysis

Infection may occur anywhere along the dialysis catheter. Peritonitis is the major infective complication; it is diagnosed by the combination of abdominal pain and/or cloudy PDF effluent with a WBC count > 100/μL.

Non-infectious complications

- Loss of ultrafiltration despite high concentration of glucose in the PDF
- Drainage problems caused by catheter migration (constipation is the most common cause)
- Fluid leaks into external genitalia, pleural space or abdominal wall
- Abdominal or back pain and exacerbation of abdominal wall hernias (caused by the presence of PDF).

KIDNEY TRANSPLANTATION

Kidney transplantation is the treatment of choice for ESKF, as it enables the patient to resume a normal life, with no restrictions in diet and fluid intake.

Pre-Transplantation Assessment

Donor

Cadaver – Patients with maintained cardiac output in whom the criteria for brainstem death have been met. Donor characteristics that preclude transplantation include: Malignancy, sepsis, infection with hepatitis B or C virus or HIV, irreversible renal impairment.

Live – Living-related transplantation results in better graft outcome. Normal renal function in the donor is a prerequisite, and transplantation of a kidney with a single large artery is preferable.

Recipient

Non-immunological

Vascular disease – Cardiovascular disease is the most common cause of death in both the dialysis and transplant populations. Diabetes is a common cause of ESKF. Other risk factors, such as hypertension, hypercholesterolaemia, smoking and obesity should be identified and treated. Extent of peripheral vascular disease should be ascertained.

Malignancy – Patients with history of malignancy should have been in remission for at least 2 years before transplantation is considered.

Infection – There should be no evidence of active sepsis. HIV infection is a contraindication because prognosis of HIV-positive patients on immunosuppression is poor.

Recurrent renal disease – Focal segmental glomerulosclerosis often recurs, with early graft loss. Diabetic and IgA nephropathy also commonly recurs, but seldom causes renal insufficiency.

Immunological – The human leucocyte antigens (HLA) are important in antigen presentation to T cells. Variation

in these proteins between individuals results in the graft being seen as 'foreign' by the immune system, resulting in rejection. HLA of donors and recipients enables assessment of their compatibility.

Immunosuppression

Glucocorticoids – After transplantation, the dose is tapered to maintenance level of 5–10 mg/day. High-dose IV corticosteroids are used in treatment of acute rejection.

Azathioprine inhibits purine metabolism and, therefore, cellular proliferation. It is used to prevent, rather than treat rejection.

Mycophenolate mofetil also blocks purine metabolism. It is more potent than azathioprine, and is used in maintenance regimens or for post-rejection rescue. GI symptoms are more common than with azathioprine.

Cyclosporine binds to and inhibits calcineurin. This blocks part of the signalling cascade responsible for lymphocyte activation. It has a narrow therapeutic window and nephrotoxicity is a major problem.

Tacrolimus also inhibits calcineurin. It is more potent than cyclosporine and therefore used as both rescue agent for treating rejection and a maintenance agent. Side-effects are similar to those of cyclosporine.

Sirolimus is synergistic with cyclosporine, but is not nephrotoxic.

Antibodies, both polyclonal (ALG and ATG) and monoclonal (OKT3), and anti-T cell antibodies are used in treatment of acute rejection refractory to corticosteroids. Their administration is commonly associated with cytokine release syndrome. Subsequent risk of opportunistic infections and lymphoid malignancies is increased. Anti-CD25 antibodies (daclizumab and basiliximab) target activated T cells only and, therefore, have few side-effects. They are used to prevent rejection in the early post-operative period. Belatacept is a fusion protein that binds costimulatory ligands (CD80 and CD86) present on antigen-presenting cells, interrupting their binding to CD28 on T cells. This inhibition leads to T cell anergy and apoptosis. Belatacept is FDA approved for kidney transplant recipients and is given monthly as an intravenous infusion.

Complications

Immediate

ATN is the most common cause of immediate graft dysfunction. Kidneys from older donors and those who are hypotensive are more likely to develop ATN.

Surgical complications include renal venous and arterial thrombosis.

Hyperacute rejection results from presence of pre-existing antibodies. There is no effective treatment except graft nephrectomy.

Early

Immunological – Acute rejection is seen in 30–60% and usually presents as decline in renal function in first few months. Renal biopsy confirms the diagnosis, assesses severity of rejection and guides treatment.

Infection – CMV infection develops in weeks or months in 60% of CMV-seronegative recipients receiving grafts from seropositive donor, unless prophylaxis with ganciclovir or valganciclovir is given.

Post-transplantation lymphoproliferative disorders – These EB virus-related malignancies are more common in patients who have received antibody therapy on induction and in children.

Mechanical – Arterial and ureteric stenoses with gradually deteriorating renal function.

Late

Chronic rejection is the most common cause of late graft failure. The process is influenced by immunological and non-immunological factors.

Malignancy is three times more common, e.g. squamous cell skin carcinoma, renal, cervical and vaginal cancers.

Cardiovascular disease is the principal cause of death post transplantation

Recurrent disease is mentioned earlier.

Drug Effects

Rapidly Progressive Kidney Failure

Rapidly progressive renal failure (RPRF) is an initial presentation in patients who present with progressive renal impairment of short duration. The underlying aetiology may be a primary renal disease or a systemic disorder (Table 17).

Clinical Features

- (i) Since anaemia is one of the important features of CKD, absence of pallor is one of the signs.
- (ii) Hypertension if underlying thrombotic microangiopathy and renal artery stenosis.
- (iii) Oral ulcer or butterfly rash suggests lupus.
- (iv) Skin petechiae may indicate lupus vasculitis.

Investigations

- (i) Ultrasound of abdomen – Presence of normal-sized kidney.
- (ii) Urine – Active urinary sediment (proteinuria, dysmorphic RBCs and RBC casts) suggests proliferative GN.

Hematuria with isomorphic RBCs is indicative of acute interstitial nephritis. (iii) Kidney biopsy – Crescentic GN is one of the most important causes of RPRF, acute tubular necrosis, acute interstitial nephritis.

Treatment

Since the causes of RPKF are heterogenous, the treatment is varied. Vasculitis and lupus nephritis need prompt immunosuppression, sometimes with plasmapheresis, chemotherapy for multiple myeloma, etc.

6. URINARY TRACT INFECTION (UTI)

UTI is the presence of microbial pathogens in the normally sterile urinary tract. UTI can be either symptomatic or asymptomatic.

Uncomplicated and complicated infections – Uncomplicated UTI occurs in healthy women. Complicated UTI is associated with anatomical, functional, or metabolic abnormalities of the urinary tract that disable the natural innate host defences and lead to tissue injury. Factors associated with UTI are listed in Table 18.

Cystitis is inflammation of the bladder. Infection is the most common cause, but there are other non-bacterial causes (Table 19).

Aetiology of UTI – Bacteria most commonly enter the urethra (ascending infection) but can enter via the blood stream. Ascending infections account for most cases of uncomplicated cystitis and pyelonephritis, and usually involve organisms of normal bowel flora – *E. coli*. *Staph. saprophyticus* is sometimes found in young women, and *Proteus mirabilis* and *Klebsiella pneumoniae* are rare causes. Predisposing factors have been tabulated earlier.

Table 17: Causes of rapidly progressive kidney failure

Primary renal disease
Antineutrophil cytoplasm antibody-associated vasculitis
Antiglomerular basement disease (Good pastures disease)
Lupus nephritis
Crescent phase of primary GN (e.g. IgA nephropathy)
Post-infectious GN
Cryoglobulinaemic GN
Acute interstitial nephritis
Systemic disease
SLE
Multiple myeloma
Thrombotic microangiopathy

PATHOGENESIS

Virulence of an organism is related to its ability to adhere to epithelial cells, e.g. *E. coli*. The bacterium has many

Table 18: Factors associated with UTI

Uncomplicated urinary tract infection

- Bacterial virulence
- Host defence
 - Colonization of vagina and mucosa
 - Polymorphisms of genes regulating complement, neutrophil biology
 - Non-secretor status
- Acquired (disruption of host defence)
- Anti-microbials (loss of commensal population)
- Sexual intercourse
- Ageing (post-menopausal oestrogen decrease, loss of detrusor power)

Complicated urinary tract infection

Outflow obstruction

- Urethral stricture
- Pelviureteric junction
- Prostatic hypertrophy
- Ureteric stricture
- Bladder neck obstruction
- Stone/tumours
- Neuropathic bladder
- Renal cysts

Abnormal kidney

- Renal scarring
- Vesicoureteric reflux
- Dysplastic kidney
- Duplex kidney

Foreign body

- Indwelling catheter
- Stone
- Nephrostomy tube
- Ureteric stent
- Tumour

Metabolic

- Immunosuppression
- Kidney failure
- Diabetes mellitus
- Alcoholism
- Pregnancy
- Iron overload

Other

- Enterocystoplasty
- Bladder diverticuli
- Ileal conduit
- Instrumentation

Table 19: Causes of 'culture-negative' cystitis**Infection**

- Treated urinary tract infection
- Mycobacterium spp.
- Fastidious organisms
- *Schistosoma haematobium*
- *Candida* spp.
- BK polyomavirus
- Adenovirus

Inflammation

- Cyclophosphamide
- NSAIDs
- Danazol
- Bladder stone
- Pelvic irritation

Cancer**Idiopathic**

- Interstitial cystitis

projecting hair-like structures (pilli or fimbriae) that interact with glycoprotein and glycolipid receptors on host cells.

INNATE HOST DEFENCE

Neutrophils are principally protective when released into the urinary tract to kill bacteria. It is only when this response is exaggerated or incomplete that neutrophils cause tissue injury.

Complement – Bacterial killing also involves complement and is enhanced by local epithelial production of IgA antibody against bacterial surfaces (acquired immunity).

Urine osmolality and pH – The survival of microorganisms is reduced in normal urine by an osmolality of 88 mOsmol/kg and pH above or below 5–7.

Colonization of distal urethra and periurethral region by anaerobic and micro-aerophilic bacteria, such as *Staph. epidermidis*, lactobacilli, corynebacteria, streptococci and *Bacteroides* spp. is a major component of normal host defence. The commensal colonies can be disrupted by antibiotic therapy and spermicidal creams, allowing virulent *E. coli* to adhere and ascend.

Bacterial washout by urine flow and bladder emptying is a major defence mechanism. Any process causing stasis of urine can lead to infection.

Uroepithelium – The uroepithelium is covered by urinary mucus and a glycocalyx that contains mannosylated proteins. These constituents bind bacteria and aid their elimination.

Blood group antigens – Women with a history of recurrent UTI are three to four times more likely to be non-secretors of ABH blood group antigens than other women.

Acquired host defence. There is no evidence that cell-mediated immunity has a role in UTI. Urinary antibodies (IgG and secretory IgA) are formed against O and K serotypes, and a systemic antibody response to O antigens occurs in pyelonephritis. Antibody binding to bacteria also aids in their elimination.

CLINICAL SYNDROMES OF UTI

Acute cystitis is associated with frequency, urgency and dysuria. Urine appears hazy and may be offensive. Microscopic hematuria is often present. There is no pyrexia.

Acute urethritis is associated with dysuria and urethral discharge. Infection is usually sexually transmitted and is caused by *Neisseria gonorrhoea* or non-gonococcal organisms including *Chlamydia trachomatis*, *Mycoplasma genitalium* and *Ureaplasma urealyticum*. The latter infections (non-specific urethritis) are often asymptomatic, and the organisms become permanent commensals.

Asymptomatic UTI Significant bacteriuria is often not associated with symptoms and does not require treatment except in pregnant women, in infants and before urological surgery.

Urethral syndrome – In 50% of women presenting with dysuria and frequency, bacterial counts are $< 10^5$ /mL or the urine is sterile. The term 'urethral syndrome' is used in those with recurrent symptoms that have not responded to antibiotics. It is a diagnosis of exclusion. The cause of urethral syndrome is unknown.

Vaginitis (*candida*, *trichomonas*, non-specific) is the cause in one-third of patients, and acute urethritis and genital herpes simplex must be excluded.

Chronic and idiopathic cystitis. Chronic cystitis with pyuria and 'sterile' urine cultures is highly suggestive of tuberculous infection (Table 20). Urine must be cultured for *M. tuberculosis*. Other diagnoses must be excluded, and urine cytology, cystoscopy and bladder biopsy are required.

A diagnosis of 'idiopathic interstitial cystitis' may be reached by exclusion. This is a severe, progressive, disabling form of cystitis that often can be relieved only by cystectomy.

Prostatitis. Bacterial prostatitis may be acute or chronic. Acute bacterial prostatitis is characterized by fever, malaise, perineal pain, urgency, frequency and dysuria. Diagnosis is usually made by urine culture.

Chronic prostatitis is a cause of recurrent UTI, particularly in those in whom IVU is normal or recurrent epididymitis is present. Patients may be asymptomatic or may suffer perineal, genital or lower back pain or discomfort on voiding.

Acute pyelonephritis is associated with fever, malaise, loin pain (which may be bilateral), bacteriuria and pyuria. There may be symptoms of cystitis. The condition can present as Gram-negative septicaemia. It can be bilateral, but CT usually shows that areas of inflammation are focal. Patients are commonly febrile and CRP is raised. Patients with an abnormal urinary tract and recurrent episodes of pyelonephritis may simply complain of general malaise, headache, loss of appetite and backache and the urine is discoloured and with an offensive odour.

Rarely there is diffuse infection causing acute renal failure. This is generally seen in alcoholics, diabetics and those receiving immunosuppression. Septicaemia (usually *Staph. aureus*) can lead to micro-abscess formation in the kidney. Occasionally with very severe infection or diabetes, papillary necrosis occurs. Rarely, subacute or chronic infection develops and an abscess may extend to form a mass (renal carbuncle), or point through the capsule of the kidney to form a perinephric abscess.

COMPLICATED UTI

Chronic pyelonephritis (reflux nephropathy) – Vesicoureteric reflux, with or without infection, can cause scarring of the kidney that varies with the degree of reflux. Much of the scarring occurs in the foetal or neonatal period. Further scarring in childhood is associated with untreated UTI. Primary vesicoureteric reflux is recognized as a common inherited disease (autosomal dominant).

Progressive loss of renal function can occur in the absence of both UTI and reflux, but only in those with GFR of less than 50 mL/minute/1.73 m². It is invariably associated with the onset of progressive proteinuria and hypertension. This condition is now termed 'reflux nephropathy' and is associated with hyperfiltration (glomerular capillary hypertension) of the remaining glomeruli.

Chronic infections of the kidney – Complete obstruction may lead to severe infection in the renal pelvis (pyonephrosis) and loss of kidney. Obstruction with stone disease may be associated with chronic xantho-granulomatous pyelonephritis. Melakoplakia is a rare chronic infection of the kidney that presents as renal mass, and results from inability of macrophages to kill *E. coli*.

Table 20: Infections causing UTI with sterile pyuria

Chlamydia trachomatis
Mycoplasma hominis
Ureaplasma urealyticum
Mycobacterium spp.
Haemophilus influenzae
Campylobacter spp.
Legionella pneumophilia
Salmonella spp.
Shigella spp.
Gardnerella vaginalis

1. Ultrasonography of kidney and bladder and plain abdominal radiography to exclude stones and lumbosacral defects.
2. Technetium 99 m-DMSA scan in case of pyelonephritis.
3. Urine flow rate and post-void ultrasonography of bladder (to measure residual volume) in any patient with evidence of bladder outflow obstruction.
4. CT with contrast to exclude abscess if renal symptoms persist.
5. Micturating cystourethrography (MCU) in children under 1 year of age once the urine is sterile. Children aged 1–7 years should undergo MCU when initial investigations reveal an abnormality, or when there is history of pyelonephritis or recurrent UTI or family history of reflux.
6. IV pyelography gives important anatomical information about the urinary tract (calyces, pelvis and ureter), provided renal function is normal.
7. MSU in patients with pyelonephritis or complicated UTI.
8. A leucocyte esterase dipstick can be used to detect pyuria and dipsticks can detect nitrite (produced by bacterial metabolism of urinary nitrate).

MANAGEMENT OF UTI

General measures – More fluid intake, alkalization of urine with potassium citrate solution to alleviate symptoms.

Antibiotics

Acute cystitis. Empirical 3-day regimens of trimethoprim, oral cephalosporin or nitrofurantoin. Ciprofloxacin is also effective, but should not be used as first-line (to prevent development of resistance). Recurrent infection may be due to – Persistent focus of infection, relapsing infection

with the same organism, re-infection with a different organism. Persisting or relapsing infection may require a 6-9 month's course of prophylactic antibiotics. Re-infection may require pericoital prophylaxis.

Acute pyelonephritis - Oral therapy with a quinolone for 7 days is usually sufficient. More sick patients (nausea, vomiting, hypotension or sepsis) may require hospitalization for initial parenteral therapy (once-daily aminoglycoside plus quinolone, or a third-generation cephalosporin or Tazocin), for first 1-3 days followed by appropriate oral therapy for up to 14 days.

Prostatitis - Lipid-soluble antibiotics (trimethoprim, doxycycline, quinolones) which penetrate tissues given for 2-4 weeks.

Antibiotic resistance - The concentration of antibiotic used to test bacterial sensitivity in the laboratory (mean inhibitory concentration) is often well below the concentration of antibiotic achieved in the urine. Thus, the organism may respond to an antibiotic despite that the microbiologist-reported resistance.

Prevention - (a) Those with residual urine after voiding should practise double micturition. (b) UTI associated with sexual intercourse may benefit from emptying of bladder afterwards, or from taking prophylactic dose of antibiotic at the time of intercourse. Vaginal oestrogen creams are effective in post-menopausal women.

Management of abnormal bladder, enterocystoplasty and conduits - Long-term antibiotics to eradicate infection from kidneys. Tetracycline and oxytetracycline are contraindicated because they are toxic to damaged tubules. Doxycycline can be used. Nitrofurantoin and nalidixic acid are avoided in patients with GFR < 50 ml/minute, because they are renally excreted and toxic in renal failure. Quinolones are not to be used as regular prophylactic antibiotic, because of risk of inducing resistance. Attempts to sterilize the urinary tract are unlikely to be successful when foreign bodies such as stones remain.

Catheter-associated UTI is the most common nosocomial infection. Bacteriuria develops in 1-2% of healthy patients following catheterization, and the risk of infection increases with duration. Microbes become embedded in a biofilm and are much less susceptible to antibiotics.

Bacteriuria in pregnancy. Asymptomatic bacteriuria may be found in a few pregnant women and is associated with premature delivery and low birth weight. Pyelonephritis develops in 30-40% with untreated bacteriuria.

UTI in children. UTI occurs predominantly in boys in the first 2-3 months of life and equally in boys and girls at 3-12 months. After 1 year, UTI in boys becomes increasingly rare.

In infants, symptoms are usually nonspecific and include feeding disorders, slow wt. gain, vomiting and diarrhoea. Neonates may present with shock and septicaemia. In children, malaise and fever with abdominal pain arouse suspicion of UTI.

Indications for Urine Culture in Children

- Infant at home with unexplained rectal temperature > 38.5°C
- Any child admitted to hospital with pyrexia
- Unexplained vomiting or abdominal pain
- Frequency of micturition, dysuria or enuresis
- Failure to thrive
- Prolonged jaundice in the newborn
- Hematuria or hypertension
- Nonspecific illness
- Suspected sexual abuse

Investigations in UTI for the following patients:

- All children
- Women with recurrent UTI
- Men who do not respond to single course of antibiotics
- All patients with pyelonephritis

7. POLYCYSTIC DISEASE OF KIDNEYS

Inherited kidney disorder characterized by multiple bilateral cysts that cause enlargement of the kidney and reduce, by compression, the functioning renal tissue.

Table 21 lists various inherited kidney disorders.

The two major genes in autosomal dominant polycystic kidney disease (PDK1 and PDK2) have been identified.

Table 21: Inherited kidney disorders

• Cystic kidney diseases
• Airport's syndrome and variants
• Metabolic diseases with kidney involvement (e.g. Anderson-Fabry disease, cystinosis)
• Tubular disorders
• Diseases with nephrolithiasis (e.g. primary hyperoxaluria)
• Syndromes with renal and extrarenal involvement Nail-patella syn. - nail and bone abnormalities with patella defects and abnormalities of kidneys.
Bardet-Biedl syn.: Mental retardation, polydactyly, obesity, pigmentary retinitis, hypogenitalism and renal disease
• Primary immune GN, occasionally familial (e.g. IgA)
• Renal diseases with genetic influence (e.g. reflux nephropathy)

Fig. 5: CECT coronal showing polycystic kidney disease (white arrows) and hepatic cyst (black arrow).

Fig. 6: CECT axial showing polycystic kidney disease (white arrows) and hepatic cyst (black arrows).

CLINICAL PRESENTATION

ADPKD can present at any age, but most commonly manifests in adults. Common presenting symptoms include hypertension, UTI, hematuria, loin pain and renal calculi (Fig. 5). Many patients present with ESKF without a preceding history.

Childhood or infantile ADPKD. Rarely, ADPKD presents in a severe form during foetal life or early childhood, and may initially be confused with autosomal recessive polycystic kidney disease, which usually presents at this age. To avoid confusion, this presentation is termed 'early-onset ADPKD'. In the absence of a positive family history, ultrasonography is useful in both parents of an affected child.

Extrarenal Manifestations

ADPKD is now recognized as a systemic disease rather than one restricted to the kidney. Cysts are commonly found in liver and pancreas (Fig. 6). Rarely hepatic cyst formation is severe (polycystic liver disease). Other non-cystic manifestations include intracranial aneurysms, mitral prolapse and colonic diverticulae. Subarachnoid hemorrhage is a devastating first presentation in some young patients.

GENETIC HETEROGENEITY

Most ADPKD families carry mutations in PKD1 (85–90%). PKD2 patients (10–15%) exhibit a milder renal cystic phenotype than PKD1, e.g. median age of onset of ESKF is 15 years later with PKD2, and incidence of hypertension, UTI with PKD1 are four to two times respectively higher

than with PKD2. Genetic classification of patients as PKD1 or PKD2 is, therefore, of prognostic relevance.

TREATMENT

No specific treatment to prevent cyst growth or the decline of renal function. Blood pressure control to a target of 140/90 mm Hg is recommended according to the guidelines from the eighth report of the Joint National Committee on Prevention, Detection, Evaluation and Treatment of High Blood Pressure (JNC VIII report) for reducing cardiovascular complications in ADPKD and renal disease progression. Some clinical trials showed V2R antagonists and somatostatin analogues slow the decline of renal function, although with some side effects such as liver function impairment, polydipsia and diarrhoea.

8. TUBULO-INTERSTITIAL DISORDERS

CKF is accompanied by tubulointerstitial atrophy and fibrosis, regardless of the cause.

CLASSIFICATION

Tubulointerstitial disorders can be classified into acute interstitial nephritis (AIN) and chronic interstitial nephritis (CIN). See Table 22 for the causes of tubulointerstitial nephritis.

Chronic interstitial nephritis

- *Allergic nephropathy – phenacetin.*

Table 22: Causes of tubulointerstitial nephritis**Acute interstitial nephritis****1. Drug-induced***Antibiotics*

- Penicillins
- Sulphonamides
- Rifampicin
- Quinolones
- Vancomycin

*Non-steroidal anti-inflammatory drugs**Anticonvulsants*

- Phenytoin
- Valproate
- Lamotrigine

Others

- Allopurinol
- Phenindione
- Furosemide

2. Infections*Viruses*

- Hantaviridae
- E-B virus
- HIV
- Measles
- Adenovirus

Bacteria

- Legionella
- Leptospira
- M. tuberculosis
- Streptococci
- Salmonella
- Campylobacter
- Mycoplasma
- Chlamydia
- Brucella

Others

- Leishmania
- Toxoplasma

Immunocompromised

- Polyomavirus
- CMV
- Herpes simplex virus

Contd...

3. Multisystem inflammatory disorders

- Sarcoidosis
- Sjogren's syndrome
- SLE (rarely)
- Granulomatous polyangiitis
- TIN with uveitis
- IgG4- related systemic diseases

4. Acute obstructive disorders

Light chain cast nephropathy ("myeloma kidney")

Acute phosphate nephropathy

Acute urate nephropathy

- *Lithium toxicity*
- *Heavy-metal intoxication*
- *Radiation nephritis*
- *Calcinuria inhibitor toxicity*
- *Eating disorders*
- Idiosyncratic drug reactions, infections and multisystem inflammatory disorders
- Vesicoureteric reflux disease
- Sickle cell disease

CLINICAL FEATURES

The mode of presentation differs between AIN and CIN and between different causes, but predominant tubulointerstitial damage has some typical effects. Patients often present with uraemia and fluid overload, occasionally with extra-renal manifestations like fever, skin rash and arthralgia, particularly in AIN. Mild albuminuria is common, microscopic hematuria is variable. There may be defects in tubular handling of water, Na and H ions, resulting in NDI, salt-losing nephropathy and renal tubular acidosis. Hypertension is variable.

TREATMENT

It consists of correction of underlying disease, stoppage of drugs and usage of steroids. Renal replacement therapy in cases of worsening renal function not responding to therapy.

Renal tubular acidosis (RTA) disorders

These are due to abnormalities of renal tubular acidification. Defects may be:

Contd...

1. *Quantitative* – as in chronic kidney failure (number of functioning nephrons too small for metabolic acid load).
2. *Qualitative* –
 - (a) Proximal RTA –
 - (i) Primary form rare with infant failing to thrive and grow.
 - (ii) Secondary form, e.g. as result of Fanconi syndrome and following renal transplantation.
 - (b) Distal RTA –
 - (i) Primary in early life with failure to thrive, polyuria, dehydration.
 - (ii) Secondary due to vitamin D poisoning, idiopathic hypercalcaemia, amphotericin toxicity.
- Other rare type of stones include xanthine, 2,8-dihydroxy-adenine, gypsum and silicate.

PREDISPOSING FACTORS

Hypercalciuria, the most common risk factor for formation of calcium oxalate stones, is idiopathic hypercalciuria. This is a complex condition that reflects excessive intestinal absorption of dietary calcium, excessive resorption of bone and (rarely) a renal calcium leak. Excessive intake of animal protein can increase calcium excretion through several mechanisms, including resorption of bone to buffer the acid component of animal protein. Idiopathic hypercalciuria is often hereditary. Hypercalciuria can also occur as a secondary consequence of primary hyperthyroidism, granulomatous disease (sarcoidosis, tuberculosis) and excessive intake of vitamin D or A.

Hyperoxaluria. Extreme hyperoxaluria occurs in the rare hereditary condition, primary hyperoxaluria. Less severe hyperoxaluria is seen in intestinal malabsorption. This is because steatorrhoea allows calcium to bind to fat rather than to intestinal oxalate, allowing ingested oxalate to remain free in solution and thus more available for absorption. Mild hyperoxaluria is more common in stone patients and reflects excessive dietary intake of oxalate (nuts, beans, beets, spinach, rhubarb, strawberries). Inadequate dietary calcium intake can allow increased intestinal absorption of dietary oxalate.

Citrate forms soluble complexes with calcium and is an important inhibitor of calcium stone formation. Foods that are high in citrate are usually also high in oxalate.

Hyperuricosuria is generally metabolic in origin, though a diet high in red meat can increase urate excretion, thus promoting precipitation of uric acid.

Urinary pH is important in case of uric acid, cystine or calcium phosphate stones. Acid urine favours formation of uric acid and cystine stones. In renal tubular acidosis, urine pH never falls below 5.5, and this allows crystals of calcium phosphate to form and grow.

Low urine volume. About 10% of stone-forming patients have no identifiable risk factor other than concentrated urine due to low urine volume.

EVALUATION OF STONE RISK

In all first-time stone formers appropriate diagnostic investigations should include analysis of the composition of the retrieved stone, urine culture, and measurement of serum calcium (for primary hyperparathyroidism), bicar-

9. URINARY CALCULI

Stones in the urinary tract occur when urinary chemistry results in concentrations of stone salts that exceeds the limit of metastability for that salt in solution. This most often reflects excessive excretion of one or more stone constituents, deficient inhibitory activity in urine, or simply a low urine volume resulting in excessively concentrated urine.

TYPES OF URINARY CALCULI

- Calcium oxalate stones (more than 70%). Often calcium oxalate is mixed with calcium phosphate or uric acid.
- Calcium phosphate usually occurs as apatite or brushite. Calcium phosphate crystals are readily soluble in acidic urine. Thus, presence of pure calcium phosphate stone is evidence of persistently alkaline urine, as occurs in distal renal tubular acidosis.
- Uric acid stones are radiolucent by simple abdominal radiography or IVP, but radiodense on helical CT and echogenic on ultrasonography.
- Cystine stones occur only in patients with cystinuria.
- Magnesium ammonium phosphate stones (also known as 'triple phosphate' or struvite) occur in UTI with an urease-producing organism. They can be very difficult to eradicate because the organisms can infect the stone matrix, where they may be sheltered from exposure to antibiotics. Cystine stones can be resistant to lithotripsy.
- Both cystine and struvite stones can grow to fill the entire renal pelvis, forming a staghorn calculus. Staghorns are uncommon with calcium and uric acid stones.
- Rarely drugs, such as triamterene, 5-fluorocytosine and indinavir can crystallise in the urine to form stones.

bonate (to screen for renal tubular acidosis) and creatinine, and urinalysis and measurement of pH. Examination of urine sediment is often useful in revealing crystals that can indicate the likely nature of the stone.

Patients with recurrent or bilateral stones should undergo more complete metabolic evaluation, including measurement of calcium, oxalate, citrate, uric acid, sodium and creatinine in 24-hour urine specimens. Daily excretion of creatinine is the only practical measure of whether the 24-hour collection was complete, it should be invariable in patients in a steady state, regardless of renal function, and should be about 15–20 mg/kg in women and 20–25 mg/kg in men.

PREVENTIVE THERAPY IN PATIENTS WITH STONE RISK FACTORS

Fluid intake should be high to avoid periods when urine is concentrated, even at night.

Dietary calcium. In patients with hypercalciuria, a calcium intake of 800–1000 mg/day to reduce risk of bone demineralization. No dietary calcium restriction for hypercalciuria.

Sodium is an important determinant of excretion of calcium and in hypercalciuric patients, sodium intake should be not more than 2 g/day. This is important in those treated with thiazide diuretics – a high salt intake here increases risk of hypokalaemia, which can promote hypocitraturia. Another reason to restrict sodium is that natriuresis promotes urinary excretion of oxalate and uric acid.

Dietary protein. In patients with hypercalciuria in whom excessive intake of animal protein is suspected (dietary history or excessive 24-hour excretion of sulphate), less dietary protein can reduce calcium excretion.

Thiazide diuretics (chlorthalidone, indapamide) stimulate renal calcium reabsorption and reduce urinary calcium excretion.

Oxalate. Patients with hyperoxaluria should restrict intake of the many sources of oxalate.

Hypocitraturia. Potassium citrate is preferred over sodium because the former promotes citrate excretion and for the need to restrict sodium for reasons already mentioned.

Hyperuricosuria. Allopurinol 100 mg/day. Urine should be maintained alkaline in case of uric acid or cystine stones using potassium citrate or acetazolamide.

Cystinuria. Chelating agents, e.g. penicillamine and tiopronin are effective in reducing stone formation, but have various side effects. Urinary alkalization must be

maintained at all times. In patients who can tolerate such a regimen, cystine stones can even be dissolved.

SYMPTOMS

1. *Pain* – (a) *Ureteric colic* – Cramping, sharp, often excruciating pain, fluctuating in intensity but not completely remitting. Associated vomiting and sweating. Pain extends from loin down the line of ureter to groin with radiation to testes in men and labia majora or ovaries in women.
(b) *Loin pain* – independent of ureteric colic or infection.
2. *Haematuria* – accompanying the colic or even frank haematuria in absence of colic.

SIGNS

1. *Loin tenderness* – is usually manifestation of associated infection.
2. *Palpable kidney* in the presence of staghorn calculus, or when obstruction has remitted.

COMPLICATIONS

1. *Impaction and obstruction* – most likely to occur at pelviureteric junction or in the ureter, either at the level where it crosses the common iliac vessels or where it is about to enter the bladder.
2. *Infection* – pyelonephritis, periureteritis, cystitis.
3. *Stricture of ureter.*
4. *Malignant change* – due to chronic irritation of renal pelvis by calculi.
5. *Anuria* – from obstruction of both ureters, or of a solitary ureter and kidney.

10. INCONTINENCE OF URINE

Incontinence is involuntary loss of urine.

Causes and Clinical Features

In women neurologically intact

Sphincter weakness (stress incontinence) – It is the most common cause. Although it usually occurs for the first time during pregnancy or after vaginal delivery, it may affect multiparous women with weakness of support to the urethra, after pelvic surgery or postmenopausal atrophy. It is exacerbated by increase in intra-abdominal pressure caused by a tumour, chronic cough or constipation. Patient invariably complains of symptoms of urinary leakage associated with physical exertion or on coughing.

Detrusor instability – The term describes uncontrolled spontaneous detrusor contractions. Such contractions occur during the filling phase of the micturition cycle and may be mild or severe, leading to extreme urgency and urine loss (*urge incontinence*) if the sphincter mechanism cannot be controlled adequately. Although such contractions are often spontaneous, they may be triggered by coughing, sneezing, or change of posture. The cause of this disorder in otherwise healthy women is not known.

Mixed stress incontinence and detrusor instability – It is common and may be difficult to treat because surgical treatment of stress incontinence may worsen detrusor instability.

In men neurologically intact

Detrusor instability – Incontinence is most often caused by detrusor instability which may be primary or secondary to bladder outflow obstruction.

Post-micturition dribble – It may result from weakness of bulbocavernosus muscle.

Chronic retention of urine – It implies incomplete bladder emptying with chronic bladder distension leading to urinary frequency with a dribbling overflow incontinence. Low-pressure chronic retention is caused by an acontractile detrusor, perhaps secondary to diabetes mellitus or due to ageing. High-pressure chronic retention is usually caused by bladder outflow obstruction.

Post-prostatectomy incontinence – It is usually caused by residual detrusor instability but may result from damage to the external urethral sphincter.

Neuropathic bladder – Neurological conditions causing incontinence:

- Multiple sclerosis
- Parkinson's disease and multiple system atrophy
- Cerebrovascular disease
- Spinal bifida
- Spinal cord injury/tumours
- *Disc prolapse*: Cervical, thoracic and lumbar

INVESTIGATIONS

Initial investigations

- Urinalysis for glucose, protein and hematuria
- Mid-stream urine sample for microscopy, cultures and sensitivity, and RBCs
- Blood chemistry for renal function, and prostate specific antigen in men, if indicated.

Further investigations

Urodynamic investigations

- *Measurement of urinary flow rate* – may indicate bladder outflow obstruction, detrusor instability, detrusor failure or urethral stricture on the basis of peak urinary flow, shape of the curve and duration and pattern of voiding.
- *Ultrasound examination of residual urine* (which may be high in bladder outflow obstruction) is often performed with flow rate measurement.
- *Filling and voiding cystometry* – measuring detrusor pressure on filling the bladder and urinary flow rate during voiding. This may define detrusor instability.
- *Video-urodynamic studies* – comprise cystometry and radiological visualization of the bladder and urethra and with radiopaque fluid during filling and voiding. These studies are performed to evaluate behaviour of a neurogenic bladder or to investigate incontinence following failed surgical treatment.
- *Ambulatory urodynamic studies* – are performed over several hours of natural bladder filling and are used when conventional cystometry has failed to detect a urodynamic diagnosis, and may detect detrusor instability not shown in conventional urodynamics.

TREATMENT

Female incontinence – Factors to be looked into are obesity, smoking, excessively high or low fluid intake, atrophic vaginitis, and physical disability (e.g. arthritis). Constipation may precipitate urge or overflow incontinence by compression of bladder or urethra. Physiotherapy and biofeedback help. Drug therapy – Oxybutynin 2.5–5 mg t.d.s. may be helpful in detrusor instability, because of side-effects, initial dose should be low.

Male incontinence

Neurologically intact – (a) Post-micturition dribble – Patient must empty bulbar urethra by massage. (b) Primary detrusor instability – Attention to fluid intake, and anticholinergic drugs. (c) Secondary detrusor instability – For bladder outflow obstruction adrenergic antagonist, tamsulosin or prostatectomy. (d) Post-micturition dribble – Compression of bladder by patient after voiding. (e) Chronic retention of urine – Relief of bladder obstruction. (f) Post-prostatectomy incontinence caused by damage to external urethral sphincter is best treated with an artificial urinary sphincter.

Neuropathic bladder - Combinations of treatment are often required including anticholinergic agents or adrenoceptor antagonists, CISC, cystoplasty, penile appliance perhaps preceded by external sphincterotomy, urinary diversion.

11. KIDNEY IN SYSTEMIC DISEASE

The kidneys are often affected in acquired or inherited multisystem diseases.

Diabetes. Diabetic nephropathy is defined as the appearance of persistent 'clinical' albuminuria (albumin excretion rate > 300 mg/24 hours) in an individual who has had diabetes for more than 5 years and who has concomitant retinopathy, in absence of UTI, other renal diseases and heart failure.

Mechanisms of kidney damage in diabetes mellitus are listed in Table 23.

Systemic lupus erythematosus - Presentation of renal disease varies and includes subclinical proteinuria with or without microscopic hematuria, overt nephrotic syndrome with progressive renal impairment, which is often gradual but may present as rapidly progressive glomerulonephritis.

SYSTEMIC VASCULITIS

Medium vessel vasculitis - Polyarteritis nodosa. Renal manifestation is of progressive renal impairment caused by ongoing renal infarction (Fig. 7) and hypertension.

Small vessel vasculitides are associated with hematuria, proteinuria and RBC casts indicating glomerular inflammation, in the form of necrotizing GN.

ANCA-associated diseases:

Granulomatous polyangiitis - Renal vasculitis produces fibrinoid necrosis and focal segmental GN with crescent formation and there is presence of noncaseating granuloma.

Microscopic polyangiitis - Glomerular pathology is indistinguishable from Wegener's apart from absence of noncaseating granuloma.

Churg-Strauss vasculitis - Necrotizing and/or crescentic GN can occur though less severe.

Cryoglobulinaemic vasculitis - Type II causes vasculitis and immune complex GN, often with crescent formation.

Henoch-Schonlein purpura - Renal disease is more severe in adults. Histopathology is that of IgA nephropathy, showing diffuse proliferation of mesangial cells and matrix, mesangial IgA and complement deposits.

RA - Glomerulonephritis or renal vasculitis can occasionally complicate RA.

PARAPROTEIN-RELATED DISEASES

Myeloma - Characteristic lesion in the kidney is 'fracturing' casts of paraprotein in the renal tubules, which block the tubules and cause an acute inflammatory reaction in the interstitium (which can cause irreversible renal damage). Renal dysfunction can also arise from associated hypercalcaemia (causing prerenal kidney failure or nephrocalcinosis), urate nephropathy, sepsis, AL amyloid.

AL amyloid - Deposition occurs in pre-glomerular arteries or glomeruli, resulting in nephrotic syndrome and progressive renal failure.

Haemolytic uraemic syndrome - HUS is the triad of - microangiopathic haemolytic anaemia (Coomb's test negative), thrombocytopenia and acute renal failure. These features are also seen in disseminated intravascular coagulation, but coagulation tests are usually normal in HUS.

Malignancy - Minimal-change nephrotic syndrome may be associated with Hodgkin's disease. Renal carcinomas are associated with AA amyloid.

Fig. 7: Bilateral renal infarcts (arrows)

Table 23: Mechanism of kidney damage in diabetes mellitus

1. Diffuse glomerulosclerosis within some cases of nodular glomerulosclerosis.
2. Pyelonephritis.
3. Necrotizing papillitis.
4. Atherosclerosis of renal vessels

Systemic sclerosis – A syndrome of severe hypertension and acute or subacute renal failure (scleroderma renal crisis) develops in 15–20% of patients with diffuse cutaneous disease.

INFECTIONS

Systemic infections causing renal involvement are listed in Table 24.

HEPATITIS VIRUS

Hepatitis virus: HBV is associated with membranous nephropathy, usually in those infected in childhood. HVC can cause cryoglobulinaemia. Cryoglobulinaemic patients often have membranoproliferative GN, presenting with proteinuria and microscopic hematuria. Nephrotic syndrome and ESKF can develop.

OTHER CONDITIONS

At times renal disease may be associated with haemoptysis (Table 25) or jaundice (Table 26).

12. ADVERSE EFFECTS OF DRUGS ON THE KIDNEY

Drugs can cause renal damage or insufficiency by:

- Sodium and water depletion (prerenal changes)
- Changes in blood supply
- Direct renal damage
- Renal obstruction

Some drugs cause renal insufficiency by more than one mechanism (Table 27).

Table 24: Systemic infections causing renal involvement

Bacterial

- Post-infection GN
- Infective endocarditis
- Leptospirosis
- Chronic bacterial sepsis and secondary amyloidosis

Viral

HIV

- HIV nephropathy: Nephrotic syndrome, and often rapid progression to ESKF
- HIV-associated haemolytic-uraemic syndrome
- Immune complex glomerulonephritis
- Renal infection: Pyelonephritis, CMV nephritis, tuberculosis
- Renal lymphoma: Non - Hodgkin's

Hantavirus: Acute interstitial nephritis

ADVERSE DRUG REACTIONS CAUSED BY INDIRECT INTERACTIONS WITH RENAL INSUFFICIENCY

Hypovolaemia causes increased sensitivity to hypotensive drugs, particularly α -receptor antagonists and ACE inhibitors.

Bleeding is more likely in patients with uraemia. The effect of anticoagulants is enhanced and aspirin and NSAIDs are more likely to produce GI bleeding.

Hyperkalaemia is often a consequence of renal insufficiency. Potassium-sparing diuretics, potassium supplements and ACE inhibitors can exacerbate this.

Nausea and vomiting can be aggravated by some drugs (e.g. theophylline).

Nephrotoxic antibiotics – With the exception of erythromycin, the antibiotics whose names end in mycin are nephrotoxic

13. RENAL DISEASE AND PREGNANCY

Patients with renal disease that is likely to progress should be advised to become pregnant early in the course of their disease. However, the following points must be considered.

Table 25: Renal failure with haemoptysis

- Goodpasture's, Wegener's, HSP, PAN, SLE, cryoglobulinaemia.
- Renal vein thrombosis with pulmonary embolism.
- Pulmonary oedema in ARF.
- Right-sided infective endocarditis with septic pulmonary emboli and immune-complex nephritis.
- Infection – TB, Legionnaire's disease

Table 26: Renal disease with jaundice

- Haemolytic-uraemic syndrome.
- Hepatorenal failure.
- Hepatitis B with nephrotic syndrome.
- Alcoholic cirrhosis with IgA nephropathy or renal tubular acidosis.
- Weil's disease (Leptospirosis).
- Polycystic disease with congenital hepatic fibrosis.
- Renal cell carcinoma with hepatic dysfunction e.g. cholestasis.
- Toxic – CCl₄, methoxyflurane.

Table 27: Drugs that can cause renal damage**Acute tubular necrosis**

- Aminoglycosides
- Amphotericin
- Cisplatin
- NSAIDs
- Radiocontrast media
- Paracetamol poisoning

Fanconi's syndrome

- Tetracyclines (if out of date)

Glomerulonephropathy

Membranous

- Captopril (high doses)
- Gold salts
- Heavy metals
- Penicillamine
- Phenytoin
- Troxidone

Minimal change

- NSAIDs

Acute nephritis

- Penicillins

Interstitial nephritis

- Allopurinol
- Azathioprine
- Furosemide
- NSAIDs
- Penicillins
- Sulphonamides
- Thiazides
- Vancomycin

Renal tubular acidosis*Proximal*

- Acetazolamide

Distal

- Amphotericin
- Lithium

Crystalluria

- Acyclovir
- Methotrexate
- Naftidrofuryl
- Sulphonamides

Renal papillary necrosis

- Aspirin plus phenacetin
- NSAIDs

Nephrogenic diabetes insipidus

- Lithium
- Dimethylchlortetracycline

- Patients with relapsing/remitting diseases (e.g. renal lupus, systemic vasculitis) must not become pregnant while taking cytotoxic agents such as cyclophosphamide. Generally, they are advised to wait until the disease has been in remission for at least 6 months.
- Patients with severe hypertension must be aware that some drugs are contraindicated in pregnancy (e.g. ACE inhibitors, ATIIR blockers) and must be discontinued in early pregnancy (by 7 weeks).
- Severely proteinuric patients are likely to become frankly nephrotic early in pregnancy, with increased risk of thrombosis.
- Patients with significant reflux nephropathy are likely to develop significant UTIs during pregnancy and should take prophylactic antibiotics throughout.
- Preconception counselling and preparation for pregnancy.

Assess renal function

- Estimate GFR
- Ultrasonography (renal size, scars, obstruction) + mic-turating cystography.

Assess anaemia

- Correct iron or other deficiencies
- Assess whether patient is likely to need erythropoietin therapy during pregnancy (aim to avoid transfusions).

Treat hypertension effectively

- Use 'pregnancy friendly' antihypertensives (e.g. methyldopa, labetalol, nifedipine)
- If ACE inhibition or ATIIR blockade is required for renal protection, warn patient of necessity to stop/change no later than 7 weeks (otherwise risk of ACE foetopathy).

Assess activity of renal disease or underlying systemic disease

- Urinary sediment
- SLE patients - Clinical assessment including screening for pulmonary hypertension, serology to assess disease serology.

General advice for all women contemplating pregnancy

- Stop smoking, take folic acid, reduce alcohol intake
- Advise use of contraception until patient is ready to conceive.

Management of underlying renal disease during pregnancy

- Renal function and proteinuria are measured monthly throughout pregnancy.
- Urine is screened for bacteriuria and frank infections, treated as appropriate and antibiotic prophylaxis considered.

- Patients with reflux nephropathy may need monitoring for renal obstruction with regular ultrasonography. Renal tract dilatation is normal in pregnancy and is commonly worse on the right – if there is doubt whether functional obstruction is present, it is safe to perform a DTPA scan with furosemide to assess outflow. If there is maternal kidney obstruction, the baby should be delivered. If it is not sufficiently mature, nephrostomies should be inserted to drain the kidneys.
- Hypertension is treated to maintain a BP < 140/90.
- Anaemia is monitored and treated with erythropoietin if necessary.
- Patients with anticardiolipin antibodies and those with nephrotic-range proteinuria are usually advised to undergo anticoagulant prophylaxis with low molecular weight heparin.
- If renal function deteriorates rapidly, if there is evidence of proliferative renal lesion or if hypertension or nephrotic state is severe, advice varies according to state of pregnancy. In early stages therapeutic abortion, once the foetus is viable, delivery should be expedited.
- High risk patients are given aspirin from early pregnancy to protect against pre-eclampsia.
- Pre-eclampsia is difficult to diagnose in women with significant proteinuria and hypertension. Regular foetal monitoring is essential to detect decrease in foetal growth rate and to screen for uterine artery notching. Doppler ultrasonography is a predictor of pre-eclampsia.
- The outlook for most babies of 30 weeks gestation or more is so good that it is not justified to risk the well-being of the mother by undue protraction of the pregnancy.

Renal disease caused by pregnancy. The most common cause of pregnancy-induced renal disease is ATN associated with acute volume depletion.

Causes of acute renal failure in pregnancy

Secondary to

- Hyperemesis
- Sepsis
- Hemorrhage
- Pre-eclamptic toxemia/HELLP syndrome/acute fatty liver of pregnancy/HUS

Timing of renal impairment – The later the renal impairment occurs, it is more likely to be pregnancy-induced renal disease.

Parity of patient. Pre-eclampsia and AFLP are more common in nulliparous women, HELLP syndrome is more common in multiparous women – the group most likely to develop ARF.

Hypertension – New-onset hypertension with or without proteinuria in third trimester strongly suggests pregnancy-induced renal dysfunction.

14. URINARY CATHETERIZATION

INDICATIONS

1. Diagnosis and relief of urinary retention.
2. Management of urinary incontinence.
3. Following urological or other pelvic surgery or trauma.
4. Measurement of urine output in critically ill patients.
5. To facilitate diagnostic tests –
 - a. Collection of bladder urine specimens with reduced contamination.
 - b. Measurement of residual bladder urine volume.
 - c. Cystometrography and cystourography

Choice of catheter – It is determined by the indication for its use.

1. *Self-retaining catheters* – A balloon or Foley catheter is preferred when the catheter must remain in the bladder – (i) A silicone coated catheter is favoured for short-term drainage. (ii) A silastic catheter is used for long-term drainage, as it is less irritant. (iii) ‘Three way’ Foley catheters have an extra lumen to allow continuous bladder irrigation following urological surgery or trauma (iv) Malecot’s self-retaining catheter with a flower at its end which keeps the catheter in the bladder. Its use is limited to females. The flower can be collapsed during catheterization with an introducer. The catheter preferred in females is a short simple open-ended catheter.
2. *Catheters for urine sampling* – Urine samples may be obtained by catheterization in patients (usually-females) who are unable to produce adequate mid-stream urine.
3. *Suprapubic catheters* – Small suprapubic catheters are designed to pass through a hollow introducer needle, and larger ones have a trocar inside the catheter to enable insertion. A Foley catheter is cheaper and can be used.
4. *Tiemann catheter* – It is more rigid, curved tip catheter effective in negotiating the posterior urethra, particularly in males with prostatic obstruction. Disadvantage is that it is not self-retaining.
5. *Whistle-tip catheter* – is firmer and has a wide lumen and used for bladder syringing in case of clot retention.

6. *Condom catheter* – is devised by making a small nick in a condom through which a Malecot's catheter is introduced with the flower resting in the nick. Advantage is no possibility of infection since bladder is not catheterized.

Catheter size – (Size – External diameter in millimetres \times 3). A small catheter 12–14F for 'in-out' and short-term catheterization. In adults who require long-term drainage, an 18–22F size is less likely to become obstructed. Length of standard Foley catheter is about 40 cm, shorter catheters are more convenient for women. Foley catheter has two balloon sizes – 5 mL and 30 mL. The larger sized balloon, which may be necessary to retain the catheter in some females and after surgery, is more likely than the smaller balloon to be associated with bladder irritation, spasm and bypassing of the catheter.

Commonly used catheters

- Simple rubber catheter.
- Malecot's self-retaining catheter.
- Self-retaining Foley catheter.
- 'Three-way' Foley catheter.
- Short plastic open-ended catheter for use in women for obtaining urine specimen.
- Tiemann catheter with curved end to negotiate prostatic urethra.
- Whistle-tip catheter for syringing the bladder in clot retention.
- Condom catheter.

TECHNIQUE

Catheterization in men – After retracting patient's foreskin, the operator scrubs and puts on a mask, sterile gown and gloves. The glans penis and urethral meatus should be cleansed with aqueous chlorhexidine (alcoholic preparations must not be used) and sterile towels are placed around the area. Sterile 2% lignocaine jelly is then gently squeezed into the urethra. After waiting for some time to ensure adequate anaesthesia, the penis is lifted towards the patient's head and catheter inserted gently until it reaches the prostatic urethra. The penis is then lowered and the catheter pushed gently across the curve of the prostatic urethra into the bladder. A flow of urine usually indicates entry into the bladder, unless patient is anuric. If a self-retaining catheter is used, the balloon should be inflated to the volume recommended on the catheter (with

Fig. 8: Commonly used catheters

sterile water or aqueous chlorhexidine). Before inflation it is necessary to ensure that the balloon is no longer within the urethra. The catheter is connected to a large volume closed drainage system, in uncircumcised patients, the foreskin must then be drawn back over the glans penis; failure to do so may cause formation of a paraphimosis.

Complications – of indwelling catheters:

- Bacteriuria* – Antibiotic treatment usually ineffective. Removal of catheter will be followed by disappearance of bacteriuria.
- Septicaemia* – is not uncommon in elderly and immunocompromised patients.
- Chronic bacterial prostatitis* – presents as relapsing acute cystitis in the weeks following catheter removal. It requires several weeks of treatment because of poor penetration of antibiotics into the prostate.
- Obstruction* – of long-term indwelling catheters by fibrous material and encrustations, hence the need for replacing the catheters at regular intervals.
- Urethritis* – and very occasionally, stricture formation may result from traumatic catheterization or failure to change catheters over a prolonged period.
- Hematuria* – from irritation of the bladder wall, usually microscopic, less commonly macroscopic.
- Failure of balloon deflation* – can be overcome by insertion of a ureteric catheter stylet into the balloon channel under fluoroscopic control.

15. STEM CELL THERAPY FOR KIDNEY DISEASE

Use of stem cell-based strategies have been used for treatment of situations where kidneys have been injured. They have been shown to work in acute kidney injury and repair, condition where modulating of immune response leads to healing and acts as a compliment to kidney transplantation.

1. The kidney itself is a source of variety of stem cells. Simplest example of these cells helping repair following injury is observed with acute kidney injury (AKI) due to ischaemic and toxic insult, where the renal tubular epithelial cells undergo regenerative response that leads to renal function.
2. Stem cells of bone marrow origin are responsible for the reparative process after ischaemia/reperfusion injury.
3. In clinical practice, both human embryonic (HFSCs) and allogenic/autologous haemopoietic stem cells have been used for some of the chronic kidney diseases which include autoimmune disease like SLE leading to lupus nephritis and CKD stage needing renal transplantation. Besides mesenchymal stem cells from bone marrow, umbilical cord and adipose tissue is a good source.
4. Graft versus host disease is yet another condition where immunomodulatory effect of mesenchymal stem cell therapy has been used successfully when resistant to steroid therapy.

Rheumatology

1. INVESTIGATIONS

Table 1 gives presentations of various rheumatological diseases based on presentation.

Table 1: Presentations of rheumatic diseases

Inflammatory		Non-inflammatory	
Monoarticular		Monoarticular	
Acute	Septic arthritis Gout Haemarthrosis Calcium pyrophosphate	Acute	Fractures Sports injuries Torn meniscus Loose body Sprain
Chronic	Tuberculosis Pauci-articular juvenile chronic arthritis	Chronic	Osteoarthritis Shoulder capsulitis Osteonecrosis Enthesitis (e.g. tennis elbow, plantar fasciitis)
Polyarticular		Polyarticular	
Acute	Viral Rheumatic fever Erythema nodosum	Acute	Rheumatoid arthritis Osteoarthritis (primary generalized)
Chronic	Symmetrical	Chronic	Generalized osteoarthritis Haemochromatosis Hypermobility syndrome Fibromyalgia Diabetic cheiroarthropathy
	Rheumatoid arthritis Seronegative juvenile chronic arthritis Polymyalgia rheumatic Chronic tophaceous gout		
	Asymmetrical Psoriatic arthritis		

Contd...

Contd...

Inflammatory		Non-inflammatory	
	Inflammatory bowel disease Reiter's syndrome Pauciarticular juvenile chronic arthritis Systemic lupus erythematosus Polyarteritis Systemic juvenile chronic arthritis (Still's disease)		
Spinal		Spinal	
Acute	Osteomyelitis Infective discitis	Acute	Disc prolapse Sprain Vertebral collapse
Chronic	Ankylosing spondylitis Spondyloarthropathies Chronic infection (e.g. brucellosis, tuberculosis)	Chronic	Spondylosis Paget's disease Neoplasia Spondylolisthesis Chronic degenerative disc disease

BLOOD TESTS

Antibodies when present are helpful in diagnosis and prognosis of autoimmune rheumatic diseases, but their absence does not exclude such diseases (Table 2).

Table 2: Autoantibodies and their relevance

Rheumatoid factor	Rheumatoid arthritis (80%), polyarteritis nodosa, cryptogenic fibrosing alveolitis
Anticyclic citrullinated peptide (Anti-CCP antibody)	Most specific marker for RA diagnosis, and also gives prognostic information
Antinuclear antibodies	Present in autoimmune diseases and other inflammatory disorders Present in 8% of the healthy population Useful screening test; other, more disease-

Contd...

Contd...

	specific antibodies are then sought IgG tends to be more pathological than IgM The higher the titre, the greater the significance
DNA	Present in 70% of patients with SLE Highly specific for SLE, but less sensitive than antinuclear antibodies Associated with lupus nephritis. Serial measures can be useful in predicting disease exacerbations in some patients
Histones	SLE (50%) Drug-induced lupus (75–90%)
U1RNP	SLE (30%), mixed connective tissue disease (also predicts Raynaud's phenomenon, deforming arthritis in these syndromes)
Sm	SLE (10–25%)
Ro and La	SLE (Ro 40%, La 15%) – associated with subacute cutaneous lupus erythematosus, photosensitive dermatitis, neonatal lupus, congenital heart block
	Sjogren's syndrome (Ro 60%, La 25%) - associated with more aggressive extraglandular systemic disease
Scl-70	Systemic sclerosis (25%) – associated with diffuse skin disease and systemic involvement, particularly cardiopulmonary
Anti RNA polymerase III	Systemic sclerosis with rapid skin involvement and contractures
Jo -1	Polymyositis (20%) – associated with interstitial lung disease
Anticentromere	Systemic sclerosis (30%)—usually limited cutaneous disease, 90% of patients with CREST
Antineutrophil cytoplasmic antibodies	cANCA – 90% of diffuse Wegener's granulomatosis, less in localized disease pANCA – broad spectrum of vasculitis and other conditions
Antiphospholipid antibodies	Includes anticardiolipin High titres of IgG antibodies plus positive lupus anticoagulant suggest greatest risk of antiphospholipid syndrome

SYNOVIAL FLUID ANALYSIS

Septic arthritis. Gram staining can give important clues to the nature of the organism and guide antibiotic treatment. Some definitive information is gained from culture of the bacteria.

Crystal disease. Uric acid crystals are needle-shaped and strongly negatively birefringent under polarized light microscopy. Between acute attacks, aspiration of an uninfamed previously affected joint can sometimes reveal uric acid crystals, and even a single crystal is pathological.

Other crystals (e.g. calcium pyrophosphate) can be identified in pseudogout.

Hemarthrosis produces uniformly blood-stained fluid that does not clot. Common causes are trauma and bleeding diathesis. Pigmented villonodular synovitis, a non-

malignant neoplasm, can cause recurrent hemarthrosis in the affected joint.

BIOPSY

See Table 3 for role of biopsy in rheumatological diseases.

Table 3: Biopsies and their use in diagnosis

Skin and subcutaneous tissue

- SLE (immunofluorescence shows immunoglobulin and complement deposition at the dermo-epidermal junction)
- Dermatomyositis
- Scleroderma
- Henoch-Schonlein purpura (IgA deposition)
- Cholesterol emboli
- Rheumatoid nodules (Fig.1)
- Gout and other crystal tophi

Muscle

- Inflammatory myositis
- Inclusion-body myositis
- Metabolic and genetic myopathies
- Steroid myopathy
- Necrotizing vasculitis (e.g. polyarteritis nodosa)
- Sarcoidosis

Salivary gland

- Sjogren's syndrome
- Sarcoidosis

Synovium

- Chronic septic arthritis not diagnosed on synovial fluid (e.g. tuberculosis)
- Crystal disease (e.g. uric acid deposits)
- Pigment villonodular synovitis
- Synovial chondromatosis
- Sarcoidosis

Renal

- SLE with renal involvement
- Wegener's granulomatosis
- Henoch-Schonlein purpura (IgA deposition)

Lung

Wegener's granulomatosis- necrotizing noncaseating granuloma

Fig. 1: Rheumatoid nodule

TESTS THAT CAN ASSIST DIAGNOSIS

ESR. It is influenced by the presence of large molecular weight plasma proteins such as fibrinogen and immunoglobulins, the concentrations of which increase in inflammation, thereby increasing the ESR. However, many other factors also affect ESR – anemia, hypercholesterolemia, greater age, female gender, obesity, pregnancy, tissue damage (e.g. stroke, myocardial infarction) and chronic renal failure increase it. Abnormal RBC shapes (e.g. sickle cell disease, microcytosis, polycythemia, CHF and cachexia decrease ESR).

C-reactive protein (CRP) is the most useful index of acute inflammation; it is specific and sensitive, increases rapidly within 6–8 hours of the initiating inflammation.

See Table 4 for the other screening tests in inflammatory arthritis.

IMAGING IN RHEUMATOLOGY

Plain radiography has limitations because changes can take months to appear in RA; only septic arthritis is likely to show abnormalities within days of onset.

Table 4: Screening tests in patients with features suggestive of inflammatory polyarthritis

Test	Comments
• Urinalysis (microscopy)	Mandatory in all patients Renal disease not to be missed
• Full blood count	Leucopenia: ? SLE Thrombocytosis: ? RA Normocytic, normochromic anemia suggests aggressive disease Microcytic anemia: Possibility of haemolysis? SLE Thrombocytopenia: SLE
• ESR and CRP	High levels suggest aggressive disease High ESR and low CRP in some with SLE
• Urea and electrolytes	Kidney disease unrelated to inflammatory arthritis or part of connective tissue disease Baseline to ensure no contraindication to drugs (e.g. NSAIDs, DMARDs.)
• Liver function tests	Usually a baseline to ensure DMARDs are not contraindicated
• Thyroid function tests	Hypothyroidism causes polyarthralgia, is more common in inflammatory arthritis, is not always obvious and is easily treated
• Bone biochemistry	Can sometimes suggest suspected malignancy that can present with polyarthralgia/polyarthritis
• Glucose	Baseline if corticosteroids might be needed
• Rheumatoid factor	May help diagnosis and prognosis. Repeated testing unnecessary
• Antinuclear antibodies	May help diagnosis and prognosis, particularly if specificities are positive
• Other tests (depending on clinical situation)	Occasionally immunoglobulins, complement levels and breakdown products, muscle enzymes (if myositis also suspected)

Contrast arthrography is performed by injecting contrast medium or air into a joint before radiography or CT. It is particularly helpful in the knee and shoulder to identify meniscal tears, intra-articular loose bodies and transchondral fractures.

Ultrasonography is used to identify a Baker's cyst of the knee, but also provides an assessment of joint effusion, synovial proliferation, intra-articular loose bodies and tendon thickening.

Isotope scanning using technetium is used to seek bone metastases. It also demonstrates bone or joint infection and inflammation, because it shows increased blood flow to, or increased metabolic activity in bone, joints or entheses. This modality is perhaps most useful in excluding significant inflammatory, infective or neoplastic musculoskeletal disease.

CT demonstrates bone well and can be used for peripheral joints and spine. Three-dimensional reconstruction of images can be useful in the spine (e.g. to diagnose spinal stenosis).

MRI is superior to CT in imaging soft tissues and is particularly helpful in the diagnosis of musculoskeletal disorders. It is the best method for demonstration of intervertebral disc pathology and prolapse, and pressure on spinal nerve roots from disc herniation, rheumatoid subluxation or spinal stenosis. It has revolutionized detection of soft tissue lesions in knee and shoulder. It can be used to assess muscle involvement in polymyositis.

GENES AND ENVIRONMENT IN RHEUMATIC DISEASES

Single-gene disorders – A single-gene disorder is one in which all the features of the disease can be attributed to one family gene (e.g. the *HFE* gene in hemochromatosis). The faulty gene contains nucleotide changes that have consequences for the translated protein. The genetic abnormalities can lead to the same clinical phenotype because they all result in the lack of an essential protein (Table 5).

Polygenic disorders – A polygenic disorder is one in which family or twin studies show evidence of heritability but a Mendelian pattern of inheritance is not seen. For example, nodal generalized osteoarthritis commonly runs in families and shows a strong female predominance but is not inherited predictably.

Comparison of the concordance of disease in monozygotic twins (genetically identical), and dizygotic twins (average 50% of genes in common) gives an indication of the role of genetic influences, e.g. in ankylosing spondylitis,

Table 5: Monogenetic disorders with rheumatic consequences

Disease	Rheumatic Phenotype	Genes involved
Familial chondrocalcinosis	Pseudogout	ANK – a gene controlling extracellular and intracellular pyrophosphate levels
Familial expansile osteolysis	Paget's disease-like lesions	RANK
Blau's syndrome – familial	Granulomatous synovitis	CARD15/NOD2 - also associated with Crohn's disease arthritis, iritis and rash
Disease	Rheumatic Phenotype	Genes involved
Multiple epiphyseal dysplasia	Growth abnormalities	Cartilage oligomeric protein, type IX collagen, matrilin-3
Multicentric osteolysis and arthritis syndrome	Vanishing bone syndrome	Matrix metalloproteinase 2
Familial Mediterranean syndrome	Recurrent serositis	Marenostrin
TRAPS	Periodic syndrome	Tumor necrosis factor α -receptor 1

50–70% of monozygotic twins are disease concordant, compared with about 25% of dizygotic twins.

Environmental influences on genes – The HLA genes particularly HLA-B27 in spondyloarthropathies and HLA-DR4 (with related alleles) in RA, are excellent examples of gene-environment interactions, because HLA antigens are the principal means by which the adaptive immune system recognizes the environment-HLA antigens present peptides derived from pathogens and self-proteins to T cells.

2. RHEUMATOID ARTHRITIS

Rheumatoid arthritis (RA) is a multisystem inflammatory disease primarily affecting the synovium and adjacent tissues.

AETIOLOGY

Immunogenic factors (e.g. HLA-DRB1) are important in determining the development and expression of the disease. The combination of conserved amino acid sequence in the third hypervariable region of HLA-DRB1 with positive rheumatoid factor identifies individuals at 13 times greater risk of developing bony erosions at 1 year.

Other factors – (a) Hormonal factors – Incidence of RA in women is greater before menopause and remission of

RA during pregnancy is well known. (b) Oral contraceptive pill – has no effect on RA risk overall, however it may postpone onset of the disease. (c) Low economic status is associated with a worse disease outcome in RA.

PATHOGENESIS

Once the inciting agent has activated the immune system, a range of intersecting immunological pathways operate, leading eventually to joint destruction. Joint deformity occurs in RA because the cartilage and then the bone is eroded by the proliferative synovial tissue. This process leads to increased laxity of ligaments around the joints, subluxation of tendons and subsequently of joints, and inflammation of many other tissues in the body.

Table 6 gives American College of Rheumatology (ACR) classification criteria for rheumatoid arthritis.

PRESENTATION

RA presents as acute polyarthritis developing over a few days, or more commonly, weeks to months. The initial pattern of joint involvement may be monoarticular, oligoarticular (≤ 4 joints) or polyarticular (> 5 joints), usually in a symmetric distribution. Systemic features such as fatigue and diffuse musculoskeletal pain may occur before frank swelling of joints. The disease commonly presents in the metacarpophalangeal joints or metatarsophalangeal joints and wrists (Fig. 2). Morning stiffness is a common

Table 6: ACR classification criteria for rheumatoid arthritis

		Score
Joint involvement	1 large joint (shoulder, elbow, hip, knee, ankle)	0
	2–10 large joints	1
	1–3 small joints (MCP, PIP, thumb IP, MTP, wrists)	2
	4–10 small joints	3
	>10 joints (at least 1 small joint)	5
Serology	Negative RF and negative anti-CCP	0
	Low-positive RF or low-positive anti-CCP antibodies (< 3 times ULN)	2
	High-positive RF or low-positive anti-CCP antibodies (> 3 times ULN)	3
Acute phase reactants	Normal CRP and normal ESR	0
	Abnormal CRP and abnormal ESR	1
Duration of symptoms	< 6 weeks	0
	> 6 weeks	1
Score > 6 indicates definite RA		

Fig. 2: Rheumatoid hand

early feature and boggy synovial tissue can be demonstrated on examination.

COURSE OF THE DISEASE

Clinically RA behaves in various ways, however most patients who have RA for more than 6 months develop progressive, erosive disease leading to significant disability. Up to 10% develop acute and progressive disease and up to 20% experience a single episode of inflammatory polyarthritis and do not suffer further.

RA causes significant morbidity - 50% of individuals with RA are unable to work 10 years after its onset, and life expectancy is reduced by 5 years in women and 7 years in men. Excess mortality is usually from cardiovascular disease.

Few patients enter true remission. ACR criteria for remission are given in Table 7.

Exclusions: Clinical manifestations of acute vasculitis, pericarditis, pleuritis or myositis and/or unexplained recent weight loss or fever secondary to RA do not allow a definition of complete remission.

Table 7: ACR/EULAR provisional definition of remission in rheumatoid arthritis

At any time point, patient must satisfy all of the following:

- Tender joint count ≤ 1
- Swollen joint count ≤ 1
- C-reactive protein ≤ 1 mg/dL
- Patient global assessment ≤ 1 (on a 0–10 scale)

OR

At any time point, patient must have a Simplified Disease Activity Index score of ≤ 3.3

Table 8: Features associated with a poor prognosis in rheumatoid arthritis

- Greater number of joints affected
- Uncontrolled polyarthritis
- Structural damage/deformity (e.g. erosions on joint radiographs)
- Functional disability
- Presence of extra-articular features (nodules, vasculitis)
- Psychosocial problems (e.g. poverty, low educational achievement, employment requiring moderate/heavy labour)
- High titre of rheumatoid factor
- Presence of HLA-DR4, particularly homozygosity
- Family history

See Table 8 for the features associated with poor prognosis in rheumatoid arthritis.

Types of Presentation

1. *Classical* - Pain, stiffness and swelling of small joints of hands and wrists. Symptoms fluctuate in severity from day to day.
2. *Palindromic* - Intermittent episodes of pain, swelling and redness, usually of a single joint, followed by rapid return to normal after several days.
3. *Systemic* - Weight loss, pleurisy and pericarditis but minimal joint involvement.
4. *Polymyalgic* - Pain and stiffness in shoulders and hips with subsequent synovitis.
5. *Monoarthritic* - Single joint involvement, usually the knee.
6. *Acute onset* - Sudden overnight onset with stiffness and pain.
7. *With generalized lymphadenopathy.*

DIAGNOSIS

- a. The *clinical criteria* for the disease must have been present for at least 6 weeks. The joints feel hot and swollen and are usually tender to touch, and generalized lymphadenopathy may also be present.
- b. *Laboratory:* Abnormal investigations may include:
 - Increased WBC count
 - Thrombocytosis
 - Mild normocytic anemia
 - High ESR or acute phase reaction
 - Positive rheumatoid factor
 - Positive anti-CCP antibody
 - Arthrocentesis of synovial fluid shows it to be straw colored with increased neutrophils

DIFFERENTIAL DIAGNOSIS

Other disorders presenting with pain and tenderness:

- Infectious arthritis - Viral (rubella, rhinovirus type 7, echovirus, E-B virus, hepatitis C), bacterial (*Mycoplasma*, Lyme disease)
- B27-associated arthropathies, which usually present as oligoarthritis (psoriatic, reactive and enteropathic)
- Crystal arthropathies - Gout and calcium pyrophosphate dihydrate deposition disease

JOINT INVOLVEMENT IN RA

Joints commonly involved are metacarpophalangeal, proximal interphalangeal joints, the wrists and the knees. In early stages joints are warm, swollen and tender. Weakening of the joint capsule and tendon along with ligament damage lead to joint instability, subluxation or dislocation and so produces characteristic deformities of RA. Eventually severe joint damage may lead to fibrous or bony ankylosis or secondary degenerative changes. Some of the characteristic joint features of RA are listed in Table 9.

Temporomandibular joints - may be affected in up to 30% of patients, most commonly young women.

Cricoarytenoid joints - may occasionally be affected causing dysphagia, hoarseness or stridor.

Extra-articular features of RA - Systemic features in RA may dominate articular manifestations and in some individuals may predate joint disease. Systemic manifestations may be divided into organ-specific and general.

SPECIFIC ORGAN INVOLVEMENT IN RA

Cutaneous - Livedo reticularis, palmar erythema, pyoderma gangrenosum (very rare).

Subcutaneous nodules - occur in 20-30% of cases. Vary between 3 and 20 mm in diameter, single or multiple, occurring over bony prominences, at sites of pressure or friction, e.g. elbow. Can breakdown and become infected. Their presence indicates an adverse prognosis Tenosynovitis. May also occur in the lungs, pleura, pericardium and peritoneum.

Myositis - Muscle wasting around inflamed joints, e.g. guttering between extensor tendons and dorsal surface of the hand, and wasting of quadriceps.

Bone - Generalized osteoporosis especially of vertebral bodies. Spontaneous vertebral collapse and wedging may occur.

Vascular - Vasculitis: (a) Small nail-fold and nail-edge infarcts, or sometimes gangrene of the digits. (b)

Purpuric rashes caused by capillaritis. (c) Indolent leg ulcers due to small vessel vasculitis. (d) Arrhythmias and heart block rarely from formation of small nodules in conducting system. (e) Rarely myocardial infarction secondary to vasculitis. (f) Neurovascular disease presenting as distal sensory neuropathy or mononeuritis multiplex.

Hematological - (1) Anemia - Pathogenesis - (a) Active inflammatory disease. (b) Felty's syndrome. (c) Iatrogenic - Aspirin/NSAID-induced GI bleeding. (i) Gold, penicil-

Table 9: Joint deformities in rheumatoid arthritis

Joint	Main deformities	Main problems	Principal solutions for medical failure
Fingers	<ul style="list-style-type: none"> • Boutonniere • Swan-neck • Ulnar deviation • Mallet 	<ul style="list-style-type: none"> • Functional (especially swan-neck) • Cosmetic 	<ul style="list-style-type: none"> • Splinting • Surgery

lamine-induced hypoplastic anemia. (ii) Sulfasalazine-induced hemolysis. (2) Lymphadenopathy.

Cardiac - (a) Mitral regurgitation. (b) Pericardial effusion. (c) Constrictive pericarditis. Have increased risk of coronary artery disease.

Respiratory system - (a) *Pleurisy and pleural effusions*. (b) *Rheumatoid nodules* - may be parenchymal or subpleural, solitary or multiple. (i) May cavitate and cause hemoptysis. (ii) In rheumatoid patients exposed to certain dusts, e.g. coal miners, nodules are accompanied by massive fibrotic reactions (Caplan's syndrome). (c) Fibrosing alveolitis - starts in lower lobes and gradually spreads upwards. (d) Obliterative bronchiolitis - rare complication, may be associated with penicillamine therapy. (e) Pulmonary hypertension. (f) Bronchopleural fistulae. (g) Stridor due to - (i) Cricoarytenoid arthritis. (ii) Nodule on vocal cords. (h) Recurrent lower respiratory tract infection (Sjogren's). (i) Iatrogenic - (i) Asthma (salicylates). (ii) Allergic/fibrosing alveolitis (gold). (iii) Goodpasture's (penicillamine). (iv) Interstitial fibrosis (methotrexate, chlorambucil).

Neurological - (a) *Neuropathy* - (i) Entrapment neuropathies - most often median nerve compression producing carpal tunnel syndrome. (ii) Peripheral neuropathy - usually sensory, occasionally sensorimotor. (iii) Vasculitis may rarely affect large nerves producing mononeuritis multiplex. (b) *Cervical cord compression* - caused by cervical subluxation may cause sudden death, or more commonly progressive cervical myelopathy. (c) *Cervical nerve root compression* - Pain, numbness or paraesthesia in arm or hand. (d) *Muscle wasting* - (a) Mechanisms - (i) Systemic hypermetabolism. (b) Disuse atrophy. (c) Inflammatory (vasculitic) myositis. (d) Neuropathic - (i) Vasculitic. (ii) Entrapment. (iii) Splint-induced nerve compression. (d) *Iatrogenic* - Corticosteroid myopathy.

Renal - No specific kidney lesion. Proteinuria, sterile pyuria, microscopic hematuria, casts and reduced glomerular function often occur. Analgesic nephropathy, drug-induced interstitial nephritis or chronic pyelonephritis may be seen in some cases. Secondary amyloidosis is rare but important cause of kidney disease.

Ocular - (a) Keratoconjunctivitis sicca. (b) Episcleritis and scleritis.

Reticuloendothelial system - (a) *Splenomegaly* - in about 5%. Mechanisms - (i) Primary disease manifestation. (ii) Felty's syndrome. (iii) Sjogren's syndrome. (iv) Amyloidosis. (b) *Generalized lymphadenopathy* - in about 50% of patients with active RA. (c) *Oedema* - of feet and ankles due to poor lymphatic drainage. RA patients have increased risk of lymphoma specially in cases of uncontrolled disease activity and Felty's syndrome.

Infection - Increased frequency in RA. - (a) *Antinuclear antibodies* - in 50%. (b) *Other abnormalities* - which reflect acute phase response - Elevated CRP, alkaline phosphatase and platelets. Decreased serum albumin and hemoglobin.

Amyloidosis - usually manifested by proteinuria. Malabsorption if GI tract involvement.

Non-specific features seen in most patients with active RA include lethargy, depression and malaise. Fever is occasionally an early feature, particularly in systemic disease. Weight loss may be a marked feature. Risk of malignancy is increased in RA; this relates principally to hematological disorders. Incidence of some solid organ tumors (e.g. adenocarcinoma of the lung) is also increased. Reduced bone density can lead to an increased risk of fractures. Amyloidosis may contribute to kidney or hepatic failure in some patients.

ORGAN SPECIFIC AND SYSTEM-SPECIFIC FEATURES

Sjogren's syndrome - is the most common syndrome which occurs in up to 40% of patients with RA. There is dryness in eyes, nose and mouth as a result of generalized exocrinopathy. Lethargy appears more intense in these patients and there is an association later with lymphoma, though this risk is less than that in patients with primary Sjogren's syndrome.

Felty's syndrome is much less common. It is characterised by severe RA, splenomegaly and neutropenia. There is greater risk of systemic infection and development of chronic leg ulcers.

INVESTIGATIONS

- Tests for inflammation** - Raised ESR, C-reactive protein and plasma viscosity. Other laboratory tests to support inflammatory disease - Normochromic, normocytic anemia (with low iron levels and iron-binding capacity), thrombocytosis, elevated hepatic alkaline phosphatase, polyclonal gammopathy, and elevation of acute phase proteins, e.g. ferritin.
- Immunological tests** - (a) *Rheumatoid factor* - RF is an autoantibody directed against the Fc fragment of immunoglobulin G (IgG). The commonly used Rose-Waller Latex agglutination tests detect only the IgM type of RF, because IgM is a multivalent immunoglobulin and hence a better agglutinator. Rose Waller test is expressed as differential agglutination titre (DTA); DTA above 1 in 16 is significant. See Table 10 for conations associated with presence of rheumatoid factor.

Table 10: Conditions in which RF may be present

• <i>Rheumatoid arthritis</i>
• <i>Connective tissue disease</i> – SLE, Sjogren's syndrome, systemic sclerosis, mixed connective tissue disease.
• <i>Other diseases with immunological factors</i> – Chronic active hepatitis, sarcoidosis, fibrosing alveolitis, Paraproteinaemias, cryoproteinaemias.
• <i>Chronic infections</i> – Infective arthritis, pulmonary tuberculosis, leprosy, syphilis, infectious mononucleosis, leishmaniasis.
• <i>Miscellaneous</i> – Normal individuals especially aged, relatives of patients with RA, myeloma.
• <i>Mixed essential cryoglobulinaemia.</i>
• <i>Anti-nuclear antibodies</i> – Test may be positive, particularly in patients with extra-articular disease manifestations.

(b) Anti-CCP predates diagnosis of RA and may be found years before symptoms of RA develop, especially in older individuals. High levels of the antibody indicate a more aggressive form of RA.

3. **Radiology** – *Sequence of changes* – (a) Periarticular osteopenia with soft tissue swelling. (b) Erosions at joint margins (Fig. 3) at junction of synovium, subchondral bone and articular cartilage. (c) Loss of joint space. (d) Deformity such as subluxation or complete dislocation of affected joints (Fig. 4).
4. **Special investigations** –
 - a. *Synovial biopsy* – Rheumatoid pattern (villus formation with thickening of synovial layer and infiltration with abnormal cells) in rheumatoid arthritis (also in Still's disease, SLE).
 - b. *Synovial fluid* – Not helpful in differential diagnosis from other types of inflammatory arthritis. WBC counts between 5000 and 50000 WBC/ μL compared to <2000 WBC/ μL for a non-inflammatory

**Fig. 3:** X-ray hand in early rheumatoid arthritis

condition such as osteoarthritis. Overwhelming cell type in the synovial fluid is the neutrophil.

- c. *Arthroscopy* – will not distinguish RA from various inflammatory seronegative arthritides. In acute RA synovium is oedematous, diffusely erythematous and friable. In more chronic conditions, it becomes thickened, polypoid.
- d. *Renal biopsy* – if reduced glomerular or tubular function.
- e. *Pulmonary biopsy* – to distinguish rheumatic nodules from carcinoma or to establish diagnosis of fibrosing alveolitis.

MANAGEMENT OF RHEUMATOID ARTHRITIS

General Measures

Education – Provides information on the disease and its therapies. It also emphasizes the role of patients in caring for and controlling their own disease.

Exercise – Much of the pain and stiffness in RA arises from periarticular tissues such as muscles and tendons and patients should perform a general (range of motion) exercise programme, to improve and maintain muscle bulk around the joints.

Physiotherapy/occupational therapy – Physiotherapeutic modalities such as electric therapy (ultrasound or interferential), heat or cold. Joint protection in form of splinting to prevent deformity during episodes of acute pain and advice regarding transference of load or alternative ways of performing tasks have an important role.

Dietary advice includes weight reduction and the addition of fish oil or evening primrose oil. Fish oil substitutes

**Fig. 4:** X-ray hand showing subluxation of wrist and MCP joints

have enabled reduction or discontinuation of NSAIDs in some patients with RA.

Pharmacotherapy

Once the diagnosis of RA has been confirmed, treatment with drugs that retard joint destruction and reduce disability (disease-modifying antirheumatic drugs) should be commenced promptly. NSAIDs have no effect on long-term disability but provide symptom relief. Pure analgesic agents such as paracetamol can provide pain relief and reduce dose requirements of:

NSAIDs

NSAIDs are derived from various chemical classes with a common mechanism of action – reduction of prostaglan-

in synthesis (Table 11). The response to NSAIDs varies and it is important to find the right NSAID for each patient.

Risk Factors for Gastric Toxicity of NSAIDs

Definite

- Age > 65 years
- Smoking
- Prior ulcer disease or complications
- High-dose multiple NSAIDs
- Concomitant corticosteroid therapy

Possible

- Alcohol
- Presence of *H. pylori*

Table 11: Non-steroidal anti-inflammatory drugs (NSAIDs)

Drug	Dose	Potential adverse effects
Propionic acids <ul style="list-style-type: none"> • Ibuprofen • Benoxaprofen • Fenoprofen • Ketoprofen • Naproxen • Zaltoprofen 	<ul style="list-style-type: none"> • 400–800 mg qds • 600 mg o.d. • 600 mg o.d. • 100 mg t.d.s • 500 mg b.d. • 80 mg b.d 	Gastrointestina (common) <ul style="list-style-type: none"> • Indigestion, ulceration, hemorrhage, perforation • Small bowe ulceration • Stomatitis Renal (common) <ul style="list-style-type: none"> • Increased serum creatinine level • Renal failure • Oedema, worsening of heart failure • Interstitial nephritis • Papillary necrosis Cardiac (reatively common) <ul style="list-style-type: none"> • Fluid retention • Cardiac flaiure • Hypertension Neurological (uncommon) <ul style="list-style-type: none"> • Headache • Dizziness Pulmonary (rare) <ul style="list-style-type: none"> • Exacerbation of asthma

DMARDs

The onset of effect is usually delayed (4 weeks to 3 months) and they have various mechanisms of action. They can alter laboratory markers of inflammation such as CRP and ESR. Incidence of toxicity is similar to NSAIDs.

Biologics

Such as IL-1 receptor antagonists and anti TNF- α agents exert their anti-inflammatory action by neutralizing the activities of TNF- α and IL-1 respectively. In contrast to older DMARDs, these agents have rapid onset of action with fewer side effects and have pronounced disease reducing activity in patients who have been treated with other

DMARDs, when administered as monotherapy or in combination with methotrexate in patients with active RA.

Guidelines for anti-TNF- α therapy (British Society for Rheumatology)

- Active disease: Disease activity score (DAS) > 5.1
- Pretreatment: Failure of at least two DMARDs after adequate trial
- Exclusion: Pregnancy or breast feeding
Active infection
High risk of infections
Malignancy or premalignancy

Table 12 gives drugs and their dosages and toxicities used in rheumatoid arthritis.

Table 12: Drugs used in rheumatoid arthritis.		
Drug	Dose regimen	Adverse effects / Monitoring
1. DMARDs		
Hydroxychloroquine	200 mg b.d. till response, then 200 mg o.d.	Retinal maculopathy. Ophthalmoscopy before treatment and at 6 and 12 months.
D-penicillamine	125 mg at night, increased by 125 mg/month. Maximum 1000 mg.	Maculopapular rash. Anorexia, nausea, loss of taste, mouth ulcers. Proteinuria. Thrombocytopenia, pancytopenia. Drug-induced SLE. Myasthenia gravis. Pemphigus reaction. Goodpasture's syndrome. Full blood count, urinalysis fortnightly until dose stable, then monthly.
Gold compounds		
Intra-muscular	Test dose 10 mg, then 20–50 mg/week. Once remission, 50 mg/month.	Rash. Stomatitis. Proteinuria. Thrombocytopenia, pancytopenia. Full blood count. Urinalysis before each injection.
Oral	3 mg b.d.	Less toxic than i.m. gold but similar hematological and renal problems can occur. Full blood count and urinalysis monthly.
Methotrexate	7.5 mg one weekly, increased in 2.5 mg increments to 15–20 mg	Marrow suppression, liver damage. Teratogenicity. Early introduction of MTX therapy in undifferentiated arthritic (UA) pts. Seropositive for anti-CCP delays differentiation of RA and retards the progression of joint destruction.
2. Corticosteroids		
Prednisolone	7.5 mg/d, monthly pulses with high dose when DMARD started Intra-articular injections into inflamed joints. IM or IV during flare up	Useful additive to control symptoms Adverse effects of steroids
3. Biologic response modifiers		
TNF- α antagonists		
Etanercept	25 mg/s.c. twice a week	Inj. site reaction, URI development of ANA and antibodies to the drug
Infliximab	5 mg IV at 0.2–6 week and every 8 weeks thereafter	+/- SR, hypotension headache rash, autoantibodies
Adalimumab	40 mg s.c. every 2 weeks	ISR, URI, rash, headache, sinusitis
Golimumab	50 mg s.c. monthly	ISR
Certolizumab	400 mg s.c weeks 0, 2, 4, then 200 mg every other week	ISR

Contd...

Contd...

Drug	Dose regimen	Adverse effects / Monitoring
T-cell inhibitor		
<i>Abatacept</i>	Weight based <60 kg: 500 mg 60–100 kg: 750 mg >100 kg: 1000 mg IV dose at weeks 0, 2 and 4 and then every 4 weeks OR 125 mg s.c weekly	↑ Risk of bacterial, viral infections
Anti CD-20 antibody		
<i>Rituximab</i>	1000 mg IV x 2, days 0 and 14 May repeat course every 24 weeks or more	↑ Risk bacterial, viral infections, infusion reaction, Hepatitis B reactivation, cytopenias
Anti-IL-6 receptor antibody		
<i>Tocilizumab</i>	4–8 mg/kg IV monthly Or 162 mg s.c. every other week (<100 kg weight) 162 mg s.c. every week (≥100 kg weight)	Risk of infection, Infusion reaction LFT elevation, Dyslipidemia, Cytopenia
IL-2 receptor antagonist		
<i>Anakinra</i>	100 mg s.c./day	ISR, infections, neutropenia
4. JAK pathway inhibitor		
<i>Tofacitinib</i>	5 mg orally bd	Risk of infection, LFT elevation, Dyslipidemia Neutropenia
5. Immunosuppressants		
<i>Azathioprine</i>	25 mg/kg/day	Marrow suppression. Occasional liver damage. Carcinogenesis. Full blood count, LFTs 2 weekly for 2 months, then monthly. Regular urinalysis.
<i>Leflunomide</i>	100 mg o.d. for 3 days, then 20 mg o.d.	Hepatotoxicity, diarrhea, hair loss, rash
<i>Cyclosporine</i>	3–5 mg/kg/day	Nephrotoxic, Hypertension, Hyperkalaemia
Cyclophosphamide	2–3 mg/kg/d	Bone marrow suppression, may be lifesaving in serious organ involvement

Side effects - Long-term therapy can cause weight gain, bruising, fluid retention, susceptibility to infection, diabetes, osteoporosis. With corticosteroid therapy, the following should be noted:

- Anti-osteoporotic drugs (calcium, 1,25-dihydrocholecalciferol or bisphosphonates) in all patients on long-term (>3 months) therapy.
- Use lowest possible dose (< 7.5 mg daily) as morning dose.
- Plan a slow dose reduction (1 mg every month) in patients in whom the disease is relatively quiescent or the side effects are becoming a problem.

Special Indications for Steroids

(first line agents) in RA

1. Pregnant women with RA
2. Rheumatoid vasculitis (high dose with cyclophosphamide)
3. Ocular disease

4. Elderly patients and those with mild to moderate renal insufficiency (low dose).

Other Treatments

- a. The concept that RA behaves much like a slowly invasive tumor moving across the joint causing cartilage destruction has led to the use of high dose chemotherapy with stem cell rescue. Genetic therapies approaches with the aim of increasing local expression of anti-inflammatory molecules in the involved synovial tissues are likely to provide significant benefits in patients with RA.
- b. Stem cell transplantation of donated hematopoietic stem cells, which mature into various blood cells have induced remission in some children with severe juvenile RA.
- c. Plasmapheresis. A device called prosorba column is used to remove inflammatory antibodies from the patient's blood. This therapy may slow or even halt progression of the disease in a good number of patients.

Surgery

In patients with significant joint destruction, surgical techniques such as arthroplasty and/or excision (as in forefoot reconstruction or wrist arthrodesis) can provide pain relief and improve function.

3. SPONDYLOARTHROPATHIES

SPONDYLOARTHROPATHIES

Is a group of disorders characterized by:

- Involvement of sacroiliac joints
- Peripheral arthropathy
- Absence of rheumatoid factor
- Pathological changes at sites of insertion of ligaments or tendons (enthesopathy)
- Involvement of lungs, heart, skin and eye (iritis)
- Clinical evidence of overlap between members of the group
- Tendency towards familial aggregation – association with HLA-B27 ranges from about 60% in psoriatic and enteropathic spondylitis to more than 90% in ankylosing spondylitis depending on ethnic group.

ANKYLOSING SPONDYLITIS

Is symptomatic sacroiliitis (persistent pain and stiffness for >3 months associated with morning stiffness and improvement with exercise/worsening with rest). Various diagnostic criteria of spondyloarthropathy are given in Tables 13 and 14.

New criteria introduced by Assessment of Spondyloarthritis International Society (ASAS) is given in Table 15.

Table 13: New York criteria for diagnosis

Clinical criteria
• Limited movement of lumbar spine in three planes
• Pain in lumbar spine or at lumbodorsal junction
• Chest expansion < 2.5 cm
Radiological
Unilateral sacroiliitis grade III–IV, or bilateral sacroiliitis grade II

Table 14: European spondyloarthropathy group criteria

Inflammatory spinal pain of synovitis (asymmetrical or predominantly in lower limb) and one or more of the following:
• Positive family history
• Psoriasis
• Inflammatory bowel disease
• Buttock pain
• Enthesopathy
• Sacroiliitis

Table 15: ASAS criteria for classification of axial spondyloarthritis

(To be applied for patients with back pain ≥ 3 months and age of onset < 45 years)

A. Sacroiliitis on Imaging Plus ≥ 1 SpA Feature

- Sacroiliitis on imaging
 - Active (acute) inflammation on MRI highly suggestive of SpA associated sacroiliitis and/or
 - Definite radiographic sacroiliitis according to modified New York criteria (as mentioned in Table 13)

OR

B. HLA-B27 Plus ≥ 2 Other SpA Features

SpA features considered for diagnosis are as follows:

- Inflammatory back pain
- Arthritis
- Enthesitis (heel)
- Anterior uveitis
- Dactylitis
- Psoriasis
- Crohn's disease or ulcerative colitis
- Good response to NSAIDs
- Family history of SpA
- HLA- $\beta 27$
- Elevated CRP

Aetiology

(a) *Sex* – More common in men than in women (2.7:1). Women tend to have more peripheral joint involvement, men have more spinal disease. Women are more likely to suffer inflammatory bowel disease (particularly Crohn's) as a co-morbidity, men more psoriatic spondylitis. (b) *Genetic factors* – HLA-B27 and HLA-DR1 confer susceptibility to the spondyloarthropathies. However, the entire HLA locus accounts for no more than 50% of the genetic susceptibility and loci on other chromosomes (e.g. 1, 2, 9, 10, 16) confer additional susceptibility, with severity loci on chromosomes 18, 19 and 21. (c) *Environmental triggers* of the disease remain unknown. Gram-negative organisms such as *Salmonella*, *Sh. flexneri*, *Campylobacter* and *Yersinia* precipitate reactive arthropathy.

Clinical Features

Suggestive of ankylosing spondylitis

- Insidious onset of discomfort
- Age at onset <40 years
- Persistence of symptoms for >3 months
- Association with morning stiffness
- Improvement with exercise

Ankylosing spondylitis does not burn out, it continues to be active. Fatigue is a major component. No system in the body is unaffected.

Sacroiliac joints and spine – Early sign is evidence of sacroiliac joint arthritis (Figs. 5 to 7). Examination of spine

Fig. 5: MRI sacroiliac joint showing erosions and subchondral oedema

Fig. 6: MRI sacroiliac showing erosions

Fig. 7: CT SI joints showing erosions

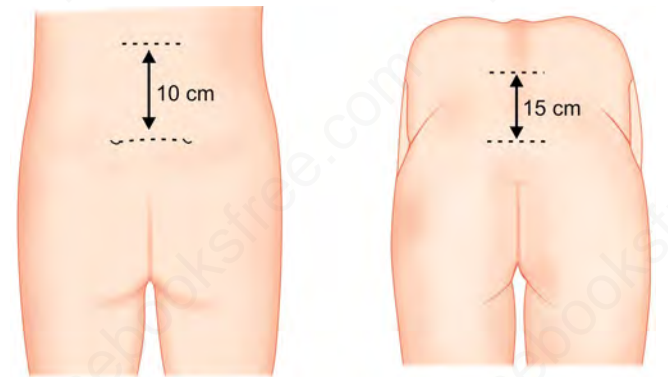

Fig. 8: The schober text detects reduced flexion. With the patient standing mark the skin overlying the fifth lumbar spinous process (usually at the level of the posterior superior iliac spine or the dimple of venous) and also 10 cm above. On forward flexion, this should increase to >15 cm

may reveal muscle spasm and loss of normal lordosis with positive Schober test (Fig. 8). There is slow forward bending of spine (Fig. 9).

Figure 16.4 The Schober test detects reduced flexion. With the patient standing mark the skin overlying the fifth lumbar spinous process (usually at the level of the posterior superior iliac spine or the dimple of Venous) and also 10 cm above. On forward flexion, this should increase to > 15 cm.

Peripheral joint involvement - Inflammatory disease of hip (Fig. 10) and shoulder may produce progressive disability.

Enthesopathic features include plantar fasciitis, costochondritis and Achilles tendinitis.

Extraarticular manifestations include acute anterior uveitis, IBD, aortic insufficiency.

Investigations

(a) *Radiology* - demonstrates sacroiliitis. Early change in lumbar spine is manifested as squaring of the superior and inferior margins of vertebral body (Fig. 11); later change results in bamboo spine (Figs. 12 to 14). Hip arthritis is seen frequently (Figs. 15 to 17).

(b) *Laboratory tests* - (i) ESR is elevated in 50%. (ii) Serum IgA may be elevated. (iii) Serum creatinine phosphokinase and alkaline phosphatase may be slightly raised. (iv) HLA-B27 is present in 95%.

Management

(a) *Physiotherapy* has a major role in long-term management. (b) *Pharmacotherapy* as in treatment of RA. (c) *DMARDs* - Sulfasalazine and methotrexate appear to have an effect only in patients with peripheral joint

Fig. 9: AS forward bending

Fig. 10: X-ray AS with bilateral hip arthritis and bilateral sacroiliitis

Fig. 11: AS X-ray spine showing anterior shining edges of lumbar vertebrae

Fig. 12: Bamboo spine AP view in AS

Fig. 13: Bamboo spine lateral view in AS

Fig. 16: Right hip arthritis MRI

Fig. 17: Bilateral hip arthritis on X-ray

Fig. 18: THR done in AS

involvement. (d) Anti-TNF α agents- Infliximab is given intravenously—3-5 mg/kg body weight and then repeated 2 weeks later, again 6 weeks later and then at 8-week intervals. Etanercept 50 mg s.c. once weekly, Adalimumab 40 mg s.c. biweekly. Golimumab 50 or 100 mg s.c. every 4 weeks. Certolizumab pegol 400 mg s.c. every 4 weeks. (d) *Bisphosphonates* may act on both the underlying osteoporosis and inflammatory disease itself. (e) *Pulsed i.v. methylprednisolone* 0.5 g on one or more occasions, may have a short-term effect allowing patient to get more benefit from physiotherapy and hydrotherapy. (f) *Surgery* is most often used in patients with advanced hip involvement (Fig. 18).

POST-INFECTIVE ARTHRITIS

Arthritis that follows an identifiable infection but does not have the characteristics of joints sepsis may be considered post-infective.

Reiter's syndrome is an episode of peripheral arthritis of more than 1 month's duration occurring in association with urethritis or cervicitis. It is a spondyloarthropathy and is associated with many bacterial GI, genitourinary and possibly respiratory infections.

Aetiology

(a) *Trigger infections* - Reactive arthritis occurs particularly during outbreaks of enteritis caused by *Salmonella*,

Fig. 19: X-ray calcaneal spur

Fig. 20: Sausage digit on Rh 4th digit

Campylobacter, *Yersinia* or *Shigella*. About 1% of cases of non-gonococcal genital tract infections are complicated by arthritis (SARA). (b) *HLA-B27* - Presence of this gene confers a 40-fold increased risk of Reiter's syndrome.

Clinical Features

Of Reiter's syndrome/reactive arthritis

- History of GI or genitourinary tract infection within the last 6 weeks
- Systemic symptoms of fever, malaise and fatigue
- Enthesitis [particularly of tendo-Achilles and plantar fascia insertions at the calcaneum (Fig. 19)] occurs in about 50%.
- Tenosynovitis at the fingers and toes, produces dactylitis or 'sausage digits' (Fig. 20).
- Acute sacroiliitis causes lower back and buttock pain.
- Psoriasiform skin and mucous membrane lesions are seen in 20% especially men. Keratoderma blennorrhagica is pustular psoriasis on soles of feet (Fig. 21). Circinate balanitis and vulvitis are also psoriasiform rashes.
- Urethritis and/or cervicitis is usually infective in SARA.
- Gut inflammation affects both small and large bowel.
- Painful red eyes occur in about 30%. This is usually conjunctivitis, but occasionally iritis occurs synchronously with arthritis.

Investigations

(a) *Blood tests* - Elevated inflammatory markers. (b) *Urinalysis* may show pyuria. (c) *Urethral or cervi-*

Fig. 21: Keratoderma blennorrhagica

cal smears show purulent exudate. (d) *Arthrocentesis* can be performed to exclude septic arthritis. (e) *Urethral and/or cervical cultures* or antigen or DNA may reveal sexually transmitted pathogens such as *C. trachomatis*. (f) *Radiography* may demonstrate erosions, particularly at small joints in chronic cases.

Management - (a) Physiotherapy. (b) NSAIDs in acute, active disease; also in chronic cases sulfasalazine and methotrexate. (c) Tendinitis and enthesitis can be treated with intralesional steroids.

ACUTE RHEUMATIC FEVER

This has been discussed in Diseases of Children.

OTHER SERONEGATIVE SPONDYLOARTHROPATHIES

PSORIATIC ARTHRITIS

Most patients have skin or nail psoriasis; joint inflammation precedes psoriasis in about 15% of patients. See Table 16 for the classification criteria for psoriatic arthritis (CASPAR criteria).

Etiopathogenesis

1. *Hormonal factors* may have a modifying role—psoriatic arthritis usually improves during pregnancy and there is a postpartum flare as in RA. 2. *Immunological mechanisms* may be important as suggested by restricted clonality of T cells in both psoriatic skin and synovium and worsening of arthritis with HIV infection. 3. *Genetic factors* – up to 10% of first-degree relatives of probands with psoriatic arthritis have this condition. Results of genome mapping studies have identified several candidate genes for psoriasis that may also be implicated in arthritis (e.g. cytokines genes, corneodesmosin, MICA genes).

Patterns of Disease

Distal interphalangeal (DIP) joint disease is almost pathognomonic of psoriatic arthropathy. Similarly involvement of interphalangeal joints of the toes in addition to the hallux is only seen in psoriatic arthritis and Reiter's syndrome (Figs. 23 and 24).

Arthritis mutilans is a deforming, destructive arthritis involving the small joints of hands and feet accompanied by osteolysis of the phalanges (Fig. 22).

Fig. 22: Arthritis mutilans in psoriatic arthritis involving right 2nd DIP joint

Peripheral oligoarthritis or polyarthritis – The greatest overlap between subgroups is seen in patients with a relative asymmetrical pattern of joint involvement initially, some of whom progress to a more symmetrical disease.

Spondylitis – About 10–15% of patients, mainly males, have principally spinal involvement with thick asymmetric syndesmophytes (Fig. 25). Cervical spine involvement is common (Figures 24 and 25).

Table 16: classification criteria for psoriatic arthritis (CASPAR criteria)

To meet the CASPAR criteria, a patient must have inflammatory articular disease (joint, spine or enthesal) with ≥ 3 points from any of the following five categories:

1. Evidence of current psoriasis, personal history of psoriasis or family history of psoriasis
2. Typical psoriatic nail dystrophy observed on current physical examination
3. A negative test result for rheumatoid factor
4. Either current dactylitis or a history of dactylitis recorded by a rheumatologist
5. Radiographic evidence of juxtaarticular new bone formation in the hand or foot

Table 17 gives differential diagnosis of psoriatic arthritis.

Table 17: Differential diagnosis of psoriatic arthritis

Causes of oligoarthritis	Causes of symmetrical polyarthritis
• Osteoarthritis	Rheumatoid arthritis
• Gout	Systemic lupus erythematosus
• Reactive arthritis/	Polyarticular gout
• Early rheumatoid arthritis	

Fig. 23: PsA hand showing psoriatic skin lesions, dystrophic nails and DIP arthritis

Fig. 24: PsA X-ray hand showing bilateral PIP and DIP arthritis

Fig. 25: PsA spine X-ray showing assymmetric syndesmophytes

Radiology and Investigations in Psoriatic Arthritis

Peripheral Joints

- Lack of periarticular osteoporosis
- Osteolysis (whittling of phalanges, 'pencil-in-cup')
- Periostitis
- Ankylosis
- New bone formation within entheses (e.g. plantar spur)

Spine

- Random asymmetrical involvement
- Paramarginal syndesmophytes
- High prevalence of cervical spine disease
- Sacroiliitis may be asymmetrical

Laboratory Tests

- Absence of rheumatoid factor
- Elevated ESR, C-reactive protein, plasma viscosity
- Sterile synovial fluid with modest increase in neutrophils

Management

NSAIDs are necessary initially, occasionally analgesics alone suffice. Sulfasalazine or low dose methotrexate (up to 15 mg/week) are added in patients with persistent peripheral joint synovitis. Antimalarials are avoided because of the acute psoriatic skin reaction. Newer agent Ustekinumab, a monoclonal antibody to the shared IL-23/IL-12 p40 subunit, is found efficacious.

SAPHO

Palmoplantar pustulosis is associated with a form of arthritis that affects the anterior chest wall (particularly the sternoclavicular and acromioclavicular joints). The 'SAPHO' (synovitis, acne, pustulosis, hyperostosis of the spine and osteitis) is used to describe some of the characteristic features of the condition, which seem to overlap with psoriatic arthritis. It has a chronic but benign course and usually responds to NSAIDs.

ENTEROPATHIC ARTHRITIS

Peripheral oligoarthritis usually affecting the lower limb accompanies inflammatory bowel disease in about 10% of patients. Other extraintestinal manifestations (e.g. uveitis, erythema nodosum, pyoderma gangrenosum) are more common in patients with arthritis and occur more often in Crohn's disease than in ulcerative colitis. Non-erosive, asymmetrical synovitis affecting the knee or ankle is the most common presentation. NSAIDs are avoided because of risk of further bowel aggravation. Corticosteroid injection of affected joints can be used in combination with sulfasalazine in persistent synovitis. Methotrexate is useful in erosive disease.

Spondyloarthritis and sacroiliitis is also seen in association with inflammatory bowel disease, its course is independent of the bowel inflammation. HLA-B27 is positive in about 60–70% of patients.

JUVENILE IDIOPATHIC ARTHRITIS

Complications

- Chronic anterior uveitis, oligo-articular onset in young female.
Growth: (a) Generalized (from chronic disease, use of corticosteroids) (b) Localized - (i) Overgrowth. (c) Leg-length discrepancy because of active knee synovitis. (d) Undergrowth because of premature fusion of epiphysis (e.g. micrognathia)
- Constitutional - Anemia, fever, weight loss
- Osteoporosis - Due to poor mobility, corticosteroids, poor dietary intake of calcium, vitamin D.
- Amyloidosis especially in severe systemic onset JIA
- Joint failure particularly with polyarticular disease
- Psychosocial, educational impact

Subtypes of JIA

1. Oligoarticular onset the most common type has the best prognosis.
2. Psoriatic arthritis in adults, more common in girls.
3. Enthesitis-related often presents with oligoarthritis, most commonly in large joints of lower limbs. Axial spine involvement is uncommon at presentation in childhood but a significant number have sacroiliitis and ultimately ankylosing spondylitis.

Table 18: Juvenile idiopathic arthritis (JIA). Classification:

Age at onset	<16 years
Minimum duration of arthritis	6 weeks
Subtypes	Clinical features
1. Systemic	Arthritis, fever, rash
2. Oligoarthritis	1–4 joints affected during first 6 months
– Persistent	Affected < 4 joints throughout course
– Extended	Affected > 4 joints after first 6 months
3. Polyarthritis	
– Rheumatoid factor negative	– Affects > 5 joints in first 6 months
– Rheumatoid factor positive	– Affects > 5 joints in first 6 months
4. Enthesitis-related arthritis	Arthritis and enthesitis or arthritis with at least two of sacroiliac tenderness, inflammatory back pain, HLAB27+, family history of HLAB27-related disease
5. Psoriatic arthritis	Arthritis and psoriasis, at least two of dactylitis, nail changes, family history of psoriasis
6. Other	Arthritis of unknown cause or not fulfilling above categories

4. Polyarticular JIA affects more than 5 joints during the first 6 months of disease with symmetrical involvement of small and large joints.
5. Systemic-onset - JIA can occur at any age, equally common in males and females, as acute illness with fever, rash, lymphadenopathy, hepatosplenomegaly and occasionally carditis. About one third of children develop severe polyarthritis.

Complications of Juvenile Idiopathic Arthritis

Chronic anterior uveitis: Highest risk – Oligo-articular onset JIA, young female (< 6 years), antinuclear antibody positive, within 2 years of onset of arthritis.

Growth

- Generalized (chronic disease, use of corticosteroids)
- Localized
- Overgrowth (e.g. leg-length discrepancy because of active knee synovitis)
- Undergrowth because of premature fusion of epiphyses (e.g. micrognathia)

Constitutional

- Anemia of chronic disease
- Fever, weight loss, malnutrition

Osteoporosis

Due to poor mobility, corticosteroids, poor dietary intake of calcium

Amyloidosis

Uncommon – principally in systemic-onset JIA

Joint Failure

Particularly patients with polyarticular disease and those with positive rheumatoid factor

Psychosocial and Educational Impact

- Depression, social isolation, unemployment more common
- Impact on the family (parents and siblings)

4. JOINT AND BONE INFECTIONS

BACTERIAL INFECTIONS

Specific bacteria may be associated with septic arthritis, osteomyelitis and triggering of reactive arthritis. Patients with RA are at greater risk of septic arthritis.

Gonococcal arthritis – is now uncommon. Presentation is usually with diffuse or migratory arthralgia and low-grade fever, or isolated monoarthritis or oligoarthritis may occur.

Brucellosis – Infection of the joints is the most common form of localized disease. The arthritis is usually monoarticular affecting large peripheral joints, sacroiliac joints and the spine.

Tuberculosis – Five clinical syndromes of articular tuberculosis are – Spondylitis (Pott's disease), peripheral arthritis, osteomyelitis/dactylitis, tenosynovitis/bursitis and reactive arthritis (Poncet's disease) in which knees, ankles and elbows are more commonly involved.

Leprosy – Three syndromes may develop – arthralgia/arthritis with or without erythema nodosum leprosum, swollen hand syndrome and vasculitis.

VIRUS INFECTIONS

Some viral infections are accompanied by arthritis more often than others.

Rubella arthritis and arthralgia may occur in up to 50% of infected women as compared with up to 60% men. Live virus and viral antigens have been detected in synovial fluid. Arthritis occurs within one week of the rash. Fingers, wrists, elbows, knees, hip and toe joints are most commonly affected, usually symmetrically.

Parvovirus B19 may be associated with rheumatoid-like polyarthritis. Symmetrical polyarthritis may occur in association with erythema infectiosum.

Hepatic viruses – Transient polyarthritis occurs in 30% of patients during the prodromal stage of acute hepatitis B. Small joints are usually affected.

Musculoskeletal presentations in *HIV infection* are listed in Table 19.

Chikungunya fever. The osteoarticular problems usually subside in 2 to 3 weeks' time. The wrists and small joints of the hands and wrists are worst affected. Major joints like knee and shoulder and spine can also be involved.

Table 19: Musculoskeletal presentations in HIV infection

Arthralgia intermittent, mild and polyarticular
HIV-arthritis commonly affects the knees and ankles and lasts from hours to a few days
Reiter's syndrome
Psoriatic arthritis
Avascular necrosis of bone (may be associated with cardiophilin antibodies)
Septic arthritis (usually caused by <i>Staph. aureus</i> or <i>Strep. pneumoniae</i>)
HIV patients can develop RA

In approximately 20% cases, they disappear after a gap of few weeks. In less than 10% cases, they tend to persist for months. In about 10% the swelling disappears, pain subsides, but only to reappear with every other febrile illness for many months. Each time the same joints get swollen, with mild effusion. Destroyed metatarsal head has been observed in patients with persistent joint swelling. The classical bending phenomena is due to lower limb and back involvement which forces the patient to stoop down and bend forwards.

PARASITIC INFECTIONS

Parasitic arthritis may be caused by (a) localization of the parasite in the joint, (b) reaction to presence of parasite in neighbouring tissues, (c) secondary to an immune-mediated response to parasite antigen/products released spontaneously, (d) occur following treatment.

Clinical Features of Septic Arthritis

It is more common in children, the elderly and immunosuppressed individuals (e.g. AIDS patients, stem cell implant recipients, patients taking immunosuppressive agents, those with damaged joints). The hip and knee are most commonly involved. *H. influenzae* is a common cause of haematogenous arthritis in children aged between 1 months and 5 years.

The inflammatory process causes the joint to become swollen through synovial membrane proliferation. Levels of enzymes within the synovial fluid (e.g. elastase, collagenase) increase and the total effect is to degrade cartilage.

DIAGNOSIS of suspected joint infection:

- Blood tests:** (a) Raised ESR and CRP. (b) Immune tests (e.g. IgM and IgG antibodies to parvovirus 19). (c) Blood cultures.
- Imaging:** Radiographic changes indicate that an infection has been present for more than 2 weeks.
- Microbiology:** Synovial fluid culture, microscopic smears and arthroscopy or open synovial biopsy may be negative in 30% of *M. tuberculosis* infections. Mantoux test may be positive in tuberculous infection.

MANAGEMENT: Early therapy with appropriate antibiotics. Abscesses should be drained, because decompression prevents further obstruction of blood vessels and resulting bone necrosis.

Palindromic Rheumatism

Periodic monoarticular or polyarticular joint swelling, "recurring arthritis", attacks last from hours to days, clear spontaneously and leave no joint residuals. Thirty to forty per cent of these cases develop rheumatoid arthritis.

Juvenile Rheumatoid Arthritis (Still's Disease)

Acute form of rheumatoid arthritis occurring usually between ages of 2 and 4 years. Certain features are quite distinct from adult disease - more frequent occurrence of high fever, characteristic rash, splenomegaly, lymphadenopathy, chronic iridocyclitis, single-joint involvement, failure to grow, striking leucocytosis, and infrequency of subcutaneous nodules. Negative rheumatoid factor.

Intermittent Hydrarthrosis

A joint disorder most common in the knees, occurs at regular cyclic intervals. The synovitis is acute, lasts for 2 days to 4 weeks and clears without residuals. Many of these patients eventually develop typical signs of rheumatoid arthritis.

5. OSTEOARTHRITIS

Osteoarthritis is an abnormality of synovial joints characterized by softening, splitting and fragmentation (fibrillation) of articular cartilage not attributable to direct contact with inflammatory tissue. This is usually accompanied by subchondral sclerosis and bone cysts, joints space narrowing and bony overgrowths at tissue joint margins (osteophytes).

AETIOLOGY

- Age* is a major risk factor
- Race* - Hip OA is less common in Chinese and Asians than in those of Western origin, whereas knee osteoarthritis is more common in Afro-Caribbean.
- Genetic predisposition* - Clinical evidence of inheritance of OA:
 - Heberden's nodes are more common in sisters of affected women than in the general population.

- 20% of individuals with osteoarthritis have a positive family history
 - First-degree relatives are at a twofold risk of generalized radiological osteoarthritis
 - There is greater concordance in identical twins at several joint sites
 - Heritability of radiological knee and hand osteoarthritis is 40-65%
- Gender and hormonal factors* - Below 45 years, the disease is in men, in whom it usually involves one or two joints. Above 55 years, it is more common in women, usually involving several joints (particularly interphalangeals, first metacarpal and knees).
 - Obesity* - The relationship is stronger in women than in men and is strongest at the knee.
 - Other systemic factors* - In women a significant association between hand disease and elevated serum cholesterol levels. Hypertension has been associated with generalized osteoarthritis in men and knee osteoarthritis in non-obese women. Trauma is associated with development of osteoarthritis.

Pathogenesis - OA is a disease of both articular cartilage and subchondral bone. The disease is characterized by progressive degradation of the components of extracellular matrix of the articular cartilage associated with secondary inflammation factors and increased bone turnover and repair.

Clinical features - OA is characterised by gradual development of joint pain, stiffness, limitation of movement and swelling, which may be caused by synovitis with effusion or from osteophyte formation (as in Heberden's nodes). The bony enlargement that accompanies osteophyte formation may lead to joint deformity (Figs. 26 and 27).

Generalized OA refers to involvement of at least three joints or a group of joints (e.g. interphalangeal joints).

Fig. 26: OA hand showing Heberden's nodes

Fig. 27: OA hand X-ray showing DIP arthritis

Fig. 28: OA knees bowing legs

Fig. 29: OA knees X-ray showing decreased medial joint space and erosions

There are two types nodal and non-nodal – The nodal type features Heberden's nodes of the interphalangeal joints, predominates in women and exhibits a strong tendency to familial transmission.

Hands – Limitations of activity that require dexterity (e.g. dressing, feeding) are affected.

Hip disease – First sign is usually pain or restriction of internal rotation followed by pain on flexion.

Knee – Tibiofemoral arthritis is usually bilateral and is associated with early morning stiffness and pain on weight bearing particularly on climbing stairs. Night pain is a sign of severe disease. In elderly patients, knee effusions and crepitus are common. Severe OA of the knee joints leads to valgus deformity of the joints (Fig. 28).

RADIOLOGY

OA knee shows reduced medial joint space with osteophyte formation (Fig. 29).

MANAGEMENT

Non-surgical treatment

Pharmacological

- Analgesics and anti-inflammatory treatment – Simple analgesics the appropriate first-line treatment for uncomplicated osteoarthritis e.g. paracetamol 4g/day. COX-2 specific agents have a better safety profile than NSAIDs. Tramadol is a centrally acting oral analgesic with efficacy similar to ibuprofen.
- Intraarticular therapies – Intraarticular glucocorticoids are used in treatment of knee osteoarthritis when pain and swelling persist despite drugs such as NSAIDs, and may temporarily relieve symptoms.

Fig. 30: OA knee postoperative with TKR done

- Chondroprotective agents – Glucosamine and chondroitin have been shown to modify symptoms to a degree equivalent to anti-inflammatory agents.

Non-pharmacological

- Self-management programmes
- Weight reduction
- Physiotherapy
- Occupational therapy
- Aids (e.g. shoe wedges, patella-taping, cushioned training shoes, stick)

Surgery

Arthroplasty is successful in both hip and knee disease. Osteotomy relieves pain and can stimulate fibrocartilaginous healing of the joints. Nowadays total knee replacement is a preferred modality (Fig. 30).

6. METABOLIC AND CRYSTAL ATHROPATHIES

GOUT

Gout is the term used to describe the constellation of clinical features that result from deposition of microcrystals of sodium urate monohydrate or uric acid from hyperuricemic body fluids. These include acute arthritis, tenosynovitis, bursitis or cellulitis, tophaceous deposits, renal disease and urolithiasis.

PATHOGENESIS

In all populations, serum urate concentration is the major determinant of risk of developing gout.

Uric acid is the end product of purine metabolism in humans, who lack the enzyme uricase (which degrades uric acid to allantoin in most animals). The miscible body pool of urate in normal individuals is about 1 g, and about 60% of this is replenished daily from catabolism of newly synthesized and dietary proteins. Two-third of urate formed each day is excreted by the kidneys and one-third from GI tract.

Genetic and environmental factors lead to gout and hyperuricemia by reducing excretion of uric acid (90%) (Table 20) and/or increased production of uric acid (10%) (Table 21).

The inherent metabolic aberration in gout is hyperuricemia which is defined as an elevation in serum urate (SUA) level ≥ 6.8 mg/dL.

Table 20: Causes of reduced renal excretion of uric acid

Primary	Secondary

	<i>Increased turnover of preformed purines</i>
	<ul style="list-style-type: none"> • Lymphoproliferative and myeloproliferative disorders <ul style="list-style-type: none"> - Hodgkin's disease - Leukaemia - Lymphosarcoma - Myeloma - Polycythaemia rubra vera - Waldenstrom's macroglobulinemia • Cytotoxic drugs • Carcinomatosis • Gaucher's disease • Chronic haemolytic anaemias • Secondary polycythemia • Severe exfoliative psoriasis

CLINICAL FEATURES

The natural history of gout has four stages:

1. **Asymptomatic hyperuricemia**
2. **Acute gout** - may be precipitated by many factors (Table 22).

Table 22: Precipitating causes of gout

• Trauma
• Unusual physical exercise
• Surgery
• Severe systemic illness
• Severe caloric restriction
• Dietary excess
• Alcohol
• Drugs
• Diuretics
Initiation of uricosuric or allopurinol therapy
Initiation of B12 therapy in pernicious anaemia
Following drug allergy
Cytotoxic drug therapy

First attack occurs commonly in men aged 30–60 years, usually monoarticular, the metatarsophalangeal joint of the great toe is the first joint affected in 70%. Acute gouty arthritis can occur in ankles, knees, wrists, elbows and small joints of hands and feet; it seldom occurs in axial skeleton or large joints such as the hip and shoulder. Acute gout can also present as tenosynovitis, bursitis or cellulitis.

The initial attack may be sudden. The affected joint becomes hot, red and swollen with shiny overlying skin and is extremely painful and tender. Very acute attacks may be accompanied by fever, leucocytosis and raised ESR.

First attacks are seldom associated with residual disability, but recurrent attacks are followed by progressive cartilage and bone erosion, deposition of tophi, secondary osteoarthritis and disability associated with permanent restriction of joint function.

**Fig. 31:** Gout foot

3. **Intercritical gout** – Variable symptom-free periods between acute attacks; with progressive shortening of the intercritical period between attacks.

4. **Chronic tophaceous gout** – inevitably follows recurrent attacks and is characterized by asymmetrical joint swelling (Figs. 31 and 32). Tophi (massive accumulations of microcrystals of uric acid and amorphous urates surrounded by histiocytes, giant cells and fibrosis) develop in periarticular tissues, cartilaginous helix of the ear, bursae and tendon sheaths. CT and MRI have revealed tumour-like masses of tophi in patients with gout and carpal tunnel syndrome, and in the spine in some patients. Rarely tophi form in the eye, tongue, larynx or heart, and interference with cardiac conduction and valvular function has been recorded.

Tophus formation is related to serum uric acid and to local factors. Tophi seldom develop in individuals with asymptomatic hyperuricemia; however they may develop rapidly in feet or hands of post-menopausal women with heart failure and renal insufficiency who develop acute or subacute gouty arthritis following prolonged diuretic administration.

DIAGNOSIS

- Sudden onset of acute inflammatory monoarthritis, particularly in foot or ankle
- Onset following provoking event
- One or more previous episodes of self-limited acute arthritis followed by periods completely free of symptoms
- History of renal colic or nephrolithiasis
- History of hypertension or renal disease
- Family history of gout, hyperuricemia, nephrolithiasis or renal disease

**Fig. 32:** Gout hand

Table 23: Differential diagnosis of gout**Acute**

- Infective arthritis
- Bursitis, cellulitis, tenosynovitis
- Other crystal arthropathy
- 'Pseudogout' caused by calcium pyrophosphate
- Apatite or brushite arthritis or peri-arthritis
- Traumatic arthritis
- Haemarthrosis
- Rheumatoid arthritis with palindromic rheumatism
- Reactive arthritis
- Spondyloarthritis with peripheral joint involvement
- Psoriatic arthritis
- Sarcoid arthritis
- Rheumatic fever

Chronic

- Nodular RA
- Psoriatic arthritis
- Osteoarthritis with Heberden's and Bouchard's nodes
- Sarcoid arthritis
- Xanthomatosis

Diagnosis is supported by:

- Raised serum uric acid
- Characteristic radiological changes (soft tissue swelling with patchy calcification, cortical erosions of phalanges, punched-out erosions and secondary degenerative changes) in patients who have had recurrent attacks (Fig. 33).

Diagnosis is established by: Demonstration of needle-shaped, negatively birefringent crystals of monosodium urate in synovial fluid neutrophils by polarizing light microscopy. Serum uric acid levels can be normal or low at the time of an acute attack. A 24-hour urine collection for uric acid can be useful in assessing the risk of stones, elucidating overproduction or under excretion of uric acid and deciding whether it may be appropriate to use a uricosuric therapy.

Table 23 gives the differential diagnosis of gout.

MANAGEMENT

Acute Attack

NSAIDs – Any can be used but aspirin should be avoided because it causes uric acid retention unless given in very large doses.

Fig. 33: Gout X-ray punched out erosions

Selective COX-2 inhibitors e.g. Etoricoxib 120 mg o.d. or Valdecoxib 20–40 mg b.d. Advantage is low risk of GI toxicity.

Colchicine 0.5 mg p.o. every 2 hours, up to 4–6 mg/day is now reserved for patients without renal, hepatic or bone marrow disease, in whom the more effective NSAIDs are contraindicated or poorly tolerated.

Corticosteroids – Intra-articular (e.g. methyl prednisolone acetate 5–25 mg per joint), systemic (oral prednisolone 20 mg/day tapered off over 4–10 days) or i.m. triamcinolone 60 mg/day repeated in 1–4 days, are highly effective, and relatively safe alternatives. In patients with acute microcrystalline synovitis in whom neither NSAID nor colchicine are recommended, e.g. elderly people and those with renal insufficiency, hepatic dysfunction, cardiac failure, peptic ulcer disease.

Note: Allopurinol or uricosuric drugs should not be started until the acute attack has settled for 2–3 weeks, because they can prolong the acute attack or trigger further episodes. Patients should be advised to avoid diuretics and/or salicylates.

Long-term management with drugs that lower serum urate: Indications –

- Recurrent attacks
- Evidence of tophi or chronic gouty arthritis
- Associated renal disease
- Young patient with high serum uric acid and family history of renal or heart disease.
- Normal levels of serum uric acid cannot be achieved by lifestyle modifications (gradual weight loss, and restriction of alcohol and food with high purine content).

Uricosuric Drugs

Allopurinol – is the drug of choice. It lowers serum uric acid by inhibiting xanthine oxidase, which is responsible for conversion of xanthine and hypoxanthine to uric acid. Kidney function should be checked before the drug is started. Dose: 300 mg daily, with an NSAID or colchicine 0.5 mg b.d., to avert breakthrough attacks of acute gouty arthritis that often follow initiation of hypouricemic therapy. Lower doses if renal function is impaired.

Febuxostat is a nonpurine selective inhibitor of xanthine oxidase (XO) that reduces serum uric acid. Dosage – Starting dose is 40 mg od to reduce and maintain SUA level below 6 mg/dL (357 µmol/L). If SUA is >6 mg/dL after 2–4 weeks treatment with the drug 80 mg/day, the dose is increased to 120 mg/day. Gout flares may appear after initiation of Febuxostat due to changing uric acid levels resulting in mobilization of urate from tissue deposits. Flare prophylaxis (NSAID or colchicine) is recommended upon initiation of Febuxostat. The drug is contraindicated in patients being treated with xanthine oxidase substrates azathioprine, mercaptopurine or theophylline.

Probenecid 0.5–1 g b.d., or sulfinpyrazone 100 mg t.d.s. as an alternative to allopurinol with colchicine if renal function is not impaired. Contraindications: (a) Gout with overproduction of uric acid and gross uricosuria. (b) Patients with kidney failure. (c) Presence of urate urolithiasis.

Benzbromarone 100 mg daily in those with moderate renal impairment when other uricosuric agents are ineffective and there is allopurinol hypersensitivity.

Pegloticase is a pegylated uricase, now available for patients who do not tolerate or fail full dose of other treatments. It is given intravenously usually at 8 mg every 2 weeks and can dramatically lower serum uric acid.

Asymptomatic hyperuricemia does not require prophylactic treatment in absence of a history, family history or clinical evidence of gout. Causes of secondary hyperuricemia should be sought.

Management of hypertension – Angiotensin receptor blocker losartan, which has uricosuric effect, instead of ACEIs, which cause uric acid retention.

Manifestations of Gout in the Urinary Tract

Urolithiasis – is common in hot climates.

Chronic urate nephropathy – results from a variable combination of renal tubular obstruction, tophus formation, hypertension, glomerulosclerosis and secondary

pyelonephritis. In case of untreated gout and prolonged hyperuricemia it usually follows treatment of leukaemia or lymphoma with cytotoxic drugs.

Acute crystal nephropathy – can result from precipitation of uric acid in the collecting ducts with secondary tubular blockage. It usually follows treatment of leukaemia or lymphoma with cytotoxic drugs.

Familial juvenile hyperuricemic nephropathy is AD inherited disorder in which hyperuricemia is associated with decrease in fractional urate clearance.

Patients may present with gout in childhood, and renal failure usually develops in 20–40 years.

Other Clinical Associations

Metabolic syndrome – Gout and hyperuricemia are often associated with obesity, hypertension, IHD, raised plasma glycerides and low levels of LDL.

Gout with overproduction of uric acid – In absence of significant renal impairment, such patients are hypersecretors of uric acid, i.e. 24 hr urine uric acid > 600 mg (3.6 mmol) on a purine-free diet. Specific enzyme defects resulting in an increase in *de novo* purine synthesis should be suspected:

- In absence of disorders resulting in increased turnover of purines
- When gout develops before age of 20
- Family history of gout commencing at early age
- Uric acid lithiasis is the presenting feature

Hypoxanthine-guanine phosphoribosyl transferase (HPRT) deficiency – Lesch-Nyhan syndrome is an uncommon, x-linked recessive inborn error of metabolism in which gout and severe overproduction of uric acid are associated with choreoathetosis, variable degree of mental deficiency and compulsive self-mutilation. The enzyme defect can be detected in RBC lysate, female carriers can be identified from skin fibroblast cultures or hair root analysis and prenatal detection by using amniotic fluid cells.

Phosphoribosyl pyrophosphate synthetase super-activity is an x-linked disorder associated with severe gout, renal calculi and variable neurological disturbance.

G6PD deficiency – Children with glycogen storage disease (GSD) type I (Von Gierke's disease) who survive to adult life develop severe gout and hyperuricemia as a consequence of impaired uric acid excretion secondary to lactic acidosis and ketonaemia and increased *de novo* purine synthesis. The enzyme defect can be detected only in the liver, kidney or intestinal mucosa.

Myogenic hyperuricemia, particularly following exercise, is a feature of GSD with primary muscle involvement (GSD types III, V and VII). Hyperuricemia results from degradation of muscle ATP.

Fructose intolerance – Ingestion and infusion of fructose are associated with hyperuricemia and accelerated purine synthesis and catabolism in normal individuals. Hyperuricemia and gout can occur in patients with hereditary fructose intolerance and aldolase B deficiency.

Infantile autism has been associated with hyperuricemia and accelerated purine synthesis, but no enzyme defect has yet been identified.

METABOLIC AND ENDOCRINE ARTHROPATHIES

Metabolic Disorders

Calcium pyrophosphate dihydrate crystal deposition arthropathy – Articular cartilage calcification caused by deposition of CPPD is more common in women. It may be asymptomatic, may occur in association with osteoarthritis or may present as acute pseudogout or associated with chronic arthritis.

Pseudogout is the most common acute monoarthritis in elderly (usually female) patients. It involves, in order of prevalence, the knees, wrists, shoulders, ankles and elbows. There is acute pain with marked tenderness and often erythema and fever. The condition develops to a peak over 6–24 hours and resolves spontaneously over 1–3 weeks. Episodes can occur intermittently over years.

Investigations – (a) Synovial fluid examination by polarizing microscopy shows typical intracellular, weakly positive, birefringent, rhomboid CPPD crystals. Synovial fluid count is elevated. (b) Blood tests – Increased ESR and plasma viscosity, CRP and leucocyte count. (c) Radiography may show chondrocalcinosis of affected joint.

Management – Anti-inflammatory drugs give relief. Intra-articular corticosteroid injection in severe cases.

Chronic pyrophosphate arthropathy – Chondrocalcinosis may be asymptomatic or may be associated with arthropathy involving knees, wrists, shoulders, elbows, hips, mid-tarsal joints, and second and third metacarpophalangeal joints. Acute attacks of pseudogout may occur.

Investigations – (a) Radiography – Calcification most commonly affects the fibrocartilage of the menisci. The articular changes are those of osteoarthritis, but there are often exuberant osteophytes. (b) Synovial fluid may show CPPD crystals.

MANAGEMENT – Weight reduction, physiotherapy, anti-inflammatory drugs and intra-articular corticosteroids.

Haemochromatosis is associated with cirrhosis, arthropathy, hypogonadism, pigmentation and diabetes. Arthropathy may be an early feature. Bony swelling and restriction of movement are typically seen in 2nd and 3rd metacarpophalangeal joints, but other joints may also be affected. There may be progressive joint damage. Radiological changes are similar to those in osteoarthritis. Diagnosis is by determination of transferrin saturation and serum ferritin concentration. *Tr.* – Regular phlebotomy, and symptomatic treatment for the arthritis.

Gaucher's disease – Most patients develop joint or bone pain which may be insidious or sudden and severe. Avascular necrosis can lead to osteoarthritis. Biopsy of bone marrow shows diagnostic Gaucher's cells.

Alkaptonuria (ochronosis) – Limitation of movement may occur at the hips, knees, and less commonly shoulders, with occasional acute inflammation. Tendons and tendon sheaths are often affected. Later, osteoarthritic radiological changes occur in the large joints, and there may be multiple intra-articular loose bodies in the knees, leading to locking.

Wilson's disease – Articular involvement occurs in up to 50% of adults. The arthropathy may be severe, leading to disability within a few years. Serum copper and ceruloplasmin are reduced and urine copper raised.

Endocrine Disorders

Diabetes Mellitus

Neuropathic arthropathy can occur in long-standing poorly controlled diabetes, leading to loss of pain sensation, proprioception and vibration sense (Charcot's joints). The foot and ankle (typically the metatarsophalangeal and tarsometatarsal joints) are most commonly affected (Figs. 34 to 36). Radiological features are diagnostic – Osteolysis is the most important, but there is also localized osteoporosis, periosteal reaction and tapering of the shafts of metatarsals and phalanges giving a 'pointed bone' appearance. Infection of joints is more common, caused by *Staph. aureus*.

Thyroid disease

Hyperthyroidism – Thyroid acropachy (pseudo-clubbing of nails) may rarely develop after years of treated hyperthyroidism. Long-standing excess thyroxine can lead to osteoporosis.

Hypothyroidism – Joint pain, synovial proliferation and non-inflammatory effusions occur in up to one

Fig. 34: Charcot foot

Fig. 35: Charcot foot X-ray with extensive destruction of ankle joint

Fig. 36: Charcot foot X-ray showing destroyed ankle joint

third. Carpal tunnel syndrome occurs in about 75% of patients.

Hyperparathyroidism – Erosive arthropathy of small joints of fingers and wrists may be present. CPPD crystal deposition may occur.

Acromegaly – Joint swelling occurs as a result of synovial and bone growth; significant effusions are uncommon. Secondary osteoarthritis can develop particularly of knees and shoulders.

7. AUTOIMMUNE DISEASES

IMMUNOLOGY

Immunity is normally concerned, not only with inactivation and rejection of micro-organisms and other foreign

substances but also in recognising that they are foreign. The essence of autoimmune disease is probably the failure at some point of this power of differentiating between the body's own material (self), and foreign material (not-self).

Immunological Mechanisms

Immune responses are generated by natural and adaptive mechanisms that consist of both cellular and hormonal components.

Natural immunity – is non-specific, i.e. not influenced by previous antigen-antibody interactions:

1. Phagocytic cells including polymorphonuclears, monocytes, macrophages form the cellular component of the natural immune response.
2. Natural killer (NK) cells are potent cytotoxic cells.
3. Complement system – A complex group of serum proteins, mediates inflammatory responses by attracting granulocytes and macrophages, promoting cell-cell interactions necessary for antigen processing, and stimulating lysis of enveloped viruses and bacteria.

Adaptive immunity – Humoral immunity involves production of immunoglobulins by natural B lymphocytes.

Immunoglobulins are vital to immune response in 3 types:

- Immunoglobulins coat invading organisms, thereby impeding their access to the host
- Immunoglobulins IgM and IgG form complement
- Immunoglobulins promote opsonization, which increases efficiency of phagocytes

IgA is the principal immunoglobulin in secreting fluids, making it the most important host defence antibody at sites of antigen entry.

Cellular immunity is mediated by T lymphocytes:

- Subpopulation of T cells -
 - Cytotoxic (T) cells are responsible for killing cells that express foreign antigen
 - Helper T (T_H) cells enhance the activity of B cells, macrophages and inhibit activity of other cells of the immune system
 - Suppressor T (T_S) cells inhibit activity of other cells of immune system
- Various types of antigen-presenting cells interact with T cells, stimulating release of lymphocytes, including interleukins, granulocyte macrophage colony-stimulating factors (GM-CSF), tumour necrosis factor (TNF) and interferon- α (IFN- α). These substances regulate various aspects of immune response.

Autoantibodies in autoimmune diseases. Detection of autoantibodies in the serum of patients with suspected autoimmune disease is an important part of the diagnostic process. The most widely used methods for detection of antibodies are indirect immunofluorescence (IIF) and ELISA.

Rheumatoid factor (RF) is primarily an IgM antibody directed against the Fc part of patient's own IgG molecules. RF is usually detected using an agglutination assay with gelatine particles coated with denatured IgG. In

presence of RF, macroscopic agglutination is seen within about 1 minute. These antibodies are not specific for RA and occur in a wide range of autoimmune diseases and infections. Antinuclear antibodies (ANA) are autoantibodies directed against cellular proteins or nucleic acids. The most common ANA react with DNA-protein or RNA-protein complexes. These antibodies are generated by a T-cell dependent process driven by the autoantigen.

High titres of ANA (> 1:160) are likely to be significant in assessment of autoimmune disease. The test is usually performed by IIF on fresh frozen sections of rodent liver and/or kidney, or on cultured human cell lines such as HEp-2 cells.

Of the RNA-protein complex targets, anti-Ro antibodies are directed against human antigen and may not be detected on rodent sections. Several immunofluorescence staining patterns occur, reflecting different antigen specificities.

Anti-DNA antibodies - Detection of antibodies to double-stranded DNA (dsDNA) is central to diagnosis of SLE. Antibodies to single-stranded DNA are found in a wide range of autoimmune and infectious conditions. The most specific method for detection of anti-dsDNA antibodies is IIF using the hemoflagellate *Crithidia luciliae*, which has a kinetoplast containing circular dsDNA.

Antibodies to extractable nuclear antigen are useful in severe autoimmune diseases (Table 24).

Table 24: Disease associations of commonly detected antibodies

Autoantibody	Disease	Prevalence	Disease specificity	Associated clinical features
• dsDNA	SLE	70%	High	Lupus nephritis
• Sm	SLE	5% (Caucasian) 30–50% (Afro-Caribbean)	High	Vasculitis, CNS lupus
• Ro (SS-A)	SLE	40%	Low	Photosensitivity, subacute cutaneous lupus erythematosus, congenital heart block, neonatal lupus erythematosus
	Sjögren's syndrome	80%	High	Extraglandular disease, vasculitis, lymphoma
• La (SS-B)	SLE	15%	Low	As for Ro
	Sjögren's syndrome	50%	High	As for Ro
• U1 RNP	SLE	30%	Low	Raynaud's phenomenon, swollen fingers, arthritis, myositis (overlap syndrome – mixed connective tissue disease)
• rRNP	SLE	15%	High	CNS lupus (psychosis, depression)
• PCNA (cyclin)	SLE	5%	High	
• Phospholipid	SLE	30%	High	Thrombosis, foetal loss, thrombocytopenia
• Topoisomerase 1	Systemic sclerosis	30%	High	Diffuse cutaneous variant of scleroderma
• Centromere	Systemic	30%	Moderate	Limited cutaneous variant of scleroderma, sclerosis absence of lung disease

Contd...

Contd...

Autoantibody	Disease	Prevalence	Disease specificity	Associated clinical features
• RNA	Systemic	20%	High	Diffuse cutaneous variant of scleroderma, polymerases sclerosis visceral involvement
• PM-Scl	Systemic sclerosis	5%	High	Scleroderma/polymyositis overlap
• Jo-1	Polymyositis	30%	High	Polymyositis with fibrosing alveolitis (antisynthetase syndrome)
• SRP	Polymyositis	4%	High	Severe myositis
• Mi-2	Polymyositis	10%	High	Dermatomyositis
• PR3	Vasculitis	90%	High	Wegener's granulomatosis
• MPO	Vasculitis	50%	Moderate	Microscopic polyangiitis, Churg-Strauss syndrome

(SLE: Systemic lupus erythematosus; SRP: Signal recognition particle; PR3: Proteinase 3; MPO: Myeloperoxidase).

Patients with these autoantibodies often have similar clinical features – the tRNA synthetase syndrome (Raynaud's phenomenon, fever, interstitial lung disease, arthralgia and myositis) are located in the cytoplasm and hence not often detected on routine ANA.

Antiphospholipid (anticardiolipin) antibodies (ANCA) are associated with increased risk of vascular thrombosis, recurrent foetal loss, livedo reticularis and thrombocytopenia.

Antineutrophil cytoplasm antibodies (ANCA) – Two main antigenic targets are proteinase 3 (PR3), which is associated with cANCA, and myeloperoxidase (MPO) associated pANCA. The combination of cANCA and PR3 is highly specific for Wegener's granulomatosis, whereas pANCA-MPO occurs in microscopic polyangiitis and Churg-Strauss syndrome but is less specific.

Autoantibodies in monitoring of disease activity – Rising levels of dsDNA antibodies in SLE correlate with increasing disease activity, and an increase PR3 levels

occur in Wegener's granulomatosis, however the increased antibody levels can precede clinical relapse by many months.

Systemic lupus erythematosus (SLE) is a multisystem autoimmune disease with protean clinical manifestations that may affect any organ or system. Table 25 gives classification criterion of SLE.

Table 25: Classification of SLE (American college of Rheumatology)

• Malar rash (Butterfly rash Fig. 37)
• Discoid rash (Fig. 38)
• Photosensitivity
• Oral ulcers
• Non-erosive arthritis
• Pleuritis or pericarditis
• Renal disorder
Persistent proteinuria >0.5 g/day or 3+ if not quantified
Cellular casts
• Neurological disorder
Seizures in absence of known metabolic derangements or offending drugs
Psychosis in absence of metabolic derangements or offending drugs
• Haematological disorders
Hemolytic anemia
Leucopenia
Lymphopenia
Thrombocytopenia
• Immunological disorder
Abnormal anti-DNA titre
Anti-Sm antibody
Antiphospholipid antibodies
• Positive antinuclear antibody
SLE is diagnosed when 4 out of 11 criteria are documented at any time in the history.

Fig. 37: Malar rash

Fig. 38: Discoid lupus

The disease is characterized by flares, remissions and autoantibodies directed against several intracellular and cell-surface antigens.

New diagnostic criteria is introduced which is as given in Table 26.

Table 26: Systemic Lupus International Collaborating Clinic Criteria for Classification of Systemic Lupus Erythematosus

Clinical manifestation	Immunological manifestation
Skin	ANA > reference negative value
• Acute, subacute cutaneous LE	Anti-dsDNA
• Chronic cutaneous LE	Anti-Sm
Oral ulcers	Anti-phospholipid
Alopecia	Low serum complement
Synovitis	Positive direct Coombs test
Renal	
Prot/Cr ≥ 0.5	
RBC casts	
Biopsy	
Neurologic	
Seizures, psychosis, mononeuritis, myelitis, peripheral or cranial neuropathies, acute confusional state	
Hemolytic anemia	
Leukopenia (<4000) or Lymphopenia (<1000)	
Thrombocytopenia (<100000)	
Renal biopsy read as systemic lupus qualifies for classification as SLE even if none of the other above features are present	
Presence of any 4 criteria (must have at least 1 in each category) qualifies patient to be classified as having SLE	

AETIOLOGY

Genetic factors – Prevalence of SLE in first-degree relatives is ten times that in control groups.

- HLA alleles A1, B8, DR2 and DR3 have shown association with SLE in Caucasian populations
- Deficiencies in classical pathway complement C1q, C₂ and C₄ are strongly associated with development of lupus-like disease
- IgG receptors on mononuclear phagocyte cells clear IgG-containing immune complexes from the circulation, and associations have been found between SLE and presence of low-affinity IgG receptors.

Humoral and environmental influences. SLE and other immune diseases, e.g. Sjogren's syndrome and RA are more common in women.

Drugs such as minocycline, procainamide, hydralazine and penicillamine can also induce a lupus-like syndrome in susceptible individuals. Ultraviolet light can exacerbate cutaneous and systemic disease in SLE.

Defective clearance of apoptotic cells is considered to be a pathogenic mechanism driving the disease process.

Table 27 enumerates the clinical features of SLE.

Table 27: Clinical features of SLE

Non-specific	Fever, fatigue, anorexia, weight loss or lymphadenopathy <ul style="list-style-type: none"> • CRP usually not raised
Musculo-skeletal	<ul style="list-style-type: none"> • Arthralgia, symmetrical, flitting and polyarticular • Synovitis and joint effusions (rare) • Non-erosive Jaccoud's arthropathy (Fig. 39) • Muscle pain, sometimes inflammatory myositis • Avascular necrosis (associated with corticosteroid use) • Osteoporosis (from lack of vitamin D from sun avoidance), menstrual cycle dysfunction, corticosteroid use or lack of exercise
Cardio-vascular	<ul style="list-style-type: none"> • Pericarditis • Conduction abnormalities often due to IHD. Congenital heart block in 1/20 in children born to mothers with anti-Ro or anti-La antibodies • Immune-related myocarditis (rare) • Accelerated atherosclerosis – Incidence of myocardial infarction and carotid artery stenosis in females aged 35–44 years 50 times than in controls. Factors involved – hyperlipidemia, hyperhomocysteinemia, antiphospholipid antibodies and coronary vasculitis

Contd...

Contd...

Pulmonary	<ul style="list-style-type: none"> • Pleuritic chest pain with or without pleural effusion • Acute pneumonitis (rare but can be fatal) • Chronic interstitial pneumonitis (seldom severe) • Pulmonary hypertension (from vasculitis, thrombosis and pulmonary artery vasoconstriction) • Shrinking lung syndrome (dyspnoea, diaphragmatic weakness, small lung volumes on radiograph)
Gastro-intestinal	<ul style="list-style-type: none"> • Anorexia, nausea, vomiting • Oral lesions (discoïd, erythematous or ulcerative) • Accelerated dental caries, gingivitis and candidiasis if coexisting Sjogren's • Bowel ischemia and infarction with resultant bleeding, perforation or peritonitis • Diarrhoea due to enteric infections
Renal	<ul style="list-style-type: none"> • Nephritis – WHO classification: <ul style="list-style-type: none"> – I Normal – IIa Mesangial deposits – IIb Mesangial hypercellularity – III Focal segmental glomerulonephritis – IV Diffuse proliferative glomerulonephritis – V Membranous – VI Advanced sclerotic lupus nephritis
Cutaneous	<ul style="list-style-type: none"> • Butterfly rash, maculopapular discoïd lesions, vasculitic lesions of fingers and toes (Fig. 40) • Alopecia (Fig. 41)

Fig. 39: Jaccoud's arthritis characterized by reducible, non-erosive joint deformities with preservation of hand function. The pathogenesis of this condition is extra-articular and secondary to tendon inflammation and shortening (Swan neck)

Contd...

	<ul style="list-style-type: none"> • Subacute cutaneous lupus (variant with anti-Ro antibodies) • Lupus panniculitis (form of lipoatrophy) • Immunoglobulin (IgG or IgM) and component are often deposited at the dermoepidermal junction in both lesional and non-lesional skin (basis of lupus band test)
Neuro-Psychiatric	<p>CNS</p> <ul style="list-style-type: none"> • Aseptic meningitis • Cerebrovascular disease • Demyelinating syndrome • Headache (including migraine, benign intracranial hypertension) • Movement disorder (chorea) • Myelopathy • Seizure disorders • Acute confusional state • Anxiety disorder • Mood disorder • Psychosis <p>Peripheral nervous system</p> <ul style="list-style-type: none"> • Guillain-Barre syndrome • Autonomic disorder • Mononeuropathy, single/multiplex • Myasthenia gravis • Cranial neuropathy • Plexopathy • Polyneuropathy • MRI may show white matter lesions (thought to represent small infarcts)

Fig. 40: Pinna rash in SLE

LABORATORY FEATURES

1. *Autoantibodies* are positive in more than 95%. dsDNA is closely related to renal disease and an increase in titre raises possibility of a flare of the disease, particularly if associated with decreasing C3 levels.

2. *Haematological features* – (a) Normochromic, normocytic anemia is present in up to 70%. Lymphopenia and leucopenia are common and thrombocytopenia in about 20%. (b) Lymphadenopathy is common and usually non-tender. (c) Antiphospholipid antibodies and lupus anticoagulant are found in about 30-40%.

Fig. 41: Alopecia in SLE

Because circulating immune complexes can deposit in tissues and activate component, a decrease in complement factors C3/C4 and increase in their degradation products C3d/C4d are often seen in active disease.

MANAGEMENT

- General principles:** (a) Sun avoidance and use of high-factor sun-blocks on sun-exposed areas. (b) Lifestyle modification (exercise, smoking cessation,

Disease severity	Drug
Mild	NSAIDs. If control not achieved: Hydroxychloroquine 200–400 mg/d Topical or intralesional corticosteroids can be used for cutaneous lesions
Moderate	Prednisolone < 0.5 mg/kg/d, gradually reduced Azathioprine useful for controlling disease and reducing corticosteroid requirement
Severe	High dose corticosteroids oral or i.v. pulse. Cyclophosphamide i.v. 6 monthly pulses of 1g/m ² followed by quarterly pulses for 2 years. As per new EULAR guidelines cyclophosphamide can be used at low dosage for induction- 500 mg iv every 15 days for 3 months. Other agents used for induction include mycophenolate mofetil 3 gm/day for 3 months followed by 2 gm/day. Cyclophosphamide and mycophenolate mofetil
	can be used alternative to each other in case of patients not responding to one agent. For those patients who are not responding to both Cyclophosphamide and mycophenolate anti-CD 20 antibody rituximab can be used.

stress management). (c) Infection risk reduction – e.g. vaccination (modified viral immunizations should not be given to patients taking > 10 mg prednisolone daily or major immunosuppressive drugs).

2. Drugs

3. Other therapies

- Methotrexate for serositis and cutaneous and articular manifestations
- Mycophenolate when standard therapy has failed
- Dapsone p.o. for vasculitic lesions, cutaneous SLE, oral ulcers and thrombocytopenia

In patients with renal involvement with proteinuria ACE inhibitors or ARBs are used. As patients are on steroid therapy calcium supplements are needed. SLE is atherogenic condition so patients with deranged lipid profile started on statin therapy.

OTHER AUTOIMMUNE DISEASES

BEHCET'S DISEASE

Is characterized by enhanced inflammatory responsiveness and vascular dysfunction, probably caused by infective and immunological insults occurring in genetically predisposed individuals.

Clinical Features

Recurrent oral ulceration similar to aphthous ulcers

Genital ulcers in females affect the vulva and vagina and sometimes the cervix, in males usually on the scrotum, less commonly penis.

Cutaneous: Pustules and acneform lesions. Also erythema nodosum. Transient erythematous rashes, small ulcers and pyoderma granulosum may also occur.

Pathergy is an excessive inflammatory reaction to non-specific injury. It is demonstrated by appearance of a papule or pustule 24–48 hours after insertion of a 20G needle into the skin of the forearm.

Ocular involvement causes reduction of vision and/or floaters. Anterior uveitis is rapid in onset, may lead to hypopyon formation. Long-term complications include synechiae, cataract, secondary glaucoma and retinal revascularization with sequelae such as vitreous hemorrhage and retinal detachment.

Musculoskeletal – Arthritis in about 40%.

Neurology – Migrainous headaches, cranial nerve palsies, monoparesis and hemiparesis, brain stem and cerebellar symptoms.

Vascular – Superficial and deep vein thrombosis which may involve lower and upper limbs, inferior and superior vena cava, dural sinuses and hepatic and renal veins.

GI ulcers can occur along the large bowel.

Nonspecific manifestations like fatigue and malaise.

Diagnostic Criteria of Behcet's Disease

- Recurrent oral ulceration plus two of the following
- Recurrent genital ulceration
- Eye lesions
- Skin lesions
- Pathergy test

Management

(a) *Cutaneous lesions*: Local corticosteroids applied in an adhesive base, spray or mouthwash. Colchicine to treat mucocutaneous disease that does not respond to local measures. In serious cases, thalidomide (100 mg/d) is effective. (b) *Systemic treatment* – Oral corticosteroids and immunosuppressive agents for significant oral or internal organ involvement. Anticoagulants for deep venous thrombosis.

ANTIPHOSPHOLIPID SYNDROME (APS)

APS is characterized by venous and/or arterial thrombosis and recurrent foetal loss associated with persistent production of antiphospholipid antibodies, a group of autoantibodies directed against cell membrane phospholipids and their associated proteins.

Pathogenesis

It is hypothesized that the interaction of aPL with β 2-GPI (and other proteins with antithrombotic function) may lead to thrombosis in both large and small blood vessels.

- There is evidence that anti- β 2-GPI antibodies are a marker of thrombogenicity in APS.
- Binding of aPL to β 2-GPI is associated with activation of endothelial cells or platelets.
- Binding may also lead to reduced activated protein C activity

Clinical Features

Thrombosis – Deep venous thrombosis in lower limb is the most common manifestation of APS. Occasionally it occurs at unusual sites (e.g. cerebral venous sinuses).

Neurological features – Stroke is the most common and aPL are an important predictor of stroke in men. aPL have also been linked with Sneddon's syndrome (recurrent stroke and livedo reticularis). Dementia and cognitive dysfunction can also occur.

Pregnancy – Persistent aPL are seen in 15% of women with recurrent pregnancy loss. Losses usually occur early (< 12 weeks' gestation). APS may also be associated with placental insufficiency and pre-eclampsia.

Catastrophic APS

Rarely patients present with acute multiorgan failure from extensive microvascular thrombosis.

Other Clinical Complications of APS

Conditions Associated with Production of aPL

- Idiopathic (primary APS)
- Secondary APS – SLE, RA, systemic sclerosis, Behcet's disease, temporal arteritis, Sjogren's syndrome
- Other conditions
 - Infections – HIV, varicella, hepatitis C, malaria, syphilis
 - Drugs – Phenothiazines, procainamide, phenytoin, quinidine, hydralazine
 - Lymphoproliferative disease (lymphoma, paraproteinemia)

Clinical Manifestations in Patients with APS

See Table 28.

Table 28: Clinical manifestations of APS

• Cardiovascular – Venous / arterial thromboembolic disease (Fig. 42), sterile endocarditis with embolism
• Obstetric – Recurrent pregnancy loss, early severe pre-eclampsia
• Neurological – Chorea, dementia, psychiatric disorders, transverse myelopathy, seizure, G-B syndrome
• Haematological – Autoimmune thrombocytopenia, autoimmune hemolytic anemia
• Dermatological – Livedo reticularis, Sneddon's syndrome

Fig. 42: Aortic thrombus (arrow)

Table 29: Diagnostic criteria of APS.**Clinical criteria**

- Vascular thrombosis – One or more episodes of arterial, venous or small vessel thrombosis in any tissue or organ (confirmed by imaging, Doppler studies or histopathology)
- Pregnancy morbidity, defined as (a) one or more unexplained deaths of a morphologically normal fetus at or beyond the tenth week of gestation; (b) one or more premature births of a morphologically normal neonate before the thirty-fourth week of gestation because of eclampsia, severe preeclampsia or placental insufficiency; or (c) three or more unexplained consecutive spontaneous abortions before the tenth week of gestation.

Laboratory criteria

- LA,
- Anticardiolipin (aCL) and/or
- Anti- β 2 GPI antibodies, at intermediate or high titres on two occasions, 12 weeks apart.

APS is considered present when at least one clinical and one laboratory criterion are met.

Diagnosis

Table 29 gives diagnostic criteria of APS.

Indications for Antiphospholipid Antibody Testing

- All patients with apparently spontaneous venous thromboembolism
- Stroke and peripheral arterial occlusive events presenting at <50 years, or older patients with no other risk factors
- Assessment of patients with SLE
- Recurrent pregnancy loss

Management

Initially low molecular weight heparin followed by warfarin; patients who suffer thrombosis while anticoagulated with a target INR of 2.5, are candidates for more intensive anticoagulation with a target of 3.5. For recurrent pregnancy loss – Low dose aspirin as soon as urine pregnancy test becomes positive, and heparin when foetal heart activity is established. It is advisable to continue therapy to term, however in women with a history of late pregnancy complications or thrombosis into the post-partum period. IV immunoglobulin (IVIg) 400 mg/kg every day for 5 days may also prevent abortions, whereas glucocorticoids are ineffective.

SJOGREN'S SYNDROME

Is a chronic inflammatory and lymphoproliferative disease with autoimmune features characterized by progres-

Table 30: Diagnostic criteria for Sjogren's syndrome

Diagnosis on presence of at least of four of the following:

- Ocular symptoms
- Oral symptoms
- Evidence of keratoconjunctivitis sicca (Schirmer's test or Rose Bengal staining)
- Focal sialadenitis by minor salivary gland involvement (lip biopsy)
- Instrumental evidence of salivary gland involvement (parotid sialography or scintigraphy)
- Presence of autoantibodies (anti-Ro or anti-La)

Note: A principal suggested change to these criteria is a positive labial salivary gland biopsy and/or positive Ro/La serology is mandatory for the diagnosis.

sive mononuclear cell infiltration of exocrine glands, notably the lacrimal and salivary glands (Table 30).

- Primary Sjogren's syndrome is defined by xerostomia (dry mouth) and xerophthalmia (dry eyes), often with extraglandular manifestations but without additional autoimmune rheumatic disease.
- Secondary Sjogren's syndrome occurs in association with RA, SLE or another autoimmune rheumatic disease.

PATHOGENESIS – (a) *Genetic factors* – Incidence is greater in relatives of patients with the disorder. (b) *Environmental agents* including herpes viruses, CMV, E-B virus and retroviruses have been known to be a site of latency for various viruses. (c) *Other factors* – such as hormones and abnormalities of apoptosis (programmed cell death) may have a role.

Clinical Features**Glandular Manifestations**

(a) Dry, gritty eyes, sensation of burning or foreign body in the eye. (b) Patients may be unable to eat a cracker without drinking fluids ('dry cracker sign'). (c) Dryness of other areas such as nose, throat, vagina, rectum, skin. (d) Swelling of major salivary glands (particularly parotid) is common. (e) Dry mouth – Difficulty with swallowing, speech, taste and wearing dentures. On examination of the mouth, the gloved hand sticks to the mucous membrane. Typical mucosal and glossal signs may include mucosal atrophy and erythema, dorsal papillary atrophy and fissuring of the tongue ('crocodile skin') and chronic candidiasis.

Systemic Manifestations

- Joints – Mainly small joints, symmetrically associated with synovitis

Fig. 43: Dilated oesophagus in systemic sclerosis

- Vasculitis of small and medium-sized vessels causing purpuric rash, skin ulceration, urticaria and neuropathy
- GI - Dysphagia from pharyngeal dryness or oesophageal dysmotility (Fig. 43), chronic atrophic gastritis and subclinical pancreatic insufficiency.
- Pulmonary - Chronic bronchitis, lymphocytic interstitial pneumonitis, pseudo-lymphoma with nodular infiltrates, pleural effusions, pulmonary hypertension and lymphoma.
- Renal - Interstitial lesion causing tubular dysfunction and renal tubular acidosis. This may cause renal calculi, nephrocalcinosis and abnormal renal function.
- Neurological - Peripheral neuropathy, mononeuropathy and autonomic neuropathy.
- Non-Hodgkin's lymphoma occurs in about 5-10% of patients.

Management

(a) *Dry eyes* - Conserving tears with glasses which shield the eye from wind currents and reduce evaporation of tears, and occlusion of the punctum of the lower canaliculus with silicone plugs. Artificial tears. (b) *Dry mouth* - Good oral hygiene, and chewing gums to stimulate residual salivary flow. Treatment of oral candidiasis. Drinking small sips of water. (c) *Drug therapies* - Oral pilocarpine or cevimeline, a derivative of acetylcholine stimulate receptors of salivary and lacrimal gland epithelial cells with improvement of ocular and oral symptoms. Cevimeline is longer lasting than pilocarpine and has fewer adverse effects. Hydroxychloroquine 200 mg b.d. may help arthralgia and myalgia. It may also be effective as immunomodulating agent.

Fig. 44: Salt and pepper skin and systemic sclerosis

Table 31: Autoimmune diseases with secondary Sjogren's syndrome

RA	Mixed connective tissue disease
SLE	Mixed cryoglobulinemia
Systemic sclerosis	Hashimoto's thyroiditis
Primary biliary cirrhosis	Multiple sclerosis

SYSTEMIC SCLEROSIS

Systemic sclerosis is a homogenous rheumatic disease within the scleroderma spectrum of disorders. These diverse conditions share several clinical features (particularly thickening of the skin resulting from dermal fibrosis and high incidence of episodic peripheral vasospasm - Raynaud's phenomenon) (Table 32). Typical 'salt and pepper' skin may be noticed (Fig. 44).

LOCALIZED SCLERODERMA

Includes linear scleroderma and morphea. Adult-onset morphea may be mild, but some cases are severe and extensive with multiple areas (plaques) of involved skin (generalized morphea).

PATHOGENESIS

Genetic associations are - (a) *Extracellular matrix components* - TIMP1, Fibronectin, and Fibrillin-1. (b) *Cytokines* - CXCR-2, transforming growth factor b3 and b2.

The pathogenesis of systemic sclerosis involves interplay between the immune system, the vasculature and fibroblastic cells.

Pathologic hallmark of SSc is the combination of widespread capillary loss and obliterative microangiopathy together with fibrosis in the skin and internal organs.

Table 32: Spectrum of scleroderma and scleroderma-like disorders**Scleroderma***Localized scleroderma*

- Plaque morphea
- Generalized morphea
- Linear scleroderma
- En coup de sabre
- Hemifacial atrophy

Systemic sclerosis

- Diffuse cutaneous systemic sclerosis
- Limited cutaneous systemic sclerosis
- Overlap syndromes
- Systemic sclerosis sine scleroderma

Isolated Raynaud's phenomenon

- Primary
- Secondary

Scleroderma-like disorders

- Eosinophilic fasciitis
- Scleromyxoedema
- Scleredema of Buschke
- Scleroderma diabeticorum

CLINICAL FEATURES

Limited cutaneous systemic sclerosis presents with long history of antecedent Raynaud's phenomenon that is often severe and associated with digital ulceration. Other manifestations are esophageal dysmotility and gastroesophageal reflux. Skin involvement limited to knees and elbows, and often to wrists and ankles. Other features – Cutaneous telangiectasia (on palms and around mouth), subcutaneous calcinosis and digital infarcts (Fig. 45). The constellation of Raynaud's phenomenon, esophageal involvement and sclerodactyly is termed 'CREST syndrome'.

Diffuse cutaneous systemic sclerosis – often includes tendon friction rub and skin inflammation, but it is the presence of sclerosis proximal to the elbows or knees or affecting the trunk that determines its classification. Affected skin is often intensely pruritic. Symptoms of Raynaud's phenomenon are always present, as also esophageal involvement. Lung fibrosis and hypertensive renal crises are relatively common.

Systemic sclerosis sine scleroderma – Few patients exhibit typical vascular and serological features of systemic sclerosis with visceral combinations such as lung fibrosis, hypertensive crisis or bowel involvement but without any evidence of skin fibrosis.

Limited systemic sclerosis – This group of patients include those who have previously been labelled as having autoimmune Raynaud's phenomenon.

**Fig. 45: Digital infarcts****INVESTIGATIONS**

Haematology: Anemia, microangiopathic RBC fragmentation (hallmark of renal crisis)

Serum biochemistry: For clues to organ-based complications including myositis, malnutrition and renal impairment.

Acute phase markers: Raised ESR suggests poor prognosis

Autoimmune serology reveals antibody status. Certain internal organ complications appear to occur more often in patients with certain serological reactivities. ANA (seen in all patients of systemic sclerosis), anti-centromere antibody (seen in diffuse systemic sclerosis), anti-topoisomerase I antibody (seen in limited systemic sclerosis).

Organ based: (a) Renal – Monitoring BP, blood, urine. Estimation of GFR. (b) Cardiac – ECG/echo-Doppler, exercise tolerance. (c) Respiratory: Chest radiograph, pulmonary function tests if abnormal CT, bronchoalveolar lavage, biopsy. (d) GI: Barium swallow or radionuclide scintiscan. (e) Other tests according to symptoms – hydrogen breath test, gastroscopy, small and large bowel barium studies.

MANAGEMENT**1. Disease-modifying therapy**

- Immunosuppressive:** Appropriate for early-stage diffuse cutaneous systemic sclerosis – Cyclophosphamide, antithymocyte globulin and mycophenolate mofetil.

- b. **Vascular:** Vasodilatation for Raynaud's phenomenon. Potential for vascular remodelling (e.g. prostacyclin, losartan).
 - c. **Antifibrotic:** None of proven efficacy. Potential strategies include transforming growth factor β neutralization, prolyl hydroxylase inhibition.
2. **Organ-based treatments**
- a. Gastro-esophageal reflux – Proton pump inhibitors.
 - b. Mid-gut disease: Antibiotics
 - c. Myositis (often low grade): Prednisolone, methotrexate.
 - d. Fibrosing alveolitis: Cyclophosphamide, prednisolone, azathioprine.
 - e. Renal insufficiency: Angiotensin converting enzyme inhibitors.
 - f. Pulmonary hypertension: Warfarin, prostacyclin analogues, bosentan, ambrisentan.

MYOSITIS

Myositis (inflammation of skeletal muscle) has many causes listed in Table 33.

Table 33: Causes of myositis

- Infectious agents
Viral: Influenza A and B, hepatitis B, Coxsackie virus, rubella, echovirus, HIV.
Bacterial: Staphylo., Strepto, Clostridium, M. tuberculosis/M. leprae
Parasitic: Trichinosis, toxoplasmosis.
- **Drugs and toxins**
Cholesterol-lowering drugs: Statins,
Drugs for infections: Rifampicin, sulphonamides, griseofulvin, zidovudine, cytotoxic agents and immunomodulators, hydroxyurea, vincristine, cyclosporine, interleukin-2.
Toxins: L-tryptophan, alcohol
Others: Colchicine, D-penicillamine, procainamide, propylthiouracil, carbimazole, growth hormone, tretinoin, corticosteroids.
- **Focal nodular myositis**
- **Eosinophilic myositis**
- **Idiopathic inflammatory myopathies:** Dermatomyositis/polymyositis, inclusion body myositis (Table 34).

Table 34: Classification of idiopathic inflammatory myositis

- Primary idiopathic polymyositis
- Primary idiopathic dermatomyositis
- Dermatomyositis/polymyositis associated with neoplasia
- Childhood dermatomyositis/polymyositis associated with vasculitis
- Polymyositis/dermatomyositis associated with autoimmune disease
- Inclusion body myositis

CLINICAL FEATURES

- **Myositis** – Onset insidious in idiopathic inflammatory myositis. Acute onset dermatomyositis in children and types associated with neoplasia. In inclusion body myositis, patients often have had symptoms for many years at presentation.
- **Muscle weakness** – Proximal muscle weakness most common complaint, causing difficulty in lifting objects overhead, inability to comb or wash hair, and problems with climbing stairs and rising from chairs.
- Digital muscle weakness and atrophy in inclusion body myositis, in which finger flexor weakness and foot drop are common.
- In addition to girdle muscle, other striated muscles including bulbar and intercostal muscles may be weak, leading to hoarseness, dysphonia, difficulty in initiating swallowing, regurgitation of fluids and dyspnoea.
- Muscle pain in 50%.

Cutaneous features – Erythematous or heliotropic rashes affect the eyelids, malar areas, 'V' areas of the anterior chest and upper back. Gottron's papules are erythematous, scaly plaques over knuckles or fingers that often extend onto the forearm (Fig. 46).

See Table 35 for the involvement of other organs with inflammatory myositis.

Table 35: Involvement of other organs with inflammatory myositis

Constitutional	Fatigue, fever, weight loss
Joints	Polyarthralgia and/or polyarthritis
Calcinosis	Intracutaneous, subcutaneous, fasciopathy, intramuscular calcification most common in children, may lead to joint contractures
Lungs	Interstitial alveolitis and fibrosis, aspiration pneumonia, pleurisy and pleural effusion
Heart	Cardiac arrhythmias, myocarditis, pericarditis and rarely cardiac tamponade
GI tract	Pharyngeal dysphagia, dysphonia, ulceration and hemorrhage secondary to vasculitis
Peripheral vasculature	Raynaud's phenomenon, periungual infarction with fissuring of digital pads without ulceration (machinist's hand)
Kidney	Proteinuria, nephrotic syndrome, mesangial proliferative GN, myoglobinuria
Malignancy	Myositis may herald underlying malignancy, notably in men over 40, dermatomyositis is more common than polymyositis

Fig. 46: Gottron's papules

INVESTIGATIONS

General: Raised ESR and CRP. Mild anemia

Muscle enzymes: CPK, aldolase, aspartate and alanine transaminases, and lactate dehydrogenase are enzymes released by damaged muscles. CPK is the most specific enzyme in polymyositis and dermatomyositis, but may be normal or minimally elevated in inclusion body myositis, as also in late stage disease with severe atrophy.

EMG: Typical findings are spontaneous fibrillation potentials, complex repetitive discharges, positive sharp waves at rest and short-duration, low-amplitude complex polyphasic potentials on contraction. Because of the focal nature of myositis, EMG is normal in up to 10% of patients.

Muscle biopsy: Presence of chronic inflammatory cells with muscle necrosis in the perivascular and interstitial areas surrounding myofibrils is pathognomonic. Perivascular inflammation is typical of dermatomyositis, interstitial inflammation of polymyositis. Muscle biopsy in inclusion body myositis shows vacuoles with basophilic granules and both intranuclear and intracytoplasmic tubulofilamentous inclusions.

Serum autoantibodies: ANA are present in more than 80% with polymyositis or dermatomyositis and include Ro (SS-A), U1 (ribonucleoprotein, centromere, mitochondria) and t-RNA synthetase. Other myositis-specific antibodies are antisignal recognition particle (anti-SRP), anti-Mi-2 and anti-PM-Scl.

Other investigations: Chest radiograph, pulmonary function tests, and echocardiography in patients with extramuscular manifestations. MRI of inflamed muscle shows increased signal intensity on T₂-weighted sequences and may help to determine which muscle to biopsy.

DIFFERENTIAL DIAGNOSIS

Neuromuscular disorders that can cause proximal muscle weakness - Spinal muscular atrophies, amyotrophic lateral sclerosis, myasthenia gravis, Eaton-Lambert syndrome, muscular dystrophies. Osteomalacia, adrenal insufficiency, hypophosphatemia, hypothyroidism and carcinomatous neuromyopathy.

MANAGEMENT

(a) **Corticosteroids** - Prednisolone 60 mg/day p.o. initially, dose then tapered. Side effects occur in 40%. (b) **Immunosuppressives** - Azathioprine, methotrexate and cyclosporine in refractory cases. (c) **IV immunoglobulin** in corticosteroid refractory dermatomyositis. Dose 2g/kg monthly given in divided doses over 3 days. (d) **Others** - Plasmapheresis, total body irradiation, thymectomy and extracorporeal photochemotherapy in patients with refractory and severe disease.

Diseases associated with scleroderma-like syndromes

1. **Immunological conditions** - Mixed connective tissue disease, eosinophilic fasciitis, dermatomyositis, SLE, graft versus host disease, acro-osteolysis, lichen sclerosus et atrophicus.
2. **Tumours** - Carcinoid, metastatic bronchial carcinoma, melanoma.
3. **Metabolic diseases** - Porphyria, amyloidosis, Hashimoto's thyroiditis.
4. **Genetic disease** - Phenylketonuria, progeria.
5. **Environmental disease** - Silica-induced and vinyl chloride-induced disease.
6. **Drugs** - Bleomycin, pentazocine.

8. VASCULITIDES

Systemic vasculitides comprise a collection of disorders characterized by presence of fibrinoid necrosis and inflammation of blood vessel walls.

RELATIONSHIP TO AGE

- Kawasaki disease is seen only in children
- Henoch-Schonlein purpura occurs mainly in children, but can present in adults
- Microscopic polyangiitis and Wegener's granulomatosis generally present in adults
- Giant cell arteritis is prominently a disease of the elderly

SMALL VESSEL VASCULITIDES

Primary Small Vessel Vasculitis

Aetiology and pathogenesis: It is an autoimmune disease of unknown aetiology with environmental and genetic factors contributing. It is commonly associated with anti-neutrophil cytoplasm antibodies (ANCA). ANCA correlate closely with clinical activity, activating cytokine-primed neutrophils by binding to antigens expressed on their surface and generating a respiratory burst, releasing proteolytic granules and pro-inflammatory cytokines. ANCA also interfere with the normal processes that resolve inflammation by disrupting apoptotic pathways and preventing apoptotic cell removal that in turn allows progression to secondary necrosis.

Activation of endothelial cells and neutrophils is important for the development of early lesions, but progression is accompanied by influx of monocytes and T cells. This may lead to a sustained cellular inflammatory response with tissue scarring and irreversible damage.

GRANULOMATOSIS WITH POLYANGIITIS (GPA WEGENER'S GRANULOMATOSIS)

GPA is characterized by:

Limited disease

Upper respiratory tract involvement: Sinusitis, otitis media, hoarseness. Complications of granulomatous inflammation can cause mucosal ulceration and nasal septal perforation with a saddle nose. Subglottic stenosis occurs in up to 16% adults and 48% of children. It often becomes fixed and irreversible and can cause life-threatening upper airway obstruction.

On histology, necrotizing vasculitis of small arteries and veins together with granuloma formation, which may be either intravascular or extravascular.

Pulmonary disease: Presentation may be with asymptomatic pulmonary infiltrates or cough, haemoptysis,

Fig. 47: HRCT lungs showing nodules with cavitations in GPA

pleuritis or dyspnoea. Life-threatening alveolar hemorrhage may occur (Fig. 47).

Renal disease with glomerulonephritis. The most common abnormality is active urinary sediment with microscopic hematuria.

Other organs – (a) *Ocular involvement* can present as conjunctivitis, scleritis or uveitis. Proptosis may occur and is due to extensive sinus disease. (b) *Myalgia and arthralgia* are common, and non-erosive arthritis can occur. (c) *Skin disease* may manifest as palpable purpura, ulcers and subcutaneous nodules. (d) *Cardiac* – Pericarditis, coronary arteritis. (e) *Nervous system* – Mononeuritis multiplex, peripheral neuropathy. (f) *GI tract* – Haemorrhagic ulceration, bowel perforation.

MICROSCOPIC POLYANGIITIS (MPA)

Microscopic polyangiitis is characterized by necrotizing small vessel vasculitis with no significant immune deposits (pauci-immune) and ANCA directed against the neutrophil protein myeloperoxidase (MPO-ANCA). Systemic symptoms like fever, wt. loss and arthralgia. Renal involvement may range from an active urinary sediment to rapidly progressive glomerulonephritis. So-called idiopathic rapidly progressive GN, without immune deposits and with no systemic features of vasculitis, is now considered part of the spectrum of microscopic polyangiitis.

Haemoptysis and dyspnoea are common. Pulmonary hemorrhage is the main risk factor for death.

EOSINOPHILIC POLYANGIITIS WITH GRANULOMATOSIS (EGPA CHURG-STRAUSS SYNDROME)

EGPA is characterized by hypereosinophilia with tissue infiltration and vasculitis.

Clinical features:

(a) Allergic rhinitis and/or asthma precede development of vasculitis often associated with non-specific symptoms. (b) A rash and mononeuritis multiplex are common presenting features. (c) Pulmonary involvement: Dyspnoea, alveolar hemorrhage or pleurisy and with non-specific pulmonary infiltrates on chest radiography. (d) Cardiac involvement is often a late manifestation and carries poor prognosis. (e) GI: Pain, diarrhoea and ascites. (f) Renal: Involvement is usually mild. (g) Cerebral: Hemorrhage or infarction.

Investigations

Routine laboratory – Generally non-specific. Leucocytosis, thrombocytosis, normochromic normocytic anemia and raised ESR and CRP. Churg-Strauss syndrome is usually associated with blood eosinophilia and elevated IgG levels.

Urinalysis – Urinary sediment with RBC and casts indicates glomerular disease. Proteinuria common. Elevated urea and creatinine levels.

ANCA – Circulating ANCA are an important feature and can be used to monitor disease activity. Wegener's granulomatosis is associated with ANCA directed against proteinase 3, giving agranular cytoplasmic staining pattern on immunofluorescence; the test is very sensitive in patients with active disease, MPO-ANCA are found in microscopic polyangiitis (70%), but PR3-ANCA can also occur. Fifty percent of patients with Churg-Strauss syndrome are positive for MPO-ANCA.

Chest radiography – Pulmonary hemorrhage is seen as diffuse pulmonary shadowing. In Wegener's granulomatosis, pulmonary nodules which often cavitate. Other changes include reticulonodular shadowing, pneumonic changes, collapse and pleural involvement with effusions.

Tissue biopsy – (e.g. skin, lung, kidney) shows three cardinal features – Infiltration by eosinophils, formation of granulomata, necrotizing vasculitis.

Other investigations – Radioisotope-labelled leucocytes scans, CT and MRI for detecting and monitoring involvement of upper respiratory tract and lungs.

HENOCH-SCHONLEIN PURPURA (HSP)

Henoch-Schonlein purpura is a systemic vasculitis characterized by IgA deposition and is most common in children, often below 5 years of age.

Aetiology is unknown, but the condition commonly follows an upper respiratory infection. The disease is characterized by:

- Rash, usually affecting the buttocks and lower limbs
- Arthralgia
- GI involvement with abdominal pain and bloody diarrhoea
- Glomerulonephritis (often more severe with increasing age)
- Other organs, including CNS (seizures) and lung (pulmonary hemorrhage) may be involved.

Diagnosis – Skin biopsy reveals leukocytoclastic vasculitis with IgA deposition in blood vessels or dermoepidermal junction. (b) Renal histology may vary from mild mesangial proliferation to focal segmental necrotizing GN, but always shows IgA deposition in the mesangium.

Management – Symptomatic treatment. Immunosuppressant in case of renal involvement, particularly with severe disease.

SECONDARY VASCULITIDES

Leucocytoclastic vasculitis (cutaneous or hypersensitivity vasculitis) is often a part of systemic disease:

- Other vasculitic syndromes – Wegener's granulomatosis, microscopic polyangiitis, Henoch-Schonlein purpura
- Rheumatoid disorders – RA, SLE, dermatomyositis
- Infections – Hepatitis B and C (often from cryoglobulins), HIV, streptococci, IE.
- Paraproteins – Cryoglobulinemia, Waldenstrom's macroglobulinemia
- Others – Inflammatory bowel disease, neoplasia, α_1 -antitrypsin deficiency

Investigations – (a) Skin biopsy: Light microscopy, immunofluorescence for IgA. (b) Laboratory tests: FBC, urea and electrolytes, CRP and ESR, antibody screen, hepatitis B and C, cryoglobulins and protein electrophoresis, blood culture.

Management – Symptomatic relief in patients with isolated cutaneous involvement, though immunosuppressants may be required.

Rheumatoid vasculitis presents in patients with severe destructive RA.

Clinical features

- **Skin:** Purpuric lesions, digital pulp infarcts, livedo reticularis; may be associated with Raynaud's syndrome. Patients with SLE are at increased risk of drug allergies.
- **CNS:** True CNS vasculitis occurs in < 10% of patients. Symptoms range from mild cognitive dysfunction to psychosis, seizures and ischemia. MRI is often unhelpful; it may reveal periventricular white matter lesions but is not diagnostic.
- **CVS:** Extramural arteries may be involved, resulting in myocardial infarction (rare). Myocardial infarction is common as a result of accelerated atherosclerosis.
- **Mesenteric vasculitis:** With or without infarction, most serious complication. Presents with acute abdomen, fever, vomiting; may have an insidious onset. High mortality. Often associated with renal disease and other internal organ vasculitis.
- **Kidney:** Focal segmental necrotizing GN with fibrinoid necrosis rare. Distinguished from primary systemic vasculitis by deposition of immunoglobulin and complement.

Investigations – ANA positive in > 95%. Antiphospholipid antibodies and lupus anticoagulants in about 30–40% of patients.

See Table 36 for the management of primary small vessel vasculitis.

Therapies that may prove beneficial include tumour necrosis factor (TNF) blockade, including etanercept (TNF receptor fusion protein) and infliximab (monoclonal chimeric anti-TNF antibody), polyclonal antithymocyte globulin, and other newer immunosuppressant drugs that have shown promise in organ transplantation.

MEDIUM VESSEL VASCULITIDES POLYARTERITIS NODOSA (PAN)

Aetiology

Some cases are associated with HBV infection. IV drug abuse causes HBV-related disease. It may develop at any age but is most common in men and women aged about 50 years.

Clinical Features

(a) Systemic: Fever, malaise, wt. loss, arthralgia. (b) Orchitis is a characteristic feature. (c) Skin – Nodules and purpura. (d) Peripheral neuropathy. (e) GI: Haemorrhage, perforation, infarction. (f) Cardiac: Angina,

Table 36: Management of primary small vessel vasculitis

Induction therapy	<ul style="list-style-type: none"> • Continued for 3 months following remission • Prednisolone, 1 mg/kg, maximum dose 80 mg; rapid reduction in corticosteroid dose – 50% over 2 weeks and to a dose of 0.25 mg/kg at week 8 • Cyclophosphamide, 2 mg/kg/day p.o., maximum dose 200 mg; age >60 years reduce by 25%, age >70 years reduce by 50% • Pulsed cyclophosphamide can also be given – 10 pulses over 25 weeks, 15 mg/kg i.v.; dose reductions must be made for age and creatinine • WBC count must be checked between day 10 and 14 following pulse because of decrease in leucocyte count; if <3 x 10⁹/litre, a suitable dose reduction must be made for the next pulse • There is controversy about the best form of administration for cyclophosphamide; it has been suggested that pulsed cyclophosphamide may be associated with fewer adverse effects but at the expense of a higher relapse rate
Adjuvant therapy	<ul style="list-style-type: none"> • Life-threatening disease includes creatinine >500 µmol/litre and/or pulmonary life-threatening disease haemorrhage • Plasma exchange or methylprednisolone should be considered
Maintenance therapy	<ul style="list-style-type: none"> • Prednisolone, 5–10 mg/day • Azathioprine, 1.5 mg/kg/day, maximum dose 200 mg • Alternatives to azathioprine include mycophenolate mofetil, 1 g b.d., and methotrexate, 0.15 mg/kg, maximum dose 15 mg once weekly (contraindicated in patients with creatinine >170 µmol/litre) • Consider addition of co-trimoxazole in Wegener's granulomatosis with upper respiratory tract involvement
Limited Wegener's	<ul style="list-style-type: none"> • Prednisolone and azathioprine or methotrexate
Granulomatosis	<ul style="list-style-type: none"> • Consider addition of co-trimoxazole
Relapse therapy	<ul style="list-style-type: none"> • Major relapse – Return to initial induction therapy • Minor relapse – Increase corticosteroid dose
Rescue therapy	<ul style="list-style-type: none"> • Standard induction therapy fails to induce remission in 10% of patients. Patients relapsing and who frequently relapse necessitating recurrent use of cyclophosphamide are also a refractory disease difficult group

myocardial infarction. (g) Renal: Ischemic nephropathy and renal infarcts leading to severe hypertension and kidney failure. (h) Hepatitis may reflect presence of chronic HBV-associated disease.

Laboratory Findings

- Elevated ESR, CRP. Eosinophilia in 20%
- Abnormalities in tests of organ function, reflecting hepatitis or renal involvement
- HBV test for hepatitis positive
- ANCA test is negative
- Angiography: Microaneurysms or stenotic lesions of medium-sized vessels in the renal, hepatic, splenic or splanchnic circulation.
- Tissue biopsy may be diagnostic, revealing vasculitic lesions.

Deposits of HBsAg, complement and immuno-globulins may be found in the vessel wall in HBV-associated disease.

Management

(a) HBV-associated: Interferon - α or lamivudine, with short-term immunosuppression. (b) Non-HBV: High dose prednisolone 1mg/kg initially tapering over 1 year to 5–10 mg as patient improves. IV cyclophosphamide 0.6 g/m² monthly for 1 year also useful.

KAWASAKI DISEASE

Aetiology

Children aged between 6 months and 8 years. Staphylococcal and streptococcal toxins are implicated in the pathogenesis. An infectious agent is suspected. Various toxins are known, including staphylococcal enterotoxins A, B and C1, toxic shock syndrome toxin and streptococcal erythrogenic toxins A, B and C (superantigens). These stimulate a large proportion of T cells in an HLA-DR-dependent, but unrestricted manner, to divide and produce inflammatory cytokines. Some evidence suggests that T cell activation during the acute phase of Kawasaki disease is mediated by super antigen that induces V β 2 expansion.

Clinical Features

Five of the following must be fulfilled:

- Fever of \pm 5 days duration (must be present)
- Conjunctival congestion
- Changes in lips and oral cavity – at least one of dry, red, fissured lips, strawberry tongue, reddening of oral and pharyngeal mucosa

- Changes to peripheral extremities – at least one of red palms and soles, indurative oedema, membranous desquamation of finger tips during convalescence
- Macular polymorphous rash on trunk
- Swollen cervical nodes, often unilateral

Cardiac: Most serious consequences are aneurysms, thrombosis and areas of narrowing that may occur in coronary arteries and can be seen on echo-cardiography. The disease can be diagnosed if less than five of the above criteria if coronary aneurysms are present. Myocardial infarction can occur acutely. Myocarditis, acute mitral valve prolapse or pericarditis develop in some.

Non-cardiac – Pyuria, urethritis, aseptic meningitis, tympanitis, arthralgia and arthritis, and abdominal organ involvement (diarrhoea, abdominal pain, obstructive jaundice or cholecystitis).

INVESTIGATIONS – (a) Lab. findings – are nonspecific. Marked thrombocytosis may develop. (b) Cardiac aneurysms can be detected by echocardiography.

Management – IV Immunoglobulin 400 mg/kg/day, and aspirin 100 mg/kg/day for 14 days given within 10 days of onset reduces prevalence of coronary artery aneurysms.

LARGE VESSEL VASCULITIDES

Polymyalgia rheumatica (PMR) is an inflammatory disease seen predominantly in the elderly.

Aetiology: Age and female gender (male:female ratio 1:3) are risk factors for PMR. The acute onset, association with infections and vaccination and occurrence in conjugal pairs suggests an association with an environmental agent.

Clinical features – (a) Diffuse musculoskeletal pain, fever, early morning stiffness in shoulder and pelvic girdles associated with constitutional upset that responds dramatically to corticosteroid therapy. (b) Constitutional symptoms – fatigue, anorexia, wt. loss and low-grade fever. GCA may complicate PMR and PMR may occur before, simultaneously with or after GCA.

Investigations – Elevated ESR and CRP, anemia, mildly elevated alkaline phosphatase and transaminases, reduced serum albumin and raised α 2 globulins. Ultrasonography and MRI may show glenohumeral effusion and subacromial bursitis.

Management – Prednisolone 15–20 mg daily reduced to 10 mg daily by 3 months and continued for further 3 months, then reduced by 1 mg/day each month to lowest dose that prevents recurrence of symptoms or increase in CPR/ESR. Addition of azathioprine 1–2 mg/kg/day or

methotrexate 7.5-1.5 mg once a week may facilitate prednisolone reduction.

GIANT CELL ARTERITIS (GCA)

GCA is uncommon before 50 years and about 4 times more common in women.

Clinical features result from combination of inflammation and ischemia in the territory of affected vessels. Extracranial arteries, which have internal and external elastic laminae, are typically involved.

Histopathologically, the disease is a panarteritis with inflammatory mononuclear cell infiltrates within the vessel wall with frequent giant cell formation.

Unilateral throbbing headache usually in temporal area (temporal arteritis) but sometimes occipital (vertebrobasilar arteritis) or diffuse. Pain is severe, can be constant or intermittent and is often associated with scalp tenderness overlying the affected arteries, which may be thickened and nodular with reduced or absent pulsation.

Facial pain and claudication of jaw muscles may occur on chewing or prolonged speaking.

Visual symptoms are caused by occlusion of orbital or ocular arteries and present with partial or complete visual loss in one or both eyes or less commonly diplopia. Visual loss is sudden, painless and usually permanent.

Other neurological symptoms - Vertigo, hearing loss, ataxia due to involvement of vertebrobasilar system.

Involvement of large vessels - Aortic involvement presents with aortic arch syndrome, absent pulses and arm claudication. Thoracic or abdominal aortic aneurysms may be found and can present as acute aortic dissection.

Nonspecific symptoms of inflammatory disease - Fever, malaise, wt. loss. Limb girdle pain and early morning stiffness may occur.

Investigations - Confirmation of diagnosis by demonstration of granulomatous arteritis in a biopsy of the affected artery (usually the temporal artery).

Management - Prednisolone 40-60 mg/day, reduced gradually over 6 months to 10 mg daily. Azathioprine or methotrexate may be added to enable corticosteroid reduction.

TAKAYASU'S ARTERITIS

Takayasu's arteritis presents before age of 40 and is about 10 times more common in women.

Clinical Features

Nonspecific symptoms of inflammatory disease often precede more specific features. Arthralgia and myalgia are

common. Some patients develop true arthritis or less commonly, lupus-like rashes, erythema nodosum or glomerulonephritis.

Large vessel disease - 'Aortic arch syndrome' is the term given to disease affecting upper extremities, heart, neck and head. Patients often complain of arm claudication, and radial and brachial pulses are absent (hence formerly called 'pulseless disease'). BP varies by more than 10 mm Hg between the arms and a bruit may be audible over subclavian artery. AR, pulmonary hypertension, angina, CHF, vertigo, syncope, stroke and visual disturbance may occur.

Descending aortic syndrome may cause renovascular hypertension, kidney dysfunction, abdominal pain and acute abdominal bleeding or perforation of a viscus from infarction. Aortic aneurysms may develop and present with acute aortic dissection.

Investigations

Angiography or MRI angiography: Most common lesion is a smooth, concentric arterial or aortic narrowing (Figs. 48 to 52). Less commonly irregular narrowing, complete occlusion and fusiform or saccular aneurysms.

Management

Initially treatment is same as GCA, but the response is slower and often cytotoxic drugs may be required. Surgery or angioplasty may be required but should be deferred until the inflammatory component of the disease has been controlled.

9. BONE DISORDERS

OSTEOPOROSIS

PRIMARY OSTEOPOROSIS

Osteoporosis is a disease characterized by low body mass and microarchitectural deterioration of bone tissue, leading to increased bone fragility and a consequent increase in fracture risk. Table 37 gives risk factors for osteoporosis.

Table 37: Risk factors for osteoporosis

Independent of bone mineral density

Age
Previous fragility fracture
Maternal history of hip fracture
Oral glucocorticoid therapy
Current smoking
Alcohol abuse
Rheumatoid arthritis
Body mass index ≤ 19
Falls
Post-transplantation

Contd...

Fig. 53: Osteoporosis of spine Lateral X-ray

Fig. 54: Osteoporosis spine AP X-ray

Contd...

Depending on bone mineral density

Untreated hypogonadism
Malabsorption
Endocrine disease
Chronic kidney failure
Chronic liver disease
Chronic obstructive pulmonary disease
Immobility
Drugs: Phenytoin, heparin, barbiturates, hypervitaminosis A

Diagnosis

- History of fracture.** Fractures associated with osteoporosis are - vertebral fractures (leading to loss of height, kyphosis and back pain), hip fracture, Colles fracture of distal radius.
- Radiographs** - of dorsolumbar spine (lateral view) - Prominence of vertical trabeculae, generalised loss of contrast between bone and soft tissue. Also at times vertebral biconcavity or invagination of the disc into the vertebral spongiosa (Schmorl's nodes). Collapse of vertebrae and anterior wedging of vertebral bodies (Figs. 53 and 54) may be asymptomatic.

3. Bone density measurements:

Dual energy X-ray absorptiometry (DXA) is the gold standard. The technique uses two X-ray beams that pass almost simultaneously through bone. The difference in attenuation between the two bones gives the bone density in gms/sq cm. The DXA scan is usually performed in the spine, both hips and both wrists.

The bone densities are then plotted against a normal database to give the standard deviation from normal i.e. the T score, which is the bone density of the patient compared to young healthy adults of the same sex.

For post-menopausal women, the T-score values are classified as follows:

1 to 0	Normal
0 to -1	Normal
-1 to -2.5	Osteopenia
< 2.5 (e.g. 3, 4.5)	Osteoporosis

4. Biochemistry (See Table 38)

Table 38: Markers for bone resorption and bone formation

Bone resorption	Bone formation
<ul style="list-style-type: none"> Calcium Osteolytic bone metastases Hydroxyproline Collagen cross links Urinary Pyridinoline Desoxypyridinoline Skeletal imaging - Radiographs GI, bone scans and MRI Tartrate-resistant acid phosphatase 	<ul style="list-style-type: none"> Serum osteocalcin Bone specific alkaline phosphatase Serum assay of IC-terminal procollagen peptide and N-terminal peptide

SECONDARY OSTEOPOROSIS

7. <i>Nutritional and GI disorders</i> Malabsorption Total parenteral nutrition Gastrectomy Hepatobiliary disease Chronic hypophosphatemia
8. <i>Others</i> Familial dysautonomia Reflex sympathetic dystrophy

Management

Calcium – 1.5–2 g/day. If calcium malabsorption or associated osteomalacia; cholecalciferol 0.25 mg (10,000 IU) or Alfacalcidol 0.5 µg/day or Calcitriol 0.25 µg/day or Calcitonin 200 IU/day intranasally, alternate nostrils daily. (b) **Oestrogen therapy** – for small thin women, early menopause or oophorectomy, parous women, strong family history of osteoporosis, and those with prolonged amenorrhoea or oligomenorrhoea. Dose – Conjugated equine oestrogen 0.625 mg daily or its equivalent.

Drugs used in osteoporosis are listed in Table 40.

Table 40: Pharmacological therapy

Bisphosphonates

Drug	Dosage	Route of administration	Indications
Alendronate	70 mg once weekly or 5 or 10 mg o.d.	Oral	Postmenopausal Glucocorticoid-induced
Etidronate	400 mg/day x 2 wks every 3 months	Oral	Postmenopausal Glucocorticoid-induced
Ibandronate	150 mg once monthly 3 mg once every 3 months	Oral IV	Postmenopausal Postmenopausal
Risedronate	35 mg once wkly or 5 mg o.d.	Oral	Postmenopausal Glucocorticoid-induced
Raloxifene	60 mg o.d.	Oral	Postmenopausal
Strontium ranelate	2 g o.d.	Oral	Postmenopausal
Teriparatide	20 µg o.d.	S.C. inj.	Postmenopausal
Parathyroid hormone	100 µg o.d.	S.C. inj.	Postmenopausal

Note: Oral bisphosphonates must be taken fasting with a full glass of water, and the individual must stay sitting or standing without food or drink for next 30–60 minutes.

Strontium ranelate is alternative front line option to alendronate or risedronate, particularly in people for whom these drugs are contraindicated or not tolerated.

Calcitonin – also inhibits bone resorption and has been shown to prevent menopausal bone loss. Given by sc injection. Side effects of nausea and facial flushing. (i) **Sodium**

fluoride – stimulates osteoblasts and new bone formation. Dose 40–60 mg/day. Side effects include GI symptoms and pain in lower limbs due to stress-fractures.

Cause	Mechanism
• Vitamin D deficiency	<p><i>Defective intake/formation</i> Lack of solar exposure (D_3) and of dietary intake or fat malabsorption (D_2) Severe chronic liver disease</p> <p><i>Increased/wasteful metabolism</i> Liver-enzyme-inducing drugs e.g. phenytoin, phenobarbitone, carbamazepine, rifampicin</p> <p><i>Failure of activation, 25 (OH) D_1-25 (OH)$_2$ D</i> Chronic renal failure Hereditary vitamin-D dependent rickets type I <i>Target organ defect</i> Hereditary vitamin-D dependent rickets type II</p>
• Phosphate deficiency	<p><i>Poor intake</i> Aluminium hydroxide excess binding of dietary phosphate</p> <p><i>Increased loss</i> X-linked hypophosphatemia (vitamin D-resistant rickets) Fanconi's syndrome Renal tubular acidosis Ureterocolic anastomosis Tumour-associated</p>
• Chronic metabolic acidosis Osteoblast / mineralization defect	<p><i>Renal tubular acidosis</i> <i>Ureterocolic anastomosis</i> <i>Hypophosphatasia</i> Etidronate therapy Aluminium intoxication (in renal disease)</p>
Cause	Mechanism
• Drug-induced osteomalacia	High doses of sodium fluoride or of first generation bisphosphonates (e.g. etidronate). Anticonvulsants in patients with marginal vitamin D supply.

OSTEOMALACIA

It is a disorder of mineralization of the adult skeleton. See Table 41 for the causes of osteomalacia.

CLINICAL FEATURES

Bone pain and tenderness, deformity, proximal muscle weakness, waddling gait. Tetany.

DIAGNOSIS

1. *Biochemistry* – (a) Plasma calcium low or normal. (b) Serum phosphate raised. (c) Raised alkaline phosphatase.
2. *Radiography* – Looser's zones, linear areas of defective mineralization especially in long bones, pelvis and ribs (Fig. 55).
3. *Therapeutic trial* – Response to vitamin D or one of its active metabolites.

TREATMENT

Depends on the cause. e.g. bicarbonate and potassium supplements in renal tubular acidosis, phosphate supplements in hypophosphataemic syndromes. Vitamin D or one of its potent derivatives alfacalcidol or calcitriol. Cholecalciferol can be administered as chewing tablets or oro spray. Vitamin D_3 orally as tablets or capsules.

Oncogenic osteomalacia is a rare tumour associated disorder characterized by hypophosphatemia, phosphaturia, normocalcemia, and osteomalacia in absence of nutritional or drug history suggestive of vitamin D deficiency or generalized renal tubular acidosis. Patients typically present with bone pain or proximal muscle weakness. Tumors associated with this disorder are generally benign, the commonest being hemangiopericytoma.

OSTEOPETROSIS

Osteopetrosis or marble bone disease is a heterogenous group of disorders characterized by a generalized increase in bone density caused by defective osteoclastic bone resorption.

CLINICAL DISORDERS

1. *Osteosclerosis* – (a) Osteopetrosis with delayed manifestations (Albers-Schonberg disease). A benign form

Fig. 56: Radiograph of the skull of patient with advanced Paget's disease showing thickening, disordered new bone formation (cotton-wool patches), and basilar impression

of osteopetrosis. May be asymptomatic. Occasionally facial palsy or deafness from cranial nerve compression.

- (b) Osteopetrosis with precocious manifestations - Presents in infancy with failure to thrive, abnormal bleeding and anemia. (c) Pyknodysostosis - Short stature, enlarged skull, short and broad hands and feet and blue sclerae.
2. *Craniotubular dysplasia* - Abnormal skeletal modelling with little bone sclerosis.
 3. *Craniotubular hyperostosis* - Overgrowth of bone, with resultant alteration of contour and increased skeletal density.

PAGET'S DISEASE OF BONE

A bone disease characterized by excessive osteoclastic bone resorption, associated with a compensatory, but disorganized increase in bone formation. Precise aetiology unknown, but the finding of inclusion bodies in the osteoclasts nuclei suggests a possible viral infection (measles or respiratory syncytial virus).

CLINICAL FEATURES

(a) Bone pain - Localised pain in affected bones, nocturnal pain common. Thickening and deformity and bowing of bones. Local warmth and tenderness from increased vascularity. (b) Osteoarthritis due to limb shortening,

(c) Kyphosis due to vertebral collapse. (d) Neurological symptoms - Involvement of spine may lead to paraparesis. Entrapment neuropathies of cranial and peripheral nerves. (e) Skull changes - Enlargement of skull vault, prominent scalp veins, platybasia due to skull base softening, cranial nerve compression and deafness due to distortion of auditory meatus or ossicles, or nerve compression. (f) Fundoscopy - Angioid streaks.

Complications - (a) High cardiac output due to increased blood flow. (b) Pathological fracture. (c) Sarcoma. (d) Urinary stone formation.

INVESTIGATIONS

1. *Radiology and scintigraphy* - (a) Early lytic lesions in long bones seen as flame-shaped resorption front, or in skull as osteoporosis circumscripta (Fig. 56).
(b) In mixed phase, bone may expand with loss of cortical and medullary differentiation. Patchy involvement of skeleton is best demonstrated by bone scintigraphy. (^{99}Tc MDP bone scan).
2. *Biochemistry* - (a) Alkaline phosphatase is a marker for bone formation. (b) Hydroxyproline is a marker of osteoclastic bone resorption.
3. *Histology* - Early lesion is replacement of normal bone by abnormally large osteoclasts. As the disease progresses sclerosis becomes more prominent.

MANAGEMENT

Indications for treatment - (a) Bone pains. (b) Osteolytic lesions in weight-bearing bones. (c) Neurological complications. (d) Delay or non-union of fractures. (e) Before and after major orthopaedic surgery. (f) Immobilization hypercalcaemia. *Drugs* - Bisphosphonates suppress or reduce bone resorption by osteoclasts - (a) Etidronate 400 mg daily for 3-6 months is effective and well tolerated, but should be avoided in patients with pseudofractures and deformities of weight bearing joints as it may cause osteomalacia. (b) Pamidronate for severe Paget's disease. Initial therapy with 2-3 60 mg infusions, followed by 60 mg at 3-month intervals. (c) Tiludronate 400 mg daily p.o. for 3-6 months is more potent than etidronate with no adverse effect on mineralization. May induce negative focal bone balance giving rise to radiological translucencies. May be repeated if necessary at interval of 6-12 months.

OSTEOGENESIS IMPERFECTA

Osteogenesis imperfecta (OI, brittle bone disease) is a disorder of bone matrix. It is AD inherited disorder and the clinical heterogeneity is largely the result of the great number of different molecular defects within the genes that encode pro- α_1 and pro- α_2 type I collagen.

Cl. Fs. – The clinical hallmark of OI is osteopenia with recurrent fracture and skeletal deformity, defective formation of dentin (dentinogenesis imperfecta) (Fig. 57).

Type I: Sclerae with bluish discoloration that is particularly apparent during childhood, relatively mild osteopenia with infrequent fractures and deafness (30% incidence). Increased numbers of cortical osteocytes may be detected by bone biopsy.

Type II: It is often fatal within first few days or weeks of life because of respiratory complications. Affected new-borns are often premature and small for gestational age, and have short, bowed limbs, numerous fractures, a markedly small skull and a small thorax.

Type III: Progressive skeletal deformity due to recurrent fractures, and short stature that partly results from fragmentation of growth plates.

Type IV: Sclerae are normal colour, but skeletal deformity, dentinogenesis imperfecta and hearing loss are typical findings.

Radiological features – Severely affected patients show generalized osteopenia, shaping defects of long bones and deformity as a result of recurrent fractures. Platybasia is common and can progress to basilar impression.

Fig. 57: Dentinogenesis imperfecta

TR. – Antiresorptive therapy with iv Pamidronate in children before 3 years. Oral bisphosphonates may be effective in older children and adults. Supportive treatment.

OTHER SCLEROSING BONE DISORDERS

Albers-Schonberg disease (autosomal dominant osteopetrosis type II) – Generalized osteosclerosis with thickening of vertebral end-plates (sandwich vertebrae) and bone within bone in the pelvis.

Pyknodysostosis – AR disorders with short stature, large cranium, small facies and skeletal fragility.

Progressive diaphyseal dysplasia – Patchy thickening of bone associated with pain, gait abnormalities and muscle wasting.

10. MISCELLANEOUS

Syndrome of remitting seronegative symmetrical synovitis with pitting oedema

RS₃PE syndrome is used to describe patients who have peripheral seronegative, symmetrical polyarthritis with tenosynovitis, and pitting oedema present mainly over the dorsum of hands, especially in men above the age of 60. The course is benign and there is good response to corticosteroids.

Table 42: Rheumatological disease associated with malignancy

• Dermatomyositis	• Carcinoma (lung, oesophagus)
• Scleroderma	• Adenocarcinoma (lung, kidney)
• Primary Sjogren's syndrome	• Lymphoma Lymphoma and myeloma
• Rheumatoid arthritis	Lymphoma and lung cancer
• Systemic lupus erythematosus	

Table 43: Rheumatological manifestations of malignancy

• Metastatic bone disease
• Myopathy
• Pancoast tumour
• Coccydynia
• Hypertrophic pulmonary osteoarthropathy
• Fibromyalgia/polymyalgia
• Gout
• Arthritis

Table 44: Differential diagnosis of arthritis and oedema of the hands

<i>Disease</i>	<i>Clinical features</i>	<i>Investigations</i>
RS ₃ PE syndrome	Aged male. Symmetrical polysynovitis. Dramatic response to low dose corticosteroids. Long term remission after withdrawal. Good prognosis	Negative RF and ANF. Absent bony erosion on X-ray
Mixed connective tissue disease (Sharp syndrome)	Young female. Raynaud's phenomenon +	High titre ANF (speckled) with anti-native ribonucleoprotein.
CPPD crystal arthropathy (chondrocalcinosis)	Predominantly elderly female. Absence of constitutional symptoms. Asymmetric oedema. Responsive to NSAIDs	Chondrocalcinosis on hands, knee, pelvis on X-ray. CPPD (calcium pyrophosphate dihydrate) crystal demonstration by polarised light analysis of synovial fluid
Reflex sympathetic dystrophy	Exquisitely painful oedema (often bilateral), vasomotor and skin alterations. True arthritis absent, predisposing factors +	Absent markers of systemic inflammation. Radiology (X-ray, bone scintigram and MRI) helpful
Amyloid arthropathy	Rare disease, firm pseudo-oedema. Frequent carpal tunnel syndrome, nodules +; slow and insidious onset without morning stiffness. Multiple visceral involvements. No response to corticosteroids	Proteinuria, monoclonal gammopathy or light chain in urine (AL type). Free amyloid debris in synovial fluid; specific birefringence with Congo Red staining on biopsies
Reiter's or psoriatic spondyloarthropathy	Axial, skin, ophthalmic or genitourinary signs and symptoms. Mostly asymmetrical. Occasionally firm and non-pitting lymphoedema	HLA-B27 +; sacroiliitis +
Late onset spondyloarthropathy	Middle aged men. Asymmetrical pitting oedema of lower limbs with oligoarthritis. Constitutional symptoms ++; poor response to corticosteroids	HLA-B27 +; Absent axial disease
Rheumatoid arthritis	Female predominance, symmetrical synovitis of MCPs and IPs. Good (not dramatic) response to corticosteroids. Unilateral pitting oedema, associated with rupture of neighbourhood joint.	RF +, bony erosions on radiography
Polymyalgia rheumatica	Elderly patient with female predominance. True peripheral synovitis rare; usually mild. Dramatic response to corticosteroids. Long-drawn treatment with frequent flares	Temporal artery biopsy

Infectious Diseases and Infections

1. DIPHTHERIA

Diphtheria is caused by superficial infection of respiratory tract or skin with toxin-producing strains of *Corynebacterium diphtheria*. The organisms do not actively invade deep tissue or blood, but multiply locally producing diphtheria toxin. This results in necrosis of mucosal cells and production of a thick, grey pseudomembrane. Diffusion of toxin into circulation causes neurological and myocardial complications.

Incubation period – 2 to 6 days.

CLINICAL TYPES

1. **RESPIRATORY GROUP** – includes majority.
 - Nasal diphtheria** – Unilateral or bilateral nasal discharge, at first serous and often blood stained; later thick, mucopurulent and foul smelling.
 - Faucial diphtheria** – The pseudomembrane adheres to the fauces, and attempts to remove it leaves a raw, bleeding surface. Cervical lymph nodes enlarge and there is oedema of the neck, which may be severe and progress to ‘bull-neck’.
 - Laryngeal diphtheria** – More common in infants. Membrane involves larynx and also spreads to trachea and bronchi. Initial symptoms are hoarseness, brassy cough and noisy breathing. Progressive laryngeal obstruction produces inspiratory stridor. Lower intercostal spaces are sucked in as not enough air flows in to fill the lungs. If not relieved child dies of hypoxia.
2. **NON-RESPIRATORY GROUP** – include vulva, vagina, umbilical cord, conjunctiva, auditory meatus, tongue and oesophagus. Glans or coronal sulcus of penis after circumcision in infants. Cutaneous diphtheria may present as a chronic ulcer or a persistent shallow ulcer with punched out areas.
 - Diagnosis** – Throat or laryngeal swab for culture on blood tellurite agar. Suspicious colonies are identified by a black or grey appearance on this medium.

Complications – Aspiration of membrane can cause respiratory obstruction.

1. **Cardiovascular** – Myocarditis with circulatory failure, cardiac arrhythmias such as heart block, cardiac failure.
2. **Neurological** – Palatal palsy, paralysis of accommodation with difficulty in reading small print, polyneuritis with weakness of muscles of extremities.

DIFFERENTIAL DIAGNOSIS

Faucial Diphtheria

1. *Acute follicular tonsillitis* – It is the most important differential diagnosis of faucial diphtheria (Table 1).
2. *Moniliasis* – Most common in infants, patches of soft deposit of fungus on buccal mucosa and tonsils. Exudate white and characteristically arranged as small linear membranes. *Monilia albicans* will be seen on smear.

Table 1: Differences between faucial diphtheria and follicular tonsillitis

<i>Diphtheria</i>	<i>Follicular tonsillitis</i>
History of epidemic, or of exposure	History of previous attacks
Insidious onset	Acute onset
Tough, ashy-grey uniform deposit	Soft, yellowish white deposits in spots or patches with intervening areas of redness
Membrane very adherent, bleeding points when torn off	Membrane easily removed leaving smooth surface
Pillars of fauces and uvula may be involved	Deposit limited to tonsils
Fever usually slight	Fever high
Cervical glandular enlargement rare	Cervical glands commonly enlarged

3. *Vincent's angina* – Gingivitis with ulceration, no toxæmia, marked foetor of breath, presence of fusiform bacillus and spirillum.
4. *Infectious mononucleosis* – occurs usually in older children. Exudate as a rule remains white. Glands in neck enlarge but remain discrete. Patient usually less ill.
5. *Agranulocytosis* – Gingivitis with ulcerating membranous lesions of tonsils, palate, or gums. Fever and malaise. Diagnostic blood picture.
6. *Acute leukaemia* – Haemorrhages, enlargement of spleen, liver and lymph glands.
7. *Post-tonsillectomy slough* – No tendency for lesions to spread.
8. *Quinsy* – Usually unilateral, glands enlarged and tender.
9. *Mumps* – may simulate periadenitis of diphtheria but swelling in mumps fills up posteriorly the depression between angle of jaw and mastoid process. Orifices of Stensen's ducts injected, no membrane, no toxæmia.
10. *Secondary syphilis* – Glairy deposit on tonsils. Hoarseness due to laryngitis.
11. *Leukoplakic patches* – Seen mainly in men over 40 years of age. White patches also on gums, cheeks or dorsum of tongue.
12. *Scarlet fever* – Tonsillopharyngitis may be membranous or ulceromembranous. Typical rash.

Laryngeal Diphtheria

1. *Acute catarrhal laryngitis* – Few constitutional symptoms, catarrh dominant, slight obstructive signs, usually no paroxysms.
2. *Measles* – Catarrhal symptoms. Koplik's spots, no membrane; later rash.
3. *Acute bronchiolitis* – Affects children mainly under 2 years of age. Initial non-specific upper respiratory infection symptoms followed by cough, reluctance to feed and rapid wheezing respirations. Short inspiratory gasps may be accompanied by widespread crepitations.
4. *Staphylococcal pneumonia* – Onset with upper respiratory symptoms with rapid deterioration, dyspnoea, pallor and grunting respirations. Signs of localized consolidation.
5. *Asthma in first attack* – Usual age 9 months onwards. Expiratory distress, no stridor. Rhonchi with expiratory spasm.
6. *Laryngismus stridulus* – Sudden onset, recurrent nocturnal attacks of dyspnoea, no membrane, few general symptoms. Rickets or other evidence of tetany.
7. *Congenital laryngeal stridor* – Starts in first week, lasts up to two years. Obstructive signs but no dysp-

Table 2: Type of diphtheria and dose of diphtheria antitoxin

Type of diphtheria	DAT
Nasal	10,000
Tonsillar (unilateral)	10,000
Tonsillar (bilateral)	40,000
Confined to tonsillar fossa	20,000
Membrane extending beyond tonsillar fossa:	
On one side of pharynx wall	30,000
To anterior pillar and palate	40,000
To palate on both sides	60,000
Laryngeal (pulse additional dose as above) for membrane on the throat	30,000
Bullneck diphtheria	1,20,000
Cutaneous	10,000
Prophylactic dose for contacts	6,000

- noea; symptoms constant but less at night; sometimes abnormalities of jaw and chest.
8. *Papilloma of larynx* – Gradual onset, chronic cough and alteration of voice, slowly progressive dyspnoea with occasional paroxysms, stridulous breathing chiefly inspiratory; direct laryngoscopy shows tumour.
 9. *Acute oedema of glottis* – Abrupt onset, persistent dyspnoea, history of nephritis or angio-oedema, etc. Oedema on laryngoscopy.
 10. *Foreign body in larynx* – Acute onset with violent paroxysms of coughing; dyspnoea persistent, may abate after onset to return later; stridulous breathing chiefly inspiratory. Foreign body seen on laryngoscopy or X-ray.

MANAGEMENT OF DIPHTHERIA

1. GENERAL CARE – (a) Complete rest in bed for 2 weeks, or longer if necessary. (b) Diet – Fluids in acute phase; soft or semisolid diet in early convalescence. (c) Glucose – IV to counteract hypoglycemia associated with toxæmia. (d) Relief of sore throat or headache with gargles and codeine.
2. DIPHTHERIA ANTITOXIN – DAT should be given as early as possible by IV drip or IM injection or half IV and half IM as a single dose. Dose for children and adults is same (Table 2).

Assessment of DAT dose – Evidence that growth of the membrane has been checked within 24 hours, no newly formed membrane and the existing membrane should be more opaque. If new membrane has formed, dose of DAT should be repeated.

3. **ANTIBIOTICS** - Erythromycin 250 mg by mouth every 6 hours for 5-7 days to terminate production of new toxin and for preventing secondary infection.

Procaine penicillin G, 600000 U IM q12 h (for children: 12, 500-25000 U/kg IM q12h) until the patient can swallow comfortably; then oral penicillin V, 125-250 mg qid to complete a 14-day course.

Eradication of *C. diphtheriae* should be documented after antimicrobial therapy is complete. A repeat throat culture 2 weeks later is recommended. For patients in whom the organism is not eradicated after a 14-day course of erythromycin or penicillin, an additional 10-day course followed by repeat culture is recommended.

4. **MANAGEMENT OF LARYNGEAL DIPHTHERIA** - In addition to general and specific measures, relief of obstruction to breathing by steam inhalations (the bed being covered with a mosquito net) alternating with O₂ inhalations and antispasmodics such as salbutamol. If restlessness persists and respiration remains distressed, tracheostomy should be performed. The air must still be kept moist. The tube can be removed after about a week. Assisted respiration may be necessary.
5. **MANAGEMENT OF COMPLICATIONS**

(a) *Respiratory and cardiac complications* can be minimized by monitoring including regular ECG and early intervention (e.g. pacing for conduction disturbances, drugs for arrhythmias). Tracheostomy or intubation may be necessary to ensure continued patency of potentially compromised airway, and mechanical removal of any tracheobronchial membrane.

(b) *Paralysis* - (i) Of palate - Thickened feeds to prevent regurgitation. (ii) Of pharynx - Raise foot of bed for drainage of mucus. Digital swabbing or mechanical aspiration. Tube feeding may be necessary or IV. (iii) Respiratory paralysis - Use of ventilator and maintenance of adequate airway. (iv) Peripheral palsies - Rest, splinting and physiotherapy.

IMMUNIZATION - For active immunization, see Chapter 12.

For passive immunity - Prophylactic dose for contacts 6000 units DAT, for babies 4000 units. Immunity lasts for about 2 weeks. May be given simultaneously with active immunization.

SCHICK TEST - to detect immunity to diphtheria.

Method - One arm is injected intradermally with 0.1 mL of diphtheria toxin, and the other arm with a control injection of 0.1 mL diluted diphtheria toxin.

Results - (a) Sensitivity is indicated by an area of induration or redness more than 12 mm in diameter, occurring within 24-28 hours at the site of control injection.

(b) Lack of immunity (positive reaction) is indicated by redness, with or without induration, at the site of toxin injection, and no or less reaction at control site. (c) Immunity (negative reaction) is indicated by a reaction at the site of toxin injection which is less than or equal to that at the control site.

2. MENINGITIS

Meningitis is inflammation of the leptomeninges caused by infectious agents; however infiltration of the meninges by leukaemic or other malignant cells also produces inflammatory meningitis. For bacterial meningitis, peak age of incidence is less than 5 years. Neonates, particularly premature are at particular risk.

PATHOGENESIS

Pathogens usually gain access to the meninges through the blood stream. Most of the organisms causing bacterial meningitis are commonly carried in the upper respiratory tract, and there is evidence that invasion is triggered or facilitated by a coincident infection with a second pathogen (e.g. influenza virus) causing mucosal damage or an immunosuppressive effect. Table 3 lists the causes of meningitis.

ASEPTIC MENINGITIS

- Viral - e.g. HSV 2, polio.
- Partially treated pyogenic meningitis.
- Non-infective causes - (i) Vasculitis (esp. SLE). (ii) Meningeal carcinomatosis. (iii) Sarcoidosis. (iv) Behcet's/Whipple's disease. Vogt-Koyanagi syndrome.
- Specific infections in which causative agent may not be identified on ordinary microscopy or culture - TB or cryptococcal meningitis, neurosyphilis, leptospirosis, brucellosis.
- Parameningeal suppuration.

BACTERIAL MENINGITIS

Epidemiology and bacteriology - Introduction of *H. influenzae* and *Neisseria meningitidis* vaccines has reduced the incidence of meningitis from these organisms. Risk of bacterial meningitis may be increased in other conditions.

Defects in the three pathways of complement activation are associated with increased susceptibility to meningococcal infection, including terminal complement components, the properdin system and mannose-binding protein. Splenic dysfunction (as in sickle cell disease) is associated with increased risk of pneumococcal

Table 3: Causes of meningitis

Infectious causes	
Bacterial	Viral
<i>Common</i>	Mumps
N. meningitidis	Echovirus
S. pneumoniae	Coxsackievirus types A and B
H. influenzae	Genital herpes simplex virus types 1 and 2
<i>Neonatal</i>	
Group B Strepto.	Other herpes viruses
E. coli	Epstein-Barr virus
L. monocytogenes	Varicella-Zoster virus
<i>Uncommon</i>	Cytomegalovirus
Staph. aureus	HIV
Ps. aeruginosa	Lymphocytic choriomeningitis virus
B.burgodoferi	
<i>Rare</i>	Adenovirus types 3 and 7
Salmonella	Arboviruses
Shigella	
N. gonorrhoea	
Mycobacterial	Protozoal
M. tuberculosis	Naegleria
Fungal	Spirochaetal
Cryptococcus	Leptospirosis
neoformans	Syphilis
Candida	Lyme disease
	Ricketssial
	Typhus fever
Non-infectious causes	
Malignant	
Leukemic meningitis	
Other non-infectious causes	
Sarcoidosis	
Connective tissue disease	
SLE	
RA	
Sjögren's syn.	
Vasculitis	
Granulomatous polyangiitis	
Eosinophilic granulomatous polyangiitis	
CNS vasculitis	

meningitis, and T lymphocyte defects (congenital or caused by chemotherapy, AIDS or malignancy), result in increased risk of *Listeria monocytogenes* meningitis. *Streptococcus pneumoniae* is the most common pathogen in cases secondary to a breach or defect in the mucocutaneous barrier such as basal skull fracture, mid-line facial defects or inner ear fistulas. Penetrating cranial trauma and CSF shunt increase risk of meningitis caused by staphylococci (particularly coagulase-negative species) and other skin pathogens.

Pathophysiology

- Transmission, colonization and invasion of nasopharyngeal epithelium.
- Survival in the blood stream by evading host immune response.
- Meningeal invasion. Bacteraemia may be rapidly followed by seeding of meningeal pathogens and secondary infection of the meninges.
- CSF inflammatory response.
- Cerebral oedema and thrombosis. Cerebral oedema may be caused by reduced CSF reabsorption by the arachnoid villi, or by vasogenic or cytotoxic means. Bacterial meningitis causes loss of cerebrovascular anticoagulation.

Clinical Features

Relate to three causes

1. *Infection* – Fever, rigors, toxæmia.
2. *Increased intracranial pressure* – Headache, nausea, vomiting, deterioration of consciousness, hypertension, bradycardia.
3. *Meningeal irritation and inflammation* – Neck rigidity, positive Kernig's sign, photophobia.

Other presenting features include

- Cranial nerve palsies most commonly IIIrd, IVth, VIth and VIIth
- Focal neurological deficits such as nystagmus, aphasia, ataxia and peripheral nerve palsies
- Partial or generalized seizures – tend to be more common in *Strep. pneumoniae* and HIV meningitis
- Purpura or petechiae in meningococcal meningitis, with or without features of septic shock (Waterhouse-Friderichsen syndrome)
- Less specific presentation may be seen in young infants and in elderly such as lethargy, poor appetite, listlessness, diarrhoea and vomiting

Diagnosis

Examination of CSF (refer investigations in Neurology).
Typical CSF findings in acute bacterial meningitis:

- Raised WBC count (usually 100–60,000 cells/mL predominantly neutrophils)
 - Reduced CSF glucose (30–40% serum glucose level)
 - Raised CSF protein (0.5–5 g/litre)
 - Increased opening pressure (>180 mm H₂O)
- Gram-staining of CSF is positive in over 90% of cases of haematologically acquired meningitis.

Blood culture – should be performed in all patients with suspected meningitis, and latex agglutination bacterial antigen test or polymerase chain reaction analysis (to detect bacterial DNA) may be performed on blood or CSF to try to obtain a diagnosis. Such tests remain positive for several days after administration of antibiotics. Laboratory markers of poor prognosis include low peripheral WBC count, thrombocytopenia, absence of CSF pleocytosis and high CSF protein levels.

Viral meningitis – Genexpert (Xpert EV) has high degree of accuracy of enteroviral meningitis.

CT – Normal CT does not exclude raised intracranial pressure in bacterial meningitis, but can be used to exclude significant space occupying lesions, which would contraindicate lumbar puncture. When a clinical diagnosis of meningococcal meningitis is made on presence of a purpuric or petechial rash, LP should not be performed. Such patients are commonly in compensated septic shock, and the procedure may worsen their cardiovascular and respiratory status.

Differential Diagnosis of Meningitis

- A. **Meningism** – Neck stiffness in presence of normal CSF. May be seen occasionally usually at onset, in typhoid fever, apical pneumonia, acute exanthema, acute pyogenic tonsillitis, pyelonephritis, cervical lymphadenopathy (Table 4).
- B. **Other infections of CNS**
1. **Poliomyelitis** (in the early ‘meningeal phase’) – usually of short duration, meningeal signs not marked, hyperaesthesiae common, paralysis common and more extensive. Lumbar puncture at once differentiates.
 2. **Viral meningoencephalitis** – Distinct CSF findings – Glucose level normal, proteins less elevated (typically 0.5–2 g/L), and lymphocytosis.
 3. **Post-infectious meningoencephalitis** – Rare sequel of measles or influenza, or less frequently chickenpox, mumps or rubella, and certain vaccines.
 4. **Focal infections** – such as brain abscess and subdural empyema may have similar clinical features.

Table 4: Difference between meningitis and meningism

<i>Meningitis</i>	<i>Meningism</i>
Slow onset usually	Rapid onset
Neck pain common	No neck pain
Delirium, convulsions or coma common	Delirium, convulsions and coma rare
Vomiting at onset and also subsequently	Vomiting at onset only
Pulse and respiration may be irregular; relative bradycardia	No irregularity of pulse rhythm, no bradycardia
Kernig's sign present	Kernig's sign usually absent
Cranial nerve palsies common	Cranial nerves rarely affected
CSF shows definite changes	Increased pressure of CSF with moderate reduction in protein and chloride content

Investigations to determine a specific aetiology include CSF examination with specific stains for mycobacteria and fungi, cytology, antigen detection, serology, viral culture and blood culture. CT or MRI of brain.

5. **Non-infectious illnesses** – though uncommon may cause CNS inflammation including malignancy, collagen vascular syndromes and exposure to toxins. CSF findings are useful.

Management

ICU – for patients with severely depressed consciousness, signs of raised intracranial pressure, shock or convulsions. Antibiotics – Antibiotic coverage for meningitis is given in Table 5.

Corticosteroids – Dexamethasone 0.4 mg/kg b.d for 4 days with the first dose of antibiotic.

Prevention – Primary prevention of bacterial meningitis may be achieved by immunization and by prevention of secondary cases of meningococcal and H. influenzae disease using chemoprophylaxis.

Vaccines – The introduction of conjugate vaccine has dramatically reduced the incidence of this pathogen as a cause of bacterial meningitis, and a pentavalent meningococcal conjugate vaccine or a quadrivalent meningococcal polysaccharide vaccine is advisable at 2, 3 and 4 months of age. Pneumococcal vaccine is poorly immunogenic in children under 2 years of age. It is used in older children and adults at high risk of invasive pneumococcal disease, such as those with reduced splenic function including sickle cell disease, the elderly, diabetics and patients with other chronic diseases.

Table 5: Empirical antibiotic coverage for meningitis

Age group	Most likely pathogens	Antibiotic daily dose
Neonates	B group streptococci, E. coli, Listeria	Ampicillin (100–150 mg/d) + Cefotaxime (50 mg/kg) or Ceftriaxone (500–1000 mg/kg/d)
1–3 months	N. meningitides, Strep. pneumoniae, Listeria	Ampicillin + Broad spectrum cephalosporin (Vancomycin 40 mg/kg)
Older infants, children and adults	H. influenzae, N. meningitides, S. pneumoniae	Ceftriaxone or Cefotaxime + Vancomycin
Elderly or immunocompromised	S. pneumoniae, Listeria bacilli, L. monocytogenes, Gram -ve bacilli	Ampicillin + Ceftriaxone or Ceftazidime + Vancomycin
Age	Organisms covered	Antibiotics
16–50 years	S. pneumoniae, N. meningitides, H. influenzae	Vancomycin 1 gm q8h (in children 60 mg/kg/d) + Ceftriaxone 100 mg/kg/d
>50 years	S. pneumoniae, L. monocytogenes, Anaerobic gram -ve bacilli	Vancomycin 1 gm q8h + Ceftriaxone 2 gm bd + Ampicillin 3 gm tds or qds
Post-surgical or post-head injury	Staph. Aureus, S. pneumoniae, Anaerobic gram -ve bacilli	Ceftazidime 2 g q8h + Vancomycin 1 gm q8h
Organism	Antibiotic	
	<i>First choice</i>	<i>Second choice</i>
E. coli	Cefotaxime 8–12 g/d	Aztreonam or Fluoroquinolone or Meropenem
P. aeruginosa	Ceftazidime 6–12 g/d or Cefixime	Aztreonam or Meropenem
Pseudomonas	Ceftazidime 6–12 g/d	Carbenicillin 18–30 g/d or Ticarcillin 12–20 g/d or Piperacillin 12–18 g/d

3. VIRAL INFECTIONS

INFLUENZA AND RESPIRATORY SYNCYTIAL VIRUS

About 30–50% of acute lower respiratory tract infections are viral in origin; of these influenza and respiratory syncytial virus (RSV) are associated with maximum disease burden.

Influenza

Influenza viruses are small RNA-containing enveloped viruses. There are three types - A, B and C. Influenza A

viruses are further classified according to the properties of their surface proteins, haemagglutinin (HA) and neuraminidase (NA) found on the surfaces of influenza viruses. There are 16 known HA subtypes and 9 known NA subtypes which can combine to create novel combinations of influenza. The typical seasonal influenza viruses exhibit frequent point mutations that lead to gradual shifts in their genomes. This process is known as antigenic drift, and it is the reason that new influenza vaccines must be prepared each year. Poultry are the natural reservoirs of type A viruses. Influenza B viruses are only found in humans and

have caused epidemics in the past, but never pandemics. Influenza C virus causes only mild illness in adults.

Incubation period – 1 to 3 days.

Clinical Features

Clinical features of influenza A and B illness.

Onset – Sudden with fever, chilly sensations, and prostration, catarrhal symptoms, headache, pains and dry cough. Sometimes erythematous rash.

CLINICAL TYPES

1. *Febrile type* – Only constitutional symptoms – fever, malaise, headache, severe bodyache, catarrh, congestion of eyes and throat, rapid prostration. Dry cough with few or no signs in chest. Fever lasts for 4 to 6 days, there may be relative bradycardia.
2. *Respiratory type* – (a) Bronchitis and bronchopneumonia. (b) Pleurisy, empyema not uncommon. (c) Pneumonia – (i) Fulminating rapidly fatal form in which pneumonia is present from the onset. (ii) Progressive form in which on the 2nd or 4th day signs of pneumonia begin to develop with copious fine crepitations usually basal. The sputum may be pinkish, frothy and copious, or tenacious mucus of several hues. (iii) Late form in which often after apparent recovery from the primary influenza, pneumonia suddenly supervenes on the 4th to 10th day after the onset.
3. *GI type* – Temperature rarely above 37.5°C, severe anorexia and vomiting, abdominal discomfort and general prostration. Tympanitis, diarrhoea and continued fever may simulate typhoid fever.
4. *Malignant type* – Severe toxæmia, cyanosis and rapid cardiac failure. Always fatal.
5. *Nervous type* – Headache sometimes very severe, delirium, intense depression which may continue after the acute illness. A true meningitis may occur.

Diagnosis

The Genexpert system can perform rapid and accurate determination of Flu A and Flu B infection along with identification of the H1N1 novel influenza virus strain. The assay results are obtained in 2 hours which is important in starting appropriate therapy and maximizing infection control measures.

Complications and Sequelae

Table 6 gives population groups with high risk of getting influenza complication.

Table 6: Population group with high risk of influenza complication

1. All children from birth to <5 years old, especially <2 years
2. All persons ≥50 years old
3. Pregnant women
4. Adults and children who have chronic pulmonary (including asthma) or cardiovascular (except isolated hypertension), renal, hepatic, neurologic, hematologic or metabolic disorders (including diabetes mellitus)
5. Persons who have immunosuppression (including that caused by medications or by HIV infection)
6. Children and adolescents (6 months to 18 years old) who are receiving long term aspirin therapy and who might be at risk for Reye's syndrome after influenza virus infection
7. Residents of nursing homes and other long-term care facilities
8. Persons who are morbidly obese (body mass index >40 kg/m ²)

1. *Respiratory* – Bacterial bronchopneumonia or lobar pneumonia, less often pure viral pneumonia. These may be concurrent with initial viral infection or follow after an interval. Staphylococcal pneumonia is a serious sequel and may be fatal, less severe infections may result in lung abscess.
2. *Nervous system* – Post-influenzal psychoses, insomnia, irritability, polyneuritis, neurasthenia, meningitis and haemorrhagic encephalitis.
3. *Circulatory system* – Cardiac dilatation, irregularities, pericarditis, endocarditis.
4. *Suppuration* – Otitis media, mastoiditis, sinusitis.
5. *Miscellaneous* – Thrombophlebitis, arthritis, orchitis, myositis, nephritis, intestinal hemorrhage.

Management

1. *Analgesics and sedatives.*
2. *Cough suppressive such as codeine.*
3. *Antibiotics* for secondary infections such as otitis media and pneumonia.
4. *Antiviral drug* – Neuraminidase inhibitors – act on viral neuraminidase, and prevent release of virus particles from infected cells and can be given po or by inhalation (see later).

Prevention – (a) *Vaccines* – Haemophilus influenzae type B conjugate vaccine 1 mL subcut; or 0.1–0.2 mL intradermally given 1–2 weeks apart gives moderate temporary protection against current strains. (b) *Anti-viral agents* – Ribavirin 100–200 mg is effective as vaccination against Influenza A strains and may be started at the same time as vaccination to provide protection until immunity develops.

AVIAN INFLUENZA

Since over last 10 years, there have been regular outbreaks of avian influenza, with H5N1 virus being detected in poultry.

Avian influenza subtypes: Avian influenzae virus are subtypes of type A influenza viruses, and there are multiple varieties of avian influenza. These can be divided into low pathogenic (H5, H7 or H9) and high pathogenic forms (H5 and H7). Infection by low pathogenic viruses may be asymptomatic and/or cause minor symptoms such as decreased egg production and ruffled feathers. Low pathogenic forms can cause disease in humans. H7 infections infrequently cause conjunctivitis and/or upper respiratory symptoms. However, infection by high pathogenic viruses may infect multiple internal organs.

Virulence of avian influenza: Possible mutations in the H5N1 virus raise the possibility of a human pandemic. As with all influenza viruses, there have been numerous changes in the H5N1 genome.

Transmission of avian influenza in humans: The main route of transmission of influenza virus is via inhalation of infected respiratory droplets from coughing and sneezing. Because humans are rarely exposed to avian influenza virus, there is minimum immunity to these particular viruses.

Symptoms vary from the typical 'flu' symptoms of fever, sore throat, cough and muscle ache, to much more severe symptoms including eye infections, pneumonia, acute respiratory distress and potentially fatal complications such as multiorgan failure. Majority of morbidity and mortality has been in healthy children and young adults as compared to seasonal influenza viruses which produce more severe symptoms in the elderly and immunocompromised.

Diagnosis: (a) A laboratory test termed. Influenza A/H5 (Asian lineage) virus Real-time RT-PCR Prime and Probe set can provide preliminary results on suspected H5 influenza samples within 4 hours of testing. (b) Isolation of virus.

Treatment: Two drugs Zanamivir and Oseltamivir are neuraminidase inhibitors which block the action of neuraminidase which normally breaks the bonds attaching new influenza viruses to the exterior of an infected cell. The viral particles cannot detach from the infected cell thus limiting the extent of the infection.

Oseltamivir can be used in individuals over 1 year of age who have symptoms for less than 2 days. **Dosage:** Adults - 75 mg bd orally for 7 days and in children dose according to body weight. To be started within 2 days of onset of symptoms. Common side effects are nausea and vomiting.

Zanamivir is approved for treatment of uncomplicated influenza virus infection in patients over the age of 7 years who have symptoms for less than 2 days. **Dose:** Two inhalations bd for 5 days. It is not recommended for chronic respiratory diseases such as asthma or COPD, because it can cause breathing problems. It may also cause headache and diarrhoea.

Vaccine. Influenza vaccine (human live attenuated) Pandemic (H1N1).

Respiratory syncytial virus - RSV is non-segmented enveloped RNA virus. It is best known as a cause of bronchiolitis in infants, but can cause respiratory tract infection in all age groups.

Transmission - is primarily through large aerosol droplets or secretions. This leads to widespread nosocomial infection.

Clinical features - Severity of RSV infection is related to age. In young infants early signs may include difficulty in feeding, nasal congestion, cough and otitis media compatible with URTI. Fever is often present.

Abnormal breath sounds, tachypnoea and hypoxemia suggest lower respiratory tract involvement. Bronchiolitis and pneumonia are the two primary manifestations of progression to LRTI; they may be difficult to distinguish and can occur simultaneously. Clinical features of bronchiolitis are wheezing and hyperaeration.

Older children and adults with RSV infection have a milder respiratory infection with a lower likelihood of LRTI. Disease in the elderly may be particularly severe, up to 50% develop pneumonia.

Investigations - (a) *Chest radiography* findings are nonspecific, and commonly include hyperaeration and peribronchial thickening, with areas of consolidation and interstitial infiltrates in patients with pneumonia. (b) *Laboratory diagnosis* depends on detection of viral antigen in respiratory secretions by immunofluorescence, rapid antigen tests or culture of the virus.

Management - Supportive care - Maintenance of oxygenation, nutrition and hydration. Ventilatory support in severe cases. Bronchodilators may be beneficial. Antiviral like ribavirin is used for those who are immunocompromised or severely ill.

No benefit has been found in the treatment of HRSV pneumonia with standard immunoglobulin; immunoglobulin with high titers of antibody to HRSV (RSVlg), which is no longer available; or chimeric mouse-human monoclonal IgG antibody to HRSV (palivizumab).

- Prophylaxis in infants <2 years receiving O₂ therapy for bronchopulmonary dysplasia
- Infants born <32 weeks with bronchopulmonary dysplasia are likely to benefit from 6-12 months prophylaxis

- Should not be used in cyanotic congenital heart disease
- Initiate treatment before RSV season
- Defer live virus vaccine (e.g. MMR) until after last dose.

H1N1 INFLUENZA

H1N1 virus Influenza results from one of the three basic types of influenza virus namely A, B or C, which are classified within the family Orthomyxoviridae. These are structurally and biologically single-stranded RNA viruses which vary antigenically. A distinctive feature of influenza viruses is that mutations occur frequently and unpredictably in the eight gene segments and especially in the haemagglutinin gene. The emergence of an inherently virulent virus during the course of a pandemic can never be ruled out.

H1N1 influenza (also called swine flu, hog flu and pig flu) caused by swine influenza virus (SIV), that usually infects pigs and is endemic in pigs.

Significant surface proteins of the virus include haemagglutinin and neuraminidase based on which the viruses are typed. These proteins determine the immunogenicity.

Transmission – Infection occurs after transfer of respiratory secretions from an infected individual to an immunologically susceptible individual. If the virus is not neutralised by secretory antibodies, it invades airways and respiratory tract cells. Once it enters the host cells, it leads to cellular dysfunction and degeneration, along with viral replication and release of viral progeny.

Communicability of the virus – A patient is infectious to others from 1 day before to 7 days after onset of symptoms. If infection persists for more than 7 days, chances of communicability may persist till resolution of illness. Children are likely to spread the virus for longer period.

Clinical features – After an incubation period of 18–72 hours, systemic symptoms ensue. Abrupt onset with varying degrees of fever. Sore throat may be severe, may be associated with rhinitis. Myalgias range from mild to severe. Ocular symptoms may develop and include photophobia, burning sensation and/or pain on motion. Weakness and severe fatigue may prevent patients from normal activities. Cough and other respiratory symptoms may be initially minimal but progress as the infection evolves. Cough may be unproductive and associated with pleuritic chest pain, and dyspnoea.

Complications – (a) *Pulmonary*: Primary viral pneumonia, secondary bacterial pneumonia and exacerbation of COPD and bronchial asthma. (b) *Extrapulmonary*: Myositis, rhabdomyolysis, myoglobinuria, myocarditis and pericarditis. At times CNS complications may occur

including encephalitis, transverse myelitis and GB syndrome and Rae syndrome.

Laboratory findings – Leucopenia and relative lymphopenia are typical findings, there may be thrombocytopenia.

Specimens for viral studies viz. RTP CR and viral culture should be stored at 4°C before and during transportation within 48 hours.

Case Definitions of H1N1 Influenza

Suspected case: A person with acute febrile respiratory illness (fever 38°C) with onset within 7 days of close contact with an individual who is a confirmed case of H1N1 virus infection/or within 7 days of travel to areas where there is one or more confirmed H1N1 cases, or resides in a community where there is one or more confirmed swine flu case.

Probable case: An individual with an acute febrile respiratory illness who is positive for influenza A, but unsubtypeable for H1 and H3 by influenza RTPCR or reagents used to detect seasonal influenza virus infection, or is positive for influenza A by influenza rapid test or influenza immunofluorescence assay (IFA) plus meets criteria for a suspected case, or an individual with a clinically compatible illness who died of an unexplained acute respiratory illness who is considered to be epidemiologically linked to a probable or confirmed case.

Confirmed case: A person with an acute febrile respiratory illness with laboratory confirmed swine influenza A (H1N1) virus infection by one or more of the following tests:

- Real time PCR
- Viral culture
- Four-fold rise in H1N1 virus specific neutralizing antibodies.

For confirmation of diagnosis, clinical specimens such as nasopharyngeal swabs, nasal swab, wash or aspirate and tracheal aspirate (for intubated patients) are to be obtained. Paired blood samples at an interval of 14 days for serological testing should be collected.

Management

1. **Critical measures** – (a) Avoid crowding patients together. (b) Hand hygiene. (c) Wear personal protective equipments which include high efficiency masks (ideally N95 mask or triple layer surgical mask), gowns, goggles, gloves, cap and shoe cover. (d) If suspected swine flu, isolation of infected individuals and household contacts.

Antiviral drug therapy: The two influenza drugs are neuraminidase inhibitors.

Oseltamivir is the recommended drug for prophylaxis and treatment (Table 7). It inhibits neuraminidase which is a glycoprotein on the surface of influenza virus that destroys an infected cell's receptor for viral haemagglutinin. The drug must be administered within 48 hours of symptom onset.

Side effects – The drug is usually well tolerated. GI side effects (transient nausea, vomiting) increase with increasing doses. Occasionally it may cause bronchitis, insomnia and vertigo, rarely anaphylaxis and skin rashes. The most frequent adverse effect in children is vomiting.

Zanamivir is a sialic acid analogue that potentiates and specifically inhibits the neuraminidases of influenza A and B viruses. Inhaled zanamivir for the prevention and treatment for influenza virus infections. Early treatment with dose 10 mg bd for 5 days of febrile influenza in ambulatory adults and children aged 5 years and older shortens the time of illness resolution by 1–3 days and in adults reduces by 40% risk of lower respiratory tract complications.

Discharge policy – Adult patients should be discharged 7 days after symptoms have subsided, and children 14 days after. The family of patients discharged should be educated on personal hygiene and infection control measures at home.

Vaccines – (a) H1N1 nasal vaccine. Side effects are dryness of nose, fever and cold and changed sense of smell and taste and mild fever. (b) Injectable vaccine. The vaccine takes up to 3 weeks for antibodies to develop. Indication for prophylactic vaccination in high risk category - (i) Pregnant women because of higher risk of complications and can provide protection to infants. (ii) Household contacts and caretakers for infants < 6 months old, because of higher risk of complications. (iii) Healthcare services workers.

HERPES VIRUSES

The herpes viruses are diverse and there are major differences between members of the group; however, they have many features in common.

Characteristics of herpes viruses

- Large dsDNA genome
- Characteristic appearance on electron microscopy
- Initial infection often asymptomatic
- Establish latency, persists for life of individual
- Most reactivations are asymptomatic

Table 7: Dosage of oseltamivir

Body weight	Dose
For prophylaxis od for 10 days	
<15 kg	30 mg
15–23 kg	45 mg
23–40 kg	60 mg
>40 kg	75 mg
For treatment bd for 5 days	
<15 kg	30 mg
15–23 kg	45 mg
23–40 kg	60 mg
>40 kg	75 mg

- Reinfections also occur
- Most herpes viruses cause more than one disease
- Interfere with immune responses

Pathogenesis – Possible mechanisms for diseases caused by herpes viruses:

- Disease may result from virus replicating in cells and destroying them by lysis (e.g. chickenpox)
- An immunologically mediated disease may develop from the host immune response to herpes virus, e.g. CMV pneumonitis and erythema multiforme triggered by herpes simplex virus reactivation.
- The virus may precipitate rearrangements of host chromosomes, such that endogenous oncogenes are activated to produce a malignant phenotype (e.g. E-B virus, Burkitt's lymphoma).

Because each herpes virus has potential to interact in multiple ways with the host, each virus can cause more than one disease.

Herpes virus infections cause different clinical conditions listed in Table 8.

α-herpes Viruses

Herpes simplex virus 1 – is spread readily within families by salivary contact. Primary infection may cause stomatitis, but is usually asymptomatic. The virus establishes latency in dorsal root ganglia supplying the trigeminal nerve. Reactivation of the viral genome may be caused by ultraviolet light, stress or menstruation. Centrifugal axonal passage of virus particles may be perceived by the patient as a prodromal tingling, 24 hours before vesicular eruption on skin. HSV replicates in the skin for 1–3 days after which epithelial cells migrate from the lesion edge to repair the damage.

Table 8: Major diseases caused by herpes viruses

Virus	Children	Adults	Immunocompromised
<i>α-herpes viruses</i>			
Herpes simplex type 1	Stomatitis	Cold sores Keratitis	Dissemination
Herpes simplex type 2		Erythema multiforme Primary genital herpes	Dissemination Bed sores
Varicella zoster virus	Chickenpox Shingles (in elderly)	Recurrent herpes	Dissemination
<i>β-herpes viruses</i>			
Cytomegalovirus	Congenital (mental retardation)		Pneumonitis Retinitis Enteritis Encephalitis
Human herpes virus type 6	Roseola infantum, febrile fits		Encephalitis
Human herpes virus type 7	Roseola infantum		
<i>γ-herpes viruses</i>			
Epstein-Barr virus		Infectious mononucleosis	Lymphomas
Human herpes virus type 8			Kaposi's sarcoma

In patients with eczema, scratching can introduce the virus at multiple sites causing a chickenpox-like rash termed 'eczema herpeticum'.

Herpes simplex virus 2 – is the main cause of genital herpes.

β-herpes Viruses

Cytomegalovirus – Congenital CMV can cause mental retardation and hearing loss. In the immunocompromised CMV causes systemic infection, with high mortality from pneumonitis and high morbidity from retinitis and enteritis.

γ-herpes Viruses

Epstein-Barr virus – Infection is usually acquired asymptotically during childhood. If primary infection is delayed until adolescence, it may be accompanied by infectious mononucleosis.

Infectious mononucleosis ('glandular fever') is an acute, self-limiting febrile illness caused by primary EBV infection (Table 9).

Mode of transmission – Virus particles are present in pharynx and saliva during acute stage, and transmission

Table 9: Causes of acute infectious mononucleosis syndromes

• Epstein-Barr virus
• Influenza A and B viruses
• Cytomegalovirus
• Human herpes virus 6
• Rubella virus
• HIV
• Coxiella burnetti
• Adenovirus
• Hepatitis A virus

occurs by close contact, e.g. kissing, sharing eating utensils, can be transmitted by blood transfusion.

Incubation period – 30–45 days.

Clinical Features

Pharyngitis is usually diffuse. An exudate is present in about 1/3 of cases. Palatal petechiae may occur.

Fever – Temperature may be high and may last 1–2 weeks.

Lymphadenopathy usually occupies the anterior and posterior cervical chains and may be diffuse.

Prodromal symptoms include malaise, anorexia, fatigue, headache and fever, all of which persist through the acute phase of illness.

Symptoms of EBV-IM usually peak 7 days after their onset and dissipate over the next 1 to 3 weeks.

Splenic enlargement is common.

Less common clinical features include upper airway obstruction, abdominal pain, hepatomegaly, jaundice, and eye lid oedema. Rash occurs in about 5% and may be macular, petechial, scarlatiniform, urticarial or erythema multiforme. A pruritic maculopapular rash develops in majority of patients who receive ampicillin, 7 to 10 days after administration. Frequency of jaundice varies with age.

Investigations

1. **Haematology** - WBC count usually increased. Absolute ($> 4 \times 10^9$ litre) and relative ($> 50\%$ of total WBC), increase in mononuclear cells of which up to 20% are atypical lymphocytes.

2. **Serology**

Nonspecific heterophile antibodies - Patients with primary EBV infection develop IgM antibodies that bind antigens on RBCs of other species, particularly sheep and horses, but not guineapig kidney cells. Heterophile antibodies also occur in normal sera and in some patients with lymphoma, but these normally also bind to guinea pig kidney cells. These differences form the basis of tests for heterophile antibodies:

- Paul-Bunnell test* - measures agglutination of sheep RBCs by patient's serum.
- Modified Paul-Bunnell-Davidson test* - The serum is pre-absorbed with guinea pig kidney cells.
- Monospot test* - measures agglutination of formalinized horse RBCs after absorption with guinea pig kidney cells.

Interpretation - Heterophile antibodies are present in 40% of patients during first week of illness, sixty percent by 2nd week and 80% by 3rd week; a negative monospot test hence does not exclude diagnosis of IM. After classical IM, heterophile antibodies usually persist for 3-6 months, and at times up to one year.

Specific antibody responses - Patients also develop specific antibodies against - (a) Viral capsid antigen. Anti-VCA IgM is specific indicator of acute infection. Anti-VCA IgG is usually present at presentation and persists for life. (b) EBV early antigens (EA). (c) EBV nuclear antigens (EBNA). These tests may be helpful in difficult cases.

3. **Biochemistry** - Mild derangement of LFTs.

Complications

- Autoimmune hemolytic anaemia** - rare. Spontaneous resolution. Rarely thrombocytopenia with bleeding. Splenic rupture.
- Neurological** - Encephalitis with predominant cerebellar features, viral meningitis, Guillain-Barre syndrome, Bell's palsy, transverse myelitis.
- Other complications** - Cardiac - Nonspecific ECG changes, pericarditis.

Management - is mainly symptomatic. Initial period of bed rest for 2-3 weeks. Gargles with soluble aspirin helpful for relieving sore throat. Antibiotics such as erythromycin if secondary infection. Ampicillin should be avoided as it produces a rash. Corticosteroids if severe pharyngitis, airway obstruction, severe thrombocytopenic purpura or acute hemolytic anaemia, and polyneuritis. Infusions of EBV-specific cytotoxic T cells have been used to prevent EBV lymphoproliferative disease in high-risk settings as well as to treat the disease. Interferon α administration, cytotoxic chemotherapy and radiation therapy (especially for CNS lesions) also have been used.

Burkitt's lymphoma - In Africa, EBV cause Burkitt's lymphoma in children in patients with HIV infection, which is immunosuppressive and provides a mitogenic signal to the B cells harbouring EBV. It also causes lymphoma in immunocompromised patients, and is implicated in Hodgkin's disease and other sporadic lymphomas.

Antiviral Agents

Antiherpes treatment is summarized in Table 10.

ACYCLOVIR - is effective and without significant side-effects. The specificity is because the phosphorylation required for its activation occurs only in cells infected with herpes viruses. In case of HSV and VZV, the viral thymidine kinase enzyme phosphorylates acyclovir. Acyclovir monophosphate is further phosphorylated to the triphosphate by cellular enzymes; the triphosphate becomes incorporated into the growing DNA chain and acts as an obligate chain terminator so inhibiting the DNA polymerase of all herpes viruses. It also inhibits the enzyme directly.

GANCICLOVIR AND PENCICLOVIR - are activated in a similar manner but have adverse effects. Ganciclovir can cause significant bone marrow depression and is only advised for life or sight threatening CMV infections. Penciclovir is well tolerated clinically.

Table 10: Recommendations for antiherpes drugs

		First-line	Alternative
Herpes simplex virus	Immunocompromised	IV acyclovir	
	Encephalitis	IV acyclovir	
	Initial genital	Oral acyclovir	Famciclovir
	Recurrent genital	Oral acyclovir	Famciclovir
	Prophylaxis genital	Valaciclovir	Oral acyclovir
Varicella zoster virus	Immunocompromised	IV acyclovir	Oral acyclovir
	Chickenpox	IV acyclovir	Valaciclovir
	Zoster		
	Ophthalmic	Valaciclovir	Famciclovir
	Elsewhere	Valaciclovir	
Cytomegalovirus	Immunocompromised		Oral acyclovir
	Prophylaxis		
	Bone marrow transplant	Valaciclovir	
	Liver transplant	Oral ganciclovir	
	Kidney transplant	Valaciclovir	
	Retinitis in AIDS	IV foscarnet	IV ganciclovir
	Neonate with CMV inclusion disease with CNS involvement	IV ganciclovir	

PRODRUGS – The bioavailability of the above compounds can be improved by use of prodrugs. Famciclovir is the prodrug of penciclovir and valaciclovir of acyclovir. After activation by virus thymidine kinase, penciclovir persists intracellularly for significantly longer than acyclovir, yet the latter is more potent inhibitor of DNA polymerase.

FOSCARNET – is used i.v. for cytomegalovirus retinitis and induction therapy for mucocutaneous HSV unresponsive to acyclovir. Side effects are renal impairment and anaemia.

PURINE ANALOGUES – *Ribavirin* inhibits DNA and RNA viruses, and is active against influenza, respiratory syncytial, herpes simplex. It can inhibit hepatitis B replication in chronic hepatitis B carriers. Aerosol form is indicated for RSV bronchiolitis or pneumonia, severe influenza and among immunocompromised for parainfluenza and measles. IV formulation has been used in Lassa fever, and haemorrhagic fever with renal syndrome due to Hantaan virus.

TRICYCLIC AMINES – *Rimantadine* and *Amantadine* inhibit influenza A virus. They are not recommended for children below 10 years. They can also be used for herpes zoster.

VIRAL MENINGITIS

Etiological agents of viral meningitis are listed in Table 11.

Clinical features: of viral meningitis.

Table 11: Causes of viral meningitis

• Mumps
• Enteroviruses (most important)
Poliovirus types 1, 2 and 3
Coxsackie virus type A
Coxsackie virus type B
• Echovirus
• Others
Enterovirus 71 (hand, foot and mouth disease)
Enterovirus 70 (epidemic conjunctivitis)
• Genital herpes simplex virus types 1 and 2
• Other herpes viruses
Cytomegalovirus
Epstein-Barr virus
Varicella-Zoster virus
• HIV
• Lymphocytic choriomeningitis virus
• Adenovirus types 3 and 7
• Arboviruses

Acute onset of fever, headache and accompanying signs of meningeal irritation. Nonspecific symptoms

include arthralgia and myalgia, sore throat, weakness and lethargy. Other symptoms and signs are specific for the causative agent.

Transmission – usually by droplet infection, close personal contact or faeco-oral contact.

Enteroviruses – comprise 70 serotypes, including polio virus, Coxsackievirus A and B, and echovirus. Most infections are asymptomatic. A rash may occur, erythematous and maculopapular, vesicular on palms, soles and feet and inside the mouth (as in hand, foot and mouth disease) or an exanthema in the oral cavity. Enterovirus serotype 71 can also induce acute flaccid paralysis identical to that caused by poliovirus.

HSV and Varicella-Zoster virus – Primary genital HSV infection can be associated with meningitis. A syndrome of benign recurrent aseptic meningitis has been shown to be caused by reactivation of genitally acquired HSV infection, most commonly HSV-2. This syndrome occurs predominantly in women. Average number of episodes is four. Headache may be associated with genital recurrence. Recurrence of VZV usually presents as shingles, but can also present as meningitis without a cutaneous component.

Mumps virus – Mumps meningitis occurs about 7–10 days after onset of parotitis. However the epidemiology has changed considerably after introduction of MMR vaccine.

Rotavirus. Rotaviruses are members of the family Reoviridae. Human illness is caused primarily by group A.

Pathogenesis. Rotaviruses infect and in the end destroy mature enterocytes in the villous epithelium of the proximal small intestine which together with proliferation of secretory crypt cells leads to secretory diarrhoea.

Cl. Fs.: GI – After incubation period of 1–3 days there is abrupt onset of vomiting followed by watery diarrhoea, fever. The symptoms subside within a week. In severely immunodeficient children or individuals after bone marrow transplant, there can be protracted diarrhoea with protracted viral excretion, and rarely can disseminate systemically.

Diagnosis can be confirmed by EIAs or by detecting viral RNA by gel electrophoresis, probe hybridization, or PCR.

Tr. is supportive with IV fluids.

Vaccine – Bovine-human reassortant vaccine containing serotypes G1, G2, G3, G4 and G9.

HIV – Headache occurs in about 50% of patients during primary HIV infection, and meningism is not uncommon. Higher HIV RNA levels correlate with neurological symptoms.

Table 12: Causes of viral encephalitis

Worldwide distribution

- Herpes simplex virus
- E-B virus
- Cytomegalovirus
- Varicella-Zoster virus
- Human herpes virus 6
- Non-polio enteroviruses
- Mumps virus
- Rabies virus

Geographically limited

- Western equine virus
- Eastern equine virus
- California encephalitis
- St. Louis encephalitis
- Japanese encephalitis
- Tick-borne encephalitis

VIRAL ENCEPHALITIS

Viral encephalitis is infection of brain parenchyma. It is also an uncommon outcome of many viral infections. Mortality is high, and there is long-term morbidity in many survivors. Infection can occur at any time from neonatal period to old age (Table 12).

Pathogenesis of infection – Viruses may reach CNS by:

Haematogenous route – used by arthropod-borne viruses, after injection into capillary blood by a tick or mosquito bite. Local replication in the surrounding skin is followed by primary viraemia. A secondary bout of multiplication produces secondary viraemia, which, if of sufficient magnitude, can cross the blood-brain barrier via infected WBCs or locally in vascular endothelia.

Neuronal route of entry – Examples are rabies and HSV which are transported directly into the brain by retrograde axoplasmic flow. This is a viral immune evasion mechanism – once inside the axon, the virus is invulnerable to immune control.

CLINICAL FEATURES – Onset is commonly acute, with fever, and headache. Because of injury to the brain, there are disturbances of higher mental function – confusion, delirium, behaviour changes, dysphasia/aphasia, temporal lobe seizures, focal neurological signs proceeding to coma. These distinguish viral encephalitis from meningitis, in which there is no nervous involvement.

Herpes simplex encephalitis – About two-thirds of cases are caused by virus reactivation; the remaining are caused by primary infection of the neonatal period (when HSV infection occurs during labour) or in childhood.

The virus accesses CNS via olfactory ganglia, but there is evidence for direct reactivation of latent virus within the brain. HSV has a particular affinity for the temporal lobe and, because it is cytolytic, considerable destruction of nervous tissue occurs. The site of replication is then reflected in the symptoms – temporal lobe seizures, speech disorders, personality changes and altered behaviour.

Infection in the immunocompromised – A slightly different (mostly latent) virus is responsible for encephalitis. CMV and VZV may lead to encephalitis and granulomatous arteritis with spinal cord myelopathy caused by CMV in HIV-infected patients. Such patients also suffer from replication of E-B virus and JC virus, leading to primary CNS lymphoma and progressive multifocal leucoencephalopathy respectively.

Diagnosis

CT – of head prior to LP to exclude space-occupying lesions and to reveal radiographic evidence of raised intracranial pressure. This is particularly important when herpes simplex encephalitis is suspected.

CSF – Typical findings in viral meningitis and encephalitis are pleocytosis, mildly elevated protein (0.5–1 g/L) and normal CSF: blood glucose ratio, and with predominant lymphocytes.

PCR analysis – can detect non-culturable enterovirus serotypes and results are available rapidly. In multiplex PCR analysis, as many as six different viruses may be tested for simultaneously.

Management

Viral meningitis – Prognosis is good in most cases. Treatment is supportive and includes adequate analgesia. Serious complications include unilateral deafness after mumps meningitis, chronic enterovirus meningitis in patients with agammaglobulinaemia, and hydrocephalus after intrauterine infection with lymphocytic choriomeningitis virus. Acyclovir for meningitis associated with primary genital herpes.

Herpes simplex encephalitis – Treatment should be started immediately after the diagnosis is suspected. Acyclovir 10–15 mg/kg i.v. t.d.s. Relapse occurs in up to 5% patients, requiring continuation of treatment for at least 10–14 days.

PARVOVIRUS B19

Epidemiology – Common between 5–15 years. One attack confers life-long immunity. Parvovirus B19 is not as infectious as varicella, but school outbreaks are not uncommon. Spread is by respiratory droplet.

Clinical features – Mild febrile illness with coryza followed by a lacy, reticular rash with widespread arthralgia 7–10 days later. Arthralgia, often without a rash, is the most common presenting symptom in adults, particularly women. In children the rash is most prominent on the face (slapped cheek syndrome - erythema infectiosum). Arthralgia generally persists for a few weeks.

Special syndromes – The virus has the ability to replicate in erythroid progenitor cells in the bone marrow; this underlines three important clinical syndromes:

Polyarthropathy Syndrome: Although uncommon among children, arthropathy occurs in 50% of adults and is more common among women than among men. The distribution of the affected joints is often symmetrical with arthralgia affecting the small joints of the hands and occasionally the ankles, knees and wrists.

Aplastic crises – In patients with reduced RBC survival (e.g. sickle cell disease, thalassemia, hereditary spherocytosis), a catastrophic decrease in haemoglobin occurs during acute B19 infection.

Transfusion-dependent anaemia – is seen in immunocompromised patients (e.g. bone marrow and solid organ transplantation, HIV infection). These patients require treatment with i.v. immunoglobulin, often over several weeks, because they are unable to mount a neutralizing antibody reaction to clear virus from bone marrow.

Pregnancy – B19 infection leads to miscarriage in 10% of cases, and there is additional 3% risk of foetal hydrops, though only when maternal infection occurs in first 20 weeks of gestation.

Diagnosis – relies on serology and virus detection using molecular methods. Virus-specific IgM is detectable from onset of rash/arthralgia, and persists for 2–3 months. In foetal hydrops and transfusion-dependent anaemia, detection of virus by DNA hybridization assays is preferable.

ADENOVIRUS INFECTIONS

Epidemiology – Adenoviruses are DNA viruses. There are 40 different adenovirus serotypes classified into six groups (A–F). Group C serotypes 1, 2 and 5 are primarily associated with respiratory disease. Transmission occurs via aerosol particles, faeco-oral route or contaminated fomites.

Clinical features – vary with age and presence of immune dysfunction (Table 13).

Investigations

Viral culture is the most sensitive method. The virus may be cultured from throat, nasopharynx, conjunctiva, sputum, urine, stool, CSF, blood or tissue specimens.

ELISA – is not as sensitive as viral culture but more rapid.

Histopathology – Presence of characteristic internuclear inclusions in tissue sections. When these enlarge and obscure the nuclear membrane, the cells are termed ‘smudge’ cells.

Serology – A fourfold increase in titre between paired sera is needed to confirm recent infection.

Management: Most adenoviral diseases are self-limiting and treatment is supportive. Bacterial superinfection may occur.

4. ACUTE CHILDHOOD EXANTHEMAS

MEASLES

Epidemiology

Age – mostly children between ages of 3 and 5 years, rare during first 6 months of life because of transferred passive immunity from mother. *Causative agent* – RNA paramyxovirus group. *Transmission* – Highly infectious and spread by direct contact or droplet infection. Patients suffering from measles shed virus from their respiratory tract during the prodromal period and for 24–48 hours after the rash appears. *Immunity* – Immune response is not fully competent in early infancy; intercurrent infection or malnutrition further reduce these responses, increasing severity of the disease. Transplacental maternal IgG provides protection during the first 3–6 months of life.

Incubation period – 8–10 days.

Period of infectivity – From onset of prodromal period to 4 days after appearance of rash.

Clinical Features

Illness of infection – Febrile catarrhal attack with fleeting rash in a few hours after exposure to measles.

Prodromal stage – usually 4–5 days.

- *Fever* – Abrupt rise of temperature to about 40°C (102°F).
- *Catarrh* – Coryza, conjunctivitis, photophobia and hacking cough.

Table 13: Adenovirus infections in various groups

Infants	<ul style="list-style-type: none"> • Pharyngitis, coryza, pneumonia • Otitis media • Diarrhoea
Children	<ul style="list-style-type: none"> • Upper resp. disease, pneumonia • Pharyngoconjunctival fever • Diarrhoea, mesenteric adenitis • Haemorrhagic cystitis
Young adults	<ul style="list-style-type: none"> • Acute respiratory disease
Adults	<ul style="list-style-type: none"> • Epidemic keratoconjunctivitis
Immunocompromised patients	<ul style="list-style-type: none"> • Pneumonia • Gastroenteritis • Hepatitis • Meningoencephalitis

- *Koplik's spots* (Enanthema) pathognomonic. Appear on 2nd day as minute pin-point bluish white specks with slight reddish mottled areola around them, on buccal mucosa usually opposite lower molars. They look like grains of salt. Variable in number. Occasionally large spots, few in number. The spots begin to fade with appearance of rash. Red blotches may be seen on soft palate. Koplik's spots may sometimes occur in the lower lip in front of the lower incisors, and in severe cases the palate and rest of the mucosa are peppered with these spots.
- *Laryngeal involvement* – Hoarseness and laryngeal stridor.
- *GI* – Persistent vomiting and diarrhoea.
- *Fleeting rashes* – either urticarial or erythematous.

Exanthematous stage – (a) *Rash* – On 5th day, red macules appear first behind ear, along hair line and on posterior parts of cheeks and spread rapidly in a few hours all over the body. Macules appear in crops which by confluence form blotches with crescentic or thumb nail edge. Fully erupted rash deepens in colour, petechiae may occur. In severe measles the rash is confluent, the face is swollen and disfigured and together with the photophobic eyes creates the typical measly appearance. (b) *Mucous membrane involvement* – includes conjunctivitis, rhinitis, stomatitis, laryngitis, tracheitis and bronchitis. There may also be gastroenteritis.

Stage of defervescence – Temperature falls by crisis or rapid lysis in 24 to 48 hours. Rash fades from face

downwards in same sequence as its appearance, and leaves brown staining often followed by branny desquamation. The more severe the measles, greater the extent of desquamation. At times the normal rash of measles instead of fading becomes a deep purple (purpuric measles) and this may persist for a week or two.

Varieties

1. *Modified measles* – In measles modified by gamma globulin or measles vaccine all symptoms and signs may be suppressed except the rash in the form of discrete macules scattered over the trunk.
2. *Measles in adults* – Constitutional symptoms may be more severe but less tendency to complications.
3. *Atypical measles* – in children who have received measles vaccine. Fever with petechial rash and oedema on lower legs and dorsum of feet.
4. *Morbilli bullosi* – Severe variety in which some of the lesions become bullous. May occur in malnourished children.
5. *Haemorrhagic measles (black measles)* – Haemorrhages into skin and bleeding from any or all of the body orifices.

Complications

1. *Secondary bacterial otitis media.*
2. *Pneumonia or bronchopneumonia* – main cause of death. During the latter part of exanthematous stage, combination of measles and adenovirus infection produces most severe symptoms and prolonged course.
3. *Laryngotracheobronchitis (croup)* – due to measles virus. May give rise to stridor.
4. *Herpes simplex gingivostomatitis* – Vesicles in mouth which rapidly ulcerate causing fever, salivation and difficulty in feeds. Disseminated herpes is rare.
5. *Acute post-infective encephalitis* – is the most common neurological complication. Headache, confusion, coma and convulsions result from autoimmune demyelination.
6. *Hepatitis* – usually in young adults with severe disease. Frank jaundice may occur. May be giant cells in the liver. Spontaneous resolution.
7. *Blindness* – In patients with protein energy malnutrition, combination of vitamin A deficiency and herpes simplex virus infection of the cornea may cause blindness.
8. Late complications – (a) Bronchiectasis. (b) Immunosuppressive measles encephalopathy – 1-6 months after an attack of mild or atypical measles in children

receiving cytotoxic drug therapy. Neurological damage is severe. (c) Subacute sclerosing panencephalitis (SSPE) – It occurs about 3-12 years after infection, with altered behaviour and personality, intellectual decline, seizures and motor disturbances. Interferons promote viral maturation and may be used to slow clinical progression of SSPE. (d) Measles inclusion body encephalitis (MIBE) is a rare but fatal complication that affects individuals with effective cellular immunity and typically occurs months after infection.

Post-measles state – results from powerful immunosuppressive effect which alters immunity and the tissue-destructive effect of measles.

Clinical features – Gradual deterioration into chronic illness. (a) Growth retardation and diarrhoea – often with anorexia. May precipitate protein-energy-malnutrition. (b) Gingivostomatitis – with oral herpes, persistent pyrexia, worsening pneumonia, increasing hepatomegaly and encephalopathy. (c) Corneal ulcers mainly in malnourished children. (d) Other uncommon complications – Gangrene of tips of fingers and toes, cancrum oris, septicaemia, candidosis, reactivation of pulmonary tuberculosis, possibly abortion or prematurity if infection occurs during pregnancy.

Diagnosis – Precise diagnosis can be achieved by using antigen detection in the saliva (enzyme-linked immunosorbent assay), immunofluorescence for antigen in bronchoalveolar lavage specimens, traditional paired serology and presence of IgG antibodies in the CSF if suspected in subacute sclerosing panencephalitis (SSPE).

Differential Diagnosis

PRE-Exanthematous stage – Common cold, influenza, catarrhal stage of whooping cough.

Exanthematous stage

1. *Rubella* – No Koplik's spots, small shotty enlargement of suboccipital, posterior cervical and post-auricular lymph nodes; catarrhal symptoms and systemic disturbances slight. In measles, mucous membrane is infected and dirty, in rubella it is pale and clean.
2. *Drug eruption* – especially that caused by ampicillin. Tends to persist longer and may have an urticarial element. Absence of catarrh and failure of rash to evolve from above downwards.
3. *Serum rashes* – Rash dense at site of injection, typical wheals.
4. *Infectious mononucleosis* – Fever, adenopathy and sore throat. Maculopapular rash, splenomegaly. Atypical lymphocytes in blood smear.

5. *Erythema infectiosum* - Rash but usually no constitutional symptoms. Rash appears in three phases. It begins with livid erythema of the cheeks (slapped cheeks), followed by maculopapular rash on extremities and trunk, and as the rash fades it has a lacy reticular appearance.
6. *Roseola infantum* (Exanthema subitum) - Acute viral disease of young children. three to four days of high fever. As fever falls by crisis, a pleomorphic, macular, erythematous rash appears on face and trunk and fades in 1-3 days.
7. *Erythema multiforme* - Circular or irregular erythematous blotches usually occurring on backs of hands and forearms. Constitutional symptoms may be present.
8. *Other exanthemas* - (a) Coxsackie virus A. Hand-foot-and-mouth disease is the most specific syndrome. After a short prodrome of malaise, anorexia and fever, a vesicular exanthem develops involving buccal mucosa. A vesicular exanthem also appears on hands and feet in many patients. (b) Other viral infections - Adenovirus, parainfluenza virus, respiratory syncytial virus may occasionally be associated with macular or maculopapular rashes.
9. *Paratyphoid* - Sometimes profuse pinkish brown maculopapules. Longer prodromal illness, characteristic temperature chart, agglutination test positive.
10. *Typhus* - Early prostration; mental symptoms; rash bright red, subcuticular mottling, no well-defined edges, not marked on face. Eschar.
11. *Scarlet fever* - Short prodromal period, sore throat, anterior cervical adenitis, scarlet rash, circumoral pallor and punctuate haemorrhages. Skin folds in groin, neck, axillae and knees become dark red (Pastia's lines). Circumoral pallor is common and skin often has a fine sandpaper texture. Strawberry tongue.
12. *Kawasaki disease* - Fever, conjunctival congestion, erythema of lips, buccal mucous membrane and tongue. Acute cervical lymphadenopathy, polymorphic exanthema, erythema of palms and soles.

Management

Frequent fluid intake. Paracetamol for fever. Irrigation of eyes with boric lotion. Cough linctus to suppress the dry cough. Antibiotics such as amoxicillin if complications such as otitis media or pneumonia. Should be given prophylactically to 'poor-risk' children. Vitamin A 200,000 IU orally for 2 days, will prevent ocular complications and reduce respiratory infections and measles-related mortality.

Antiviral treatment (ribavirin) for viral pneumonitis. Acyclovir may be used to treat secondary herpetic infection. Antifungal therapy (e.g. fluconazole) for oral and intestinal candidosis (anaphylactic egg-protein hypersensitivity).

Prevention

- (a) ACTIVE IMMUNIZATION - (i) Single dose of attenuated live-virus vaccine for all children at the beginning of second year of life. *Contraindications* - Personal history of convulsions, intercurrent illness or recent exposure to other infectious disease, those receiving corticosteroids, or other immunosuppressive agents, leukaemia, tuberculosis, and in any stage of pregnancy. *Untoward effects* - Febrile reaction after one week, sometimes rash. Rarely convulsions and very rarely encephalitis. (ii) Inhalation of measles vaccine aerosol, it takes the pathway taken by the viral antigen to enter the body thereby inducing a strong immune response.
- (b) Passive immunization - with immunoglobulin is useful in debilitated patients in contact of measles patients followed in 3 months by vaccine. Dose 0.25 mL/kg IM. It should be given within 6 days of exposure.

RUBELLA (GERMAN MEASLES)

Rubella is an exanthema caused by a RNA virus of the togavirus family.

Transmission - Droplet inhalation from an infected person. Neonates with congenital infection are prominent shedders of the virus, which may be found, often as long as 6 months.

Incubation period - 14-21 days.

Period of infectivity - from 7 days before to 2 weeks after onset.

Clinical Features

Exanthem - Rash occurs more often in older children and adults on first or second day of illness, first on face and behind the ears, and then spreads downwards to trunk and limbs. The rash is variable but commonly starts as discrete, pink, punctate, erythematous, perifollicular macules that rapidly become confluent. Alternatively, there may be blotchy pink rash or confluent blush. The rash seldom persists for more than 4 days and is not followed by staining or desquamation. Rubella without rash is common in young children. In a dark-skinned patient all that may be seen is prominence of hair follicles giving a goose-pimpled appearance.

Arthralgia is common and occasionally arthritis. Distribution is usually symmetrical polysynovitis involving the small joints of hands, knees, hips and intervertebral joints, which occasionally may not remit promptly.

Lymphadenopathy – Slight enlargement of lymph nodes, particularly of suboccipital and posterior auricular groups.

Buccal mucous membranes – are inflamed, with blotchy erythema and prominent follicles on soft palate, (Forschheimer spots) accompanied by mild conjunctivitis and coryza.

Complications – are common and include encephalitis, G-B syndrome, thrombocytopenia and hepatitis.

Treatment – Bed rest and analgesics suffice for the uncomplicated attack. Rubella proven by antibody estimation in first 4 months of pregnancy is a strong indication for termination.

Strategies for Immunization

1. Combined MMR vaccine is given routinely to all children in the second year of life, with a booster in the second decade.
2. All women are screened when they reach childbearing age and are immunized with monovalent rubella vaccine, if non-immune. It is necessary to maintain adequate contraceptive measures for 3 months.
3. Routine screening and immunization are undertaken in the immediate postnatal period. Immunized mothers excrete the vaccine virus in breast milk for up to 1 month; this is not a contraindication to vaccination or breastfeeding.

Adverse reactions – to vaccine are limited and include transient arthralgia, and egg and neomycin hypersensitive reactions.

Congenital rubella syndrome – occurs when the foetus is infected during maternal viraemia (virus can be isolated from 90% of foetuses in infected pregnancies). The virus gains widespread access to foetal tissues, causing cytopathic effects or promoting immune response.

Defects – The consequences of rubella in pregnancy are varied and unpredictable, ranging from foetal death to birth of an infected but otherwise normal child.

1. TEMPORARY DEFECT – if cytopathic damage to non-organ tissue: (a) *Thrombocytopenic purpura* – at birth or shortly after. (b) *Hepatosplenomegaly*. (c) *Hepatitis*. (d) *Low birth weight*.
2. PERMANENT – when there is cytopathic effect in early organogenesis. (Triad of Gregg).

- Cataracts and retinopathy.
- Microcephaly.
- Congenital heart defects (PDA with or without PS most common).

LATE CONGENITAL RUBELLA. In some infants, particularly those infected after the first trimester, there is no obvious congenital defect, but the infant sheds the virus. In this group, late congenital rubella features include:

- Quadriparesis
- Growth retardation
- Behaviour disorders
- Psychiatric manifestations
- High-tone deafness
- Insulin-dependent diabetes mellitus

PROCEDURES TO BE ADOPTED IN A PREGNANT WOMAN

- (a) *Suspicion of having rubella* – Accurate diagnosis should be established by serological tests. If IgM is positive, explain the degree of risk to the patient and decide about termination of pregnancy.
- (b) *Suspicion of having been in contact with rubella* – (i) If possible, confirm the diagnosis by serological studies on the original case. (ii) If contact is close and the pregnant woman has decided to continue with pregnancy give 1500 mg of immunoglobulin IM as soon as primary sample of serum is obtained. If there is no detectable antibody, give further 1500 mg immunoglobulin within 72 hours, it reduces but does not eliminate the risk of rubella. (iii) If she does not want to continue with pregnancy, or if the contact is not close, do not give immunoglobulin. (iv) In either case, take a second sample of blood after 3–4 weeks to see if there has been sero-conversion. The risk to the foetus when the mother has a subclinical attack is not known with certainty but appears to be slight. Should the mother develop an illness with serological evidence of rubella, the risks should be explained and decision taken about termination of pregnancy.

Immunization: Rubella vaccine live attenuated.

Parvovirus infection – has already been described.

Roseola infantum (exanthema subitum)

Aetiology and pathogenesis – Causative agent human herpes virus 6 at 6–24 months of age. It is a lymphocytic virus that targets CD₄ + cells and causes a common acute febrile illness of infancy. In adults, replication and elevated antibody titres are associated with lymphoid malignancies, SLE, Kikuchi's disease, atypical pneumonia, hepatitis, glandular fever-like illness and multiple sclerosis.

Reactivation of latent infection occurs in immunocompromised patients, particularly those who have undergone organ marrow transplantation or who have AIDS.

Clinical Features

Incubation period about 2 weeks.

Onset with high fever, coryza and cervical lymphadenopathy. After 2–4 days, fever settles and is followed by a pleomorphic, macular, erythematous, blotchy rash on face and trunk. The disease is seldom severe. Most patients have fever only, but the height of fever and CNS replication are associated with febrile convulsions.

Laboratory tests – At onset, there may be neutrophil leucocytosis, but this rapidly declines, leaving relative lymphocytosis. Serology is necessary to distinguish roseola infantum from other exanthemata.

CHICKENPOX

Epidemiology

Age – Primarily children, uncommon in adults in whom the disease tends to be more severe. *Causative agent* – Virus is identical to virus of herpes zoster and hence designated varicella zoster virus (V-Z virus). *Transmission* – Droplet discharges from air passages. May be direct skin contact or by recently contaminated utensils.

Incubation period – 14 to 15 days.

Period of infectivity – Patients are infectious 48 h before onset of the vesicular rash, during the period of vesicle formation (which generally lasts 4–5 days) and until all vesicles are crusted.

Clinical Features

Stage of Invasion or Prodromata

not constant. Headache, sore throat and fever for 24 hours. Prodromal rashes – Erythematous, scarlatiniform, morbilliform or urticarial. Rarely haemorrhagic.

Stage of Eruption

1. ENANTHEM – Earliest lesions on buccal and pharyngeal mucosa.
2. EXANTHEM – (a) *Evolution* – in crops; at first back, then chest, abdomen, face, and lastly limbs. (b) *Character* – At first macule, in few hours' dark pink papule which soon turns into vesicle – (i) superficial, i.e. 'on' rather than 'in' the skin (glass pox), (ii) elliptical or oval ("tear drop" vesicles) with axis parallel to ribs, (iii) unilocular, hence collapse if pierced with a needle. Vesicles turn into pustules in 24 hours. Scabs in 2 to 5 days. (c) *Distribution* – centripetal, i.e. more on

upper arms and thighs and upper part of face, and in concavities and flexures. Less commonly lesions on genital mucous membranes, conjunctivae and cornea. (d) *Cropping* – Rash matures very quickly and most spots dry up within 48 hours of appearance. But for 2–3 days' new spots continue to appear so that on any area of the body vesicles, pustules and scabs are found side by side (Polymorphism). In immunocompromised patients both children and adults, particularly those with leukaemia have lesions (often with a haemorrhagic base) that are more numerous and take longer to heal than those of immunocompetent patients.

3. OTHER SYMPTOMS – Pruritus of varying degree. Generalized lymphadenopathy may occur and enlargement of suboccipital and posterior cervical lymph nodes from secondarily infected scalp lesions.

Unusual Forms

1. *Varicella hemorrhagica* – Haemorrhages into vesicles, skin, subconjunctiva or from intestines. The complication is not due to overwhelming toxæmia as in smallpox but due to thrombocytopenia.
2. *Varicella bullosa* – Few or many of the lesions become bullous; common in children with impetigo.
3. *Varicella gangrenosa* – due to infection with hemolytic streptococcus producing the fulminating type, or with diphtheria bacillus causing the subacute type. Necrosis of lesions with toxæmia.
4. *Congenital and Neonatal chickenpox* – Virus may pass through the placenta and the baby is born with chickenpox or develops it in neonatal period.

Complications

(a) *Bacterial infection of skin* (usually group A streptococci or Staph.aureus) causing impetigo, cellulitis and post inflammatory scarring. (b) *Other uncommon complications* – The most common extracutaneous site of involvement in children is the CNS. The syndrome of acute cerebellar ataxia and meningeal inflammation generally appears – 21 days after onset of the rash and rarely develops in the pre-eruptive phase. Others are otitis media, pneumonia, cerebellar ataxia, Reye's syndrome and aseptic meningitis. Post varicella angiopathy is a rare complication which presents as acute hemiparesis, aphasia, hemianaesthesia or other focal neurological or retinal deficits with mononuclear pleocytosis. VSV specific antibodies in CSF. Varicella encephalitis usually appears 3–7 days after onset of rash with headache, fever, seizures, coma or paraplegia. Complications tend to be more severe in adults or in immunocompromised children.

Laboratory Diagnosis

A Tzank smear, performed by scraping the base of an acute lesion and staining with Giemsa's or Papanicolaou's stain, may demonstrate multinucleated giant cells containing intranuclear inclusions. Other tests include fluorescent antibody against membrane antigen, immuno-adherence haemagglutination and enzyme-linked immunoabsorbent assay.

Differential Diagnosis

1. *Papular urticaria* - Haphazard distribution, face rarely invaded and mouth never, lesions appear in crops chiefly at night, intense itching, dietetic disturbances.
2. *Infected scabies* - Lesions never occur in mouth, face not affected except occasionally in children, identification of *Sarcoptes scabiei* from burrows.
3. *Impetigo contagiosa* - Mostly on face, mucous membranes not affected.
4. *Herpes zoster* - Unilateral distribution corresponding to nerve roots.
5. *Insect bites* - on the face, which have become septic. Central puncta.
6. *Dermatitis herpetiformis* - Erythematous papulovesicular and urticarial lesions markedly pruritic. Runs a chronic course with residual pigmentation.
7. *Rickettsial pox* - Appearance of primary lesion, influenza-like illness and generalized papulovesicular eruption.
8. *Bullous eruptions* - of bullous impetigo, pemphigus, and bullous form of erythema multiforme. Iodide or bromide or barbiturate rashes.
9. *Hand, foot and mouth disease* - Lesions involve mainly the palms, soles and oral mucosa and do not crust.

Complications

Rare in children. In adults the disease tends to be more severe and is more likely to be fulminant or complicated by pulmonary involvement.

1. *Cellulitis or impetigo* - due to secondary Strepto. or Staphylococcus infection from scratching of the lesions.
2. *Pneumonia* - (a) In children due to secondary infection. (b) Pneumonitis - due to VZ virus may complicate severe attacks, particularly in adults or in patients on long-term corticosteroid or immunosuppressive therapy. Chest X-ray shows large nodular opacities scattered throughout the lung fields.
3. *Neurological complications* - Post-varicella encephalitis more common in children than adults. Differs from other virus encephalitides because of predominance

of cerebellar signs such as ataxia, vertigo, and nystagmus. Cranial nerve palsies particularly of oculomotor and facial nerves may develop. Reye's syndrome (particularly if aspirin has been given to the child), transverse myelitis and Guillain-Barre syndrome may also occur.

4. *Thrombocytopenia* - is sometimes seen after the rash has begun to heal. Probably due to megakaryocyte infection or unmasking of latent ITP.
5. *Congenital abnormalities* - very rarely in first trimester of pregnancy in the form of scarred and atrophied limbs, microcephaly and ocular damage.
6. *In the immunocompromised child* - Varicella is often severe and the rash and high fever continue for up to 2-3 weeks. Visceral involvement causing hepatitis, pneumonitis and encephalitis is common.

Management

1. No need to confine patient to bed unless symptoms are severe. 2. For pruritus - Calamine lotion with or without phenol (0.4%) and sedative antihistaminics by mouth. If there is much scabbing, gauze soaked in 1 in 5,000 solution of potassium permanganate which is changed every 4 hours may be applied to areas most affected. 3. For secondary infection - Antibiotics. 4. For true varicella pneumonia - Oxygen. 5. For encephalitis - Oxygen and corticosteroids. 6. Paracetamol for fever. Aspirin is contraindicated because of the association with Reye's syndrome. 7. Oral acyclovir initiated within 24h of rash results in a decrease in the duration and magnitude of the fever, and in the number and duration of skin lesions. Indications - High risk individuals such as healthy non-pregnant females 13 years of age or more, children older than 12 months with a chronic cutaneous or pulmonary disorder, children receiving long-term salicylate therapy, and possibly children receiving oral or inhaled corticosteroids. Dose - 20 mg/kg qds. with maximum of 800 mg qds.

Prevention

(1) *Varicella zoster immunoglobulin*. Indications: (a) Following significant exposure to chickenpox in immunocompromised and susceptible children. (b) Susceptible adolescents and adults, particularly pregnant women. (Patient should receive VZIG as soon as possible but not >96 h after exposure). (c) Newborn infants whose mothers have chickenpox within 5 days before delivery or within 48 hours after delivery. (d) Premature infants of less than 28 weeks gestation. (e) Premature infants whose mothers do not have a history of chickenpox. Dose - 125 units (1.25 mL)/10 kg body wt., i.m. within 48 hours and preferably not later than 96h after exposure. Maximum suggested dose is 625 units. (2) *Vaccine* - Live attenuated varicella

vaccine. Safe and highly protective in both healthy and immuno-compromised children. Adverse effects – Minor rash, often accompanied by fever. Dose: In children 2–12 years, who have not had chickenpox, two doses recommended the first at 12–15 months of age second at 4–6 years of age. VZV -seronegative persons > 13 years of age should receive two doses of vaccine at least 1 month apart.

5. MUMPS

AETIOLOGY

Age – Majority in children under 15. *Causative agent* – Paramyxoma virus. *Portal of entry* – Upper respiratory tract; it spreads through blood stream and has tendency to multiply in glandular structures. Spreads from human reservoir by direct contact, airborne droplet nuclei, or fomites contaminated by infected saliva.

Incubation period – 16–21 days.

CLINICAL FEATURES

Onset – (i) Moderate fever, sore throat, drawing or puckering feeling at angle of jaw. (ii) Swelling of face may be the first to draw attention. (iii) Onset with rigor or convulsion. (iv) With meningeal reaction – “cerebral mumps”.

Early signs – (i) Pain or tenderness on pressure beneath angle of lower jaw. (ii) Reddening of parotid duct orifice.

Parotid glands – usually one gland affected followed by the other after a varying interval; or only one gland affected throughout; or simultaneous enlargement of both. The swelling reaches its maximum in about 3 days, remains at its peak for about 2 days and then slowly recedes. The lobe of the ear is in the centre of the swelling which is tender on pressure.

Fever – may rise to 40°C after appearance of parotitis; remittent, or intermittent, falls by lysis in 3–7 days.

Other symptoms – Diminished salivation, furred tongue and foul breath. Marked enlargement of parotid may cause trismus and deafness.

OTHER NON-PAROTID MUMPS – Submaxillary and less frequently sublingual glands may enlarge, ovaries, pancreas, thyroid and breasts may be affected.

COMPLICATIONS

A. COMMON

1. *Orchitis and epididymitis* – usually unilateral. Common in young adults, may occur without parotitis. Fever returns and may go up to 40.5°C. Testis swollen, tender and tense with or without epididymitis. At the height of the attack delirium or stupor

may occur. Lasts for about 10 days; may result in sterility.

2. *Meningitis* – Usually follows parotitis but may occur at the same time or even before salivary gland enlargement.
 3. *Oophoritis* – Less common than orchitis. Bilateral suprapubic pain.
 4. *Acute pancreatitis* – in 2nd week. Occasionally the disease presents with pancreatitis without salivary gland involvement. Diabetes may be a sequel.
- B. RARE**
1. *Neurological complications* – (a) Meningoencephalitis – as a rule appears 3–10 days after onset of glandular swelling, but sometimes precedes it and at times appears in absence of glandular swelling. CSF cell count often $50\text{--}200 \times 10^6$ lymphocytes/litre with slightly raised protein. (b) Cranial nerve involvement – Facial, and auditory, nerve deafness may be permanent. (c) Polyneuritis usually temporary. (d) Other CNS problems occasionally associated with mumps include cerebellar ataxia, facial palsy, transverse myelitis, hydrocephalus, Guillain-Barre syndrome, flaccid paralysis and behavioural changes.
 2. *Arthritis* – Occasionally of one or more large joints, often the knee follows mumps, but no permanent damage results.
 3. *Mastitis* – Mild and transient enlargement of breasts of either sex. *Prostatitis* – in males.
 4. *Thyroiditis*.
 5. *Nephritis*.
 6. *Foetal endocardial fibroelastosis* – very occasionally during pregnancy, or if contacted in the first trimester, abortion.

DIAGNOSIS

- (a) *Viral isolation* – from saliva or nasopharynx in acute illness or from CSF in mumps meningitis. (b) *Antibody titre* – Four-fold rise 1–2 weeks after infection.

DIFFERENTIAL DIAGNOSIS

1. INFECTION AND INFLAMMATION

- (a) *Acute suppurative parotitis* – Painful, swollen, tender gland with, oedema of subcutaneous tissues. Fever. Oedema and redness around orifice of parotid duct. Pressure over gland may produce flow of pus in mouth.
- (b) *Recurrent parotitis* – usually unilateral. Constitutional disturbance slight. Gland may not be

enlarged, in quiescent stage but its limits are often palpable. X-ray after injection of lipiodol into ducts shows dilatation of ducts.

- (c) *Chronic parotitis* – Late stage of recurrent parotitis due to recurrent exacerbations, or associated with calculus.
2. Obstruction – of major salivary ducts usually by salivary calculi, rarely by injury or tumour.
3. DRUG REACTIONS – Hypersensitivity to phenothiazines, thiouracil, iodides, thiocyanate, isoprenaline, copper, lead and mercury.
4. NEOPLASMS – So-called mixed tumour. A slow growing, nodular or rounded, painless and mobile swelling, usually unilateral.
5. Associated with systemic disease
 - (a) *Sialosis* – Painless, soft, diffuse, non-tender enlargement of parotid glands may be associated with diabetes mellitus, cirrhosis, hyperlipoproteinaemia, anorexia nervosa.
 - (b) *Sarcoidosis* – May rarely cause parotid enlargement. Dry eyes and xerostomia are common features.
 - (c) *Sjögren's syndrome* – Firm, non-tender enlargement of parotid and submandibular glands which may vary in size over several weeks or may persist.
6. Miscellaneous
 - (a) *Mikulicz's disease* – Bilateral chronic painless enlargement of parotid, and other salivary glands and lacrimal gland.
 - (b) *Uveoparotid tuberculosis* – Bilateral swelling of parotid glands with inflammation of uveal tract. Lymph glands may be enlarged and spleen palpable. Gland firm, painless and often nodular. No reddening of orifice of Stensen's duct.

MANAGEMENT

1. *Diet* – Liquids, or semisolids depending on patient's ability to chew.
2. *Oral hygiene* – Frequent mouth wash.
3. *Paracetamol* – for pain and fever.
4. *Management of orchitis* – Complete bed rest, ice compress to scrotum, sling support for testicle. Prednisolone if swelling very severe 15 mg qds. for 4 days and then gradually tapered. Reduces testicular pain and swelling, but does not shorten duration of orchitis or lessen risk of testicular atrophy. If pain severe, incision of tunica vaginalis or injection of spermatic cord at the external inguinal ring with 10–20 mL of 1% procaine solution.

5. Mumps vaccine is not recommended over 6 years of age because reactions are more common in older children. Risk of vaccination (brain damage) can be reduced if vaccine is not given to infants with brain injury, CNS damage, personal or immediate family history of fits, or previous reaction to vaccine.

6. WHOOPING COUGH (PERTUSSIS)

EPIDEMIOLOGY

Age any, but mostly in children. Seasonal incidence. Sporadic and epidemic. Association with measles common. *Causative organisms* – Gram negative bacillus *Bordetella pertussis*, or less commonly, *B. parapertussis*. Spread – by droplet route.

Incubation period – 7–14 days.

CLINICAL FEATURES

Three stages, each lasting about 2 weeks.

1. CATARRHAL – Insidious onset with nonspecific symptoms such as rhinorrhoea, sore throat, conjunctivitis and non-productive cough.
2. SPASMODIC – The cough becomes paroxysmal and episodes of coughing may cause cyanosis or facial discoloration as a result of venous congestion. Paroxysms can occur several times per day and are common at night. They occur spontaneously or are precipitated by external stimuli such as noise or cold air.
3. Convalescent stage – About the 4th week, paroxysms diminish in intensity, child ceases to vomit, then to whoop, and finally to cough. Appetite returns with improvement in general nutrition.
See Table 14 for the atypical features of pertussis.

LABORATORY INVESTIGATIONS

Culture – of secretions is highly specific, but 80% sensitive. A specimen is collected via a pernasal swab or by nasopharyngeal aspiration.

PCR analysis – is more sensitive than culture and specific.

Serology – Most widely used antigens are pertussis toxin and filamentous haemagglutinin and both IgA and IgG antibody response can be measured by enzyme-linked immunosorbent assay methods.

Lymphocytosis – is nonspecific.

COMPLICATIONS

Secondary infections are suspected when a new fever develops or symptoms, signs become apparent between paroxysms.

Table 14: Atypical features of pertussis

Infants
• Apnoea
• Cough (no whoop)
• Cyanotic episodes
• Vomiting
• Poor feeding
• Seizures
• Sudden infant death syndrome
Partially immunized
• Duration of catarrhal stage may be reduced
• Whoop may not occur
Adults
• Prolonged cough
• Paroxysmal cough
• Whoop
• Phlegm
• Posttussive vomiting

- Bacterial pneumonia may be caused by vomiting and aspiration or local damaging effects of the organism.
- Atelectasis due partly to viscid mucus secretions and partly to bronchial and peribronchial inflammation (see Table 15).

DIAGNOSIS

A child presenting with classic symptoms of paroxysmal cough, posttussive vomiting and whoop is likely to have infection caused by *B. pertussis*. In older children it may be difficult to differentiate infections caused by other respiratory tract infections and cultures of nasopharyngeal secretions on appropriate media are necessary.

MANAGEMENT

General (a) Isolation in a well-ventilated room. (b) Feeding: Food finely divided and in small feeds. (c) During a paroxysm, child should be lifted from the cot and held in a head low position, patting the back until the spasm is over.

Feeds should be given immediately after vomiting which frequently follows a paroxysm of coughing.

Drugs - (a) Antibiotics: Erythromycin 50 mg/kg day in 3 divided doses for 7–14 days may reduce severity of infection. (b) Antispasmodic: Salbutamol liquid 1 mg tds.

Prevention: Erythromycin 40 mg/kg/day in 4 divided doses may prevent or modify whooping cough in the non-

immune neonate who has been exposed to the disease. (For immunization schedule, see Diseases of Children).

DTaP vaccine, a cellular pertussis vaccine containing antigen components of *B. pertussis* may be available in future.

7. ENTEROVIRUS INFECTIONS

Classification: Enteroviruses are a large group of human pathogens and approximately 64 serotypes infect humans, including the polioviruses, group A and B, coxsackieviruses and echoviruses. Spread is via faeco-oral route. They can lead to a wide variety of clinical diseases given in Table 16.

POLIOMYELITIS

Paralytic poliomyelitis is, by definition, caused by one of the three poliovirus serotypes, though other, non-polio enterovirus may occasionally cause a similar syndrome. More commonly polioviruses cause aseptic meningitis or mild nonspecific symptoms.

Virology

Majority outbreaks of paralytic polio are due to type 1 poliovirus, however type 2 virus appears to be the most effective immunogen and thus the highest rate of seroconversion following immunization with the trivalent vaccine is to this type.

Table 16: Clinical entities associated with enterovirus infections

Organ system	Clinical entity	Main serotypes involved
CNS	• Paralytic Polio	Poliovirus 1-3
	• Aseptic meningitis	Numerous
	• Encephalitis	Numerous
Cardiac and skeletal muscle	• Myocarditis	Coxsackievirus
	• Dilated cardiomyopathy	Coxsackievirus
	• Pericarditis	Coxsackievirus
	• Bornholm disease	Coxsackievirus
Skin and mucous membrane	• Hand, foot and mouth disease	Coxsackie A16
	• Rash	Enterovirus 71
	• Herpangina	Numerous
	• Viral conjunctivitis	Coxsackievirus A
	• Acute haemorrhagic conjunctivitis	Numerous
Respiratory tract	• Summer cold	Enterovirus 70, coxsackievirus A 24
	• Nonspecific febrile illness	Numerous

Pathogenesis

Poliovirus enters GI tract by ingestion and then spreads to various organs of the body. Replication of the virus occurs in three phases:

Phase 1 - Primary replication occurs in the epithelial cells of the oropharynx and intestinal mucosa, and also in subjacent lymphoid tissue (the tonsils and Payer's patches). Substantial amplification of the virus does occur but this is insufficient to cause clinical symptoms.

Phase 2 - After primary multiplication, virus spreads via the draining lymphatics into regional lymph nodes (deep cervical and mesenteric lymph nodes) and undergoes further replication and amplification. It then enters the bloodstream and results in a transient viraemia which clinically manifests as a mild, febrile illness.

Phase 3 - Following the transient viraemia, virus is disseminated into various extraneural tissues, e.g. the brown fat and reticuloendothelial cells of a number of viscera. Here extensive replication of virus occurs; this continuously supplies the bloodstream and produces a persistent viraemia. From blood the virus passes to the central nervous system.

Infection of CNS occurs in majority. Virus reaches CNS via two routes - (a) Haematogenous, i.e. directly through capillary walls of CNS. (b) Neurological by travelling up the autonomic nervous system of the intestine.

RELATIONSHIP OF PATHOGENESIS TO CLINICAL FEATURES - This method of spread within the body accounts for the four stages of the disease at any of which it may be arrested:

- Silent infection* - Virus in alimentary phase.
- Abortive poliomyelitis* - Virus in both alimentary and viraemic phases.
- Non-paralytic polio* - Virus in alimentary, viraemic and neural phases.
- Paralytic poliomyelitis* - Virus in all three phases, its action on neuron causing paralysis.

Clinical Features

- Prodromal stage** - Start of systemic phase of the infection. (a) *Respiratory* - Coryza, sore throat or cough. (b) *Gastrointestinal* - vomiting, diarrhoea or constipation, or (c) *Constitutional* - Fever, headache, drowsiness, restlessness, irritability and sweating. Temperature falls to normal in 36-48 hours and rises again as the pre-paralytic stage is reached, giving a double humped or dromedary chart.
- Preparalytic stage** - Start of neural phase of the infection. Symptoms and signs of meningeal irritation:

Symptoms

- Fever - Temperature rises to 39°C, associated back pain and stiffness.
- Headache - moderate.
- Nausea, vomiting may occur.
- Pains - spontaneous or provoked by movement of back, neck, limbs and sometimes abdomen.
- Cutaneous hyperaesthesia - may be present; generalized or localized presaging paralysis of that part.
- Nuchal and spinal rigidity - (a) Active tests - (i) Tripod sign - The child is made to sit up unassisted; the knees flex upward and the child places his hands on the bed behind him due to spinal rigidity. (ii) Kiss-the-knee test - Ask child to sit up and kiss his knees. He is able to do so only by flexing the knee. (b) Passive tests - (i) Positive Kernig's and Brudzinski's signs. (ii) Nuchal rigidity. (iii) Head drop sign - The head falls backward when the shoulders are elevated.
- Muscle fasciculation - may be observed.
- Micturition disturbance - Difficulty of micturition or retention of urine may occur.
- Reflexes - Superficial and deep reflexes - in early stages active and remain so unless paralysis supervenes.

Signs

- Pulse fast and out of proportion to rise of temperature.
 - Excessive perspiration.
 - Patient is alert.
3. **Paralytic stage** – usually develops between 2nd and 5th days after onset of signs of involvement of nervous system. May set in without initial symptoms. Characteristics are – (i) Usually appears while there is still fever. (ii) Maximum at onset. (iii) Distribution often asymmetrical. (iv) Usually begins within 1 to 5 days after onset of illness, progresses for 1 to 3 days, remains stationary for about a week and then shows rapid improvement for some weeks and then slower. (v) Absence of sensory loss.

Distribution of Paralysis

Usually patchy, may produce monoplegia, paraplegia or quadriplegia.

- (a) *Lower limbs* – more frequently affected. Usually quadriceps, tibialis anterior and peroneal group.
 - (b) *Upper limbs* – most commonly deltoid.
 - (c) *Trunk* – abdominal muscles, muscles of back, intercostals or diaphragm.
 - (d) *Respiratory disturbances* – due to paralysis of diaphragm and intercostal muscles, or affection of respiratory centre in bulbar type – anxiety, increasing weakness of voice, cough, sucking of epigastric or intercostal spaces with increasing use of accessory muscles of respiration, diminution in the numbers a patient can count after one inspiration, and cyanosis.
4. **Convalescence** – Initial paralysis usually diminishes to some extent after two or more weeks, and improvement may continue for several months. The affected muscles become flaccid whilst contraction will tend to produce severe deformities unless these are prevented. When chronic stage is reached six months to a year after initial infection, no further spontaneous improvement can be expected.

Clinical Types

Infection of a susceptible individual may result in one of 3 clinical manifestations:

1. **Inapparent infection** – in majority of cases. Does not progress beyond involvement of regional lymphnodes. However, replication of virus in lymphoid tissue stimulates the immune system.
2. **Abortive illness** – occurs in 4–8% cases. Infection reaches viraemic phase and foreign protein from virus is released into blood stream, as also endogenous

pyrogens and other toxins from necrotic cells. This results in:

- (a) *Abortive poliomyelitis* – Presumptive diagnosis during epidemic. Brief influenza-like illness with one or more of the following symptoms – malaise, anorexia, nausea, vomiting, headache, sore throat, constipation and localized abdominal pain. Fever seldom more than 103°F. Coryza and cough uncommon.
- (b) *Non-paralytic poliomyelitis* – Subjective symptoms as in abortive type but headache, nausea, vomiting more intense, and soreness and stiffness of posterior muscles of neck, trunk and limbs. Fleeting paralysis of bladder not uncommon.

3. Paralytic poliomyelitis

- (a) *Spinal form* – Paralysis of flaccid type usually asymmetrical and scattered in distribution, though more severe in one extremity. Legs most frequently involved. Respiratory paralysis may result from involvement of diaphragm and intercostal muscles. Transient bladder involvement in some.

IM injections increase the risk of paralysis in the involved limb(s).

- (b) *Bulbar form* – Muscles supplied by bulbar nuclei involved alone or with spinal musculature. Facial, palatal and sometimes pharyngeal paralysis causes change in voice, difficulty in swallowing, nasal regurgitation and choking when attempting to drink. Respiratory paralysis is the usual cause of death. Tonsillectomy predisposes to bulbar poliomyelitis.

Postpolio Syndrome - presents as a new onset of weakness, fatigue, fasciculations and pain with additional atrophy of the muscle group involved during the initial paralytic disease 20–40 years earlier. More common among women and with increasing time after acute disease. Onset - usually insidious and weakness occasionally extends to muscles that were not involved during the initial illness. Prognosis - generally good; progression is usually slow, with plateau periods of 1–10 years. Thought to be due to progressive dysfunction and loss of motor neurons that compensated for the neurons lost during the original infection and not to persistent or reactivated poliovirus infection.

Diagnosis

1. *CSF* – Increased white cell count (usually below 500/mm³), often with high polymorph count in first few days followed by predominance of lymphocytes. Sugar normal.

2. *Isolation of virus* – from nasopharyngeal swabs during the first 5 days of illness only, but from stools and rectal swabs containing faecal material up to 5 weeks after onset.
3. *Serology* – A fourfold rise in level of antibody to the strain of virus isolated.

Management

1. **Preparalytic stage** – (i) *Rest in bed* – on a firm mattress with as little disturbance of patient as possible. A padded footboard serves to protect the legs from pressure of bed-clothes and keep ankles flexed at 90°. (ii) *Analgesics* – for pain relief. (iii) *Heat* – in form of moist (but not wet) packs of value in relieving muscle soreness or spasm. These should be applied to painful areas for an hour or two, morning and afternoon.
2. **Paralytic stage** – (a) *Splints* – Paralysis of muscles which results in stretching or malposition may require application of removable splints. (b) *High fluid intake* – Particularly in patients who need to be catheterized, as secondary infection and calcium phosphate calculi are common. (c) *Physiotherapy* – when muscle tenderness has subsided, gentle massage, together with active and passive movements for purpose of relaxing the muscles and preventing contractures. These procedures should not be carried out to the point where they produce pain or fatigue. (d) *Catheterization* – may be necessary for few days. (e) *Enemas* – if abdominal muscles are weak.

Paralysis of respiratory muscles or bulbar involvement – Use of assisted ventilation if normal acts like speaking make patient breathless, if cough is ineffective, if he cannot count up to 20 after deep inspiration, if chest excursions are feeble or he cannot push out his upper abdomen. Tracheostomy may be needed when air passages are occluded by mucus or spasm of laryngeal muscles, or may be done as a routine procedure. IV fluids. Use of assisted ventilation should be continued in bulbar cases until respiratory centres have recovered. Antibiotics to prevent pulmonary complications.

3. **Convalescent stage** – Physiotherapy, muscle re-education, application of appropriate corrective appliances and orthopaedic surgery. Rehabilitation of the severely paralysed patient.

Prevention

ACTIVE IMMUNIZATION – Two types of polio vaccine are used. (1) *Inactivated polio vaccine (IPV)* administered by s.c. or i.m. injection. (2) *Live attenuated oral vaccine*

(*OPV*). IPV is used in pregnancy, immunosuppressed and for those over age of 50 receiving vaccine for the first time because of risk of vaccine-associated paralysis with live vaccine.

Vaccination is normally given in three doses 1 month apart, to infants from 2 months of age. OPV is more practical for mass vaccination, and is more widely used. However occasionally cases of vaccine-associated paralytic poliomyelitis caused by neurovirulent revertant OPV virus have occurred in vaccinees and unvaccinated contacts. In some countries IPV/OPV schedules are being used.

Contraindications to vaccine – (1) *Breastfeeding*. It is recommended that breastfeeding be stopped 30 minutes before polio immunization, until 2 hours afterwards. This is because several antiviral substances present in breast milk interfere with replication of viruses, including poliovirus. (2) *Intercurrent infections* – such as gastroenteritis. (3) *Pregnancy* – Polio immunization should be delayed until after pregnancy unless immediate protection is required. (4) *Immunosuppressed individuals* – should receive IPV instead of OPV.

PASSIVE IMMUNIZATION – with 5-15 mL according to age of child, of gamma globulin. Some measure of protection is afforded for 6 weeks. **Indications** – Newborn in hospital who are exposed to infection, unimmunized children in hospital ward in which a case of poliomyelitis develops, nurses and medical students who have not been immunized and who have come in contact with early cases of polio.

Aseptic meningitis – Enteroviral meningitis is usually benign, though encephalitis or meningoencephalitis occurs in a few cases. Patients with gammaglobulin deficiency are susceptible to chronic meningoencephalitis. Neonates with perinatal infection are also highly susceptible, and may present with generalized sepsis. Rapid diagnosis is achieved by isolating virus or detecting viral RNA in CSF and, when used in conjunction with bacterial culture results, is useful in differentiating viral from bacterial meningitis.

Acute myocarditis – Coxsackievirus B is the most common viral cause. Patients may present with a recent history of febrile illness, symptoms of heart failure or pericarditis. Evidence suggests that enterovirus may persist in the heart, leading to chronic myocarditis or dilated cardiomyopathy.

Hand, foot and mouth disease – is an ulcerative exanthema involving buccal mucosa, hands and feet. Most cases are uncomplicated, but other manifestations (e.g. meningitis) may also occur. It often occurs in epidemics, and is caused most commonly by Coxsackievirus A16 and enterovirus 71.

Type 1 diabetes – has an extended preclinical phase, and enterovirus infections may coincide with development of islet cell autoantibody responses in pre-diabetic individuals. Thus, enteroviruses may contribute to diabetogenesis at different stages.

8. TOXOPLASMOSIS

Toxoplasmosis is a zoonotic infection caused by the protozoan parasite *Toxoplasma gondii*. Worldwide, infection is most common in warm, wet countries. Incidence of infection increases with age.

Sources of infection – Sexual phase of *T. gondii* occurs in members of the cat family; only the cat's faeces (particularly those of kittens) are infectious. Oocysts sporulate 1–2 days after excretion, producing millions of infective sporocysts. In other animals and birds, cysts in the tissues are source of infection. Infection may also occur following blood transfusion or transplantation.

CLINICAL FEATURES

Acute acquired infection – Incubation period 3–21 days. Most patients have nonspecific flu-like symptoms with fever, malaise, myalgia and headache.

Lymphadenopathy, particularly of cervical lymph nodes is the most common presentation. The nodes are firm, unattached to overlying skin and initially tender. Lymphadenopathy usually lasts several months.

Retinochoroiditis – can be a result of congenital or acquired infection.

Lungs: Among patients with AIDS who die of toxoplasmosis, 40–70% have involvement of the lungs and heart. Interstitial pneumonitis can develop in neonates and immunocompromised patients.

Rare manifestations are involvement of heart, muscle or skin. Toxoplasma encephalitis is seen typically in patients with AIDS and can be fatal.

Congenital Toxoplasmosis: Acute infection in mothers acquiring *T. gondii* during pregnancy is usually asymptomatic; most such women are diagnosed via prenatal serologic screening. Infection of the placenta leads to haematogenous infection of the fetus. As gestation proceeds, the proportion of fetuses that become infected increases, but the clinical severity of the infection declines. Although infected children may initially be asymptomatic, the persistence of *T. gondii* can result in reactivation and clinical disease—most frequently chorioretinitis—decades later. If treated appropriately, upwards of 70% of children have normal developmental, neurologic and ophthalmologic findings at follow-up evaluations.

Reactivation of chronic infection following resolution of active infection. Toxoplasma cysts are scattered throughout the body and produce no symptoms.

Chronic infection may result from acute or reactivated infection. Symptoms are similar to those of chronic fatigue syndrome. Acute or chronic infection may become reactivated as a result of depressed immune function, and can manifest systemically or as localized ocular disease, which usually presents as retinochoroiditis.

Immunocompromise occurs as a result of disease (e.g. HIV/AIDS), treatment, (chemotherapy or radiotherapy) or organ transplantation.

INVESTIGATIONS

Laboratory – Dye test – Methylene blue is used to stain live *Toxoplasma*. Current infection is indicated by a four-fold increase in the dye test titre, increase in *Toxoplasma* specific IgG or presence of IgM. In newborns, specific IgA denotes congenital infection.

Imaging – CT and MRI – are useful in CNS toxoplasmosis because serology is often not diagnostic. Multiple bilateral contrast enhancing lesions are often found, but occasionally there is a solitary lesion. MRI is better in monitoring response to anti-*Toxoplasma* treatment.

MANAGEMENT

Indications for *anti-toxoplasma* treatment: Pregnancy, active ocular disease, infection in immunocompromised, and occasionally chronic infection.

First-line treatment – Pyrimethamine 200 mg loading dose followed by 50–75 mg/day po plus sulphadiazine 1–2 g po qds. (or dapsone) and folinic acid 15 mg/day po for 6 weeks. Clindamycin 0.6–1.2 g po qds. may be used when sulphonamide toxicity occurs. Immunocompromised patients must receive life-long treatment (usually 50% of actual dose). In pregnancy and neonates, spiramycin is alternated with first-line treatment. In ocular disease, corticosteroids. Congenitally infected neonates are treated with daily oral pyrimethamine (1 mg/kg) and sulphadiazine (100 mg/kg) with folinic acid for 1 year.

9. TETANUS AND OTHER CLOSTRIDIAL DISEASES

Tetanus is caused by a powerful neurotoxin (tetanospasmin) produced by strains of *Clostridium tetani* when introduced into the tissues that blocks the inhibitory synapses on motor neurons in CNS, resulting in unrestrained reflex spasm.

The toxin travels up local motor axons from the site of infection, causing local tetanus, and spreads through the blood stream to reach many axons and hence the CNS. Cranial nerves are usually affected because they are shorter, hence the common initial presentation is lock-jaw.

Predisposing factors – Wounds most likely to endanger tetanus are those for which treatment is delayed more than about 6 hours, those which are deep or contaminated with soil, metal, wood, calcium salts or bacteria; and those complicated by vascular damage causing necrosis of muscle. Spores of *C. tetani* occur in faeces of herbivorous animals and men. Any kind of damage to skin or mucous membranes may admit spores to underlying tissues (Table 17).

GENERALIZED TETANUS

Incubation period – usually 6 to 10 days, rarely several months.

Clinical Features

PRODROMAL SYMPTOMS – Nonspecific such as malaise, fever, sweating, headache and irritability.

PRESENTING SYMPTOMS – Trismus (lock jaw) and dysphagia (often described as sore throat) due to painful rigidity of masseters and muscles of deglutition. Pain and stiffness in the neck and back.

SYMPTOMS OF ESTABLISHED DISEASE

- (a) **Rigidity** – Rigidity affects the erector spinae and abdominal muscles producing exaggerated lumbar lordosis, neck retraction and abdominal rigidity.
- (b) **Muscle spasms** – Often involve facial muscles producing the typical appearance of raised eyebrows, tightly closed eyes and drawing back of the lips to expose clenched teeth (risus sardonicus). In more severe cases painful muscle spasms also occur from time to time, either spontaneously or in response to stimuli such as loud sounds, injections, movements and attempted nasogastric intubation. Spasms of erector spinae muscles may produce opisthotonus. Pharyngeal spasms produce dysphagia, spasms of the larynx and respiratory muscles may cause asphyxiation or respiratory arrest. Paroxysmal increases in tone in all the affected muscle groups produce uncoordinated spinal convulsions, a form of diffuse spasm. Retention of urine is frequent. Tremor is not uncommon.
- (c) **Symptoms due to sympathetic overactivity** – Patients with severe tetanus may develop cardiac arrhythmias, fluctuating BP, marked variation in pulse rate, impairment of cardiac output, peripheral vasoconstriction

Table 17: Portals of entry of Clostridium tetani

1. Punctured or war wounds.
2. Otitis media.
3. Injections especially IM injections of quinine, or by narcotic addicts. Also vaccination.
4. Unsterile surgery including use of infected cat gut and swabs, criminal abortions, ritual circumcision, and ear piercing.
5. Bowel surgery and infarction of bowel.
6. Burns.
7. Animal bites and stings.
8. Firework injuries.
9. Intra-uterine death.
10. Unsterile division of umbilical cord.
11. Compound fractures.
12. Miscellaneous – Chronic skin ulcers, plaster sores, gangrenous limbs, eye infections, human bites, dental extractions.

or vasodilatation, exaggerated pressor response to tracheal irritation, increased metabolic rate, pyrexia, excessive sweating and salivation. These symptoms are particularly severe in the elderly and in drug addicts.

Clinical Variants

1. **Local tetanus** – Mild form in which stiffness remains confined to the injured limb, sometimes to a single muscle. It may develop into generalized tetanus.
2. **Ascending form** – Local spasm of muscles in the vicinity of the wound, spread to neighbouring muscles and to limbs, head and trunk. After recovery the original muscle spasm may persist for days or weeks. May be the result of immunization.
3. **Cephalic tetanus** – results from injuries to head and neck and infections of the eye and orbit. One or more of the cranial nerves particularly VII nerve may be involved with spasm and apparent paralysis of the muscles which they supply, together with features of generalized tetanus. When pharyngeal muscles are involved selectively dysphagia caused by spasms may be induced by attempts to drink (hydrophobic tetanus).
4. **Splanchnic tetanus** – may follow abdominal or thoracic wounds or be post-operative. Spasms limited to muscles of deglutition and respiration.
5. **Neonatal tetanus** – due to sepsis of the umbilical stump. Typically a week-old infant presents with inability to suck because of spasm of facial and pharyngeal muscles, or with generalized convulsions. Crying

is hoarse and the face screwed up, with tightly closed eyes and wrinkled forehead. The arms are flexed and crossed with tightly clenched fists and the toes flexed. The back is very rigid. Cyanosis and apnoea accompany the more severe spasms.

Severity of Tetanus: Grading

Gr. I (mild) - Mild to moderate lockjaw, generalized spasticity, no spasms or respiratory difficulty.

Gr. II (moderate) - Well marked rigidity, brief spasms, mild dysphagia, tachypnoea (> 30-35/min).

Gr. III (severe) - Severe trismus, generalized spasticity, prolonged spasms often spontaneous, tachypnoea (> 40/min), apnoeic spells, marked dysphagia, tachycardia, increased autonomic NS disturbance.

Gr. IV (very severe) - (Gr. III features plus severe autonomic storms) - severe hypertension and tachycardia alternating with relative hypotension and bradycardia, or severe persistent hypertension or hypotension.

In assessing prognosis, the speed at which tetanus develops is important. The incubation period (time from wound to first symptom) and the period of onset (time from first symptom to first generalized spasm) are of particular significance; shorter times are associated with worse outcome. In neonatal tetanus, the younger the infant is when symptoms occur, the worse the prognosis.

Differential Diagnosis

- Other causes of trismus* - (a) Irritant local lesions of teeth (dental abscess, pericoronitis), throat (peritonsillar abscess), temporomandibular joint, masseter muscle and cervical lymph nodes. (b) Occasionally postvaccinal and postinfectious encephalitis, serum sickness and even poliomyelitis. It is commonly observed in patients envenomed by sea snakes.
- Meningitis* - Neck rigidity can occur in both tetanus and meningitis. Signs of meningeal irritation, diagnostic CSF.
- Rabies* - Dysphagia associated with spasms of inspiratory and pharyngeal muscles also occurs in rabies. No trismus. Relaxation of muscles in between paroxysms.
- Tetany* - Spasms start in periphery with carpopedal spasm. Usually associated with overbreathing or thyroid surgery.
- Drug dystonia* - Dystonic reactions to drugs such as phenothiazines and metoclopramide. Grimacing, spasmodic neck retraction and torticollis, wide opening of the mouth and eyes. Prompt response to diazepam or benzotropine.
- Acute peritonitis* - Board-like abdominal rigidity as in tetanus, but in tetanus there is little or no tenderness.
- Functional muscle spasms* - Bizarre movements or posture, absence of constant rigidity of involved muscles, history of previous personality disorder.
- Catatonic schizophrenia* - might cause confusion in absence of background information.

CLINICAL COURSE - Most deaths occur by 10th day. Spasms usually subside by end of second or third week, but residual muscle stiffness may persist for more than a month.

Complications

- Respiratory* - (a) Bronchopneumonia common cause of death, results from aspiration of stomach contents, blockage of airways by sticky secretions and lung collapse. (b) Asphyxia - may be due to one or both of the following - (i) Pharyngolaryngeal spasm - Sudden and unexpected stridor, respiratory distress or cyanosis in an early case of tetanus is due to spasm of muscles of upper airway. (ii) Respiratory muscle fixation - A patient without any major reflex muscle spasms may still die from complications of chest fixation in which the general hypertonicity involves pectoral muscles, intercostal muscles and muscles of the abdominal wall reducing vital capacity markedly. (c) ARDS - chiefly due to respiratory sepsis.
- Due to spasms* - Spasms can tear muscles and even avulse their insertions, with subsequent articular and periosteal calcification and myositis ossificans. Wedge fracture of thoracic vertebrae can also result from spasms.
- Complications due to tracheostomy and prolonged ventilatory support.*
- Multiple organ dysfunction* - In severe fulminant tetanus. Besides respiratory system, CVS (hypotension requiring inotropic support), GI system (ileus and massive bleeds), liver (rise in serum enzymes and bilirubin), renal insufficiency (rise in serum creatinine, rarely acute kidney failure).
- Sudden death* - from cardiovascular instability, excessive vagal tone giving rise to bradycardia and cardiac arrest, hypoxia due to prolonged laryngeal spasm or continuous seizures, hyperpyrexia, massive pulmonary embolism, heart block.

Diagnosis

Is confirmed by microbiology. A tissue sample (preferably) or a swab of the wound site is taken for Gram-staining and anaerobic culture. Cultures of *C. tetani* are tested for toxin production.

Prognosis

Can be assessed from:

1. *Type of infection* – Neonatal and puerperal tetanus carry a very bad prognosis.
2. *Type of patient* – Prognosis bad in elderly and drug addicts.
3. *Frequency and severity of spasms*.
4. *Incubation period* – Mortality higher if incubation period is short.
5. *Period of onset* – Interval of less than 48 hours between the first symptom (usually trismus) and the first spasm, carries double or treble the mortality.
6. *Severity of tetanus* – as described above.

Management

AIMS OF TREATMENT – 1. Neutralize existing toxin before it gains access to the nervous system. 2. Reduce further production of toxin. 3. Control neuromuscular and autonomic manifestations. 4. Sustain the patient until effects of the toxin resolve.

1. **Neutralization of unbound toxin** – Hyperimmune human anti-tetanus immunoglobulin 1000–3000 units IM/IV as a single dose or anti-tetanus serum 10000 units IV after testing for sensitivity. Intrathecal HITG 1000–3000 units given before onset of major spasms may prevent disease progress.
2. **Reduction of further toxin production** – (a) *Care of the wound* – Removal of foreign material and debridement of non-viable tissue of entry wound. (b) *Antibiotic* – Benzyl penicillin 600 mg 6-hourly IM or IV, or Erythromycin 500 mg 6-hourly for 10 days to minimize risk of bacterial infection. Metronidazole can be used in patients allergic to penicillin.
3. **Control of rigidity and tetanic seizures**
 - (a) *Avoidance of provocative stimuli* – such as noise, unnecessary movement, and keeping injections to minimum.
 - (b) *Sedative drugs* (Table 18)

Note – Respiratory depression can occur when using combinations and the doses above are for single dose regimens.

If drug treatment cannot control muscle spasm and seizure without impairing consciousness or respiration, muscle paralysis and assisted ventilation become necessary.
 - (c) *Tracheostomy* undertaken early in patients whose disease is not controlled with conservative sedative regimen, because inadequate control of mus-

Table 18: Sedatives used in tetanus

Drug	Daily dose
Diazepam	20–200 mg p.o./p.r./i.m./i.v. continuous infusion 1–6 hrly (alternating with chlorpromazine)
Chlorpromazine	100–300 mg po, im or iv 6–12 hrly
Phenobarbitone	60–600 mg po 6 hrly (alternating with chlorpromazine) or 50–400 mg 6 hrly. im or iv (alternating with chlorpromazine)
Paraldehyde	12 mL pr or im 4–hrly
Morphine sulphate	10 mg im or iv over 10 minutes 2–6 hrly

cle spasms results in asphyxia and depression of swallowing reflex.

- (d) **Induced paralysis with ventilatory support** – Neuroparalytic agents pancuronium 2–4 mg bolus $\frac{1}{2}$ –1 hrly initially or gallamine 20–40 mL iv, the dose being so adjusted that the neuromuscular paralysis achieved allows for efficient ventilatory support (PaO₂ should be maintained > 70 mm Hg and PaCO₂ at 35–40 mm Hg.) When spasms abate, pancuronium or gallamine is stopped; but ventilatory support is continued till the patient is fit to be weaned.
4. **Autonomic circulatory disturbances** – (a) Hypotension (systolic BP < 70) – Fluids if volume depletion, if ineffective or inadvisable, dopamine iv. (b) Hypertensive spells (systolic BP > 200, diastolic > 110) – Propranolol 5–10 mg po or Labetalol or Esmolol bolus infusion. Morphine 2–5 mg as infusion may be used if shock-like state. (c) Sinus tachycardia – Verapamil 40 mg tds (d) Bradycardias – Atropine iv.
 5. **Nursing support** – (a) ICU – Moderate and severe cases should be nursed in ICU. (b) Nutrition – Continuous drip feeding via nasogastric or nasojejunal tube.
 6. **General measures and physiotherapy** – to prevent bed sores and complications of prolonged unconsciousness. Low molecular weight heparin s.c. 12-hourly to prevent deep vein thrombosis.
- Management according to severity of tetanus* –
Mild: Sedatives + Muscle relaxants
Moderate: Sedatives + Muscle relaxants + tracheostomy
Severe: Sedatives + tracheostomy + neuromuscular paralytic agents + ventilatory support

Prevention

1. IMMUNIZATION - (a) *Active immunization* - with 1 mL tetanus toxoid to be repeated after 3 months, or 3 doses of 1 ml each at 3–4 weeks intervals. For prevention of tetanus neonatorum and puerperal tetanus the pregnant woman must be vaccinated against tetanus unless she has received a booster dose within the previous 5 years. (b) *Passive immunization* - with toxoid, immunoglobulin for all clean and minor wounds, and toxoid immunoglobulin plus antibiotic or metronidazole for infected wounds.
2. *Destruction of spores* - e.g. in operation theatres by filtered ventilation and by use of antiseptics on floors and walls. γ -irradiation or autoclaving of surgical instruments and dressings. Povidone-iodine for skin decontamination.
3. *Treatment of wounds* - Thorough cleaning, removal of foreign material and debridement of necrotic tissue. Use of antimicrobials.

OTHER CLOSTRIDIAL ASSOCIATED DISEASES

Various clostridial organisms giving rise to different diseases are listed in Table 19.

Botulism - The highly potent botulinum neurotoxin is produced in inadequately canned, cured or bottled food-stuffs contaminated with *C. botulinum*.

Botulinum toxin causes flaccid paralysis (symmetrical cranial- nerve palsies followed by bilateral descending flaccid paralysis) by blocking neuromuscular transmission. Management consists of intensive care and artificial ventilation.

Infant botulism (floppy-baby syndrome) results from growth of *C. botulinum* in infant intestine.

Wound botulism results from growth in infected wounds, and has been associated with non-iv injecting drug use (as with *C. novyi*). Commercially produced botulinum toxin is used parenterally for local muscle spasm and many other conditions.

10. LYME DISEASE

Lyme disease is caused by the tick-borne spirochete *Borrelia burgodoferi*. Erythema migrans is the early skin lesion, and is the most common clinical manifestation. The organism may spread, causing various later manifestations.

Transmission usually takes place when an infected tick (Ixodid tick) bites.

Table 19: Various diseases caused by clostridial organisms

Disease	Species
Gas gangrene, myonecrosis,	<i>C. perfringens</i>
necrotizing fasciitis, cellulitis	<i>C. novyi</i>
	<i>C. septicum</i>
	<i>C. sordellii</i>
	<i>C. histolyticum</i>
Antibiotic associated diarrhoea,	<i>C. difficile</i>
pseudomembranous colitis	
Food poisoning (diarrhoea)	<i>C. perfringens</i>
Botulism	<i>C. botulinum</i>

CLINICAL FEATURES

Localized (stage I) borreliosis: Erythema marginatum, a localized erythematous rash appearing 2–30 days after a bite. There may be local lymphadenopathy.

Early disseminated (stage II) borreliosis: After dissemination, the organism can affect many tissues, principally the nervous (isolated facial palsy which may be bilateral, other cranial n. lesions, lymphocytic meningitis and painful radiculoneuritis), musculoskeletal (persistent arthralgia and small joint arthritis) and cardiovascular system (conduction defects, rarely cardiomyopathy).

Chronic (stage III) borreliosis is uncommon. (a) Chronic Lyme arthritis, which in a few patients continues for months or years. (b) Chronic neurological manifestations include radiculoneuropathy, Lyme encephalopathy (uncommon), Lyme encephalomyelitis (rare). (c) Acrodermatitis chronica atrophicans - Lesions on the limbs initially violaceous, eventually becoming atrophic.

INVESTIGATIONS

Diagnosis is largely clinical.

(a) *Borrelia culture* is slow and has a low yield. (b) *Borrelia* DNA detection by PCR analysis is slightly more sensitive in biopsies from suspected erythema migrans. (c) *Antibody tests* are the mainstay of laboratory diagnosis.

Treatment - Amoxicillin, doxycycline and cefuroxime axetil orally. Parenteral antibiotics include benzyl penicillin, ceftriaxone and cefotaxime.

11. LEGIONNAIRES' DISEASE

A rare form of pneumonia caused by a gram-negative bacterium *Legionella pneumophila*.

AETIOLOGY

The organism although water-borne, can infect man only if it is inhaled into the lungs. Individuals most susceptible are elderly men, particularly smokers, and those with low resistance due to immunosuppression or chronic debility.

CLINICAL FEATURES

Most characteristic are rapidly progressive asymmetrical patchy infiltrates. (a) Onset – 2–10 days after exposure with high fever, rigors, headaches and pains in muscles. (b) Breathlessness and cough common and haemoptysis in about 25%. (c) Mental confusion with neurological signs and diarrhoea and vomiting.

Laboratory features – WBC count raised, proteinuria, abnormal liver function tests, hyponatremia.

TREATMENT

Doxycycline 200 mg (IV/PO) bd for 72 hours followed by 100 mg bd, or Erythromycin 500 mg qds. po, or in severe cases 1g IV q6h with oral rifampicin 600 mg bd Ciprofloxacin 500 mg orally bd or 400 mg IV immediately, can be given instead of or in addition to rifampicin. Treatment should be continued for 3 weeks.

MISCELLANEOUS

Gram-staining – Common organisms

1. *Gram-positive cocci* – Staph. spp., Strep. spp.

2. *Gram-negative cocci* – Gonococcus, meningococcus.
3. *Gram-positive bacilli* – Clostridium spp., Bacillus spp., C. diphtheriae, Actinomyces israeli, Gardenerella vaginalis, Listeria monocytogenes.
4. *Gram-negative bacilli* – Enterobacteriaceae (E. coli, Proteus, Klebsiella, Salmonella/Shigella spp.). Pseudomonas aeruginosa. H. influenzae, Campylobacter jejuni/coli, Brucella abortus.
5. *Acid-fast bacilli* – Mycobacteria spp., Nocardia asteroides (weakly acid-fast).

Nosocomial Sources of Infection

1. Air conditioners – Aspergilli, Staphylococcus.
2. Humidifiers – Acinetobacter spp., Pseudomonas spp.
3. Water reservoirs – Legionella pneumophila, pseudomonas spp.
4. Foods – Staphylococcus., Streptococcus.
5. Endogenous flora – Enterobacteriaceae, staphylococcus
6. Reactivation – Herpes virus, TB, mycoses.
7. Parenteral nutrition – Candida, Staphylococcus
8. Blood transfusions – (a) Hepatitis B, C, CMV. (b) Malaria, Chaga's disease, kala-azar.
9. Hydrotherapy pools – Ps. aeruginosa folliculitis.
10. Other patients and staff – Herpes viruses (esp. zoster), Listeria spp., C. difficile.

Table 20: Incubation periods of various organisms

Incubation periods	Infection
Short (<10 days)	Acute gastroenteritis (bacterial, viral)
	Arboviral infections, e.g. dengue, chikungunya
	Meningitis (bacterial, viral)
	Relapsing fever (Borrelia spp.)
	Respiratory tract infection (bacterial, viral including influenza)
	Rickettsial infection, e.g. tick typhus, scrub typhus
	Bacterial
	• Brucellosis
	• Enteric fever (typhoid and paratyphoid fever)
	• Leptospirosis
• Q fever	
Fungal	
• Coccidioidomycosis	
• Histoplasmosis (can be as short as 3 days)

CMV = cytomegalovirus; EBV = Epstein-Barr virus; HIV = Human immunodeficiency virus.

Tropical Diseases

1. PROTOZOAL INFECTIONS

MALARIA

Acute febrile illness characterised by paroxysms of fever as a result of asexual reproduction of plasmodia within the red cells. *Plasmodium vivax*, *P. ovale* and *P. malariae* are associated with morbidity but no major mortality; *P. falciparum* and also are the parasites responsible for some potentially fatal malaria.

Transmission

Requirements for transmission of infection are (a) presence of suitable anopheline mosquito, (b) reservoir of malaria infection in the area, (c) suitable non-immune or partly immune hosts and (d) an environmental temperature with suitable humidity. (Malaria usually does not occur at altitudes of over 6,000 feet). Infection is normally transmitted to man by the bite of a mosquito, rarely it may occur across the placenta, or as a result of blood transfusion, or syringe-transmitted malaria among drug addicts.

Infection is initiated by sporozoites from the bite of a female *Anopheles mosquito*. The sporozoites multiply within hepatocytes, giving rise to thousands of merozoites, which invade RBCs. In the RBCs the small ring forms grow through the trophozoite stage to the schizont form, which ruptures and releases further merozoites.

In *P. vivax* infection, gametocytes are produced early in the disease, thus making for more efficient transmission than *P. falciparum*. Hypnozoites in the liver can cause multiple relapses. Complications regularly associated with *P. vivax* are thrombocytopenia, anaemia and occasionally splenic rupture.

This asexual cycle in the blood lasts 48 hours in *P. falciparum*, *P. vivax* and *P. ovale* infections, and 72 hours in *P. malariae*. The parasites often do not develop synchronously, however, and the fever associated with schizont rupture may be continuous rather than periodic, particularly in *falciparum* malaria.

See Figure 1 for the life cycle of malarial parasites.

Pathogenesis

Clinical symptoms and signs are caused by the asexual forms of the parasite, which invade and destroy RBCs, localise in tissues and organs by binding to endothelial cells (cytoadherence), and induce release of many pro-inflammatory cytokines [e.g. tumour necrosis factor- α (TNF- α)].

The initiating step in pathogenesis is when merozoites invade RBCs. Once inside the cell, the ring matures via the trophozoite to the schizont stage, which binds specifically to endothelial cells in post-capillary venules in organs such as the brain. Cytoadherent parasites probably cause microvascular obstruction. Cytoadherence may also localise the effect of putative parasite 'toxins', which leads to endothelial cell activation and, or damage as a result of cytokine release.

The mature parasite is also capable of 'rosetting', a process in which RBCs containing the more mature stages of parasite bind uninfected RBCs to the surface.

Clinical Features

ONSET - Lassitude, anorexia, headache, chilliness for several days before actual attack.

PAROXYSM - 3 clinical stages:

- Cold stage* - Patient shivers from head to foot, his teeth chatter and he covers himself with blankets. Temperature goes on rising. The stage lasts for about half hour.
- Hot stage* - Shivering abates and gives place to a feeling of intense heat, the patient throwing off the blankets. Flushed face, headache, vomiting, dry and burning skin. Temperature rises to 40°C or more. The stage lasts for 3-4 hours.
- Sweating stage* - Patient breaks into profuse perspiration, and the temperature rapidly declines with feeling of relief.

Complications in severe malaria are seen as either sequestration related such as cerebral malaria or non-sequestration related in *P. vivax* infection such as anaemia

Fig. 1: Life cycle of malaria parasite

and thrombocytopenia. Severe manifestations include cerebral malaria, hepatic and kidney dysfunction, ARDS, severe anaemia, pulmonary oedema and haemoglobinuria.

Late Complications

Tropical splenomegaly syndrome (TSS) - is seen in endemic falciparum malaria. Clinical features: marked splenomegaly, lesser degree of hepatomegaly, anaemia and pancytopenia. Laboratory features - Polyclonal elevation of serum IgM levels, and high malaria antibody titres.

Quartan malarial nephropathy - is associated with *P. malariae* infection. Predominantly affects children between 5-8 years of age. Patient presents with nephrotic syndrome several weeks after onset of quartan fever.

Disease progresses slowly to end-stage kidney failure in 3-5 years.

Manifestations of severe malaria are listed in Table 1. Lactic acidosis occurs in severe malaria due to increased anaerobic glycolysis in tissues with sequestered parasites, increased lactic acid production by parasites, decreased lactate clearance by liver and kidneys and hypotension.

Anaemia in malaria, the most common complication, is due to accelerated RBC removal by the spleen, RBC destruction at parasite schizogony and ineffective haemopoiesis.

Poor prognostic factors: Deep coma, convulsions, shock, anuria, hypoglycemia <45-50 mg/dl, platelets <50,000/mm³, PCV <15%, bilirubin >3 mg/dl, AST and

Table 1: Manifestations of severe malaria

• Cerebral
Drowsiness progressing to coma
Repeated generalised convulsions
Retinal haemorrhages
Peripheral parasitaemia
Hyperpyrexia
• Severe anaemia
Normocytic anaemia
Hb <5 g/dl in presence of parasitaemia
• Respiratory distress
Pulmonary oedema or
ARDS
Rapid, laboured breathing
• Acute kidney failure
Urine output <400 ml in 24 hours
Serum creatinine >3 mg/dl
Macroscopic haemoglobinuria
(black water fever)
• Hypoglycemia
Whole blood glucose <40 mg/dl
• Shock (algid malaria)
Systolic BP <70 mm or
Core-skin temperature difference 10°C
• Coagulation failure
Spontaneous bleeding and/or
Laboratory evidence of DIC
• Intravascular haemolysis
Haemoglobinaemia and haemoglobinuria
• Hyper-parasitaemia >10%
Impaired consciousness of any degree
Prostration
Jaundice
Intractable vomiting
• Hepatic dysfunction
Jaundice (bilirubin >3 mg/dL) (haemolytic)
• Hypovolemia with signs of dehydration
• Acute pancreatitis (rare)
• Acidosis (pH <7.5)
• Hyperpyrexia
• Acidotic breathing
• Peripheral gangrene
• Prostration (extreme weakness without other signs)

Table 2: Causes of abdominal pain in falciparum malaria

• Acalculus cholecystitis
• Splenic rupture
• Splenic infarction
• Splenic torsion
• Hepatitis/hepatomegaly
• Acute pancreatitis

ALT > normal, parasitaemia >100000/microlitre in non-immune individuals.

Causes of abdominal pain in falciparum malaria are given in Table 2.

Diagnosis

1. *Clinical* – Periodic fever with rigour, sweating, anaemia and perhaps enlarged spleen.
2. *Blood film* – Identification of the parasites in thick and thin blood film. More likely to be found during a spike of fever. Common microscopic characters of falciparum malaria are – high concentration of parasites, predominance of thin ring-shaped trophozoites. Quantitative buffy coat analysis.
3. *Malarial antigen spot test using parasite LDH* – P. falciparum antigens, e.g. histidine-rich protein 2 (PfHRP2), LDH in blood from finger prick. These tests use monoclonal antibodies to capture the parasite antigens and are read out as coloured bands.
4. *Immunofluorescent microscopy and PCR.*

Management of Malaria

General Management

- *Admission to ICU*
- *Measurement of glucose and if possible lactate and arterial blood gases*
- *Fluid balance* – because both dehydration and overhydration can occur as a result of disease or treatment
- *Treatment of convulsions* with diazepam
- *Attention to hypoglycemia and hyponatremia*
- *Blood for cross-matching and coagulation studies*
- *Parameters for monitoring treatment* include twice daily parasite counts, regular pH and blood gas measurements and when appropriate, measurement of glucose (during iv quinine therapy), lactate, CRP and kidney function.

Table 3: Summary of pharmacotherapy for non-severe malaria in adults (adult doses given except where specified)

Indication	Drug	Side effects/contraindications
Non-severe falciparum (initial treatment): choice of three regimens	For adults: 600 mg Quinine sulphate every 8 hours for 5-7 days For children: 10 mg/kg Quinines salt every 8 hours for 7 days + 2nd agent as follow-on	Mild side effects: tinnitus, hearing loss, dizziness, nausea, blurring vision Unpleasant taste Hypoglycaemia Can induce arrhythmias in context of pre-existing cardiac disease Serious cardiovascular and neurological side effects occur rarely
	Atovaquone-proguanil 4 'standard' tablets daily for 3 days. Weight <40 kg requires reduced dose	
	Artemether-lumefantrine Doses at 0, 8, 24, 36, 48 and 60 hours > 5 kg: 4 tablets per dose 25-35 kg: 3 tablets per dose 14-24 kg: 2 tablets per dose 5-14 kg: 1 tablet per dose	Use as first-line treatment for non-severe malaria in adults and children
	Arterolane 150 mg + Piperaquine phosphate 750 mg 1 tablet daily for 3 days	Avoid in early pregnancy Complete parasite clearance Good tolerability
2nd agent follow-on treatment: choice of 3 agents	Doxycycline 200 mg orally daily for 7 days	May cause gastritis, photosensitivity and complications of antibiotic use Contraindicated in pregnancy and children <12 years
	Clindamycin For adults: 450 mg every 8 hours for 7 days For children: 7-13 mg/kg/dose every 8 hours for 7 days	Choice in pregnancy and children < 12 years, but liquid formulation, difficult to obtain
	Sulfadoxine-pyrimethamine	May cause skin rashes and (rarely) Stevens-Johnson syndrome
	In children only – single dose: Up to 4 years (>5 kg) tablet 5-6 years 1 tablet 7-9 years 1 tablet 10-14 years 2 tablets 15-18 years 3 tablets	Can be taken safely whilst breastfeeding, in absence of other co-morbidities
Non-falciparum	In adults: Chloroquine 600 mg base orally followed by 300 mg at 6, 24 and 48 hours + treatment for hypnozoites to prevent relapse in vivax and ovale	
Eradicating hypnozoites (additional treatment for ovale, vivax ovale and mixed infection)	Primaquine 15 mg (ovale) or 30 mg (vivax) per day orally for 14 days Children require weight-related dosing	Contraindicated in pregnancy Screening for G6PD deficiency required prior to use as primaquine causes haemolysis in patients with G6PD deficiency and is contraindicated

Summary of pharmacotherapy for non-severe malaria in adults is given in Table 3.

Multiple drug resistance (MRD) occurs when a parasite that is resistant to one classes of drugs antimalarials develops resistance to another separate class of drugs.

Alternative oral drugs can be given when resistance is expected or patient cannot tolerate drugs such as quinine (Table 4).

Management of severe falciparum/vivax malaria is given in Table 5.

Table 4: Alternative oral drugs

Drug	Dose	Comments
Mefloquine	15 mg/kg single dose, repeated after 6 hours (usual adult dose three 250 mg tablets and further three after 6 hours)	Contraindicated in early pregnancy and in those with neuropsychiatric history. Can cause minor GI upset, abnormal sleep patterns and dreams and sometimes incoordination
Atovaquone-proguanil (Malarone)	Adult – 4 tabs/day for 3 days (Atovaquone and 100 mg proguanil)	In falciparum malaria resistant to other drugs
Artesunate/mefloquine	4 mg/kg for 3 days, plus mefloquine 15-25 mg/kg single dose on day 3	Particularly highly resistant malaria

Table 5: Management of severe falciparum/vivax malaria

Drug	Dose					
Quinine sulphate or dihydrochloride	20 mg/kg in 500 ml N saline infused over 4 hours 8-hrly until parasites cleared, then doxycycline or pyri-sulpha when patient can take po.					
Artesunate						
Day	Hours	IV	IM			
1st	0	2.4 mg/kg	2.4 mg/kg			
	After 12 hrs		1.2 mg/kg			
2nd to 7th	After q24 hrs	1.2 mg/kg	1.2 mg/kg			
Artemether based combination (ACT)						
Artemether 20 mg + Lumefantrine 120 mg						
Body weight	Day 1		Day 2		Day 3	
	0 hrs	8 hrs after	Morning	Evening	Morning	Evening
5-15 kg	1 tablet	1 tablet	1 tablet	1 tablet	1 tablet	1 tablet
15-25 kg	2 tablets	2 tablets	2 tablets	2 tablets	2 tablets	2 tablets
25-35 kg	3 tablets	3 tablets	3 tablets	3 tablets	3 tablets	3 tablets
Adults and children >35 kg	4 tablets	4 tablets	4 tablets	4 tablets	4 tablets	4 tablets
Artesunate 50 mg + Mefloquine 250 mg				Dose: One tablet bd for 3 days		
Other ACTs recommended:						
Artesunate + Amodiaquine						
Artesunate + Sulfadoxine - pyrimethamine						

Management of Specific Complications

Cerebral malaria – Antimalarial drugs. Mannitol in patients with raised intracranial pressure.

Hypoglycemia – Dextrose iv

Acute renal failure – Dialysis or haemofiltration. Non-oliguric renal failure may be managed conservatively.

Acidosis – Adequate fluid replacement. Transfusion has been shown to improve severe acidosis in anaemic young children. Early haemodiafiltration and/or ventilation may be used.

Anaemia – is mainly caused by rupture of infected cells and haemolysis. Transfusion if Hb falls below 7.5 g/dl.

Bacterial superinfection – with organisms such as *Strep. pneumoniae* or *Salmonella* spp. is common and antimicrobial drugs should be given.

Jaundice – Mild jaundice is mainly caused by haemolysis. Deeper jaundice may result from major liver involvement, but may be caused by viral hepatitis.

Hyperparasitaemia – if complicated, may be treated with exchange transfusion. Indications – (a) Parasitaemia > 30%. (b) Parasitaemia is lower but there are manifestations of severe malaria, associated medical complications (e.g. diabetes, ischaemic heart disease), patient elderly or pregnant.

Management of mixed infection – Treatment should be principally for falciparum malaria as quinine and artesunate are effective in all species. Additional treatment will later be required to eradicate dormant trophozoites if there is co-infection with vivax or ovale.

Malaria in pregnancy – In addition to increasing likelihood of severe malaria, malaria presents a significant risk to the pregnancy. Rapid therapy with an effective antimalarial is the key to good management.

Recommendations for Malaria

Chemoprophylaxis

1. All pregnant women.
2. Children under 5 years of age.
3. Patients receiving corticosteroids or other immunosuppressive drugs or suffering from immune deficiency diseases.
4. Individuals homozygous for abnormal haemoglobins (e.g. SS, thalassemia).
5. Travellers to endemic areas. Prophylaxis should begin 2 weeks prior to arrival, and continued for 6 weeks after leaving.

Drugs for Malaria Chemoprophylaxis

Areas where P. falciparum is absent or chloroquine sensitive and risk of malaria is low and/or seasonal–Chloroquine phosphate 300 mg/week.

Areas with some chloroquine-resistant P. falciparum or P. vivax but with low risk of malaria

Chloroquine phosphate 300 mg/week plus
Proguanil 200 mg/day⁵

Areas with chloroquine-resistant P. falciparum or P. vivax and high risk of transmission

Mefloquine 250 mg/week

or Chloroquine 300 mg/week plus

Proguanil 200 mg/day

or Doxycycline 100 mg/day for upto maximum 8 weeks

- Should be used with caution in women who are pregnant or who might become pregnant.

LEISHMANIASIS

Leishmaniasis denotes a disease caused by genus Leishmania. There are four major clinical syndromes:

1. Visceral leishmaniasis.
2. Cutaneous leishmaniasis
3. Mucocutaneous leishmaniasis.
4. Post-kala-azar dermal leishmaniasis.

VISCERAL LEISHMANIASIS (KALA-AZAR)

Kala-azar is a disease caused by the protozoal parasite *Leishmania donovani*. The disease manifestations are many and varied, but in general it is characterised by chronicity, irregular fever, enlargement of liver and spleen, anaemia and leucopenia.

Transmission

L. donovani is transmitted by female sand-flies of the genera *Phlebotomus* and *Lutzomyia* from infected animals to humans. Other possible modes of transmission are transfusion, sexual contact, salivary and nasal secretions (when mucosae are involved) and very rarely congenital transmission. See Figure 2 for the life cycle of *Leishmania donovani*.

Pathogenesis

The inability of Leishmania-infected macrophages (in which amastigotes Leishman-Donovan bodies survive and reproduce) to produce nitric oxide appears to allow the parasite to multiply. Macrophages and dendritic cells present Leishmania antigens to T cells, which result in either an effective cellular (Th1 pattern), or an ineffective humoral (Th2 pattern) response. Each Leishmania species produces characteristic pattern of disease, but host cellular immunity determines whether the disease is clinical or subclinical, whether the site of infection is visceral, cutaneous or mucocutaneous, whether lesions are few or diffuse, and whether response to treatment is complete or partial.

Clinical Features

Incubation period – between 2 and 6 months.

ONSET – Endemic VL mainly affects children and is of gradual onset.

SYMPTOMS

Abdominal pain – Discomfort and pain especially in left hypochondrium.

Other symptoms – Headache, malaise, cough, epistaxis, loss of weight and diarrhoea.

SIGNS

General appearance – Emaciated with pallor, protuberant abdomen, legs thin with sometimes oedema of feet.

Fever and toxæmia – may be the only physical signs in early cases. No characteristic form of pyrexia except double rise remittent or intermittent, lasts 2-6 weeks followed by apyrexia. A prominent feature is patients retain their appetite and are active in spite of fever.

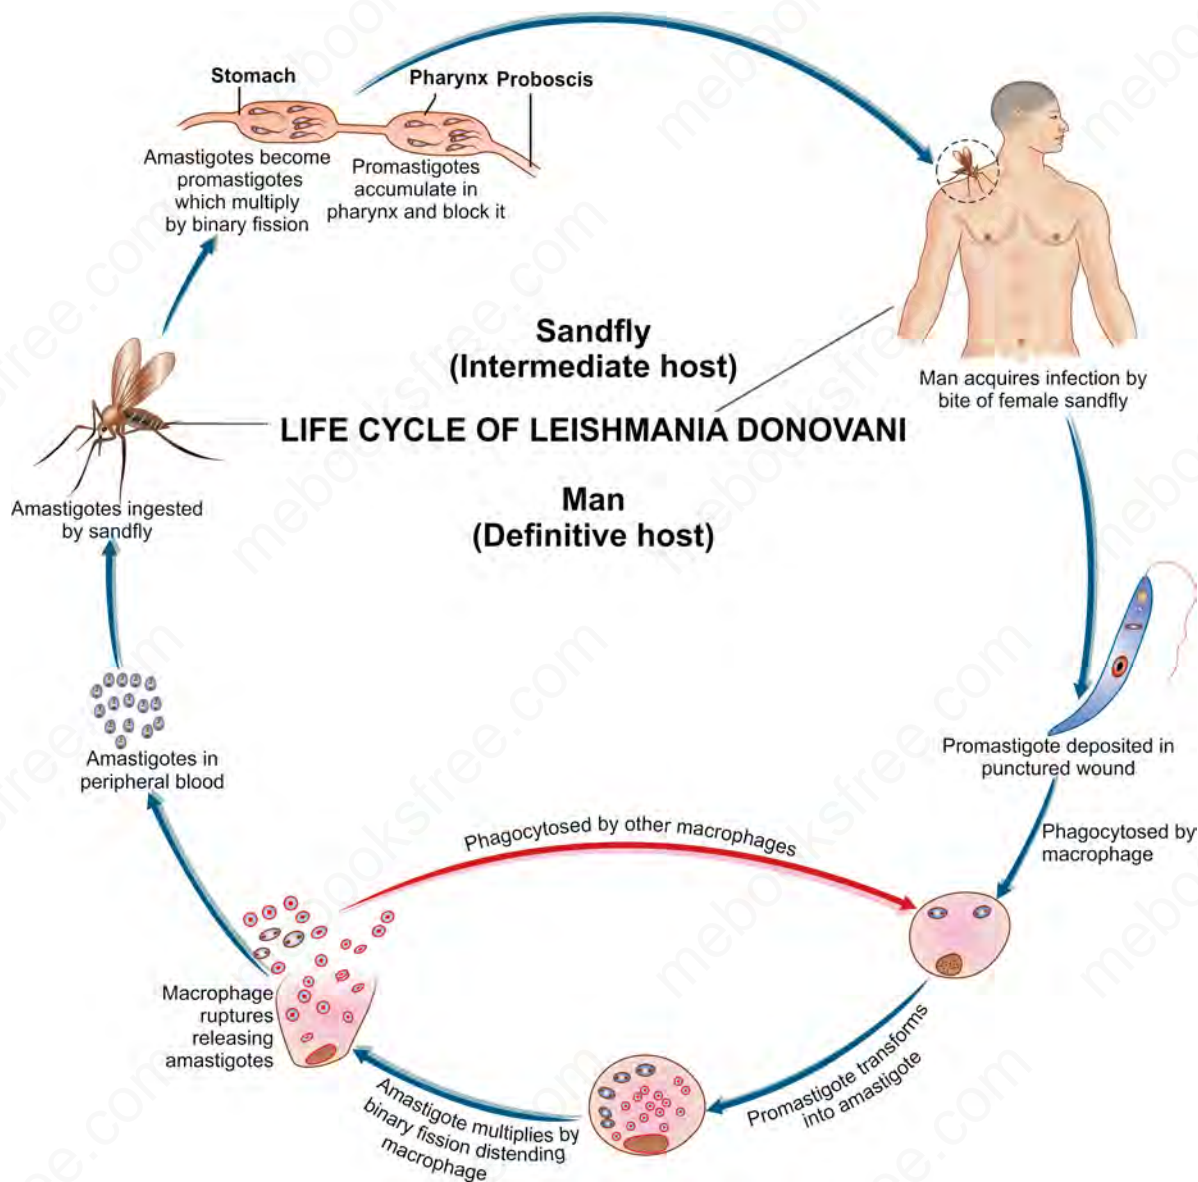

Fig. 2: Life cycle of *Leishmania donovani*

Pigmentation of skin – around malar bones and temples and around the mouth (hence labelled black sickness). Hair becomes dry, thin, brittle.

Splenomegaly – Firm, non-tender, may be massively enlarged.

Hepatomegaly – Moderate, neither painful nor tender.

Lymphadenopathy – Mainly nodes in the groin are slightly enlarged.

Jaundice – occasional.

Haemorrhagic manifestations – Epistaxis seen often, haemorrhages of skin, mucous membranes and retina rare.

Complications – Intercurrent infections especially of GI and respiratory tract (including pulmonary tuberculosis), uncontrolled bleeding.

Diagnosis

Parasitological diagnosis – In visceral leishmaniasis, demonstration of amastigotes in smears of tissue aspirates is the gold standard for the diagnosis, positive yields are aspirates from spleen, bone marrow or liver, lymphnode (Fig. 3). Buffy coat of blood (in HIV-positive patients). Culture can aid further to above yields. *Leishmania* can be isolated from skin in cutaneous leishmaniasis and PKDS

Fig. 3: Morphology of *Leishmania donovani*. (A) Amastigote (LD body); (B) Promastigote

or mucosal lesions in mucocutaneous disease. Slit-skin smears are taken from the raised edge of cutaneous leishmaniasis ulcers, or the centre of the nodule.

Immunological diagnosis – Direct agglutination test (DAT). Because of the difficulties associated with parasite detection, DAT based on agglutination of trypsinised whole promastigotes has been found to be highly specific and sensitive. ELISA has been used as a serodiagnostic test but its specificity depends on the antigen used. An amastigote-specific recombinant 39 amino antigen (rk39) derived from *L. chagasi* has been shown to be specific for antibodies in patients with VL caused by members of the *L. donovani* complex. A ready-to-use immuno-chromatographic strip test has been developed as a rapid test for use in field conditions. The limitation of rk39 test is that it can remain positive several years after cure and so cannot be used to detect relapse or reinfection.

Management

First-line Agents

Pentavalent antimonials – Sodium stibogluconate or meglumine antimoniate are effective in a daily dose of 20 mg/kg iv or im. Maximum tolerated dose is 30 mg/kg/day. A 28-day course in visceral and early mucocutaneous leishmaniasis, 20 days in uncomplicated cutaneous disease, and a variable duration in PKDL. Children tolerate these drugs better than adults. Full blood count, biochemistry and ECG are required.

Side effects – Increased serum amylase and liver enzymes, arthralgia and myalgia, thrombocytopenia, leucopenia, anorexia and thrombophlebitis. Pancreatitis is common. Patients complain of headache, lethargy, nausea, vomiting, a metallic taste in the mouth and pruritus.

ECG shows ST segment and T wave changes. If QT is prolonged to more than 0.5 seconds, may herald ventricular arrhythmia and sudden death, therapy should be stopped for 1-2 days and the dose then reduced.

Amphotericin B – is a first line drug if resistance to antimonials. Dose: 20 doses of 1 mg/kg on alternate days.

Lipid-associated amphotericin B – Three compounds have lower toxicity than amphotericin B. (a) Liposomal amphotericin B is used for visceral leishmaniasis, is rapidly effective and non-toxic. Total dose 20-30 mg/kg in five or more daily dose of 3-4 mg/kg over 10-21 days. (b) Amphotericin B lipid complex in doses of 2 mg/kg/day for 7-10 days. (c) Amphotericin B lipid complex i.v. doses of 3 mg/kg on alternate days.

Second-line Drugs

Miltefosine 100 mg/day or 50 mg bd for 3-4 weeks or Sitamaquine or Kalozoquine 1 mg/day po for 2 weeks. Interferon α – improves cure rates with pentavalent antimonials in relapsed or unresponsive patients.

Leishmaniasis in HIV-infected patients – Symptoms may be vague, laboratory abnormalities less severe, and hepatosplenomegaly may be absent or slight. Amastigotes may be found in bone marrow aspirates or skin biopsies of febrile HIV-positive patients. GI symptoms may predominate, and amastigotes of *Leishmania* can be found in rectal or duodenal biopsies. About 80% of patients respond to antileishmanial treatment but most relapse 2-12 months later.

Cutaneous leishmaniasis – Here amastigotes multiply in dermal macrophages near the sand-fly bite, typically on cheeks, ears or limbs, lesions may be nodular or ulcerative, single, or multiple satellite nodules or lymphangitic spread. Most typical lesion is a chronic 2-5 cm ulcer with indurated margins that may be covered by a fibrous crust. The ulcers are painful if large or infected. Biopsies show intense lymphoid and monocytic infiltrate with granulomas. A 'tissue paper' scar remains after healing. Because of natural healing, cutaneous leishmaniasis requires treatment only when lesions are large, multiple, disfiguring or cover a joint.

Post-kala-azar dermal leishmaniasis (PKDL) – Occurs months to years after visceral leishmaniasis. The lesions of PKDL are hypopigmented patches, nodules and plaques on face, upper chest and hands. The disease is sometimes severe with desquamation of skin and mucosae. PKDL has been described in acute visceral leishmaniasis and in patients who have been symptomless earlier or who have not been treated for the disease. Parasites are scanty or absent in biopsies.

Treatment – treated with pentavalent antimonials for 60-120 days. This prolonged course leads to noncompliance. The alternative—several courses of AmB spread over several months is expensive and unacceptable for most patients. Oral miltefosine for 12 weeks, in the usual daily doses, cures most patients. (a) Pentavalent antimony or intralesionally – About 2 ml of undiluted drug is infiltrated into the base and edges of the lesion every 2-3 days for 2-3 weeks. (b) Topical preparation – 15% Paromomycin in 12% methylbenzethonium chloride as ointment. (c) Cryosurgery – Freezing with CO₂ snow.

Paromomycin 15% in methylbenzethonium chloride b.d. for 10-30 days by topical application.

Mucocutaneous leishmaniasis – usually follows cutaneous leishmaniasis by months or years, but some with mucocutaneous leishmaniasis have active cutaneous leishmaniasis. Usually, tip of the nose or upper lip are first involved with painless induration or ulceration. It may remain static or spread slowly over months to years into nasopharynx, palate, uvula, larynx and upper airways. Biopsies show chronic inflammation with scanty amastigotes. Early lesions respond well to antimonials or amphotericin B, but relapses are common.

TRYPANOSOMIASIS

African trypanosomiasis (sleeping sickness) – is caused by the parasite *Trypanosoma brucei*. The main mode of transmission is through the bite of infected tsetse flies.

Clinical Features

Insidious Onset

Haemolympathic stage (stage I) – About 5 days after the infective bite, a small, raised papule develops at the site and increases rapidly in size. It is surrounded by an erythematous tissue reaction with regional lymphadenopathy (trypanosomal chancre) that resolves after 2-4 weeks.

Following the multiplication at the site of inoculation, trypanosomes invade the haemo-lymphatic system. Release of cytokines during periods of increased cell lysis results in intermittent fever, chills, headache and joint pains. Hepatosplenomegaly and generalised lymphadenopathy are common. Enlargement of lymph nodes in the posterior triangle is a reliable sign – Winterbottom's sign. Other signs are a fleeting patch, rash, myxoedematous infiltration of connective tissue (puffy face syndrome).

Meningoencephalitic stage (stage II) – Cerebral involvement occurs as trypanosomes cross the blood-brain barrier. There is increasing headache, change in

behaviour. Convulsions are common. Sleep abnormalities lead to a somnolent and comatose state followed by death.

Diagnosis

Detection of the parasite in chancre or lymph node aspirates, blood or CSF. Serology is useful for detection of antibodies in gambiense sleeping sickness. The card agglutination test is used for rapid screening.

Management

Stage I – (a) *Pentamidine* im 4 mg/kg daily or on alternate days for 7-10 injections. Side-effects are hypotension, shock and renal, hepatic and pancreatic dysfunction, and polyneuropathy. (b) *Suramin* by slow iv injection. Serious adverse effects are rare. Test dose 5 mg/kg on day 1. Days 3, 10, 17, 24 and 31, 20 mg/kg.

Stage II – (a) *Melarsoprol* – by slow iv injection clears trypanosomes rapidly. Dose: Day 1-10: 2.2 mg/kg. Serious side-effect is acute, often haemorrhagic coagulopathy. Simultaneous administration of prednisolone is beneficial in patients with high CSF cell counts. (b) *Eflornithine* – 100 mg/kg qds. for 14 days. Adverse effects are those as with cytotoxic drugs. (c) *Nifurtimox* – is second-line drug for Melarsoprol-refractory disease. 5 mg/kg tds for 30 days.

AMERICAN TRYPANOSOMIASIS (CHAGA'S DISEASE)

It is caused by *T. cruzi*, and usually transmitted to vertebrates by blood-sucking triatomine bugs. Also through blood transfusion and congenital.

Clinical Features

Acute phase – Local reaction at site of inoculation, often presenting as orbital oedema (Romana's sign) with local lymphadenopathy. After about 2 weeks a toxæmic phase may follow with fever, hepatosplenomegaly. Death in this phase results from cardiac involvement.

Chronic phase – Gradual development of serious complications. (a) *Heart* – Amastigotes form pseudocysts in myocardial tissue causing cardiomyopathy, arrhythmia and cardiac failure. (b) *Intestinal tract* – Dilatation of intestinal organs (mega-oesophagus, mega-colon).

DIAGNOSIS – (a) Direct methods – for acute Chaga's disease – Demonstration of trypanosomal parasites or DNA. (b) Indirect methods – for chronic Chaga's disease – Demonstration of specific antibodies.

Fig. 4: Life cycle of *Entamoeba histolytica*

MANAGEMENT – (a) *Nifurtimox* 8-10 mg/kg/day in 3 divided doses for 30-120 days. (b) *Benznidazole* 5-10 mg/kg/day in 2 divided doses for 30-60 days, more effective than nifurtimox and well tolerated.

2. PROTOZOAL GI INFECTIONS

AMOEBIASIS

Amoebiasis is a common infection of the GI tract by the protozoan parasite *Entamoeba histolytica*. Although the parasite often behaves as a commensal causing no symptoms or signs (luminal amoebiasis), it can be pathogenic and result in invasive amoebiasis. This can be in the form of (a) Intestinal features (diarrhoea or dysentery). (b) Extra-intestinal lesions (usually liver abscesses) from blood-borne dissemination of amoebae.

Transmission

Infection is generally acquired by swallowing cysts of the parasite in foodstuffs faecally contaminated by unclean

habits or agency of flies or use of human faeces as fertiliser, rarely contamination of water. In addition, there are high rates of infection among male homosexual populations, and epidemic outbreaks can occur in institutions such as mental hospitals and schools. See Figure 4 for the life cycle of *E. histolytica*.

Reservoir of infection – *E. histolytica* is essentially a parasite of man, but is occasionally found in dogs, rats and other animals.

Intestinal Amoebiasis

1. **Asymptomatic carriers** – in general excrete small number of cysts. Only about 10% have GI symptoms.
2. **Acute rectocolitis** – usually presents as non-toxic dysenteric syndrome. Onset is gradual with loose, watery stools that rapidly become blood-stained with mucus. Tenesmus may occur.
3. **Fulminating necrotising colitis** (toxic megacolon) – is more common in malnourished infants, the elderly and immunocompromised patients, or after inappropriate use of corticosteroids. Features are numerous bloody

Table 6: Comparison between amoebic and bacillary dysentery

	<i>Amoebic</i>	<i>Bacillary</i>
Onset	Gradual	Sudden
Clinical appearance	Toxic in children, usually non-toxic in adults	Often toxic
Dehydration	Common in children, unusual in adults	Common
Tenesmus	Severe	Moderate
Hepatomegaly	Common	Uncommon
Stool	May be semiformed, blood and mucus Leucocytes uncommon	Blood and mucus, usually liquid Leucocytes common
Colonic ulcerations	Usually segmental	Diffuse

**Figs. 5A to E:** *Entamoeba histolytica* (A) Trophozoite; (B) Precystic stage; (C) Uninucleate cyst; (D) Binucleate cyst; (E) Mature quadrinucleate cyst

stools, generalised abdominal pain, rectal tenesmus, high fever, nausea and vomiting. Colonic perforation is a common complication. Toxic megacolon occurs occasionally and is characterised by marked abdominal distension. Diagnosis - Presence of amoebic trophozoites in stools, positive serology, leucocytosis. Abdominal radiographs may reveal a paralytic ileus located in the area of the colon if there is associated perforation. In toxic megacolon generalised distension of the colon with intramural gas may be seen.

- Post-dysenteric colitis** - (a) A milder functional form constituting the irritable bowel syndrome. (b) Ulcerative post-dysenteric colitis.
- Amoeboma** - is a late complication of previous amoebic dysentery. Clinical finding is a tender mass lesion that is usually single (often in the caecum) or occasionally multiple. It may rarely present as an intestinal occlusion simulating colonic carcinoma. Amoebae may be difficult to find in the lesion. Histology shows granulation tissue and in contrast to amoebic dysentery, amoebic serology is always positive.
- Amoebic appendicitis** - Clinical features same as that of bacterial appendicitis, but often there is also involvement of caecum, giving rise to blood-stained diarrhoea.
- Amoebic typhlitis** - Sometimes the localisation of amoebae is confined to caecum and ascending colon

and clinical picture may be that of chronic typhlitis rather than acute dysentery.

Table 6 compares amoebic and bacillary dysentery.

Investigations

- Rectosigmoidoscopy and colonoscopy** - of benign cases show small ulcerations covered by a yellowish exudate containing many trophozoites. In more advanced cases ulcers are large and more numerous, with sub-mucosal haemorrhages.
- Microscopy** - for presence of cysts and trophozoites of *E. histolytica* in stools or scrapings of affected mucosa (Figs. 5A to E).
- Serology** - Anti-amoebic antibodies are present in 75-85% of patients with invasive amoebiasis. Antigenemia is present in more than 90%, and all have IgA antibodies to cysteine-rich area of the galactose-inhibitable lectin of *E. histolytica*.

Extraintestinal Amoebiasis

- Amoebic liver abscess** - **Predisposing factors** - More common in adult males, excessive alcohol, malnutrition or trauma over hepatic area. History of dysentery may or may not be obtained. The abscess is usually single and the most common location is the right lobe of the liver.

Fig. 6: Upward enlargement of liver in hepatic amoebiasis

Fig. 7: CT scan of a single amoebic liver abscess

Clinical Features

Onset – insidious with no symptoms till abscess is large, or symptoms of chronic ill-health, or abrupt onset suggestive of right basal pneumonia, or sometimes acute abdomen. Rarely first noticed when abscess bursts through lung or bowel.

- Pain or discomfort in liver area** – (i) At first dull and aching or sensation of heaviness in right hypochondrium, later sharp and stabbing; usually over hepatic area, rarely in epigastrium or axillary region. (ii) Pain is referred to tip of right or left shoulder when abscess is located high in one or other lobes of the liver, and there is commonly an irritant cough. (iii) Pain on firm pressure with fingertips in an intercostal space and over a limited area (compression test, point tenderness) common and valuable localising sign. Pain may be increased by deep inspiration or coughing. Patient tends to lean to the left side to relieve the pain.
- Enlarged tender liver** – Localised visible bulge in epigastrium, right hypochondrium or lower intercostal spaces.
- Local oedema** – of chest or abdominal wall.
- Icterus** – Moderate in about 25%. Rarely deep jaundice due to obstruction by an abscess of intrahepatic bile ducts.
- Abdominal tenderness** – Marked tenderness over caecum and colon if associated dysentery.
- Constitutional symptoms** – (i) Fever varies between 38°C and 40°C, often in spikes, with rigours and profuse sweating in upper half of body, particularly at night. Rigours may occur and indicate threatened rupture. (ii) Profuse sweats. (iii) Emaciation. (iv) Sallow skin. (v) Rheumatic-like pains in joints.

Investigations – (a) Leucocytosis. (b) Alkaline phosphatase elevated (the most reliable biochemical indication of amoebic liver abscess). (c) CXR – Elevated right diaphragm (Fig. 6). (d) Ultrasonography or CT – Space-occupying lesion may be seen (Fig. 7). (e) Anti-amoebic serum antibodies – in more than 90%, titres reach a peak by second or third month. (f) Cellulose acetate precipitate (CAP) and immunofluorescence antibody test. CAP is usually positive in acute infection. IFAT can also reflect previous colitis infections.

Note: Stool microscopy for trophozoites or cysts is of little value because few patients have associated intestinal amoebiasis.

Different Diagnosis

(a) **Pyogenic liver abscess** – History of hepatobiliary disease, abdominal sepsis, appendicitis, diverticulitis or abdominal surgery. Jaundice, pruritus and septic shock common. Hepatomegaly and elevated diaphragm on chest radiography uncommon. Negative amoebic serology. (b) **Hepatocellular carcinoma** – when patient is febrile and wasted with vague abdominal discomfort. Distinct images on CT, and tumour markers such as α -fetoprotein or carcinoembryonic antigen are useful. (c) **Infected hydatid cyst**. (d) **Subphrenic abscess**.

Complications

Pleural effusion in more than 50%.

Extension of ALA outside the liver:

- Brain** – Necrotising abscess-like lesion.
- Lung** – Through anterior abdominal wall or through chest wall or through diaphragm into pleura or lung, or penetration of bronchus followed by coughing up of usually chocolate coloured material.

Table 7: Management of amoebiasis

Clinical condition	Drug	Dose (Adult)
Cyst-passers	Diloxanide furoate	500 mg tds × 10 days
	Iodoquinol	650 mg tds × 20 days
Amoebic dysentery or amoeboma	Metronidazole or	500 mg tds × 5 days
	Tinidazole or	600 mg tds × 5 days
	Ornidazole	500 mg tds × 5 days
	Secnidazole plus	2 g single dose
	Nitazoxanide	500 mg bd
	Diloxanide furoate	As above
Liver abscess	Dehydroemetine	1.5 mg/kg/day × 5 im (maximum 90 mg/day)
	Metronidazole or	As above 500 mg iv q6h × 6-10 days
	Tinidazole or	2 g od × 3 days
	Secnidazole or	2 g od × 3 days
	Ornidazole	2 g od × 3 days

- *Pericardium* – A left lobe abscess may extend into pericardium.
 - *Peritoneum* – May burst into peritoneum presenting as an acute abdomen.
 - *Bile duct* – May press upon bile duct and manifest as obstructive jaundice.
 - *Intestines* – Rarely it may work its way into the colon or duodenum when the patient may have a large loose motion.
 - *Retroperitoneal* – It may extend into the posterior abdominal wall retroperitoneally with a swelling over the kidney region as presenting manifestation.
 - *Skin of chest or abdominal wall* – Involvement of skin of abdominal wall after percutaneous rupture of abscess.
 - *Other organs* – Extension to spleen or rupture into stomach, renal pelvis or vena cava, long bones and testis.
2. **Pleuropulmonary amoebiasis**
 3. **Amoebic pericarditis** – Amoebic abscess of left lobe may rupture into pericardium and cause acute cardiac tamponade.
 4. **Cerebral** – Abscess of brain from blood-borne infection.
 5. **Urogenital** – Subacute cystitis and prostatitis, abscess of kidney, epididymis or testis, ovary or perianal region. Ulcer of urethra in male and cervix in female. *E. histolytica* may be found in urine if fistula between rectum and bladder. Amoebic vaginitis. Amoebic ulceration of glans penis.
 6. **Abscess of spleen.**
 7. **Cutaneous** – Ulceration of skin around anus, at the site of drainage of a liver abscess, around colostomy wound in a case of chronic ulcerative colitis, or sinus of an empyema.

Management of amoebiasis is depicted in Table 7.

Management of Liver Abscess

Percutaneous aspiration of liver abscess is done with wide bored needle. Indications for liver abscess aspiration are listed in Table 8.

Site – The needle is introduced into area of maximum tenderness or into 8th or 9th intercostal spaces in midaxillary line. All available pus should be removed. If abscess is in left lobe or presenting on lower surface aspiration should be performed through the open abdomen.

SURGICAL DRAINAGE – performed under ultrasound or CT guidance. *Indications* – (i) Rupture of liver abscess. (ii) Imminent rupture of an inaccessible liver abscess (particularly of left lobe). (iii) When there is risk of peritoneal leakage of necrotic fluid after aspiration.

Lung Abscess

Primary – Development of small bronchopneumonic areas due to embolic invasion of the pulmonary circulation by *E. histolytica*.

Secondary – (a) Pulmonary abscess. The liver abscess gets through adherent visceral pleura into the lung. Patient has incessant cough and brings out chocolate-coloured material for one or two days followed by blood-stained expectoration (bronchobiliary fistula). (b) Bronchohepatic fistula with pulmonary involvement. (c) Consolidation. (d) Empyema extending from liver abscess.

Bronchitis and bronchopneumonia – sometimes amounting to gangrene.

Table 8: Indications for liver abscess aspiration

- Left lobe abscess.
- Abscess is pointing.
- Massive abscess.
- Persistent localised tenderness.
- Markedly raised hemidiaphragm.
- Pleuritic pain suggesting an impending leak.
- Failure of symptoms to remit on drug therapy.
- Pyogenic or mixed infection is suspected.

Perforation – Gastric suction, IV fluids and electrolytes together with tetracycline 1 gm daily. IV metronidazole. Surgery should be avoided.

GIARDIASIS

Giardia lamblia is a micro-aerophilic, flagellate protozoan parasite of the proximal small bowel in humans, where the motile, free-living trophozoite replicates sexually and cyst formation is initiated. Many of those infected are asymptomatic cyst-excretors. Giardiasis causes diarrhoea of varying severity, and malabsorption in some patients.

Transmission

Occurs by ingestion of cysts in contaminated food and water, or through person-to-person contact in sexual activity and among children. Contaminated swimming pools can be a source of infection. Hypogammaglobulinaemia predisposes to persistent severe or relapsing giardiasis. *Giardia* is not an uncommon cause of diarrhoea in AIDS.

Pathogenesis

Carbohydrate-bearing lectins are involved in adhesion of trophozoites to the enterocyte brush border. The organism damages the fuzzy coat (a site of extracellular digestion) and the enterocyte surface membrane, impairing digestive functions. *Giardia* affects vitamin B₁₂ absorption by altering intraluminal events rather than damaging the mucosa.

Clinical Features

- Diarrhoea with pale, foul smelling faeces (diarrhoea can be acute)
- Abdominal discomfort, distension and flatulence
- Marked lethargy
- Weight loss
- Symptoms regress spontaneously after several weeks, rarely they persist for months.

Investigations

- Stool microscopy after formol ethyl acetate concentration reveals cysts. Smears of fluid stools from acute onset cases may show trophozoites.
- Antigen tests.
- Jejunal fluid and biopsy sections show trophozoites.
- Barium meal – Thickening of mucosal folds and dilated loops of small bowel.
- Jejunal biopsy – Reduced villous height, increased crypt depth and increased lamina propria infiltrate of plasma cells and lymphocytes in patients with more severe symptoms and malabsorption.

Differential Diagnosis

Acute gastrointestinal infections

- Salmonella, Shigella, Campylobacter (usually associated with fever, colicky abdominal pain and often dysentery); pus cells in stools.
- E. coli and rotavirus
- Clostridium difficile infection
- Cryptosporidium (self-limiting in immuno-competent patients)
- Cyclospora cayetanensis

Persistent diarrhoea and malabsorption

- Coeliac disease (*giardia* may render overt previously covert coeliac disease)
- Jejunal diverticulosis
- Intestinal stricture
- Pancreatic disease

Treatment: Drugs

- Tinidazole 2 g (50-75 mg/kg) single dose, may be repeated after 7 days *or*
- Metronidazole 2 g single daily dose for 3 days, can be repeated after 7 days.

If treatment fails

- Mepacrine (quinacrine) 100 mg tds for 7 days *or*
- Paromomycin 500 mg tds for 10 days

Treatment during pregnancy – Metronidazole 200 mg tds for 7 days (to be avoided in the first trimester).

BALANTIDIASIS

Balantidium coli is the only ciliate that infects humans. Human infection is common only in those living in close proximity to pigs. The organism can survive outside its mammalian host as a cyst, by which the disease is transmitted.

Clinical features – The trophozoites produce an illness that clinically resembles amoebic colitis.

Treatment – Tetracycline 500 mg qds for 10 days. The organism is also sensitive to ampicillin and metronidazole.

CRYPTOSPORIDIOSIS

Clinical features – Illness varies from asymptomatic carriage to a severe, life-threatening diarrhoeal disease in HIV/AIDS patients, cryptosporidiosis is generally found in patients with low CD₄ counts.

AIDS patients may also develop a sclerosing cholangitis-like disease that presents with right upper quadrant abdominal pain and/or jaundice.

Diagnosis – Microscopy of stool smears. Faecal immunofluorescent test and faecal antigen tests.

Treatment – Paromomycin and nitazoxanide may be effective.

3. GASTROENTERITIS

BACTERIAL GASTROENTERITIS (ACUTE INFECTIOUS DIARRHOEA)

Mechanisms

Bacteria cause gastroenteritis by one of three principal processes associated with distinctive but overlapping clinical syndromes:

- Production of preformed toxins which induce vomiting and abdominal cramps within a few hours.
- Secretion of toxins after adhering to surface epithelium – Non-invasive bacteria that secrete toxins usually cause watery diarrhoea without fever.
- Invasion of intestinal mucosa causes either dysentery or enteric fever.

Bacterial causes of gastroenteritis and commonly associated clinical syndromes are listed in Table 9.

Campylobacter gastroenteritis – Infection largely occurs in children under 2 years in the developing world, and in older children and young adults elsewhere. Infection is acquired through ingestion of contaminated food or milk or close contact with infected pets.

Clinical features – Spectrum of clinical disease varies from asymptomatic carriage to life-threatening toxic megacolon. After an incubation period of 1-6 days, there is fatigue and myalgia followed by anorexia, fever, lower abdominal pains and diarrhoea. Stool samples always contain pus cells.

Complications – Guillain-Barre syndrome though rare.

Table 9: Bacterial causes of gastroenteritis and commonly associated clinical syndromes

Intoxication
Staph. aureus
Bacillus cereus
Clostridium perfringens
Watery diarrhoea
Vibrio cholera
Salmonella spp.
Enterotoxigenic E. coli
Enteropathogenic E. coli
Clostridium difficile
Listeria monocytogenes
Bacillus cereus
Dysentery
Shigella spp. (shigellosis)
Enteroinvasive E. coli
Enterohaemorrhagic E. coli
Campylobacter
Yersinia
Enteric fever
Salmonella typhi
Salmonella paratyphi

Management – Erythromycin or ciprofloxacin. Racecadotril, a potent inhibitor of enkephalinase is effective as single dose in acute infective diarrhoea in adults. Dose 1.5 mg/kg.

Shigella – Sh. infection is the classical cause of *bacillary dysentery*. Four species in decreasing order of severity of disease gives rise to dysentery are Sh. dysenteriae, Sh. flexneri, Sh. boydii and Sh. sonnei. Shigella spp. has been implicated as a cause of ‘gay bowel’ syndrome in homosexual men. There is no known animal reservoir (in contrast to many Salmonella spp.).

Shigella bacteraemia is uncommon except in immunocompromised host (e.g. HIV infection).

Cl. Fs. – Following an incubation period of 2-3 days, high fever, headache, malaise and anorexia occur, along with frequent small-volume stools progressing to passage of blood and pus and severe abdominal cramps, tenesmus and abdominal tenderness on palpation.

Diagnosis – Stool culture and identification of the organism by specific serological testing.

Treatment – Fluid replacement. (a) Antibiotics – Ofloxacin is drug of choice in most adults, co-trimoxazole and

Table 10: Main categories of diarrhoeagenic *E. coli*

Category	Epidemiology	Clinical features	Management
<i>Enterohaemorrhagic E. coli</i> 0.57:H7	Reservoir – Cattle Transmission – undercooked meat and unpasteurised milk, person-to-person	Produce bloody diarrhoea, no pus cells	Antibiotics contraindicated
<i>Enteropathogenic</i>	Infants <2 years. Reservoir – humans Transmission by hand and infected food	Watery diarrhoea High fatality rate Symptoms often prolonged	Cotrimoxazole in severe cases
<i>Enteroinvasive</i>	Reservoir – humans Transmission – person-to-person	Less severe than <i>Shigella</i> infection	Ciprofloxacin
<i>Enterotoxigenic</i>	Infants <3 years Reservoir – humans Transmission – food and water Most common cause of 'travellers', diarrhoea	Watery diarrhoea, in severe cases can mimic cholera, minimal fever	Cotrimoxazole, doxycycline or ciprofloxacin

ampicillin are alternatives in children. (b) Antidiarrhoeal agents – Single dose of Racecadotril (enkephalinase inhibitor) or Octreotide (Somatostatin analogue).

Diarrhoeagenic *E. coli*

Table 10 gives details about various diarrhoeagenic *E. coli* with epidemiological and clinical features and management.

Vibrio cholerae – The causative organism of *cholera*, is a short, curved, motile Gram-negative bacillus. The major pathogenic strain possesses a somatic antigen (O1) with two biotypes – classical and El Tor. Also, a strain with somatic antigen O139, the Bengal strain has appeared.

PATHOGENESIS – The major factor distinguishing O1 and O139 serotypes from other 'non-cholera' vibrios is the ability to produce an enterotoxin. This consists of a ring of five 'B' subunits around a central 'A' unit. This pentameric ring structure binds to GM₁ ganglioside on the enterocyte cell membrane and the A subunit stimulates enterocyte adenylate cyclase, leading to conspicuous secretion of small intestinal fluid and ultimately diarrhoea.

Clinical features – (a) Stage of evacuation – Sudden onset with frequent loose stools, first yellow soon become colourless, watery and copious with flakes of mucus (rice water stools). Copious and incessant watery vomit. Sub-normal temperature. (b) Stage of collapse – Depletion of water and salts occurs rapidly, leading to severe dehydration and hypovolemic shock, and ultimately to death.

Diagnosis – is mainly clinical. The organism can be grown from stool either directly or after alkaline enrichment.

Management – (a) Fluid and electrolyte replacement:

Mild case – Oral rehydration therapy with glucose-electrolyte solution. Constituents (g/litre):
Sodium chloride 3.5

Sodium bicarbonate 2.5

Potassium chloride 1.5

Glucose 20

Other solutions containing glucose polymers (e.g. rice water) and electrolytes are highly effective.

Severe case – IV fluids. Rate of infusion determined by skin turgor, whether eyes are sunken, pulse volume, auscultation of lung bases, measurement of urinary output.

Antibiotics – shorten duration of diarrhoea. Tetracycline 100 mg iv q6h for 24 hours, then 500 mg po for 3 days. Amoxicillin preferred in pregnant women. Doxycycline 300 mg single dose for contacts.

Immunisation – Vaccine containing suspension of 8000 organisms/ml, 0.5 ml followed after 7 days by 1 ml.

Clostridium difficile – is a Gram-positive, anaerobic spore-forming bacillus, and produces a syndrome ranging from a mild diarrhoea to pseudomembranous colitis and is often associated with antibiotic use (broad-spectrum cephalosporins). Additional risk factors are gastric acid suppression with proton pump inhibitors, enteral feeding, immunosuppressants and haemopoietic stem cell transplantation.

Clinical Features – Symptoms usually begin 4-9 days after starting antibiotic therapy to 6 weeks after finishing. Profuse watery diarrhoea, abdominal tenderness, fever and leucocytosis indicate probable colitis. The condition can progress to toxic megacolon and ultimately colonic perforation and death.

Diagnosis – 1. Toxin detection - (a) Cytotoxin assay. (b) Enzyme immunoassay. (c) PCR of stool. 2. Organism detection - (a) Common antigen testing antigen (GDH antigen). (b) Stool culture. 3. CDJ (*Xperia difficile*). 4. Colonic or histopathologic findings demonstrating pseudomembranous colitis.

Treatment – Stoppage of antibiotics especially clindamycin and cephalosporin. If severe colitis or if antibiotic needs to be continued, specific therapy with oral vancomycin or metronidazole. Cholestyramine and ion exchange resins which bind the toxins are alternatives.

ENTERIC FEVER

Enteric fever is usually caused by *S. typhi* (typhoid) or *S. paratyphi* (paratyphoid), and occasionally by other salmonella serotypes.

TYPHOID FEVER

Epidemiology

Causative organism – Gram-negative bacillus *Salmonella typhi*, a human pathogen which depends on man-to-man transfer for continued existence, and can survive for many weeks in sewage. *Transmission* – Main source of transmission in contamination of food and water with faeces from infected patients and carriers.

Pathogenesis

After ingestion and passage through gastric acid barrier, the organisms attach to small intestinal mucosa, penetrate it, and are transported by the lymphatics to the mesenteric lymph nodes. Following multiplication, they enter the blood stream via thoracic duct, then spread to bone marrow, spleen and liver, where they multiply. Secondary invasion of the blood and re-invasion of the bowel via infected bile then occurs. A particularly strong inflammatory response occurs in the ileal Payer's patches, and may lead to necrosis, ulceration, bleeding and occasionally perforation.

Incubation period – 10-15 days.

Clinical Features

Classically there is gradual onset of fever in the first week, remittent in second week and falling in third week. Patients complain of headache, anorexia, vague abdominal pain, constipation or diarrhoea, and dry cough. Rigours are uncommon. Occasional features include sore throat, epistaxis, coated tongue (typhoid V tongue), and relative bradycardia.

In the second week tender hepatomegaly, (typhoid hepatitis) and palpable spleen, and signs of bronchitis. Meningism may occur. Rose spots are scanty pink macules, usually on the trunk, that blanch on pressure are seen from second week onwards.

In the third and fourth weeks of illness gastrointestinal bleeding and intestinal perforation occur; both are life-threatening and require immediate fluid resuscitation and surgical intervention.

Untreated patients can become toxic, mentally stuporose and dehydrated, and may develop ileal perforation, GI haemorrhage, coma, shock, pneumonia, nephritis and acute psychosis.

Laboratory Diagnosis

Various tests used in laboratory diagnosis of typhoid are listed in Table 11.

Differential Diagnosis

- Paratyphoid fever* – (a) Mode of onset often acute and atypical. (b) Wider remissions of temperature. (c) Eruption more profuse. (d) Less toxæmia. (e) Sweating and rigours more common. (f) Intestinal complications rare.
- Short fever* – A fever lasting for 8 to 10 days; no associated signs, probably of viral origin. Subsides spontaneously. No complications.
- Amoebic liver abscess* – Pain in right hypochondrium and lower chest, moderate fever, enlarged tender liver or compression tenderness over right lower intercostal spaces. Right hemidiaphragm may be elevated and immobile on fluoroscopy.

Table 11: Laboratory diagnosis of typhoid

Test	Comments
<i>Microbiological tests</i>	
Blood culture	Gold standard test, but sensitivity may be low in endemic areas with high rates of antibiotic use
Bone marrow culture	Greater sensitivity but invasive and thus of limited clinical value
Urine culture	Variable sensitivity
Stool culture	Sensitivity lower and not used routinely
<i>Molecular diagnostics</i>	
PCR	Similar sensitivity to blood culture but lower specificity
Nested PCR	May replace blood culture as the new 'gold standard'
<i>Serological diagnosis</i>	
Widal test (tube dilution and slide agglutination)	Classic and inexpensive Positive by 10th day. Lacks sensitivity and specificity
Typhidot	Lower sensitivity than Typhidot-M
Typhidot-M	Higher sensitivity than Typhidot in some series
Tubex	Promising initial results

4. *Viral hepatitis* – in pre-icteric stage. Marked nausea and vomiting, hepatic tenderness, high coloured urine.
5. *Tuberculous meningitis* – Absence of abdominal discomfort, greater frequency of vomiting, persistence of headache after first week, irritability, irregular pupils, CSF changes.
6. *Miliary tuberculosis* – Increased respirations, irregular temperature, tachycardia, cough and cyanosis, symptoms referable to alimentary tract less pronounced. Early loss of flesh. Diagnostic CXR.
7. *Heat fever* – Not uncommon in children and aged. Fever may be continuous or touch normal for some hours every day. Absence of other physical signs. Response to lowered temperature.
8. *Subacute infective endocarditis* – (a) Fever seldom continuous or high. (b) Frequent chills with septic type of temperature. (c) Cardiac signs. (d) Anaemia. (e) Embolic phenomenon. (f) Positive blood culture.
9. *E. coli infection* – Pyelitis or septicaemia – High fever, though not of continuous type. May last for 2-3 weeks. Leucocytosis, tenderness in loins, pus in urine or positive blood culture.
10. *Malaria* – Sudden onset, wide diurnal variation, early splenic enlargement, malarial parasites in blood, response to antimalarial drugs.
11. *Kala-azar* – May have typhoid type of onset. Progressive splenic enlargement. Characteristic double rise of temperature. Good appetite. No toxæmia.
12. *T.B. peritonitis* – Slow onset, continuous fever and meteorism as in typhoid. Caseous masses palpable, negative serology.
13. *Brucellosis* – An epidemic disease of long duration, characterised by fever, continuous, remittent and intermittent in type, in most cases enlarged spleen, profuse perspiration, listlessness and almost invariably relapses, accompanied by pains of a rheumatic or neuralgic character, arthralgia or swelling of joints. Positive agglutination test.
14. *Infectious mononucleosis* – Abrupt onset with sore throat, prolonged pyrexia; the temperature at first remittent may later become intermittent. Considerable constitutional disturbance. Papular or maculopapular rash chiefly on trunk. Spleen rarely enlarged. Late glandular enlargement.
15. *Rickettsial infections* – Usually sudden onset. General malaise, headache, fever, chills, photophobia. Occasional vomiting. Eschar particularly in scrub typhus and Rocky Mountain spotted fever. Rash common.
16. *Psittacosis* – History of contact with parrots, pigeons or budgerigars. Influenza-like illness with atypical pneumonia. Rising titre of antibodies or single high titre to the complement-fixing antigen of Chlamydia group B.
17. *Collagen disease* – e.g. SLE or polyarteritis nodosa. Symptoms and signs referable to multiple organ systems. Weakness and weight loss.
18. *Tularemia* – “typhoid type” may occur in laboratory workers. Sudden onset with headache and fleeting pains; pyrexia may subside to normal or nearly so on 3rd to 6th day. Spleen not palpable. Positive agglutination of serum by *F. tularensis*.
19. *African trypanosomiasis* – Trypanosomal chancre. Periods of febrile illness (haemolymphatic stage) lasting for one week or more and accompanied by severe headache, general malaise, myalgia and joint pains, and progressive lymphadenopathy (especially in *T. brucei gambiense* infection). Transitory erythematous rash (circinate erythema). Other organ lesions may develop – myocarditis, splenomegaly, hepatomegaly. Meningoencephalitis may develop during the course of infection. Diagnosis – Trypanosomes in blood or tissue fluid (Fig. 8). Immunodiagnostic tests – Indirect, fluorescence antibody test (IFAT) and ELISA. CSF in case of meningo encephalitis.
20. *Melioidosis* – with acute septicaemia. Clinical features of Gram-negative septicaemia with metastatic abscesses particularly in lungs, liver and spleen. Diagnosis – Demonstration of bipolar Gram-negative rods in films of pus or secretions. Culture – Isolation of *Burkholderia pseudomallei*.
21. *Opportunistic infections in AIDS* – See AIDS.

Management

Antibiotics used in treatment of enteric fever are given in Table 12.

Fig. 8: *Trypanosoma rhodesiense*, blood smear Giemsa stain, magn × 1100

Table 12: Antibiotics used in treatment of enteric fever

Optimal treatment				Alternative effective treatment		
Susceptibility	Drug	Daily dose (mg/kg)	Course (days)	Drug	Daily dose (mg/kg)	Course (days)
<i>Uncomplicated typhoid fever</i>						
Fully sensitive	Fluoroquinolone (such as ofloxacin or ciprofloxacin or gemifloxacin)	15	5-7*	Chloramphenicol	50-75	14-21
				Amoxicillin	75-100	14
				TMP-SMX	8-40	14
Multidrug resistance	Fluoroquinolone or Cefixime	15	5-7	Azithromycin	8-10	7
Quinolone ⁺ resistance	Azithromycin or Ceftriaxone	15-20 8-10 75	7-14 7 10-14	Cefixime	15-20 20	7-14 7-14
<i>Severe typhoid fever requiring parenteral treatment</i>						
Fully sensitive	Fluoroquinolone (Such as ofloxacin)	15	10-14	Chloramphenicol	100	14-21
				Ampicillin	100	14
Multidrug resistant	Fluoroquinolone	15	10-14	TMP-SMX	8/40	14
				Ceftriaxone or	60	10-14
Quinolone resistant	Ceftriaxone or Cefotaxime	60 80	10-14 10-14	Cefotaxime	80	10-14
				Fluoroquinolone	20	14

* Three-day courses also effective, particularly so in epidemic containment.

⁺ Optimum treatment for quinolone resistant typhoid fever has not been determined. Azithromycin, third generation cephalosporins, or a 10-14-day course of high dose fluoroquinolone is effective. Combinations of these are now being used.

Corticosteroids – Dexamethasone 3 mg/kg stat, followed by 8 doses of 1 mg/kg 6-hourly for 48 hours, each given by IV infusion over 30 minutes, is beneficial in severely ill patients (delirious, obtunded, stuporose, comatose or shocked patients).

GENERAL CARE

1. Fluid and electrolyte replacement. Inotropic support in shock.
2. Diet – To provide about 3,000 calories per day. Advantages are – increases patient's resistance, haemorrhage and perforation less likely, prevents rapid emaciation. Articles of diet given – milk, lactose, toast, butter, mashed potatoes, lightly boiled egg, boiled chicken or fish, corn flour or well-boiled rice pudding, and custard, bananas and apples. Feeds 2 hourly.

Symptomatic management and management of complications

- (a) *Abdominal distension* – (i) Omit sugar. (ii) Reduce amount of milk. (iii) Flatus tube.
- (b) *Diarrhoea* – may be due to disease itself or sometimes the drug. (i) Reduce quantity of milk or dilute it further. Give butter-milk and sago kanji or rice kanji in water, apple juice or pomegranate juice. (ii) Omit sugar. (iii) If intractable stop milk and give albumen water or whey for few days.

- (c) *Hyperpyrexia* – (i) Tepid sponge. (ii) Ice bag to head. (iii) Sponging with ice-water. (iv) Ice water enema.
- (d) *Haemorrhage* – Most episodes of GI bleeding are self-limiting, and only a few patients require transfusion.
- (e) *Perforation* – (i) Slow perforation – Gastric suction and IV fluids. Broad spectrum Gram-negative agent (e.g. cefotaxime with metronidazole). (ii) Acute perforation – Laparotomy.

Relapse comprises a second episode of fever, usually milder than the first, occurring 1 or 2 weeks after recovery from the episode. It is managed as in the initial episode.

Treatment of carriers – 4-week course of fluoroquinolone gives best results.

Immunisation

- (a) *Anti-triple typhoid vaccine* containing in each ml. 1,000 million typhoid organisms, 250 million each of paratyphoid 'A' and 'B' organisms. Course of 3 injections of 0.5 ml, 1 ml and 1 ml subcutaneously at intervals of not less than 7 days or not more than 28 days. Immunity lasts for about 12 months. Disadvantages are: (i) The paratyphoid antigens in the vaccine are of doubtful effectiveness but also presence of extra proteins of Paratyphi organisms cause local pain, headache and

fever. (ii) Vaccination with TAB does not stimulate cell mediated immunity. (iii) Antibodies produced by TAB differ from those produced during the disease. Hence WHO has recommended that TAB should be discontinued.

- (b) *V1 capsular polysaccharide typhoid vaccine* - 25 mg in each dose. Single dose (0.5 ml) SC or IM gives protection for 3 years. However, the V1 antigen does not invariably provoke V1 antibody. Booster every 2 years.
- (c) *Ty21a-oral vaccine* - TY21a is a galactose epimerase mutant *S. typhi* given as oral enteric coated capsules. The bacilli invade mononuclear cells and undergo 4-5 cell divisions in intestinal tract. This stimulates immunity, but the bacilli do not survive within the cells, as they lack the essential enzyme UDP-galactose-4 epimerase and are therefore avirulent. The vaccine stimulates cell mediated immunity and also stimulates intestinal IgA. Dose - One capsule on days 1, 3 and 5 irrespective of age one hour before meal with milk or water. Not recommended for children under 6 years of age. Protection commences 2 weeks after last capsule and lasts for at least 3 years. Booster every 5 years. Contraindications - Immunodeficiency states including treatment with immunosuppressive and antimetabolic drugs, acute febrile illness and acute intestinal infection. Adverse reactions - Mild GI disturbance, transient exanthema.

Salmonella gastroenteritis - Animals are a reservoir for human infection which usually follows consumption of food, water or milk contaminated with animal faeces. Person-to-person spread can also occur, most notably from infants and individuals with faecal incontinence. Epidemics have resulted from infected eggs involving *S. enteritidis* and *S. typhimurium* from infected beef. Treatment - Ciprofloxacin especially neonates, and immuno-suppressed patients.

Viral Gastroenteritis

Various viruses infecting the human gut are listed in Table 13.

4. PLAGUE

EPIDEMIOLOGY

Causative organism - Gram negative bacilli *Yersinia pestis*. **Transmission** - It is normally transferred from rodent to rodent (in whom it is enzootic) by fleas (*Xenopsylla cheopis*). Man can be infected through the infected flea or occasionally by louse or bedbug, and sometimes from

droplet infection from cases of pneumonic plague. Permanent immunity results from an attack.

Incubation period - 2-4 days.

CLINICAL FEATURES

- Bubonic plague** - commonest variety.
 - Stage of invasion** - Bodyache, mental confusion. Bubo appears on second or third day, usually in groin. Very tender and associated with cellulitis of surrounding tissues.
 - Febrile stage** - Onset may be with high fever without prodromata. The temperature continues as a high remittent fever for 2-5 days and then falls suddenly, or gradually after 3-4 days, synchronous with the full development of the buboes. It may rise again if and when the buboes suppurate. Congested eyes, speech dull resembling alcoholic intoxication. Marked prostration, delirium, vomiting and oliguria, retention of urine, coma and convulsions may occur. Thready pulse, dilatation of heart and perhaps haemorrhages in later stages. Spleen and liver enlarged. Death may occur on third or fifth day.
 - Stage of recovery** - Constitutional symptoms abate usually on 10th day with fall of temperature and perspiration. Bubo continues to enlarge and may burst, or suppuration may not occur.

2. **Primary pneumonic** – Rigour, malaise, vomiting, fever, and prostration. Chest pain, dry cough, dyspnoea and cyanosis with profuse, watery, blood-tinged sputum. Haemorrhages frequent. Unilateral to begin with, later might progress to bilaterally.
3. **Septicemic** – Systemic dissemination via blood stream with involvement of many organs. Haematogenous invasion of lungs results in secondary pneumonic plague. It can occur prior to lymph node involvement, persons older than >40 years are at increased risk.

UNUSUAL PRESENTATIONS

Cervical bubonic plague – less common than inguinal, femoral or axillary forms.

Carbuncular plague – presents with ulcerating skin lesion.

Meningitis – may be the presenting feature and is diagnosed by isolation of *Y. pestis* from CSF.

LABORATORY DIAGNOSIS

1. *White cell count* – Leucocytosis with absolute predominance of neutrophils.
2. *Detection of Y. pestis* – which is easily recovered from bubo aspirates, blood or sputum on culture media such as blood agar or MacConkey's agar, where it grows aerobically. *Y. pestis* is a Gram-negative bacillus with bipolar beading that gives it a 'safety-pin' appearance.
3. *Serology* – Haemagglutinating antibodies to F1 antigen appear within one week of onset of illness and specific IgM and IgG can be demonstrated by ELISA techniques.

MANAGEMENT

1. *Specific* – (a) Streptomycin 30 mg/kg/day IM in 2 divided doses for 10 days to prevent relapse. (b) Tetracycline if allergy to streptomycin. 2-4 g/day in 4 divided doses for 10 days. (c) Chloramphenicol – for patients with meningitis 25 mg/kg loading dose IV followed by 60 mg/kg in 4 divided doses and after clinical improvement continued orally for 10 days. (d) Levofloxacin 500 mg OD is also approved for treatment and prophylaxis of plague
2. *Local* – In early stages buboes painted with iodine, or glycerine and belladonna, or treated with infra-red rays. Opened only when they point, allowed to drain, and dressed with antibacterial powder.
3. *General* – Good nursing. Sedatives for pain and restlessness. Pneumonic plague patients must be strictly isolated to prevent droplet infection.

Immunisation – Vaccine containing 2,000 million killed organisms per ml. 0.5 followed by 1 ml after 7-10 days. Immunity lasts for 6-12 months.

Protection of contacts – Tetracycline 500 mg 6-hourly for 7 days for close contacts of plague patients or those believed to be incubating the disease. Doxycycline 200 mg/day and levofloxacin, as mentioned above, also used for prophylaxis.

5. BRUCELLOSIS

Brucellosis is a zoonosis usually caused by *Brucella melitensis*, *Brucella suis*, or *Brucella abortus* (in decreasing order of virulence in man). Brucellae are small, non-motile, coccobacilli.

Various zoonotic diseases affecting humans are listed in Table 14.

EPIDEMIOLOGY

Organism – Intracellular parasite belonging to the genus *Brucella*.

Transmission – (a) Consumption of infected unsterilised milk, and its products. (b) Milking or tending infected animals, particularly those infected animals which have delivered or aborted. Organisms may enter the body through cuts and abrasions on the hands, conjunctivae or respiratory tract. (c) Handling carcasses or meat of infected animals in abattoirs, butchers. Veterinarians and microbiology workers are also at risk. (d) Sexual transmission may occur in man. *Age* – Rare below age of 15, three times more common in men.

Incubation period 2-4 weeks. (7-10 days following accidental inoculation).

Table 14: Zoonoses—Diseases transmitted to humans by animals

Anthrax – Goats, sheep.
Leptospirosis – Rats.
Brucellosis – Cattle.
Salmonellosis (esp. typhimurium and enteritidis) – cattle, poultry (esp. hen's eggs).
Toxocariasis – Bite wounds (ps. multocida) – canicola fever, hydatids – Dogs.
Toxoplasmosis – Dogs.
Campylobacter enteritis, yersiniosis – Birds, poultry, pigs, dogs, cats.
Rabies – Dogs, cats, foxes, bats, etc.
Rat bite fever – Rats.

CLINICAL FEATURES

1. *Acute brucellosis*

(a) **Non-specific early features** – Period of ill-health for about 2 weeks with fever, headache, sweating, fatigue and joint pains precede acute onset. Profuse sweats and sacroiliac arthralgia characteristic symptoms. Lymphadenopathy, splenomegaly and hepatomegaly may occur. Acute disease lasts for 2-4 weeks.

(b) **Localised disease**

- *Joint involvement* – Back pain (due to sacroiliitis) or involvement of lumbar spine. Affection of weight-bearing joints such as hip or knee with swelling and tenderness due to infection of joint or reactive arthritis. Sternoclavicular, and metacarpophalangeal and costochondral joints may be involved.
- *Cardiac involvement* – Endocarditis affecting aortic valve rare.
- *Neurological involvement* – rare. Meningitis. Radiculitis presenting as sciatica or cauda equina syndrome. Encephalopathy, myelopathy, cranial nerve palsies, transient ischaemic episodes, vascular occlusion in brain and spinal cord and ruptured mycotic aneurysm.
- *Miscellaneous* – Pleural effusion. Skin – Red, papular skin eruption mainly on the extremities, measles-like rash or pustular lesions. Epididymo-orchitis. IgA nephropathy. Lung, liver, spleen and eye involvement.

2. **Subacute brucellosis** – Illness fails to resolve after 4 weeks, or exacerbations occur after this time. Muscle weakness and extreme fatigue may be mistaken for neurosis. Painful joints. Periods of good health interrupted by symptoms.

3. **Chronic brucellosis** – Recurring exacerbations persisting for many years. Clinical picture resembles repeated attacks of influenza. Fever uncommon. Localisation of *Brucella* in liver, spleen, bone marrow lead to formation of granulomata.

DIAGNOSIS

Clinical – Brucellosis should be suspected in any patient with prolonged pyrexia, musculoskeletal pains and a slightly enlarged firm spleen, especially if there is history of consumption of raw milk or milk products, or occupational exposure to infected animals.

ISOLATION OF THE ORGANISM – (a) *Blood culture* – positive in more than half the patients in acute phase of *B. melitensis* infection, usually by about 14 days. (b) *Culture of bone marrow aspirate, liver or lymph gland tissue culture*. (c) *Serology* – Rising titres suggest acute infection, but negative serology may be found in patients with positive blood culture. (i) Standard agglutination test – IgM antibody production is associated with acute infections. Peak titres are reached 4-6 weeks after infection. (ii) 2-mercaptoethanol test – Rising titre in acute cases. (iii) Anti-human globulin test (AHG test) – useful in chronic brucellosis when agglutination titres are negative or low, and for recurrent disease. (iv) Radioimmunoassay and enzyme-linked immunosorbent assay used for individual classes of antibodies.

IMAGING – Isotope scanning with technetium detects vertebral and peripheral joint involvement before radiological changes.

Other tests – (i) Anaemia, normochromic, normocytic. (ii) Normal leucocyte count with lymphocytosis. (iii) LFTs may be abnormal with mild elevation of aminotransferases and more marked elevation of alkaline phosphatase, suggesting presence of portal tract granuloma. (iv) CSF – Elevation of protein with lymphocytic pleocytosis.

MANAGEMENT

(a) Patient > 8 and no indication of focal disease or complications – Doxycycline 100 mg bd × 45 days + Streptomycin 1 gm IM od × first 14 days or Doxycycline + Rifampicin 900 mg (15 mg/kg/d) od × 45 days or Doxycycline 200 mg od × 6 weeks. (b) Children < 8 – Rifampicin + Cotrimoxazole (2 tabs bd) × 45 days or Rifampicin × 45 days + Gentamycin/Netilmicin 5 mg/kg/d × first 5 days. (c) Neurobrucellosis – Doxycycline + Rifampicin with or without Streptomycin/Gentamycin or Doxycycline + Cotrimoxazole with or without Rifampicin. (d) Neurologic disease requires prolonged treatment (for 3-6 months), usually with ceftriaxone supplementation. (e) *Brucella* endocarditis is treated with three drugs regimen aminoglycoside + tetracycline + rifampin).

Prevention – 1. Pasteurisation or boiling of milk. 2. Vaccination of female calves. 3. Slaughter of infected cattle.

MELIOIDOSIS

It is caused by *Burkholderia pseudomallei*, a Gram-negative bacillus found widely in soil and surface-water of

paddy and other fields. Man usually acquires infection through respiratory tract or skin. DM increases the risk manifold, clinical manifestations vary from subclinical disease to overwhelming infections, and practically every organ can be affected. *Diagnosis* – Blood culture and serology. *Treatment* – In septicemic infection, combination of cotrimoxazole, doxycycline and chloramphenicol. Other useful drugs are Ceftazidime, and imipenem.

Pinta – Non-venereal spirochaetal infection caused by *Treponema carateum*. Transmission by direct contagion from infectious skin lesions. Begins at inoculation site by a small papule that progresses to erythematous plaques in several months. Erythematous, squamous patches develop later, mainly on extremities, face and neck. Tertiary stage of the disease is characterised by depigmented or atrophic lesions of the skin, often of the legs with hyperkeratosis of the soles.

Treatment – Single dose of benzathine penicillin 1.5 g IM.

6. LEPROSY

A chronic infectious disease caused by *Mycobacterium leprae* with a predilection for cooler, superficial regions of the body, namely skin, mucous membrane, and peripheral nerves. Clinical manifestations depend upon the host's cellular responses to the infecting organism. Patients with low resistance develop generalised infection termed *lepromatous leprosy*, whereas those with high resistance develop *tuberculoid leprosy*, with the disease localised to skin and peripheral nerve. Intermediate forms are known as '*borderline*'.

EPIDEMIOLOGY

M. leprae, is a slowly multiplying organism which has been grown in the footpads of mice and in the armadillo.

Transmission – Lepromatous individuals discharge bacilli from the nose. Infection occurs through the nose followed by haematogenous spread to skin and nerve.

PATHOGENESIS

M. leprae has a predilection for Schwann cells and skin macrophages. The patient's immune response determines the features of the disease; the two poles are tuberculoid (paucibacillary) and lepromatous (multibacillary) leprosy. At the tuberculoid pole, cell-mediated immunity and

delayed hypersensitivity control bacillary multiplication. In the lepromatous form, there is cellular anaergy towards *M. leprae*, resulting in abundant bacillary multiplication. Between these two is a continuum, varying from moderate cell-mediated immunity (borderline tuberculoid) through true borderline, to little cellular response (borderline lepromatous).

IMMUNOLOGY

Both T cells and macrophages are involved.

Tuberculoid leprosy – Skin tests with lepromin elicit strongly positive responses. Patients have a Th1-type response to *M. leprae*, producing interleukin-2 (IL-2) and interferon-g (IFNg). This strong-mediated response clears antigen, but with concomitant local tissue destruction.

Lepromatous leprosy – Skin tests with lepromin are negative. Lepromatous patients exhibit T cell failure and macrophage dysfunction, with defect in production of IL-2 and IFNg, they produce Th2-type cytokines.

Immune-mediated Reactions

Type 1 reactions are episodes of delayed hypersensitivity occurring at sites of localisation of *M. leprae* antigens.

Type 2 reactions – Erythema nodosum leprosum results from immune complex deposition.

Classification – Depending on immunological clinicopathological and bacteriological features, leprosy is classified into polar (stable) leprosy and borderline unstable leprosy.

- Tuberculoid leprosy (TT) (in patients with good immunity)
- Borderline leprosy (BT)
- Midborderline (BB)
- Borderline lepromatous (BL)
- Lepromatous leprosy (LL) (in patients with poor immunity)

Other types of leprosy are:

1. Intermediate leprosy
2. Histoid leprosy
3. Neuritic leprosy

Clinical features: According to WHO, in an endemic area, an individual should be considered as having leprosy if he/she shows one of the following cardinal signs:

- Skin lesions consistent with leprosy with definite sensory loss, with or without thickened nerves
- Skin smears positive for acid fast bacilli

- A person presenting with skin lesions or symptoms suggestive of nerve damage in whom cardinal signs are absent or doubtful should be labelled as a 'suspected case'.

SKIN LESIONS

- Can be single (TT) or multiple (LL)
- Usually hypopigmented, though may be erythematous.
- Usually macules or papules, in BL or LL papules or nodules may be seen.
- May be well defined (TT, BT), or poorly defined (BL, LL), when nodules of BL and LL subside there may be dermal atrophy.
- Absent hair and sweating are more conspicuous in TT and BT. Hence these lesions may appear dry.
- Anaesthesia/hypoanaesthesia - Anaesthetic lesions in TT, BT, BB, BL hypoaesthetic, neuroaesthetic in LL. First sensation to be affected is temperature and pain.

Thickened peripheral nerves - Peripheral nerves are vulnerable at sites where they are superficial or lie in fibroosseous tunnels. Nerves most often involved are ulnar (elbow), median (wrist), radial cutaneous (wrist), common peroneal (knee), posterior tibial and sural (ankle), facial (crossing zygomatic arch) and great auricular (posterior triangle of neck). Affected nerves may be enlarged and tender.

Eye involvement - Blindness is a complication in patients with anaesthetic hands and feet. Eye closure is impaired when facial nerve is affected. Damage to trigeminal nerve causes anaesthesia of conjunctiva and cornea, which is then susceptible to trauma and ulceration.

Tuberculoid (TT) Leprosy

- Nerve lesions* - The patient complains of sensory and/or motor symptoms depending on the type of nerve involved. Usually one single nerve is affected, or two at most.
- Skin lesions* - There is one or very few skin lesions. They are large, dry, anaesthetic, sharply delineated, hairless and are hypopigmented. When they are active, they are erythematous or coppery, occurring as macular or annular lesions with thin raised rims or as plaques. The lesion is anaesthetic to touch and pinprick.

Borderline Tuberculoid Leprosy

Skin lesions more numerous, and more variable in size, shape and definition. Sensation is usually impaired. Many peripheral nerves are thickened. An acute reaction causing

nerve pain or sudden weakness of hand or foot is often the presenting symptom.

Lepromatous Leprosy (LL)

(a) *Rash* - usually commences with the appearance of numerous, small, symmetrical, hypopigmented macules with normal sensation and indefinite edges, and small papules also with indefinite edges. The rash mainly affects the face, extensor surfaces of limbs and upper trunk, sparing the midline of back, axillae, groins and scalp. (b) *Thickening of nasal mucosa* - causes nasal blockage and blood-streaked discharge.

As the disease progresses, the skin, especially over the face becomes thickened and nodular (leonine facies), and ear lobes enlarge. Plaques and nodules develop; nodules may also occur on palatal mucosa, nasal septum and sclera. Eyebrows and eyelashes become scanty; lips, fingers and feet often swell. The hands become enlarged and fingers sausage-shaped or distorted by phalangeal fractures. Iritis and keratitis are common. Nasal cartilage and bones tend to be destroyed gradually (saddle-nose deformity), and laryngitis may give rise to hoarseness. Nerves of predilection steadily thicken; and destruction of the dermal nerves leads to generalised anaesthesia, which in turn leads to shortening of fingers and toes due to oft-repeated trauma. Lymph nodes enlarge and testicular atrophy leads to sterility and often gynaecomastia. Mild to moderate testicular dysfunction seen or ENL may cause orchitis.

Borderline Lepromatous Leprosy

Skin lesions are less symmetrical, and more easily seen than in lepromatous disease. Nodules are often discrete, red and succulent. Nerve damage is detectable earlier, but lesions of eye, nose, testes, muscles and bones are seldom present.

Indeterminate leprosy - Seen on face in children in endemic areas. Always a macule, ill defined, hypopigmented or slightly erythematous lesion with or without nerve thickening.

Clinical features of leprosy are summarised in Table 15.

LEPRA REACTIONS

Acute episodes in chronic course of leprosy.

- Type 1 lepra reaction* - can occur in borderline leprosy and is characterised by swelling and redness of skin lesions accompanied by pain and swelling in one or more nerves. Oedema of face, hands and feet often

Table 15: Clinical features of leprosy

Clinical features	Tuberculoid	Borderline	Borderline tuberculoid	Borderline lepromatous	Lepromatous
<i>Skin</i>					
Infiltrated lesions	Defined plaques, irregular plaques, healing centres	Polymorphic partially raised edges, satellites	Papules, nodules punched-out centres	Diffuse thickening	Diffuse thickening
Macular lesions	Single, small	Several, any size	Multiple, all sizes, bizarre	Innumerable, small	Innumerable, confluent
<i>Peripheral nerve lesions</i>					
	Solitary, enlarged nerves	Irregular enlargement of several large nerves, asymmetrical pattern	Many nerves involved, symmetrical pattern	Late neural thickening, asymmetrical anaesthesia and paresis	Slow, symmetrical 'glove-and-stocking' anaesthesia

occur. Skin lesions may break down, and nerve damage from cellular reaction and oedema may lead to facial palsy, claw hand, or footdrop.

When type 1 lepra reactions precede initiation of appropriate antimicrobial therapy, they are termed downgrading reactions and the case becomes histologically more lepromatous; when they occur after the initiation of therapy, they are termed reversal reactions and the case becomes more tuberculoid.

- (b) *Type 2 lepra reaction (Erythema nodosum leprosum)* – An antigen-antibody reaction in lepromatous leprosy. Characterised by transient erythematous nodes and patches occurring in crops in any part of the skin but particularly on face, arms and thighs, usually fading in a few days and being replaced by fresh lesions, but sometimes becoming necrotic and ulcerating. Other manifestations include fever, neuritis, swollen joints, painful tibiae, swelling and tenderness of one or more lymph glands, epistaxis, epididymo-orchitis, iridocyclitis, and proteinuria. This type of reaction can be precipitated by intercurrent infection, mental and physical stress, vaccination of various types, injury, surgical operation, and by over-enthusiastic chemotherapy.

DIAGNOSIS

1. *Slit smear* stained by modified Ziehl-Neelsen method. The number of bacilli seen are estimated as the *bacillary index*, which is useful for classification. The percentage of bacilli staining homogeneously – *morphological index*, is useful in assessing response to treatment.

2. *Histopathology* – Characteristic features are (a) Granuloma – (i) At the tuberculoid end of the spectrum, the granuloma is made of epithelioid cells, giant cells and lymphocytes. (ii) At the lepromatous end of the spectrum, the granuloma is ill defined and full of foamy macrophages and AFB. (b) Nerve involvement including perineural infiltrate and nerve destruction.

Lepromin test is not a diagnostic test but is of prognostic importance. If positive, it indicates good immunity to *M. leprae* and that the patient has been able to contain the infection i.e. he has tuberculoid or borderline tuberculoid leprosy.

MANAGEMENT

- A. **Chemotherapy** – Treatment of various types of leprosy is given in Table 16.
- B. **Acute reactions** – (a) Rest and sedatives. (b) Anti-leprosy drug should be stopped. Treatment of acute reactions in leprosy is given in Table 17.
- C. **Surgical treatment** – (a) Excision of small lesions. Large nodules touched with strong carbolic or nitric acid. Removal of necrosed bones and splitting of nerve sheath if a nerve is constricted by dense fibrous tissue. (b) For persistent localised severe nerve trunk pain, infiltration of the thickened nerve sheath or the nerve itself with 10 ml. 1% procaine, or with the latter solution to which 25 mg of hydrocortisone and 1,500 units hyaluronidase have been added. The injection may be repeated. (c) Reconstructive surgery is required for paralysed fingers, foot-drop, and hammer toe, and plastic surgery can correct facial disfigurement caused by loss of eyebrows, facial palsy, saddle-nose deformity, ectropion, pendulous ear lobes.

Table 16: Treatment of leprosy

Type of leprosy	Regimen	Treatment duration
<i>Paucibacillary</i> (5 or < lesions)	Monthly supervised Rifampicin 600 mg	Daily self-administered Dapsone 100 mg
<i>Multibacillary</i> (>5 lesions)	Rifampicin 600 mg Clofazimine 300 mg	Clofazimine 50 mg Dapsone 100 mg
<i>Paucibacillary</i> <i>single lesion</i>	Rifampicin 600 mg Ofloxacin 400 mg Minocycline 100 mg	Single dose

Table 17: Treatment of lepra reactions

	Type I reaction	Type II reaction
Mild	NSAIDs	NSAIDs
Moderate	NSAIDs	NSAIDs
	Prednisolone (10-20 mg/d)	Thalidomide (100-400 mg/d) Chloroquine Clofazimine (300 mg/d)
Severe	NSAIDs	
	Oral steroids	Thalidomide
		Oral steroids for impending nerve damage Orchitis, necrotic ENL Antimony parenteral

Note: Thalidomide is contraindicated in females in reproductive age group.

PREVENTION – Child contacts may be given BCG vaccination, especially infants born in leprosy families. Children who have been in close contact with lepromatous leprosy can be given prophylactic dapsone for a minimum of three years. Now that quantities of *M. leprae* are available from experimentally infected armadillos, a specific vaccine becomes a possibility.

7. RICKETTSIAL DISEASES

SCRUB TYPHUS

Scrub typhus or tsutsugamushi disease is a febrile illness caused by bacteria of the family Rickettsiae which are small, obligate, intracellular gram negative, non-flagellate, pleomorphic coccobacilli.

Transmission – Scrub typhus is transmitted by bite of larval stage of trombiculid bites or chiggers.

Pathogenesis – Endothelial cell invasion and injury leading to increased vascular permeability, oedema, hypovolemia and ischaemia is the central physiological mechanism of all rickettsiosis. This vascular injury leads

to capillary leak syndrome manifesting as multiple organ dysfunction.

Clinical features – Common symptoms include fever, maculopapular rash, headache, myalgia, dry cough and GI symptoms simulating common flu.

In scrub typhus an eschar 5 to 20 mm in diameter is formed at the site bitten by mites, and this may be considered an important finding. The site bitten by chiggers is initially a papulae followed by a blistered ulcer, and this is then covered by a black crust. Such a typical eschar is formed at the time when symptoms are manifested. It is also associated with regional lymphadenopathy. However, the characteristic eschar and rash may not always be present.

Complications – Serious complications include pneumonia, myocarditis, meningoencephalitis, acute kidney failure and GI bleeding.

Diagnosis – Specific gold standard techniques like immunofluorescence antibody test (IFA) and indirect immunoperoxidase are tests considered the tests of choice. It has the advantage of ability to detect antibodies to a number of rickettsial antigens simultaneously with the

same drop of serum and allows detection of IgG and IgM antibodies. (b) Weil Felix test – A four-fold rise in agglutinin titres in paired sera is diagnostic. However, with a single serum sample available, the test is suggestive of infection only at a high cut-off titre (>1:320).

Treatment – See Table 18 for drug treatment for rickettsial fever.

8. RABIES

Rabies is a viral encephalomyelitis transmitted in the saliva of infected animals. Rabies is most prevalent in the canids (dogs, foxes, wolves, jackals), followed by skunks, farm animals, cats, bats and mongooses. It is uncommon in rodents, lagomorphs (rabbits, hares) and insectivores (shrews, voles, hedgehogs).

Transmission – (a) Rabies virus is transmitted when the virus is introduced into bite wounds or open cuts in the skin on to membranes. (b) Non-bite exposure – (i) Individuals exposed to aerosolised rabies virus in the laboratory. (ii) Recipients of infected cornea.

CLINICAL FEATURES

Incubation period – varies from 20 days to 90 days in majority. Varies with – (i) Age – shorter in children. (ii) Site of infection – Face about 30 days, hands 40 days, legs 60 days. (iii) Severity of wound. (iv) Animal – Shorter period in order – wolf, cat, dog.

Prodromal symptoms – Pain and irritation or discomfort at site of bite, fear and anxiety, depression, intolerance to loud sounds. Periods of irritability. Hoarseness of voice and sense of constriction in throat with difficulty in swallowing. Slight rise of temperature. Duration 1-2 days. Subsequently, symptoms of either furious or paralytic rabies develop, depending on whether the spinal cord or brain are predominantly infected.

Furious rabies – (a) *Hydrophobia* – a combination of inspiratory muscle spasm, with or without painful laryngopharyngeal spasm, associated with terror in response to attempts to drink water. Various other stimuli can excite the reaction, including a draught of cold air (aerophobia), and the sight, sound or mere mention of water. Hydrophobic spasms may end in opisthotonos and generalised convulsions with death from respiratory or cardiac arrest. (b) *Periods of excitement* – are common during which the patient becomes wild and hallucinated alternating with lucid intervals. (c) *Other features* – include meningism, cranial nerve lesions (especially III, VII, VIII), spasticity,

Table 18: Drug treatment for rickettsial fever

Age group	Drug/Dosage	Duration (days)	Alternate treatment
Adult	Doxycycline 100 mg bd	12-14	Chloramphenicol Azithromycin Clarithromycin
Children	Doxycycline 4 mg/kg/day	12-14	Chloramphenicol Azithromycin Clarithromycin
Pregnancy	Azithromycin 500 mg od	12-14	Chloramphenicol Clarithromycin Rifampicin

involuntary movements, fluctuating body temperature and blood pressure, signs of autonomic over activity such as salivation, sweating and tachycardia. Priapism. Death may occur during hydrophobic spasm or patient may lapse into coma and generalised flaccid paralysis.

Paralytic rabies (dumb rabies) – is rare and seen especially in those bitten by vampire bats. Flaccid paralysis often begins in the bitten limb and ascends symmetrically or asymmetrically until it involves muscles of deglutition and respiration killing the patient in 2 or 3 days. Sensory involvement is mild and sphincter involved commonly. Hydrophobia is unusual but a few spasms may occur late in the illness.

DIAGNOSIS

Immunofluorescent testing – of skin biopsies (normally taken from the neck or face to show viral antigen in sensory nerve endings) or corneal impressions (obtained by gently abrading the cornea with a microscope slide) can establish diagnosis ante-mortem. The former is more sensitive and less damaging. Risks of brain biopsy prohibit its use as a method for diagnosis.

Viral detection – in saliva, throat swabs and tracheal aspirates is possible in 100% on days 0-4, 50% on days 5-8 and 9-12, and 14% on days 13-16. Virus isolation may take several weeks. However, PCR can establish the diagnosis rapidly when applied to saliva.

Antibody detection – is the most successful method for confirming diagnosis; however its success depends on maintaining life until antibody can be detected.

Post-mortem diagnosis – can be achieved by observation of Negri bodies in the brain, virus isolation, immunofluorescence of viral antigen in the brain, PCR and electron microscopy of brain. Negri bodies are intracytoplasmic eosinophilic inclusions; they are not pathognomonic for rabies.

MANAGEMENT

Aim is to neutralise the inoculated virus before it can enter the nervous system.

- Treatment of wound** - (a) Scrub with soap (or detergent) and water under a running tap for at least 5 minutes. (b) Remove foreign material. (c) Rinse with plain water. (d) Irrigate with virucidal agent, e.g. 40-70% alcohol, Povidone iodine or 0.01% aqueous iodine. (e) Explore, debride and irrigate deep wounds (if necessary, use local or general anaesthesia). Avoid suturing and occlusive dressings. (f) Consider tetanus risk and treat accordingly.
- Post-exposure prophylaxis** - Indications - (i) Bitten by rabid animal. (ii) The animal dies during observation and Negri bodies are found. (iii) Broken skin is soiled with the saliva of a rabid animal. (iv) Dog has disappeared or been killed without diagnosis of rabies being established and rabies is known to be present in the area. (v) Bite on face or head.

Active immunization - Human diploid cell strain vaccine (HDCSV) induces excellent antibody levels and no risk of neuroparalytic complications. *Intramuscular regimens* - 1.0 ml on days 0, 3, 7, 14, 30 and 90. Injections must be given into deltoid or anterolateral thigh in infants, not into the buttock (because antibody induction is unreliable).

Intradermal regimens

- Two-site regimen each containing one-fifth of im dose. Vaccine is given on days 0, 3 and 7, in two sites on upper arm over each deltoid. A single intradermal dose is given on day 29 and on day 90 at one site on upper arm.
- Eight-site - Injections containing 0.1 ml are given at each of eight sites over deltoid, lateral thigh, suprascapular region and lower quadrants of abdomen. On day 7, 0.1 ml is given at each of four sites over deltoids and thighs, and 0.1 ml is given at one site over deltoid, on days 28 and 90.

Side effects - (a) Local - Irritation at site of injection. (b) Systemic - Headache, fever and flu-like illness.

PASSIVE IMMUNISATION - Administration of RIG (rabies immunoglobulin) 20 IU/kg human RIG or 40 IU/kg heterologous RIG given once, at the beginning of antirabies prophylaxis, to previously unvaccinated individuals to provide immediate antibodies until patient responds to vaccination by actively producing antibody. RIG can be given upto 7 days after administration of potent tissue culture vaccine. Beyond day 7, RIG is not indicated because an antibody response to vaccination should have occurred. RIG should be infiltrated around and into the wound even when the lesion has begun to heal. Before administrating

equine RIG, hypersensitivity should be assessed by intradermal testing with a 1:10 dilution.

Indications for passive immunisation

- Exposures involving animals suspected of being rabid.
- Following unprovoked bites in endemic areas unless the animal is proved negative by laboratory examination.
- Those exposed to a rabid domestic animal, or an animal that is unavailable for examination.
- Individuals at high risk groups, including laboratory workers handling the virus (who should undergo regular antibody tests and receive booster vaccination when necessary).
- Workers in enzootic areas who may be exposed to unusual risks of infection.
- Travellers to remote areas where enzootic dog rabies is present.

SUMMARY OF POST-EXPOSURE PROPHYLAXIS

Minor exposure - including licks of the skin, scratches or abrasions, minor bites on covered areas of arms, trunks and legs:

Unprovoked attack by cat or dog available for observation.

Vaccine

Stop treatment if animal remains healthy for 10 days.

Stop treatment if animal's brain fluorescent antibody test proves negative.

Administer serum, if positive diagnosis, and complete course of vaccine.

Attack by wild animal or domestic dog or cat unavailable for observation.

Serum and vaccine.

Major exposure - including licks of mucosa or major bites (multiple on face, head, fingers or neck).

Unprovoked attack by cat or dog or attack by wild animal or domestic dog or cat unavailable for observation.

Serum and vaccine.

Stop treatment if domestic dog or cat remains healthy for 10 days.

Stop treatment if animal's brain fluorescent antibody test proves negative.

Pre-exposure prophylaxis

Indications - Those exposed to mammals before or during quarantine in kennels, zoos or laboratories, those working with rabies virus, veterinary surgeons, explorers, naturalists and speleologists travelling to rabies-endemic areas.

Vaccine - 1 ml IM or 0.1 ml intradermal on days 0, 7 and 28.

Table 19: Causes of death despite post-exposure vaccination

1.	Inadequate wound cleaning.
2.	Delay in starting vaccine.
3.	Injections of vaccine into buttock.
4.	Lack of passive immunisation.
5.	Failure to infiltrate RIG around the wound.
6.	Use of immunosuppressive drugs, e.g. corticosteroids.
7.	Impaired immune response, e.g. cirrhosis.

Booster doses of 1 ml IM or 0.1 ml intradermal should be given every 2 years, if continued protection is needed, but laboratory personnel working with rabies virus should receive booster dose every 6 months.

Post-exposure treatment in those who have received pre-exposure vaccination – If a full pre-exposure course of HDCSV (or other established tissue culture vaccine) has been given, or if neutralising antibody, 0.5 IU or more, has been demonstrated, passive immunization with RIG is not needed. If the bite is severe or antibody titre unknown, three doses of HDCSV 1ml IM are advised on days 0, 3 and 7. If bite is not severe, only two doses on days 0 and 3. Table 19 gives causes of death despite post-exposure vaccination.

9. DENGUE

Dengue is viral infection transmitted by mosquitoes. Dengue viruses are flaviviruses related to yellow fever virus and Japanese encephalitis virus. There are four serotypes, infection with one serotype does not induce solid immunity to the others, and individuals may suffer from dengue more than once.

TRANSMISSION

Transmission is from infected to susceptible individuals by day-biting *Aedes aegypti* mosquitoes. It is not transmitted directly between humans. The virus passes from the mosquito's intestinal tract to salivary glands after an extrinsic incubation period of about 10 days. Mosquito bites after this result in infection. In the skin, dengue virus infects immature dendritic cells which mature and migrate to local or regional lymph nodes where they present viral antigen to T cells. There is also evidence of replication of DENVs in liver parenchyma cells, macrophages of lymph nodes, liver and spleen.

PATHOPHYSIOLOGY

DENVs produce several syndromes depending on age and immunological status of the host: (a) During initial infections most children have subclinical reaction or mild febrile syndromes. (b) During secondary infection, pathophysiology of the disease changes dramatically, such infections can result in acute vascular permeability syndrome leading to dengue shock syndrome (DSS). The severity of DSS is age dependent, with vascular leakage being more severe in young children. In adults, primary infection has been predominantly subclinical. Nonetheless there is a tendency for bleeding that can lead to severe haemorrhages.

Predisposing factors for life-threatening dengue infection - Individuals with asthma, diabetes and chronic diseases. Most factors include female sex, HLA class 1 alleles and AB blood group. The longer the interval between the first and second infection, the more severe is the accompanying disease. Tertiary dengue infection can cause severe disease but only rarely.

CLINICAL FEATURES

Subclinical infection may be present as undifferentiated febrile disease, often with maculopapular rash, particularly in infants and young children.

Dengue Fever (DF)

A benign febrile illness, begins abruptly with fever 5-8 days after a bite from an infected mosquito. Fever is often accompanied by severe headache, retro-orbital pain, and intense myalgia and arthralgia ('break bone fever'). A rash, macular or scarlatiniform, starts on hands and legs and then becomes generalised sparing the face. The fever usually lasts 4-7 days and is followed by complete recovery. *Complications* – are uncommon. Bleeding may occur without evidence of vascular leak. GI bleeding and menorrhagia can occur. Encephalitis or encephalopathy may occur and result in neurological sequelae.

Dengue Haemorrhagic Fever/dengue Shock Syndrome (DDS)

Pathogenesis – Pre-circulating antidengue antibody is the predominant risk factor in DHF/DSS. This may have been acquired from previous infection with a different serotype or in infants, from transplacental transfer of maternal antibody.

Table 20: WHO diagnostic criteria for DHF/DSS

Dengue haemorrhagic fever: The following all must be present
• Fever or history of acute fever
• Haemorrhagic tendencies demonstrated by at least one of the following
– Positive tourniquet test
– Petechiae, ecchymoses or purpura
– Bleeding
• Thrombocytopenia
• Evidence of plasma leakage
– Haematocrit >20% above average
– Decrease in haematocrit >20% after volume replacement
– Clinical signs (e.g. pleural effusion, ascites)
Dengue shock syndrome – All above are present, plus evidence of circulatory failure
• Rapid and weak pulse
• Narrow pulse pressure
– Hypotension
– Cold, clammy skin and restlessness

The major pathophysiological abnormality differentiating DF from DHF is the plasma leakage syndrome (haemoconcentration, hypoproteinemia and/or serous effusion). The severity of disease in DHF depends on the quantum of plasma leakage. Patients with DHF presenting with shock due to excessive plasma loss are labelled as dengue shock syndrome. DHF/DSS are potentially fatal conditions.

CLINICAL FEATURES – DHF/DSS is usually clinically indistinguishable from dengue fever during the initial phase of illness (Table 20). After 2-7 days, more serious manifestations of disease become apparent, reflecting disordered haemostasis and increased permeability. Capillary leak is caused by mediators like TNF alpha and IL-1 released from infected monocytes and macrophages. The capillary leak explains the rise in haematocrit, peripheral oedema, pleural effusion and ascites.

Capillary leak and thrombocytopenia may give a positive capillary test which is more than 20 petechiae in an area of 1 inch when the BP cuff is inflated midway between systolic and diastolic pressures for 5 minutes. Shock often occurs 24 hours before or after defervescence supporting a role for immune mediated injury. Encephalopathy, GBS and acute transverse myelitis have also been associated with dengue virus infection.

A coagulopathy may occur due to consumption of coagulant factors due to DIC, liver dysfunction and molecular mimicry between the viral proteins and coagulant factors.

Prognostic factors. BP 90/60, haematocrit 50%, platelet count < 50000, bleeding other than petechiae e.g. ecchymoses. haematemesis or epistaxis.

Grading of severity of dhf

- I Positive tourniquet test and/or easy bruising
- II Spontaneous bleeding
- III Early signs of circulatory failure
- IV Profound shock

Diagnosis – (a) Dengue antigen (NS1) detection test - NS1 Ag and Ab combicard - Rapid visual test for detection of dengue NS1Ag and IgM and IgG antibodies in human serum/plasma/whole blood. (b) Combination of both dengue antibody IgG and IgM with NS1 antigen is essential for diagnosis of early dengue fever and differentiate between primary and secondary dengue infection. NS1 is a glycoprotein produced by all Flaviviruses and is essential for viral replication. NS1 detection rate is higher in the acute phase of primary infection, it has been detected in serum of DENV as early as the first day post the onset of symptoms and remains positive upto 9 days.

MANAGEMENT – There is no specific antiviral therapy.

Treatment: For shock – Crystalloids like Dextrose normal saline or Ringer's lactate 10-20 ml/kg over 30 minutes, then every hr. till pulse, BP, CVP and urine output normalise. In profound shock initially colloids like hetastarch or haemaccel. Platelet transfusion for symptomatic thrombocytopenia.

Dengue fever – Paracetamol. Avoid aspirin because of increased bleeding tendency and risk of developing Reye's syndrome.

DHF/DSS – Plasma expansion with crystalloid solutions is the mainstay of therapy.

VIRAL HAEMORRHAGIC FEVERS

Viral haemorrhagic fevers – are acute illnesses characterised by fever and, in most severe cases, shock and bleeding.

Transmission – Person to person transmission to body fluids, and secretions or excreta.

Major viral haemorrhagic fevers

Lassa virus – The host is the rat *Mastomys natalensis* which excretes large amounts of virus in its urine.

Clinical features – Insidious onset with influenza-like symptoms. Abdominal pain, diarrhoea and vomiting may occur. Common physical signs are fever, pharyngitis and conjunctival injection. In severe cases bleeding begins towards end of first week. Hypotension and shock, encephalopathy and ARDS is seen in very severe cases.

Ebola virus – Initial symptoms resemble those of Lassa fever. A transient morbilliform, desquamative rash may occur. Hiccups are common.

Marburg virus – Clinical features resemble those of Ebola haemorrhagic fever.

Investigations – Specific diagnosis of these infections is by demonstrating the virus, antigen, IgM antibody, or a fourfold rise in IgG antibody in blood.

Treatment – Ribavirin reduces mortality if given in first week in Lassa fever Dose: 30 mg/kg iv loading dose, then 16 mg/kg iv 6-hrly for 4 days, then 8 mg/kg i.v. 8-hrly for 6 days (total duration of treatment 10 days).

Yellow fever, the prototype of viral haemorrhagic fever, is an acute infection characterised, by renal failure, cardiovascular collapse and bleeding. Causative agent, a mosquito-borne RNA virus belonging to the family Flaviviridae.

Transmission – A zoonosis transmitted between tree-hole-breeding mosquitoes and monkeys in forests of Africa and South America.

Clinical features – Spectrum of illness in yellow fever is variable, it ranges from nonspecific febrile disease which cannot be diagnosed without virological tests, to a severe infection characterised by liver and kidney failure, shock and haemorrhage.

Lab. findings – Neutropenia and thrombocytopenia, proteinuria elevated serum aminotransferases, and elevated bilirubin and creatinine, prolonged prothrombin time and partial thromboplastin time.

Investigation – Detection of virus in serum by ELISA or PCR. Virus can also be cultured from serum.

Management – is supportive.

10. CHIKUNGUNYA

Chikungunya fever is a viral disease transmitted by the bite of infected *Aedes aegypti* mosquito. The term is derived from Kungunyala meaning to become contorted or more specifically as 'that which bends up'. This refers to the stooped posture adopted by the patient as a result of arthritic symptoms. The disease is almost always self-limited and rarely fatal.

CLINICAL FEATURES

After incubation period of usually 3-12 days, there is sudden onset of flu-like symptoms including severe headache, chills, fever (>40°C, 104°F), arthralgia or arthritis, conjunctival suffusion, mild photophobia, nausea and vomiting. Joints of the extremities in particular become swollen and painful to touch. In some, joint pain is incapacitating and arthritis may last for weeks and months. Dermatological manifestations include a petechial or maculopapular rash on the limbs. Other features observed have been lichenoid eruption and hyperpigmentation in photodistributed areas, aphthous like ulcers over scrotum, crural areas and axilla, vesiculobullous lesions in infants, and subungual haemorrhage.

Acute chikungunya fever typically lasts a few days, but as with dengue and other arboviral fevers, some patients have fatigue lasting several weeks.

Diagnostic tests available are detection of antigen and antibody in blood by ELISA test. An IgM capture ELISA is necessary to distinguish the disease. Elevated levels of aspartate aminotransferases and C-reactive protein is seen.

Management. Treatment is symptomatic with relief of pain with ibuprofen, naproxen, aceclofenac or paracetamol. Aspirin should be avoided. Chloroquine phosphate 250mg/day has been found useful.

Chikungunya and pregnancy. There have been cases of mother-to-foetus infection between 2 and 4.5 months into pregnancy. IgG that is produced around day 15 passes through the placenta and confers immunity to the foetus. However, there is a possibility of risk of infection at birth if the virus is present in the mother's blood. Such infection in the foetus is rarely serious and majority recover quickly without sequelae.

11. HANTAVIRUS INFECTION

Aetiology. This bunya virus infects vascular endothelium and causes two major syndromes. The virus is acquired by exposure to aerosols of rodent urine and saliva and also faeces. Its manifestations can closely mimic either dengue or leptospirosis.

PATHOPHYSIOLOGY

Virus infection of the endothelium does not result in significant injury. Like dengue it is the immune response against viral antigens expressed on the endothelial cells in the heart, lungs, kidneys and lymphoid organs that causes most of the damage. This immune response is mediated by T cells and macrophages which release cytokines like TNF-alpha and IL-1 beta which increase capillary permeability and cause leakage of protein rich fluid into the interstitium. Nitric oxide released by TNF plays an important role in the vasodilation underlying the shock state. The virus however may damage renal tissues.

CLINICAL FEATURES

Cardiopulmonary syndrome (HCPS). Incubation period about 3 weeks. Illness begins with nonspecific constitutional symptoms that last about 3-7 days followed by a capillary leak syndrome that lasts for 3-7 days causing hypotension and shock. Leak into the pulmonary bed causes a noncardiogenic pulmonary oedema that can lead to rapid hypoxia, arrhythmias and cardiac arrest. There may be a separate oliguric phase lasting 3-8 days which precedes a polyuric phase lasting for a variable period of time.

DIAGNOSIS

Thrombocytopenia, leucocytosis, increased immunoblasts (upto 10% of circulating lymphocytes) with increased LDH is characteristic and should prompt diagnosis with more specific tests like ELISA for IgM and IgG antibodies.

Treatment is mainly supportive with IV fluids, inotropes, mechanical ventilation, extra-corporeal membrane oxygenation and blood products.

Haemorrhagic Fever with Renal Syndrome (HFRS)

The renal manifestations are more prominent than the pulmonary and renal injury occurs due to a combination of shock, immune injury and possible direct invasion by the virus. Nonspecific constitutional symptoms are followed by shock, oliguria, DIC and haemorrhagic manifestations. Survivors enter a diuretic phase by day 10-14.

Diagnosis involves similar parameters as HCPS.

Treatment includes both supportive treatment (including dialysis) and use of ribavirin.

12. JAPANESE B ENCEPHALITIS

This is an arbovirus encephalitis caused by a flavivirus that is transmitted to humans by bite of the *Culex mosquito*. Birds and pigs are the natural hosts of the virus and humans are dead end hosts.

PATHOPHYSIOLOGY

Most infections are asymptomatic with about 1 in 25 non-immune adults having symptoms. The virus can infect brain parenchyma (especially thalamus and basal ganglia) of the cerebral hemispheres, brain stem and anterior horn cells of spinal cord.

The spectrum of disease can present as mild flu-like illness, aseptic meningitis or severe encephalomyelitis. 50-60% of encephalitis survivors have neuropsychiatric sequelae with a high incidence in children compared to adults.

After inoculation into the skin the virus replicates in subcutaneous tissues, lymph nodes and blood stream before entering the brain. Previous infection due to other flaviviruses like dengue may protect against severe disease.

CLINICAL FEATURES

Patients with encephalitis present with altered sensorium, seizures and abnormal posturing. Severe brainstem injury can cause a locked-in state. Involvement of basal ganglia can present with a Parkinsonian syndrome, opisthotonus, choreoathetosis, myoclonic jerks and opsoclonus myoclonus.

INVESTIGATIONS

(a) Nerve conduction studies show reduced or absent compound muscle action potential with preserved sensory action potentials and normal conduction velocities. EMG is consistent with denervation. (b) Initial leucocytosis may be followed by leucopenia. (c) MRI is more sensitive than CT for showing characteristic lesions involving thalamus and basal ganglia.

Diagnosis is with an IgM capture ELISA or reverse transcriptase PCR of blood or CSF.

Prophylaxis – Japanese B encephalitis vaccine.

Treatment is nonspecific, only symptomatic for seizures and raised ICP.

Table 21: Differential characters of *S. minus* and *S. moniliformis* infection

	<i>Spirillum minus</i> infection	<i>Streptobacillus moniliformis</i> infection
Incubation period	5-30 days	2-10 days
Wound from bite	Recurrence of local lesion with each onset of fever	Local lesion at onset of disease, heals promptly
Lymph nodes	May be involved	Regional lymphangitis and lymphadenitis
Systemic manifestations	Regularly relapsing type of fever Generalised maculopapular rash in some cases Myalgia, no arthritis	Intermittent but not regularly relapsing fever Erythematous maculopapular rash in most cases Arthritis usually present
Laboratory tests	Isolation of spirillum by animal inoculation Agglutination test negative	Isolation by blood culture Agglutination with <i>S. moniliformis</i> positive

13. RAT-BITE FEVER

AETIOLOGY

Organism – *Spirillum minus* and *Streptobacillus moniliformis*. **Transmission** – Either of these infections in man may result from the bite of a rat but *S. moniliformis* infection may be acquired by swallowing material containing the organism, e.g. milk or infected food.

Incubation period – Average 2 weeks.

CLINICAL FEATURES

1. **Onset** – Sudden with often rigour, headache, high fever, pains in joints and muscles.
2. **Rat-bite wound** – Local response of allergic type with redness, swelling and oedema at site of bite with increase of discharge if not healed. Regional lymphangitis and lymphadenitis.
3. **Rash** – Dark purplish macular or maculopapular eruption over arms, legs, trunk and sometimes face. Rarely mucous membranes. May be absent. Rash fades during febrile periods and may reappear during relapses.
4. **Fever** – High remittent temperature for 4 to 5 days falling to normal with profuse sweats and subsidence of primary lesion. Recurrence of fever in few days but duration shorter. Such relapsing type of fever may continue for weeks or months in untreated cases. Usually paroxysms become less in height and duration and infection subsides spontaneously.
5. **Other symptoms** – Arthritis, delirium, rarely coma.

Differential characters of *S. minus* and *S. moniliformis* infection are given in Table 21.

DIAGNOSIS

S. minus – Leucocyte count normal or elevated. Organism may be visible on examination of blood or injection into peritoneum of mice or guinea pig; organisms will be

visible 5-15 days later in blood or peritoneal fluid of the animal. *S. moniliformis* – Neutrophil leucocytosis. Organism may be isolated from blood or joint fluid. Agglutination tests positive in 2nd week.

TREATMENT

Benzathine penicillin 1.2 million units/day IM or Penicillin V 2 g/day orally for 7-10 days. If penicillin hypersensitivity, Erythromycin 2 g/day orally, or Tetracycline 2 g/day orally for 7 days.

14. LEPTOSPIROSIS

An acute infectious disease caused by *Leptospira interrogans*, highly motile, tightly coiled thin organisms with hooked ends. It is characterised by a broad spectrum of clinical manifestations, from unapparent symptoms to fulminating and fatal infection.

EPIDEMIOLOGY

(a) **Animal hosts** – Rats and small rodents are the most important reservoirs. Dogs, pigs, cattle, goats, wolves, foxes and other wild animals can also carry the organisms. (b) **Transmission** – Human infection results from contact with tissues of an infected animal or indirectly from contaminated water or soil. (c) **Routes of infection** – Moist or abraded skin, intact mucous membrane (nasopharynx, conjunctivae, vagina). (d) **Individuals at risk** – include sewer workers, abattoir workers, coal miners, farmers, fish workers and those employed on canals, docks and river drainage. Recreational water users (e.g. canoeists, windsurfers, swimmers, water-skiers) are also at risk. Infection via conjunctiva follows swimming or accidental immersion in contaminated water. In the home pet dogs can transfer the disease to children and adults through infected urine. Laboratory workers are at risk from handling animals.

PATHOPHYSIOLOGY

Most patients have a nonspecific febrile illness, but in a few the disease manifests with a severe illness characterised by hepatorenal dysfunction often with pulmonary haemorrhage (*Weil's syndrome*) which usually develops 4-9 days into the illness and is characterised by severe jaundice, bleeding (purpura or petechiae) and impaired kidney function and disorientation. The leptospirae directly or through immune mechanisms damage blood vessels, cause centrilobular necrosis of liver, and renal tubular dysfunction by causing an interstitial nephritis and acute tubular necrosis. Renal function recovers completely by 6 months in most individuals.

Incubation period – 7-12 days.

CLINICAL FEATURES

Febrile illness (first week)

- (a) **Septicemic phase** – Fever, headache, skin rash and myalgia simulate influenza and leptospirae appear in blood and CSF. Renal involvement is invariably present and ranges from urinary sediment changes and mild proteinuria to kidney failure in severe leptospirosis. Jaundice may be present. This stage lasts for 4 to 7 days followed within 48 hours by:
- (b) **Immune phase (second week)** – lasts 4-30 days. Leptospirae disappear from all tissues except kidney and aqueous humour in parallel with rise in circulating antibodies. Symptoms may include rash and secondary fever, meningeal symptoms, uveitis; hepatic and renal manifestations of febrile phase remain and may be more severe in some patients.

The following clinical spectrum can be seen in the second phase:

- (i) **Haemorrhagic fever with renal syndrome.** Leptospirosis is an important infectious cause of ARF. Renal manifestations include an oliguric renal failure due to acute tubular necrosis or tubular interstitial damage leading to non-oliguric renal failure, high excretion of potassium and hypokalaemia, which can cause hyporeflexic paralysis. Widespread haemorrhages in GI tract, lungs, subarachnoid space and adrenals are also common because of extensive vasculitis.
- (ii) **Atypical pneumonia syndrome.** Pulmonary symptoms and signs occur. Delayed resolution, small nodular densities and confluent areas of consolidation are radiological findings. Leptospirosis should be suspected in rapidly developing pneumonia with myalgia.
- (iii) **Aseptic meningoencephalitis.** Sporadic cases of aseptic meningitis have leptospiral aetiology. Neurological manifestations include encephalitis and in rare cases hemiparesis.

- (iv) **Myocarditis.** Cardiac dilatation, atrial fibrillation, cardiac failure and sudden death have been recorded.

INVESTIGATIONS

1. **Biochemical laboratory features** – (a) Leucocytosis with neutrophilia. (b) Thrombocytopenia. (c) Urinalysis – Cellular elements, granular and pigmented casts and mild proteinuria. (d) Other tests done to confirm diagnosis are PCR, Indirect haemagglutination test assay (IHA) and IgM ELISA. IgM antibodies become positive by 5th day. MAT does not have any diagnostic significance in 1st week and peaks about 3rd week. (e) CSF may show aseptic meningitis like picture.
2. **Chest X-ray** – often shows dense confluent shadows suggestive of pulmonary haemorrhage.
3. **Serology** – Microscopic agglutination test (MAT) is the gold standard with either a fourfold rise in titres or a single titre of > 1:800 being diagnostic. Other serological tests are ELISA and a commercially available Dridot test which detects IgM antibody by an enzyme based dot immunoassay with a sensitivity of 30% at 3 days and of 100% at 10 days into the illness.
4. **PCR assay** – Positive in acute infection. Suggests antigenemia. Positive before antibodies appear in blood.

MANAGEMENT

Treatment should be started as soon as possible. (a) **Antibiotics** – Mild leptospirosis – Doxycycline 100 mg po bd, Amoxicillin 500 mg po bd Moderate/severe leptospirosis – Inj. Ceftriaxone 1g/day IM or by IV slow infusion for 7 days. Signs and symptoms may include rigours, high fever, low BP, headache and myalgias. (b) **Dialysis** – for kidney failure. (c) **Blood transfusions** and/or platelet transfusions may be necessary.

CHEMOPROPHYLAXIS – Doxycycline 200 mg once a week, Azithromycin 250 mg once or twice week.

15. ANTHRAX

Anthrax is a life-threatening zoonotic infection that normally affects individuals, especially ruminants. It is caused by *Bacillus anthracis*. The most common mode of infection is through the skin, which causes a painless sore that usually heals without treatment. If untreated cutaneous anthrax may progress in some cases to septicaemia with potentially fatal outcome.

Anthrax is a potential agent for use as a biological agent for terrorist activities however it is technologically difficult to use anthrax as a weapon on a large scale.

TRANSMISSION

Anthrax can be transmitted to humans by contact with infected animals or their products. It does not spread from person to person.

CLINICAL FEATURES

Anthrax can infect humans in three forms of the disease.

1. *Cutaneous anthrax* is the most common type and occurs when the spores or bacteria itself enter the body through a cut or abrasion. Symptoms begin to develop within 48 hours as a small, red, itchy papule at the site of infection. Within about 2 days it develops into a blister that eventually ruptures. The lesion ultimately dries into a coal-black scab (eschar). Some patients may have painful enlargement of lymphnodes, in some others infection can spread through the blood stream and prove fatal due to release of toxins.

Diagnosis can be confirmed by Gram stained smears and culture of the material obtained from culture of the cutaneous lesion and blood culture.

Tr. Ciprofloxacin or Doxycycline for 14 days.

2. *Inhalational anthrax* results from inhalation of spores into the lungs (wool sorter's disease). In the initial stages there is low grade fever, myalgia, malaise followed within 1-4 days by dyspnoea, haemoptysis, fever, cyanosis, pleural effusion, bronchopneumonia and coma.

Tr. antitoxin monoclonal antibody raxibacumab is available with antibiotics.

3. *Gastrointestinal anthrax* can give rise to bloody diarrhoea which can be the cause of death.
4. *Fulminant meningitis.*
Prevention - Vaccination: anthrax vaccine adsorbed (AVA)

16. FILARIAL INFECTIONS

Filarial infections are caused by parasitic, tissue-dwelling, filarial nematode worms, which are transmitted by biting insects. Two main types of filariasis are:

1. Lymphatic filariasis transmitted by mosquitoes.
2. Subcutaneous filariasis (onchocerciasis and loiasis) transmitted by biting flies.

LIFE CYCLE - Adult female worms situated in various tissues in the human host produce embryonic microfilariae which are sucked up by mosquitoes or biting flies during a blood meal. Microfilariae develop to their larval stage in the insect vector and are passed on to a new human host in which the final maturation to adult worms takes place.

Adult filarial worms do not multiply in man. See Figure 9 for the life cycle of *W. bancrofti*.

Periodicity of microfilariae - In most endemic areas the microfilariae of *W. bancrofti* appear in greatest numbers in peripheral blood in the night between 10 p.m. and 2 a.m., during the day they return to the pulmonary capillaries. Microfilariae of *B. malayi* exhibit either nocturnal periodicity or diurnal periodicity with a peak in the early evenings.

Lymphatic filariasis - can be caused by:

- *Wuchereria bancrofti*, transmitted by Anopheles, Culex and Aedes mosquitoes.
- *Brugia malayi*, transmitted by Mansonia and Anopheles mosquitoes.
- *Brugia timori*, transmitted by Anopheles barbirostris.

Clinical features - Two syndromes

- (a) Lymphatic filariasis caused by adult or developing adult worms, producing episodic inflammation of lymphatic vessels, followed by obstructive lymphatic lesions.
- (b) Syndrome caused by immune hyper-responsiveness of human host against microfilaria, producing occult filariasis (circulating filarial antigens or microfilaraemia).

ACUTE CLINICAL FEATURES

1. **FILARIAL FEVER** - Attacks of fever with rigours and with headache and malaise, lasting 3-7 days, recurring at intervals, and sometimes associated with an attack of filarial adenolymphangitis.
2. **FILARIAL LYMPHANGITIS AND LYMPHADENITIS** - (a) *Acute lymphangitis* - in extremities with fever with rigours and toxemia. The tender inflamed lymphatics are seen as red streaks. It may be accompanied by itchy, irregular erythematous swelling of the skin scattered over the body, which may sometimes appear in absence of local lymphangitis. Lymphatics anywhere in the body may be involved, those of spermatic cord and testis are especially susceptible. (b) *Lymphadenitis* - occurs episodically, most often in inguinal area. Other sites are medial aspect of leg, axilla or medial side of arm. Occasionally in the breast. Involvement of intra-abdominal lymphatics may produce clinical appearances of acute abdomen. Secondary Gram-positive bacterial infections cause suppurative lymphadenitis or abscess formation particularly in the breast, or in muscle resembling tropical pyomyositis.

Fig. 9: Life cycle of *Wuchereria bancrofti*

Chronic Features (Late Obstructive Phase)

1. *Hydrocele* – is common with *W. bancrofti*.
2. *Lymphoedema* – is most common in lower limbs but also occurs in the upper limb or the breast.
3. *Elephantiasis* – results from further progression with dermatosclerotic and papillomatous changes superimposed. Lymphoedema and elephantiasis are much more pronounced on one side of the body, possibly because the parasites tend to congregate. Thickening of both skin and overlying tissues. One or both legs and scrotum most commonly involved. Upper extremities, breast and labia may also be affected.
4. *Rupture of lymphatic varices* – into renal pelvis or bladder gives rise to chyluria (when the lymph vessel is draining the intestine) or lymphuria (when it is not). Chyluria occurs intermittently and is more pronounced after a heavy meal. It is often symptomless, but may cause fatigue and weight loss due to loss of fat and protein.
5. *Tropical eosinophilic syndrome* – A hypersensitive reaction to lymphatic-dwelling parasites and characterised by chronic cough, wheezing and persistent eosinophilic count which may reach more than

50,000/ μ l. Increased specific serum IgE and characteristic histological lesions (Meyers-Kouwenar bodies) in lymph nodes, lungs, spleen and liver. Microfilariae are usually absent in blood. Chest radiography shows small-volume lungs with soft parenchymal infiltrates.

DIAGNOSIS

(a) Simple parasitological confirmation depends on finding the characteristic sheathed microfilariae in a thick blood film taken at the peak of periodicity of the strain (usually midnight) and stained with Mayer's haemalum (Fig. 10). (b) Enzyme-linked immunosorbent assay card test detects circulating *W. bancrofti* antigens, and *W. malayi* DNA can be detected using PCR analysis.

MANAGEMENT

1. **DRUGS** – Diethylcarbamazine citrate (DEC) kills the microfilariae and a proportion of the adult worms of the lymphatic-dwelling filariae. A single dose of 6 mg/kg given annually is effective in the long-term killing of microfilariae and adult worms. It is usually given in mass campaign to reduce transmission, along with

Fig. 10: Microfilaria in blood film

an annual dose of albendazole 400 mg which supplements its antifilarial action.

DEC must not be used in areas where onchocerciasis and/or loiasis are co-endemic. In these areas, the alternative is an annual dose of Ivermectin 150 mg/kg with albendazole 400 mg.

Use of DEC-fortified salt (0.2-0.4% w/w) for cooking and seasoning food over at least 9-12 months is a cheap, safe and effective means of eliminating lymphatic filariasis from an infected population.

Simple hygiene effective in preventing infection in secondary collateral lymph channels, which can re-establish lymph flow.

2. PALLIATIVE TREATMENT

(a) *Acute lymphangitis* - Rest, elevation of limb, hot fomentations, infra-red rays or short wave diathermy. Analgesics for relief of pain. Broad spectrum antibiotics to control infection.

(b) *Chyluria* - Treated surgically.

(c) *Elephantiasis* - Since bacterial and fungal infections trigger most episodes of adenolymphangitis in tissues with compromised lymphatic function, simple hygiene measures are - (i) Twice daily washing of affected parts with soap and water. (ii) Raising the limb at night. (iii) Working the foot up and down to promote lymph flow. (iv) Keeping the nails clean. (v) Wearing shoes. (vi) Use of antiseptic or antibiotic creams to treat small wounds or abrasions.

Long-term low-dose DEC may also help to reverse chronic lymphoedema and elephantiasis. For resistant case lymphnode-venous shunt operation, followed by surgical removal of excess tissue.

ONCHOCERCIASIS

It is a chronic filarial disease caused by *Onchocerca volvulus* and transmitted by black flies of the genus *Simulium*. In mild infections there is pruritus with papulourticarial dermatitis. Generalised onchocerciasis presents with involvement of skin, eyes and lymphnodes. *Diagnosis* - confirmed by demonstration of microfilariae in skin snips, or cornea or anterior chamber (using slit lamp), or of adult worms in subcutaneous nodules. *Drug treatment* - Suramin kills adult worms, also DEC or ivermectin.

17. TROPICAL POLYMYOSITIS

This is a bacterial invasion of skeletal muscle usually due to *Staph. aureus*.

Pathogenesis involves the seeding of sites of muscle injury following transient bacteraemia. Large skeletal muscles such as the thigh, calf, gluteal and shoulder regions are typically involved.

Clinical stages. (a) First stage. Muscle pain, swelling and low grade fever. (b) Second stage 1-2 weeks later with progressive suppuration of muscle which may be followed by (c) Third stage of bacteraemia with complications like septic shock, endocarditis, pneumonia, pericarditis, septic arthritis, brain abscess and rhabdomyolysis.

Investigations. Leucocytosis. Blood cultures may be positive and serum CPK raised markedly.

Imaging with MRI or CT will often show abscess formation.

Tr. Cloxacillin 1-2 g iv or Cefazolin 2 g iv q8h. Addition of Clindamycin 600-900 mg iv q6-8h in mixed infection. Abscess drainage and debridement.

18. INTESTINAL HELMINTHS

Various worms that can infest humans are listed in Table 22.

HOOKWORM

Hookworms are nematodes belonging to the family Ancylostomatidae. Human infection is caused by *Ancylostoma duodenale* and *Necator americanus*. Transmission - may occur wherever faeces are allowed to remain in contact with damp soil at a suitable temperature.

Life Cycle

The first-stage larva hatches in 24-48 hours and develops in the soil to become the infective third-stage larva. It penetrates the skin and is carried in the blood to the heart and pulmonary blood vessels. It breaks out of the pulmonary blood vessels into the alveoli, then crawls up the trachea

Table 22: Worms infest humans

Infection Nematodes	Parasite
Filariasis	W. bancrofti (Bancroftian filariasis) Brugia malayi (Malayan filariasis) Loa loa (loiasis) Onchocerca volvulus (onchocerciasis)
Dracunculiasis	Dracunculus medinensis (guinea-worm)
Toxocariasis	T. canis or T. cati (visceral ocular larva migrans)
Trichinosis	Trichinella spiralis
Enterobiasis	Enterobius vermicularis
Hookworm infection	Ankylostoma duodenale (hookworm anaemia) Ankylostoma braziliensis or A. caninum (cutaneous larva migrans – creeping eruption) Necator americanus (hookworm anaemia)
Trichuriasis	Trichuris trichuria
Ascariasis	Ascaris lumbricoides
Strongyloidiasis	Strongyloides stercoralis
Trematodes (flukes)	
Schistosomiasis	Schistosoma mansoni Schistosoma japonicum Schistosoma haematobium
Fascioliasis	Fasciola hepatica (liver fluke)
Clonorchiasis	Clonorchis sinensis (oriental liver fluke)
Fasciolopsiasis	Fasciolopsis buski (intestinal fluke) Cestodes (Tape worms)
Taeniasis	Taenia saginata
Taeniasis/cysticercosis	Tinea solium (cysticercosis)
Diphyllobothriasis	Diphyllobothrium latum (fish tapeworm)
Hydatid disease cystic	Echinococcus granulosus
Hydatid disease alveolar	Echinococcus multilocularis

and enters the intestinal tract. Finally, it attaches itself to the mucous membrane of small intestine and matures into the adult worm.

Clinical Features

These are listed in Table 23.

Diagnosis

Detection of ova in faeces.

Treatment

When Hb is less than 5 gm% it is advisable to raise it to about 8 gm. with iron therapy before expelling the worms.

Table 23: Clinical features of hookworm infestation

Cause	Clinical features
Penetration of skin and subcutaneous migration of filariform larvae	Local erythema, macules, papules (ground itch)
Migration of larvae through lungs, bronchi and trachea to oesophagus	Bronchitis Pneumonitis
Injury to intestinal mucosal surface by attachment of adult worm	Anorexia Pica Epigastric pain and tenderness GI haemorrhage Diarrhoea (during acute invasion)
Sucking of worms causing chronic intestinal blood loss	Iron-deficiency anaemia Protein-losing enteropathy causing hypoalbuminemia and oedema
Chronic iron-deficiency anaemia	Exertional dyspnoea. Oedema
Loss of nutrients into intestine	Hypoalbuminemia, oedema Growth retardation
Iron deficiency	Impaired work productivity, learning, cognitive development.

Mebendazole – 100 mg bd for 3 days, not to be used in pregnant women or children < 2 years.

Albendazole – One dose of 400 mg for all patients over 2 years of age or

Pyrantel pamoate – 10 mg/kg (maximum 750 mg in adults) in a single dose for 3 days.

ROUNDWORM

(*Ascaris lumbricoides*)

Life Cycle

The eggs leave the body in the faeces. At this stage they consist of unsegmented ova protected by a thick shell, which in suitable conditions will develop into larval worms in 2 or 3 weeks. Man acquires the infection by swallowing the larvae, usually in contaminated food. The larvae hatch in the intestine, penetrate the wall, enter the blood stream and pass to the lungs. Here they leave the capillaries and enter the alveoli where they remain for about 10 days. They then pass up the air passages, down the oesophagus to the intestine where they grow to maturity.

Clinical Features

TISSUE PHASE – Ingested larvae migrate from intestine to liver and lungs and provoke immunological and inflammatory reactions, e.g. – (a) Transient hepatomegaly. (b) Pneumonitis with symptoms varying from cough to severe dyspnoea and occasionally haemoptysis. (c) Loeffler's syndrome. (d) Bronchial asthma. (e) Urticaria.

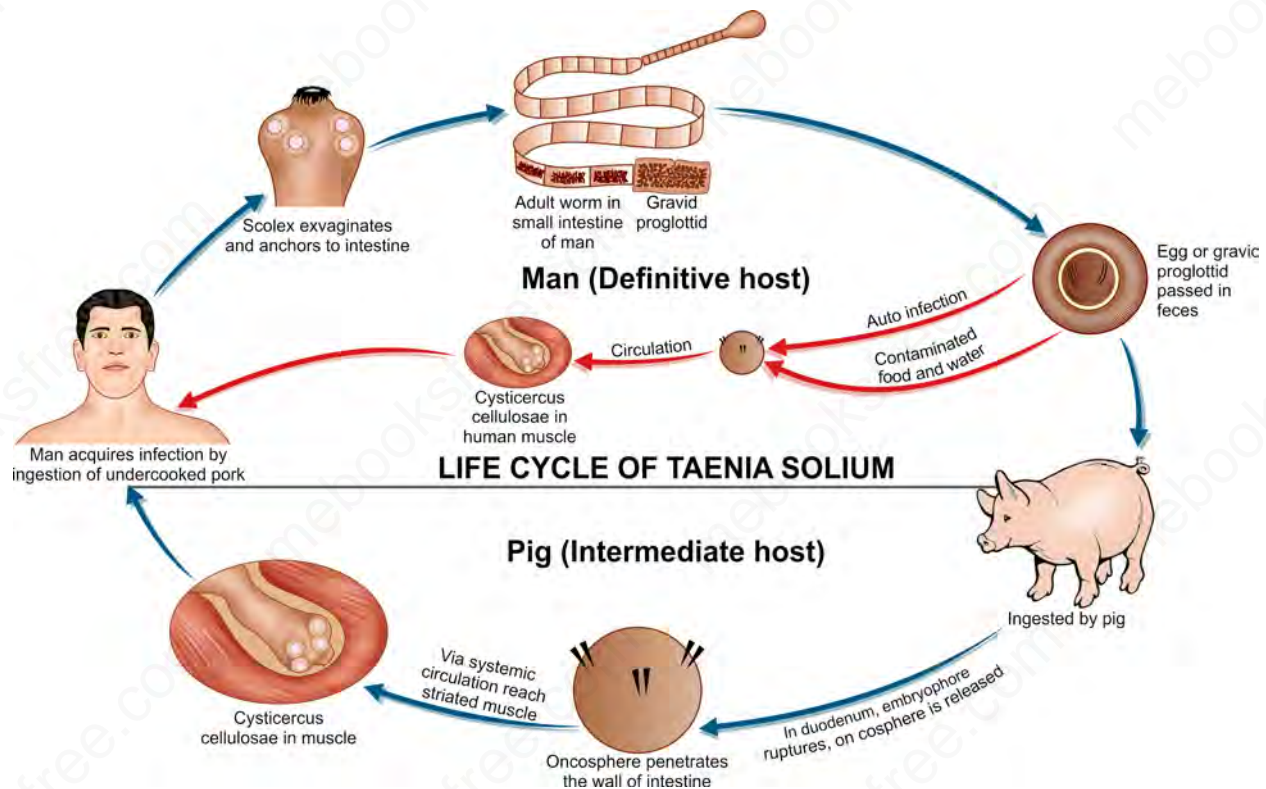

Fig. 11: Life cycle of *Taenia solium*

INTESTINAL PHASE – (a) *Intestinal ascariasis* – Intestinal colic and passage of worms in stools in mild to moderate infection. In heavy infections intestinal obstruction with at times perforation and volvulus may occur. In addition malabsorption, malnutrition and abdominal distension. (b) *Migration of worms* into orifices such as appendix, bile duct and pancreatic duct will produce signs of acute appendicitis, or clinical features of cholecystitis or pancreatitis. Worms that migrate from bile duct to hepatic duct and from there into the substance of the liver may die and form the focus of a hepatic abscess. Occasionally worms migrate to the stomach and are vomited, or migrate to unusual sites, such as the pharynx and are inhaled or block the Eustachian tubes.

DIAGNOSIS – (a) Finding adult parasites expelled from anus or mouth, or eggs in faeces. (b) Radiograph of gut – Adult *A. lumbricoides* may be seen. (c) In early ascariasis larvae may be found in sputum, there is marked eosinophilia and specific serological tests are positive.

TREATMENT

Mebendazole – 100 mg for 1 day only (for all age groups).

Albendazole – Children 2-12 years – One dose of 200 mg.
Older children and adults – One dose of 400 mg.

Pyrantel pamoate – One dose of 10 mg/kg (maximum of 750 mg for adults).

TAENIASIS

(Tape worm) – is caused by either the beef tapeworm, *Taenia saginata*, or the pork tapeworm, *Taenia solium*.

T. saginata – is the commonest tapeworm affecting man. The larval stage (cysticercus) is found in beef and infection is acquired by eating beef containing a living cysticercus.

Life Cycle

When a living cysticercus is swallowed, the tapeworm head which it contains will emerge, attach itself to the mucous membrane of the upper jejunum and develop into a full-grown worm over the next 3 months (Fig. 11).

Symptoms

Segments of the worm are passed in stool or come out of the anus spontaneously. Other symptoms are weight loss, excessive hunger, abdominal pains and gurgling. Occasionally, straying proglottids may cause appendicitis or cholangitis.

Fig. 12: MRI T2 image showing neurocysticercosis

Diagnosis

Finding of proglottids or rarely scolex in stools. Eggs may be found in perianal area.

T. solium - Infection is caused by eating pork which contains a living cysticercus. Human cysticercosis arises either from swallowing *T. solium* eggs on contaminated food or by autoinfection from eggs produced by an adult worm in the host's intestine.

Life-Cycle

Life cycle resembles that of *T. saginata* except that hogs rather than cattle serve as intermediate hosts. Humans may also act as intermediate hosts.

Clinical Features

Infection with adult worm is usually asymptomatic. Heavy larval infection (cysticercosis) may cause:

1. **Non-specific symptoms** - during early stage of invasion by cysticerci such as fever, headache and urticaria with eosinophilia.
2. **Localising symptoms and signs** - (a) *Neurocysticercosis* - leads to intracranial hypertension and mental disorders, either separately or in combination (Figs. 12 and 13). Focal features such as ataxia, dysarthria are common and sudden death may occur. (b) *Skin and muscle* - Visible or palpable subcutaneous cysts felt as nodules of varying dimension especially in abdominal muscles and pectorals. (c) *Other sites* - (i) *Eyes* - Unilateral disturbance of vision. (ii) *Liver and lungs* may be involved.

Diagnosis

- Epilepsy (most common manifestation).
- Focal signs - Pyramidal tract signs, sensory abnormalities, signs of brain stem dysfunction. Increased intrac-

Fig. 13: Multiple neurocysticercosis showing 'starry sky appearance'

ranial pressure or dementia due to hydrocephalus or massive cysticercal infection of brain parenchyma. Muscular pseudohypertrophy due to massive infestation of skeletal muscles.

Diagnostic Criteria for Human Cysticercosis

Absolute criteria

- Histological demonstration of the parasite
- Direct visualisation of the parasite by fundoscopy
- Evidence of cystic lesions showing the scolex on CT or MRI ('hole-with-dot' image).

Major criteria

- Evidence of lesions suggestive of neurocysticercosis on neuro-imaging studies
- Positive immunological tests for detection of anti-cysticercal antibodies.
- Resolution of intracranial cystic lesions spontaneously or after therapy with albendazole or praziquantel alone.

Minor criteria

- Lesions compatible with neurocysticercosis detected by neuroimaging studies
- Demonstration of antibodies to cysticerci or cysticercal antigen in cerebrospinal fluid by ELISA
- Presence of clinical manifestations suggestive of neurocysticercosis
- Evidence of cysticercosis outside the central nervous system (cigar-shaped soft-tissue calcifications)

Epidemiologic criteria

- Residence in a cysticercosis-endemic area
- Frequent travel to a cysticercosis endemic area
- Household contact with an individual infected with *Taenia solium*

Fig. 14: Eggs of common intestinal worms

Diagnosis is confirmed by either one absolute criterion or a combination of two major criteria, one minor criterion and one epidemiologic criterion. A probable diagnosis is supported by the fulfillment of (1) One major criterion plus two minor criteria; (2) One major criterion plus one minor criterion and one epidemiologic criterion; or (3) three minor criteria plus one epidemiologic criterion (Fig. 14)

Management

Nicosamide - Adults - Single dose of 2.0 gm. Children under 5 years of age - Single dose of 0.5 gm. Older children - Single dose of 1.0 gm. The tablets should be given on empty stomach, chewed thoroughly and washed down with a little water. A purgative is recommended if the dead segments are not passed out within a few hours.

Mepacrine - for nicosamide resistant *S. saginata*. Dose 1 gm po or via nasogastric tube following by 5 mg metoclopramide iv.

Praziquantel - Single dose of 5-10 mg/kg after a light breakfast (all age groups).

For cerebral cysticercosis - Praziquantel 50 mg/kg/day for 15 days, or Albendazole 5 mg/kg/day for 30 days.

Corticosteroids are indicated in patients with cysticercotic encephalitis or angiitis, and in those with massive cysticercal infection of the brain parenchyma.

Treatment is considered successful when the scolex is found, no proglottids appear within 4 months of therapy in case of *T. saginata*, faecal examination remains negative for 3 months after treatment in case of *T. solium*.

ENTEROBIASIS

Is caused by the pinworm (thread worm) *E. vermicularis*. The adult threadworms live in the colon and rectum, and the gravid female emerges from the anus to deposit

the eggs on the surrounding skin. These eggs if swallowed liberate the contained larvae which mature as they pass down the intestine.

Clinical Features

Minimal, except for anal and perianal itching. Heavy infestation may cause insomnia due to pruritus, anorexia and abdominal discomfort.

Complications

Appendicitis is a known intestinal complication. *Non-intestinal complications* - include vulvo-vaginitis in young girls and occasionally endometritis and chronic pelvic peritonitis due to granulomas formed round straying enterobius worms. Invasion of the urinary tract, which facilitates bacterial infection may cause enuresis. Some patients with protracted or recurrent infection have psychological problems.

Diagnosis

Adult female *E. vermicularis*, can be seen in perianal area, in faeces, or during proctoscopy or vaginoscopy. Presence of eggs can be demonstrated by applying adhesive cellophane tape to the perianal skin for microscopic inspection at night, removed and examined the next morning.

Treatment

Mebendazole - Single dose of 100 mg (all ages). Repeated after 2 weeks.

Pyrantel - Single dose of 10 mg/kg (maximum 500 mg). Repeated after 2 weeks.

Sporadic infections are usually cured by one treatment. In intensive and symptomatic infections, drug therapy should be repeated after 2 weeks, and then if necessary every 2 months.

Adjuvant measures - to prevent reinfection. Nails should be cut short and gloves and close-fitting sleeping drawers should be worn at night. Child's hands must be scrubbed with brush before meals. All infected members of the family should be treated simultaneously.

STRONGYLOIDIASIS

Is caused by the nematode *Strongyloides stercoralis*. Infection is acquired in the same way as hookworms and thereafter it is self-perpetuating.

Clinical Features

(a) *Asymptomatic*. (b) *Skin* - Penetration of larvae causes transient, linear, itching erythema. (c) *Respiratory* - Pneumonitis and Loeffler's syndrome (during lung migration).

(d) *Intestinal* – Ulcerative and/or haemorrhagic enteritis due to superficial inflammation of jejunal mucosa, resulting in severe hypoproteinemia and anaemia. (e) *Acute disseminated strongyloidiasis* – may develop during pregnancy, puerperium, or in immunosuppressed subjects when it may prove fatal.

Diagnosis

Larvae of *S. stercoralis* may be found in sputum or in lung and jejunal biopsy samples, as also duodenal contents and faeces. ELISA for serum antibodies to antigens of *Strongyloides* is a sensitive method for diagnosing uncomplicated infections.

TREATMENT – Ivermectin is drug of choice. 200 mg/kg/day for 1-2 days or Thiabendazole 50 mg/kg/day in two doses for 2 days or Albendazole 400 mg daily for 3 days.

DIPHYLLOBOTHRIUM

Is acquired from consuming fresh water fish. Most infections are asymptomatic. Stool microscopy of eggs and inspection of stools for presence of proglottids are mainstay of diagnosis. Tr. – Praziquantel 25 mg/kg as single dose or Niclosamide 2 g as single oral dose for adults.

TRICHURIASIS

(Whip worm) – It is a common infection of large intestine caused by *Trichuris trichuria*. The adult worms dwell in the large intestine with their thin anterior ends buried in the mucosa. Ova leave the intestine in the stools and after about 2 weeks are infective if ingested.

Clinical Features

(a) Mild infections are usually asymptomatic. (b) Less heavy infections may cause vague abdominal pain and diarrhoea. Iron deficiency anaemia may result from bleeding ulcers. (c) Severe massive infantile trichuriasis is characterised by protracted profuse mucus and bloody diarrhoea with abdominal pain, and rectal prolapse. Severe anaemia, digital clubbing, hypoproteinemia and growth retardation are not uncommon.

Diagnosis

Brown, barrel-shaped eggs with a plug at each end in the stools. In severe infection adult worms can be seen in rectal mucosa. Eosinophils and Charcot-Leyden crystals are often abundant in stools.

Treatment

Mebendazole – 100 mg/b.d. for 3 days or Albendazole single dose of 400 mg.

HYMENOLEPIASIS

Is caused by the dwarf tapeworm *Hymenolepis nana* and is a faecal-borne infection and can be long-lasting due to auto-infection. It is a common human tapeworm and is unique in having a direct human life-cycle, and autoinfection within the gut can occur.

Clinical Features

Common symptoms are weakness, weight loss, anorexia, abdominal pain and diarrhoea. Disturbances in protein digestion and absorption, protein-losing enteropathy, stunted growth and allergic phlyctenular keratoconjunctivitis may occur.

Diagnosis

Repeated examination of stools may be necessary to see the eggs.

Treatment

Niclosamide 60-80 mg/kg/day (maximum 2 g/day) for 5-7 days or *Praziquantel* single dose of 20 mg/kg for all age groups.

19. SCHISTOSOMIASIS (BILHARIZIASIS)

Schistosomiasis is a group of diseases affecting mainly the genitourinary and gastrointestinal systems and caused by trematodes of the genus *Schistosoma*. The three common species to infect man are *S. haematobium*, *S. mansoni* (predominantly human parasites) and *S. japonicum*.

Two more recently described species are *S. mekongi* and *S. intercalatum*.

PATHOGENESIS

When the cercariae penetrate human skin, they cause acute symptoms (swimmer's itch). This occurs a few hours to days after infection, and is probably related to the development of humoral and cellular immunity to the cercariae. Few weeks later some patients experience a syndrome termed 'Katayama fever', which is thought to represent an immune complex disease, similar to serum sickness, as the immune response to schistosomal eggs begins.

The chronic features of schistosomiasis are organ-specific and related to the host response to deposited eggs. Egg deposition starts about 6-9 weeks after infection. Although the eggs are released into venous blood, many reach the lumen of the gut or bladder. Eggs reaching the lumen are excreted and subsequently hatch to form miracidia. Eggs not excreted lodge in the mucosa of bladder and bowel, and some reach the liver via the portal circulation. In the tissues, a cell-mediated response to the eggs leads to

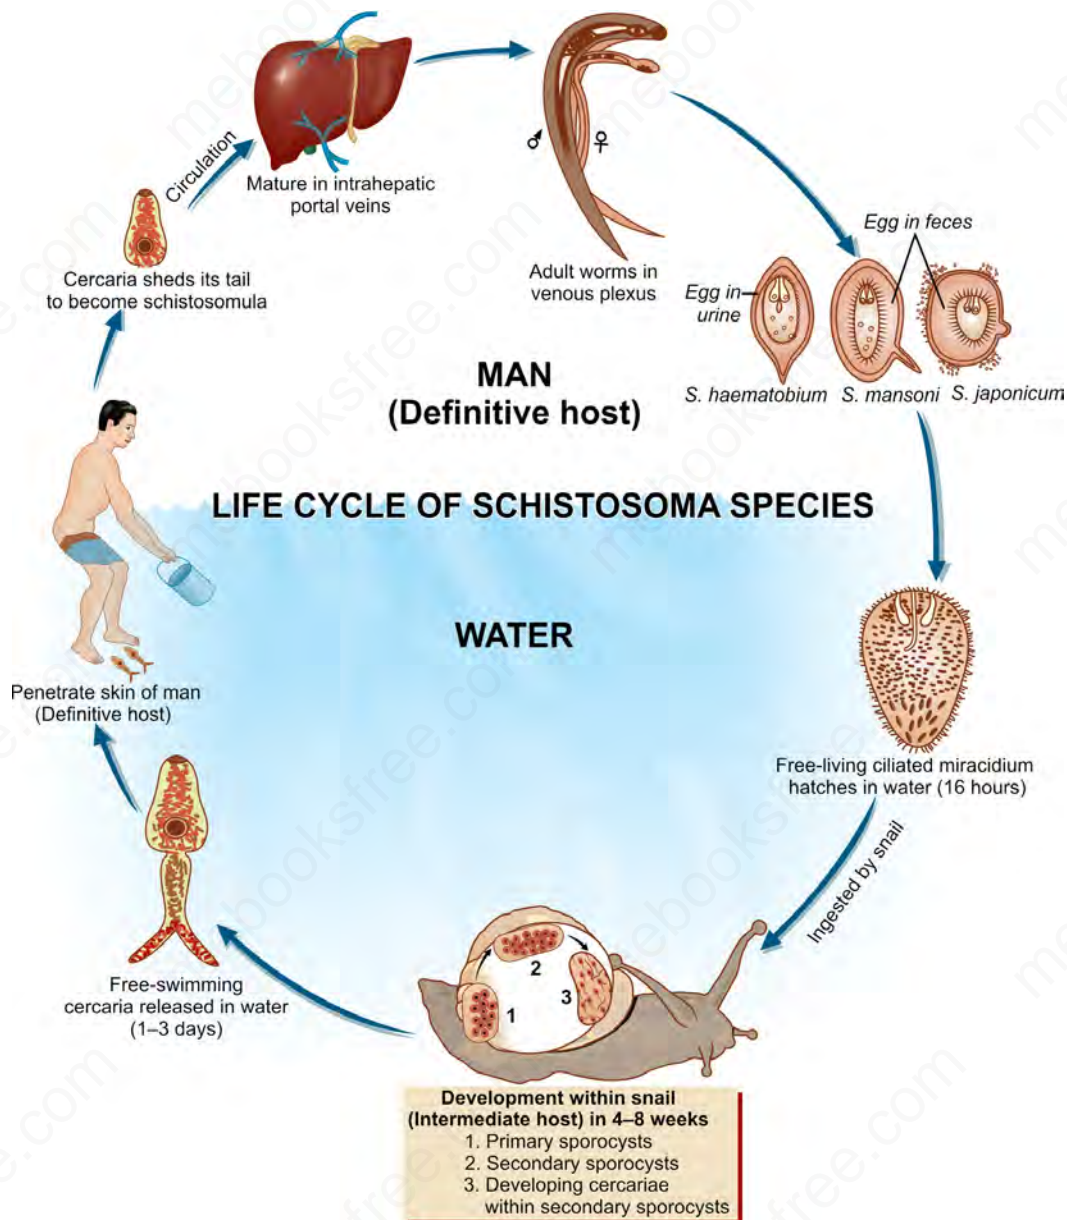

Fig. 15: Life cycle of *Schistosoma* spp

granuloma formation. See Figure 15 for the life cycle of *Schistosoma*.

CLINICAL FEATURES

Acute

Swimmer's itch occurs 1-2 days after exposure to fresh water containing cercariae. Affected individuals develop a macular, papular, itchy rash that lasts for few days before remitting spontaneously in those not previously exposed

or a papular eruption in those with repeated exposures. It is mainly seen in association with *S. haematobium*.

Over subsequent weeks migration and maturation of the schistosoma can result in **Katayama syndrome**. This typically presents with fever, headache, myalgia, abdominal pain and, occasionally radiographically opaque flitting pulmonary infiltrates occurring 14-84 days after exposure. This syndrome occurs more commonly with *S. japonicum*. There is generalised lymphadenopathy and hepatosplenomegaly in this syndrome.

Figs. 16A and B: (A) *S. haematobium* infection is confirmed by finding the terminal-spined eggs in the urine. *S. mansoni* infection is confirmed by finding the lateral-spined eggs in the stools

Chronic

Urinary tract – *S. haematobium* primarily causes dysuria, frequency and terminal haematuria. Renal ultrasonography may show bladder wall thickening, hydronephrosis and calcification in bladder and ureters. Cystoscopy may show ‘sandy patches’ on bladder mucosa.

Intestinal and liver disease – Infection with *S. mansoni* leads to egg deposition in intestinal mucosa and liver. Common symptoms are abdominal discomfort and/or diarrhoea. Egg deposition in liver ultimately leads to portal hypertension.

Other sites – (a) Lungs – Eggs may be deposited in the lungs, usually in patients with severe hepatic fibrosis. Multiple granuloma form in the lungs leading to cor pulmonale. (b) CNS – Eggs may migrate to the brain causing generalized or focal seizures. (c) Renal – Chronic glomerulonephritis. (d) Skin – Nodular rash from eggs migrating to skin.

DIAGNOSIS

(a) Eggs of *S. haematobium* are often seen in urine. Eggs of other schistosomal species may be detected in faeces. Biopsy of affected tissues (e.g. rectal biopsy) can also demonstrate eggs. (b) Serological tests are sensitive but are not useful for detecting active infection (Figs. 16A and B).

MANAGEMENT

Praziquantel 40 mg/kg in a single dose. The drug is well tolerated. Main side-effects are abdominal pain, and sometimes nausea and vomiting. In patients with CNS involvement, simultaneous use of corticosteroids.

20. HYDATID DISEASE

Hydatid disease of man is zoonosis caused by infection with tapeworm larvae of the genus *Echinococcus*.

There are two forms – (a) Cystic: The much more common *E. granulosus* causes unilocular hydatid cysts and is widespread in dogs and livestock (sheep, goats, cattle and camels) and in man. (b) Alveolar: caused by *E. multilocularis*, the ‘malignant’ hydatid is transmitted between foxes and rodents, but is very rare in humans.

LIFE CYCLE OF ECHINOCOCCUS

The adult worm lives in the small intestine of the dog. Eggs are shed in the faeces and ingested by sheep, usually from contaminated pasture. The eggs hatch in the duodenum and larvae migrate through the gut wall. Blood stream dissemination follows usually to the liver.

CLINICAL FEATURES

Hydatid cysts especially if calcified may be asymptomatic and first noted incidentally during routine physical examination. Symptoms and signs depend on the organ affected.

1. **Liver** – Hydatid cyst may present as:

- Painless hepatomegaly.
- Pyrexia of unknown origin following secondary pyogenic infection.
- Jaundice due to pressure on the bile ducts.
- Severe systemic reaction following rupture into peritoneal cavity, gut itself or pleural cavity.
- Cholangitis from rupture into biliary tree.

2. **Pulmonary**

Primary

- Solitary or at times multiple cysts on plain radiograph.
- Shortness of breath or chest pain if cyst is large.
- Haemoptysis following ulceration into a bronchus.
- Expectoration of watery fluid and daughter cysts (‘grape skin’ expectoration) following rupture into the bronchial tree.
- Respiratory distress due to aspiration of fluid elsewhere in the lungs, may be associated with urticaria and anaphylactic shock.
- Fever, cough and purulent sputum, if secondary pyogenic infection occurs.

Secondary (metastatic) – A rare form due to breaking of a primary visceral cyst into a vein or heart.

Fig. 17: Hydatid cyst of lung. Homogeneous rounded opacity

Fig. 18: HRCT thorax showing one hydatid cyst in right lung with water lily sign and another cyst in left lung

3. Cerebral

- Seizures or signs of increased intracranial pressure of subacute onset and progressive course that resembles slow-growing brain tumour. Neurological manifestations tend to evolve more rapidly with alveolar hydatid disease.

4. Spinal cord

- Root pain and motor or sensory deficits, may be seen in both cystic and alveolar disease.

5. Orbital

- Unilateral proptosis.

6. Abdomen

- Pseudocyesis from rapidly growing cysts.

INVESTIGATIONS

1. IMAGING

Chest radiograph – (a) Classical appearance of a circular shadow sharply defined with no reaction in surrounding lung parenchyma (Fig. 17). The cyst may change shape on maximum inspiration and expiration (Escudero nimerove sign). (b) Crescent sign or pulmonary meniscus sign – If the cyst communicates with a bronchus, a cap of air may be seen above the cyst (also seen in lung abscess partially filled with inspissated pus or blood clot, tuberculous cavity containing a Rasmussen aneurysm, and in intracavitary fungal ball). (c) Double arch (Cumbo's) sign – As more air enters between pericyst and endocyst, the shrinking cyst

ruptures with resultant air fluid level within the endocyst capped with crescent of air between pericyst and endocyst. (d) Water lily sign – With further separation of endocyst and evacuation of fluid, a wavy endocyst membrane floats on top of remaining fluid. (e) Membrane sign – Introduction of contrast medium which enters the layers of the ruptured hydatid membrane produces a radiolucent undulating line (lucent membrane sign).

2. HRCT thorax (Fig. 18).

3. Ultrasonography – for detection of hepatic cysts. Cystic hydatid disease is usually characterised by large, unilocular, liquid-filled vesicle that is well demarcated from surrounding brain or liver parenchyma. Hepatic hydatid cysts can be classified into: (a) Univesicular hypodense cyst containing 'hydatid sand'. (b) Univesicular hypodense cysts with double or undulating membrane. (c) 'Mother and daughter' cyst which is highly specific for hydatidosis. (d) Detachment of the germinal layer which produces classical 'Water lily' sign. (e) Cyst wall calcification. (f) CT scan is useful to visualize the relation of the hydatid cyst to surrounding liver tissue, bile ducts, portal and hepatic veins and its segmental location (Fig. 19).

IMMUNOLOGICAL DIAGNOSIS – by ELISA can be helpful but is not always accurate, because of cross-reactions with other parasite infections. ELISA has about 90% sensitivity for hepatic cysts of *E. granulosus*. Detection of circulating antigens by immunoblot may be of diagnostic value in some cases particularly in those with false-negative ELISA.

Fig. 19: Hydatid liver disease with daughter cysts (white arrow) and calcific wall (black arrow head)

SEROLOGY

Unlike ADA, white cell count is usually normal unless cysts are leaking or infected. LFTs commonly show an obstructive picture. Eosinophilia if present, suggests the cyst has recently ruptured or leaked.

MANAGEMENT

- Operative surgery** - for removal of cyst. Leakage of hydatid fluid should be avoided to prevent anaphylactic reaction. The type of operation can be pericystectomy, lobectomy or pneumonectomy is decided at time of operation.
If surgery is not an option, single cysts that are easily accessible, an alternative approach is percutaneous drainage with installation of sclerotic substance (usually ethanol), a technique known as PAIR (percutaneous aspiration, injection and re-aspiration). Medical treatment alone has low cure rates and most patients require additional surgery or PAIR. 15 mg/kg body wt/day in two divided doses for 3 weeks every month for 6 months.
- Chemotherapy** - Indications - (a) Inoperable hydatid disease. (b) Post-operative recurrence when re-operation is not possible. (c) Multiple cysts. (d) Involvement of the eye. Albendazole 15 mg/kg body wt/day in 2 divided doses for 3 weeks every month for 6 months.
- Combined therapy** - Along with surgery Albendazole starting 4 days preoperatively and continued for 1 month after operation.

21. DRACUNCULIASIS (Guinea-Worm disease)

Human dracunculiasis is caused by infection with meter-long round worm *D. medinensis*.

LIFE CYCLE AND PATHOGENESIS

The adult female *D. medinensis* lives in subcutaneous tissue. About a year after infection, transient fever and dermatitis occur, and the gravid female worm can be seen migrating just under the dermis. A chemical irritant released from the worm's uterus results in formation of a blister above the anterior end of a worm, filled with motile first-stage larvae; this is usually accompanied by symptoms of anaphylaxis. When sufferers enter ponds or wells to 'cool' the affected limb or fetch drinking water, the blister ruptures and releases thousands of larvae which are ingested by several species of crustaceans in which they become infective after about 2 weeks. Following ingestion by human host, larvae undergo several molts. Mating and maturation occurs in deeper tissues and body cavities, and then maturing female worms return to the subdermis to complete the 12-15 month prepatent period.

CLINICAL FEATURES

PRODROMAL SYMPTOMS - Transient fever and dermatitis before appearance of mature worm migrating in subcutaneous tissue, or subcutaneous blister which appears as a reddish papule on the extremities or trunk.

SECONDARY INFECTION - Exit lesions become secondarily infected. Attempts to extract the complete worm often causes it to rupture; large amounts of protein are thus released into the wound site, exacerbating inflammatory processes and resulting in painful abscesses. Chronic recurrent infection may cause ankylosis of joints. Gangrene and tetanus may develop.

CRYPTIC INFECTION - Symptomatic infections with adult worms in sterile deep tissue, abscesses in ectopic sites frequently occur with or without the presence of emerging worms. Most commonly, these worms are subdermal, or are located in axial lymph nodes, scrotum, or in intramuscular sites. Neurological manifestations include subdural abscesses with paraesthesiae, and paralysis.

INVESTIGATIONS

(a) Motile first-stage *larvae* - may be recovered from superficial abscess exudates and seen microscopically on wet mount. (b) *Adult worm* - Remnants of adult worm cuticle surrounded by granulomatous tissue or calcification

may be seen in surgical specimens from deep tissues. (c) *Serological tests* – ELISA can detect antibodies in patients with cryptic or prepatent infections.

MANAGEMENT

Minor surgical enlargement and firm massage along the tract of the worm can facilitate removal of emerging worms. The worm is wound on a rod, few centimetres each day, avoiding excessive tension. Septic abscesses and anaphylaxis require appropriate therapy.

TISSUE NEMATODES

Toxocariasis results from dog roundworm *Toxocara canis* or cat roundworm *T. cati*. Infection manifests as

1. Visceral larva migrans more common in children, in whom pica is a risk factor. Cl. Fs.: Anorexia, abdominal pain, fever, hepatomegaly, cough and wheeze. Tr. Symptomatic and anthelmintic (albendazole, diethylcarbamazine).
2. Ocular larva migrans. Cl. Fs.: Asymptomatic or visual loss, squint, fixed pupil or a red eye. On examination, posterior chorioretinitis with a mass lesion, or peripheral intraretinal granuloma.

Trichinosis is caused by infection with *Trichinella spiralis*, for which humans are 'dead-end' hosts. Cl. Fs.: Most infections in humans are asymptomatic, or with symptoms in 2 phases:

- (a) Intestinal phase with nausea, vomiting, abdominal cramps and diarrhoea, occasionally bloody.
- (b) Extraintestinal phase with prominent muscle invasion. Common symptoms are fever, myalgia, periorbital oedema and headache, and occasionally macular or petechial rash. Myocarditis is potentially fatal, and CNS involvement may lead to fits, paralysis, coma and death. Tr. Albendazole or thiabendazole.

Angiostrongylus infection. Human infection occurs from ingestion of salads contaminated with larvae contained in mucus from snails or undercooked dishes containing snails, crabs or prawns. Cl. Fs.: Meningitis, papilloedema, extraocular n. palsies and cerebral abscess. Tr. Albendazole.

Gnathostomiasis. *Gnathostoma spinigerum* is a parasite of feline and canine hosts. Humans become infected after eating undercooked fresh water fish, frogs or snakes. Cl. Fs.: Larvae can cause intermittent subcutaneous swellings, pleural effusion, abdominal pain, eosinophilic meningitis or myeloencephalitis. Tr. Albendazole.

22. TROPICAL SPRUE

It is GI dysfunction characterised by deficiency in gastric secretion and inability to absorb adequately fat, glucose, calcium and certain other food constituents and characterised by morning diarrhoea, bulky gaseous stools, sore tongue, megalocytic anaemia and wasting.

AETIOLOGY

Age – usually middle age. *Sex* – more in females especially when pregnant. *Geographical distribution* – Tropics and subtropics and mainly in hot, damp coastal climates. *Season* – Onset usually after rains. *Race* – mostly amongst Europeans. *Other predisposing causes* – Prolonged residence in endemic area and hills, chronic dysentery, mucous colitis or hill diarrhoea. *Cause* – An alimentary dysfunction in which a series of interlocking pathophysiological events occur.

CLINICAL FEATURES AND DIAGNOSIS

See Malabsorption syndromes.

Course – Sprue relapses are uncommon after adequate treatment (unlike idiopathic steatorrhoea) and when they do occur, ultimately respond to treatment. Fatal cases are rare.

DIFFERENTIAL DIAGNOSIS

1. *Other megaloblastic anaemias*.
2. *Idiopathic steatorrhoea* – Long history. In sprue onset and course often more rapid, diarrhoea almost invariable, anaemia tends to be more severe and is commonly normochromic or hypochromic. Hypocalcaemia and cramps uncommon, stomatitis more marked, anorexia and abdominal pain more common. No specific response to folic acid or antibiotics.
3. *Chronic pancreatitis* – Faeces contain high percentage of neutral fat but split fat content low, the reverse is true in sprue.
4. *Giardiasis* – may cause steatorrhoea. Diagnosis made by finding cysts of the parasite in formed stools and vegetative forms in fluid stools.
5. *Intestinal strictures* – e.g. due to TB.

MANAGEMENT

Aims – (i) Rest to alimentary canal by dietary regime. (ii) Correction of anaemia and gross deficiency conditions.

1. **Diet** – High protein, low carbohydrate and low fat – (a) Milk diet – Skimmed milk or Proprietary dried milk; or protein hydrolysates and concentrates; 2 hourly feeds. Fruits and glucose. (b) Mixed diet – Skimmed milk, eggs, meat, bread, green vegetables, fresh fruits, and milk pudding.
2. **Folic acid** – Effect most marked in cases with prominent megaloblastic anaemia. 30 mg day po or 15 mg IM for 3 weeks controls diarrhoea and causes improvement in stomatitis and glossitis. Maintenance dose of 5 mg bd. The effect on fat absorption defect is minimal.
3. **Antibiotics** – Short course treatment with broad spectrum antibiotics such as oxytetracycline 250 mg qds by mouth can be effective.
4. **Corticosteroids** – if folic acid therapy fails. Prednisolone 50 mg/day for 7 days, dose gradually reduced to 15 mg/day.
5. **Treatment of anaemia and other deficiencies** – (a) Vitamin B₁₂ 50-100 mcg twice a week together with folic acid for optimal haemopoietic response. (b) Vitamin B complex. (c) Pancreatic enzyme tablets 0.4 gm bd after meals. (d) Calcium salts and vitamin D. (e) Transfusions in severely anaemic patients.

23. EFFECTS OF HEAT

High environmental temperature with high relative humidity can result in heat syndromes.

CLINICAL MANIFESTATIONS

1. **Heat fever** – is common in the aged and in children in summer months. Fever is continuous in the range of 101°-104°F and may have a spontaneous onset or follow about a week after surgery. A change in the mental state of the patient (apathy, drowsiness) may occur after about a fortnight of pyrexia with tremulousness of the hands and increased tone in the extremities. Drowsiness may progress to coma and if undiagnosed may result in death.
Tr. – Shifting the patient to cooler environment and maintenance of electrolyte balance.
2. **Heat cramps** – of striated muscle from excessive salt loss due to profuse sweating in high environmental temperatures. It is common in boiler room workers, steel workers and miners. Calf muscles are most commonly affected but cramps may occur in the chest, and when affecting abdominal muscles simulate an acute abdomen.
Tr. – Cramps can be rapidly relieved by drinking fluids containing sodium chloride or by 1/2-1 litre of normal saline IV.
3. **Heat syncope** – A fainting spell or 'blackout' from excessive heat and humidity. The individual drops to the ground if standing and there is transient loss of consciousness.
Tr. – Lying down flat in cool surroundings is followed by quick recovery.
4. **Heat stroke** (Sunstroke, heat hyperpyrexia) – Characterised by sudden loss of consciousness which may be preceded by prodromal signs typical of cerebral irritation – headache, dizziness, nausea, convulsions, and visual disturbances. Failure of the heat regulating centre gives rise to high fever and cessation of sweating. On examination the skin is hot and flushed and dry, pulse rapid, irregular and weak and low BP. Temperature may reach as high as between 105°-107°F. If the patient is not treated the temperature continues to rise and a state of hyperpyrexia supervenes. Rhabdomyolysis, cardiac dysrhythmias, acute renal failure and coagulopathy ensue and contribute to the high mortality rate.
Management – (a) Cooling by fanning after sprinkling with water. Immersion in cold water or use of ice packs or ice water enemas. (b) Massage of extremities to maintain circulation. (c) Sedatives contraindicated unless convulsions. (d) Normal saline 1000 ml IV slowly if dehydration or cramps.
5. **Heat exhaustion** – Three types:
 - (a) **Due to anhidrosis** – Due to acute heat stress after long residence in tropics; may follow prickly heat. Feeling of heat and exhaustion and headache, giddiness and palpitation. Fever 99°-100°F, tachycardia and increased respiratory rate. Collapse and coma may occur.
Management – Removal to cool surroundings.
 - (b) **Due to salt deficiency** – Predominant salt depletion prone to occur during periods of acclimatisation. Anorexia, nausea, vomiting, syncope, giddiness, painful spasms of muscles of abdomen and extremities. Skin moist and cool, pulse rapid, and low blood pressure. Circulatory failure or sudden collapse may follow.
Management – Half-strength normal saline by mouth with fruit juice, normal saline IV.

Table 24: Differentiation between heat stroke and heat exhaustion

	Heat stroke	Heat exhaustion
Cause	Inadequate or failure of heat loss	Depletion of fluids and electrolytes
Warnings	Headache, weakness, sudden loss of consciousness	Gradual weakness, headache, anorexia, faintness
Clinical features	Hot, red, dry skin. Little sweating, tachycardia, hyperpyrexia	Pale, cold, clammy skin, weak pulse, hypotension

(c) **Due to water deficiency** – Syndrome of predominant dehydration with elevated serum sodium. Usually seen during illnesses which prevent proper intake or absorption of water e.g. cardiac or cerebral disease. Intense thirst main complaint. Also lethargy, fatigue, irritability, abdominal discomfort and tingling in the limbs with ultimately mental confusion and muscular incoordination.

Management – Large amounts of water by mouth, or IV 5 per cent glucose. Since the total body sodium is likely to be reduced, sodium depletion may occur during phase of rehydration and salt-containing drinks should be administered as soon as improvement is observed.

Table 24 shows differentiating features between heat stroke and heat exhaustion.

- Heat oedema.** Swelling of ankle and wrist can occur in first 4 days of heat exposure which disappears after acclimatisation.
- Exertional heat disorders.** Physical exertion (e.g. marathon runners) in hot and humid condition can cause headache, fever, diaphoresis, nausea and vomiting and muscular incoordination and hypotension and tachycardia. *Tr.* control of fever with cold water sponging, massage of the extremities and IV infusion of 5% dextrose in saline.

24. ENDEMIC FLUOROSIS

A disease entity resulting from ingestion of excessive quantities of fluoride in drinking water over a prolonged period. It primarily affects hard tissues of the body manifesting as mottling of enamel and osteosclerosis of the skeleton.

FACTORS INFLUENCING TOXICITY OF FLUORIDE

- Fluoride concentration of drinking water** – is the most important factor.

- Duration of exposure.**
- Occupation and sex** – Most cases of skeletal fluorosis occur in those doing hard manual labour. Incidence is higher in males.
- Nutrition** – Poor nutrition particularly lack of proteins and calories.
- Climate** – Hot climate favours increased ingestion of water which may contain excess fluorine.

CLINICAL FEATURES

- Dental fluorosis** – ‘Mottled enamel’ due to dental hypoplasia with areas of hypocalcification best seen on incisors of upper jaw. Besides brownish discolouration there is pitting of enamel surface.
- Skeletal fluorosis** – (a) *Symptoms* – Pain and rigidity of spine and later on of joints. Paraesthesiae in limbs. (b) *Skeletal changes* – (i) Irregular bone deposition may be felt as exostosis along anterior borders of tibia, near tibial tubercle, olecranon and along medial border of scapula and near the vertebral spinous processes. (ii) Fixed flexion deformity from ossification of interosseous membrane of forearm and leg. (iii) Kyphosis.
- Neurological complications** – (a) Due to compression of spinal cord – Paraesthesiae with patchy sensory involvement, weakness, wasting and fasciculations with spasticity and loss of sphincter control. (b) Uncommon features – Cerebrovascular insufficiency or cerebellar ataxia from compression of vertebral artery in spine, peripheral neuritis, headache, nerve deafness.
- Urinary system** – (a) *Acute poisoning* with fluorine causes polyuria, excessive thirst, nocturia and frequency of micturition (Diabetes insipidus fluorique). (b) *Chronic ingestion* – may lead to chronic nephritis, and kidney failure.
- Soft tissue lesions** – (a) Thyroid goitre due to iodine deficiency since fluorine competes with iodine. (b) Anaemia. (c) Monckeberg’s atherosclerosis.
- Systemic or visceral intoxication** – is characterised by constipation, furunculosis, urticaria, alopecia and brittle nails.

Investigations

1. *Urine* - Mean 24 hour urinary excretion of fluoride increased (>1.5 ppm).
2. *Radiology* - Osteosclerosis in spine and pelvis (Fig. 20). Beaking and chalky white ground-glass appearance. Calcification of inter-vertebral ligament, sacrospinous and sacrotuberous ligament and of interosseous membrane of forearm.
3. *Blood biochemistry* - (a) Fluoride level in blood >0.27 ppm. (b) Plasma alkaline phosphatase may be elevated.

Management

Preventive - (a) Drinking water should contain 0.5-0.8 ppm of fluorine. Defluoridation of water if high content, or deep bore drinking water. (b) Vitamin C and calcium give protection against toxic effects of fluorides.

Fig. 20: Milky white appearance of pelvic bones in fluorosis

Of the disease - Avoid seafood, cheese, tea. Do not use toothpastes and other product supplements with fluoride.

Diseases of Children

1. NEWBORN INFANTS

RESUSCITATION OF THE NEWBORN

Asphyxia can occur at birth. Asphyxia is characterized by progressive hypoxia, hypercapnia, hypoperfusion and acidosis. Apnoea occurs when a baby is deprived of oxygen. Continuation of asphyxia leads to stoppage of respiratory movements, fall in heart rate, diminution of neuromuscular tone – *primary apnoea*. In most cases stimulation and exposure to oxygen will induce respiration.

If the asphyxia continues, the baby develops deep gasping respirations, heart rate continues to slow, and it enters a period of *secondary apnoea*. There is now no response to stimulation and respiratory effort will not begin until resuscitation with assisted ventilation and oxygen are initiated without delay.

It must be noted that due to foetal hypoxia, the infant may go through primary apnoea and into secondary apnoea while *in utero*. In both instances the infant is not breathing and the heart rate may be less than 100. The importance is that when faced with an apnoeic infant at birth, it must be considered as a case of secondary apnoea and resuscitation undertaken.

See Table 1 for the equipments and drugs needed for resuscitation.

Indications for resuscitation – The Apgar score is not used in deciding when to initiate resuscitation or deciding the course of action. Plan of action depends on:

- Respiration
- Heart rate
- Colour

Resuscitation Procedure: TABCs

T – Maintenance of temperature

- Radiant heat source with an overhead radiant warmer which should be preheated to allow the baby to be placed on a warm mattress.

Table 1: Equipment and drugs required for resuscitation

Radiant warmer

Suction equipment

- Mucous aspirator
- Meconium aspirator
- Mechanical suction
- Suction catheter, 10 or 12F size
- Feeding tube 8F
- 20 mL syringe

For bag and mask ventilation

- Ambu bag with face masks, newborn and premature sizes
- Oxygen cylinder with flowmeter and tubing

For intubation

- Laryngoscope with straight blades, No. 0 (preterm) and No. 1 (term)
- Endotracheal tubes 2.5, 3, 3.5, 4 mm and stylet
- Scissors and gloves

Drugs

- Epinephrine
- Naloxone hydrochloride
- Sodium bicarbonate
- Volume expanders
- Dopamine
- Sterile water

- Drying the infant with prewarmed towel or blanket.
- Removing the wet linen.

A – Airway

- Positioning. The neonate is placed on its back with the neck slightly extended. A rolled towel can be put under the shoulders to maintain position.
- Suction of mouth and nose of the meconium with mucus aspirator or mechanical suction. The suction pressure should be kept around 80 mm Hg (100 cm water).

Table 2: Medications during resuscitation

Medication	Indication	Dose/route
Adrenaline (1:10000)	HR zero or < 80 after 30 secs of PPV and CC	0.1 ml–0.3 ml/kg iv, IT
Volume expanders N saline/Ringer's	Bleeding with hypovolemia	10 ml/kg IV Infusion
Naloxone	Resp. depression following narcotic given 4hr before delivery	0.25 ml (0.1 mg/kg) IV
Dopamine	Persistent hypotension	5–20 mcg/min. continuous infusion
Sodium Bicarbonate	Metabolic acidosis Apgar 5 or less at 5 min.	4 mL/kg IV slowly

Table 3: Apgar score

Score	0	1	2
Respiratory effort	None	Slow, irregular	Good crying
Heart rate/min.	Absent	100	100
Colour of body	Blue or pale	Body pink, extremities blue	Pink
Muscle tone	Flaccid	Some flexion	Actively moving the extremities
Reflex stimulation (catheter in nose)	No response	Grimace	Cries, coughs or sneezes

- Clearing the airway of meconium. This is best carried out when the head is delivered. After delivery if the infant is passing thick, particulate meconium, first residual meconium in the hypopharynx should be removed by suctioning through a laryngoscope. This is followed by intubation of the trachea and suctioning of meconium from lower airways, by applying suction directly to an endotracheal tube. After tracheal suctioning, the trachea should be suctioned to prevent aspiration of meconium containing gastric contents into the lung, in case vomiting occurs.

B – Breathing

- If breathing is not spontaneous, provide tactile stimulation by rubbing the baby's back or flicking the soles of the feet.
- PPV if baby remains apnoeic or is gasping in spite of tactile stimulation or respiration is spontaneous but heart rate is < 100/min. (Heart rate is counted by auscultation of the heart or palpating umbilical pulsations for 6 seconds and multiplying the figure by 10).

Bag and mask ventilation – The infant's neck is slightly extended and the mask placed in position and the seal checked by ventilating 2 or 3 times. If chest does not rise look for and correct inadequate seal, blocked airway or inadequate pressure. Ventilate at a rate of 40–60/min. The best indication of successful bag and mask ventilation is an easy rise and fall of the chest.

After 15–30 seconds of ventilation, further action will depend on the heart rate.

> 100: Monitor heart rate, respiration and colour if spontaneous respiration.

If not breathing or gasping: Continue ventilation.

60–100 and increasing: Continue ventilation

60–100 and not increasing: Begin chest compression if heart rate < 80/min. Continue ventilation

< 60: Continue ventilation and chest compressions

C – Maintain Circulation

Chest compressions – are done with thumb or two fingers, applying pressure to the lower third of the sternum. Ventilations are interposed between compressions and a ventilation should follow every third compression. Chest compressions are stopped if the heart rate is 80 beats/min. or more.

If heart rate < 80: Continue chest compression along with bag and mask ventilation, and start medications.

Endotracheal intubation – to ensure open airway.

Indications:

- Prolonged PPV is required
- Bag and mask ventilation is ineffective
- Tracheal suction is necessary
- Suspicion of diaphragmatic hernia.

The tube varies from 2.5–4 depending on infant's weight and gestational age.

Prolonged asphyxia – Therapy only after adrenaline and volume expanders have been given and preceded, accompanied and followed by ventilation.

Apgar score – is a quantitative method for assessing the infant's respiratory, circulatory and neurological status and overall condition of the newborn (Table 3).

SCORE

- 8–10 Normal
- 5–7 Moderately asphyxiated
- < 4 Severe distress

Ideal score at 1 minute is 9. But one minute score is not useful for deciding upon intervention, because action must be initiated before that. A 5 minute score is useful as an objective measure for baby's condition for future reference.

Table 4: Danger signs in the newborn

• Poor feeding
• Cold to touch (hypothermia) or febrile (hyperthermia)
• Inability to suck
• Respiratory distress
• Drowsiness or irritability
• Blue discolouration of lips/tongue
• Convulsion
• Bleeding
• Jaundice in first 24 hours after birth
• Vomiting, abdominal distension
• Umbilical discharge

Timing of the Score

- At first cry
- Once regular respiration is observed
- Delayed if any neurological deficit.

Significance

A low score may indicate:

- Birth asphyxia
- Effect of drug administered to mother during labour
- Intrauterine infection
- Congenital malformations
- Prognostic significance: Serious outlook if score < 4 at 20 minutes

Note: While the Apgar score is not useful for decision-making at the beginning, it is useful for assessing the infant's condition, and the efficacy of resuscitation. Hence, an Apgar score should be done at 1 and 5 minutes of age. When the 5 minute score is < 7, additional score should be obtained every 5 minutes for up to 20 minutes or until two successive scores are 8 or more.

Fallacies

Scoring cannot be used in

- Preterm baby
- Floppy infant
- Infant markedly sedated
- Presence of Erb's palsy
- Does not estimate duration of asphyxia
- Respiration cannot be judged if newborn is on IPPR

Table 5: Cyanosis in newborn

• Congenital heart disease with right-to-left shunt (2As, 5Ts)
Atresia of aorta
Atresia of pulmonary artery
Transposition of great vessels
Tetrad of Fallot

Truncus arteriosus
• Congenital cardiac lesion with CHF
Transposition of great vessels
Aortic atresia
• Pulmonary
Hyaline membrane disease
Pneumonia
Septicaemia
Meconium aspiration syndrome
Transient tachypnoea of newborn
• Neurological
Birth asphyxia
Intracranial hemorrhage
• Haematological
Polycythemia

FIRST CRY OF NEWBORN

Mechanism

- Fall in pulmonary vascular resistance with increase in pulmonary blood flow
- Increased venous return to LA with increase in LA pressure and functional closure of foramen ovale
- Increase in arterial oxygen tension causing functional closure of ductus arteriosus

Significance of first cry – During intrauterine existence, foetal lungs are non-functional because the foetus derives its oxygen needs from the placental circulation. During normal vaginal delivery, there is compression on the foetal thorax in the birth canal and the fluid present in the alveoli, a one-third of which is emptied out of the lungs.

With the first cry of the newborn, a high inspiratory pressure is created, which forces the remaining lung fluid into the lymphatics from where it is absorbed and the lungs begin to function on their own for the first time.

Table 6: Causes of a weak cry

- Caesarean section.
- Precipitate labour.
- Intrauterine hypoxia.
- Inability to initiate respiration due to congenital cerebral abnormality.
- Prematurity
- Hyaline membrane disease

Table 8: Diagnostic criteria for asphyxia neonatorum

- Signs of foetal distress
- Acute metabolic acidosis
- Apgar score at 5 minutes < 5
- Initiation of respiration > 5 minutes
- Features of ischemic hypoxic encephalopathy
- Multiorgan damage

Note: Any four of the above

Causes of a weak cry – If the pressure required to force the fluid out of the foetal lung is not sufficient there is transient tachypnoea (Table 6).

2. DISEASES OF THE NEWBORN

RESPIRATORY DISTRESS IN THE NEWBORN

Asphyxia Neonatorum

Asphyxia neonatorum is a state of anoxia as a result of lack of oxygen and/or deficiency of perfusion to various organs arising from absence of normal respiratory function at birth.

Aetiology

- Persistence of intrauterine hypoxia (major cause)
- Placental: Functional failure of placenta to function as respiratory organ, e.g. inefficient uteroplacental circulation, early separation of placenta, small size of placenta or its infarction, circumvallate placenta
- Maternal hypoxic states: Anemia, eclampsia, cardiac disease, severe bronchial asthma, hypotension

Table 7: Clinical features asphyxia neonatorum

CNS

- Hypoxic ischemic damage (cortical infarcts, damage to thalamus/basal ganglia)
- Signs of increased intracranial tension

Renal

- Acute tubular necrosis
- ADH syndrome

GI

- Necrotising enterocolitis
- Liver damage

Cardiac

- Transient myocardial ischemia
- MR, TR

Lung: Haemorrhage, oedema, respiratory distress syndrome, meconium aspiration

Haematological: DIC

Table 9: Factors of poor prognosis

- Prolonged duration and severe asphyxia
- Seizures
- Raised intracranial pressure
- Persistent oliguria
- CT brain shows hypodensities

- Neonatal injury: Prolonged head compression, abnormal lie such as breech or oblique causing increased intracranial pressure and thus asphyxia
- Medications to mother (prenatal and intranatal, e.g. anaesthetic agents, sedatives) depress respiratory centres of the newborn, resulting in continuation of intrauterine asphyxia

Clinical features, diagnostic criteria and prognostic factors of asphyxia neonatorum are given in Tables 7, 8 and 9, respectively.

Management

- IV fluids
- Warmth
- Management of cerebral oedema
- Symptomatic treatment of seizures, hypoglycemia, hypocalcemia
- Cerebral cooling
(See Resuscitation in Newborn)

HYALINE MEMBRANE DISEASE IN THE NEWBORN

Predisposing Factors

It is one of the major causes of death in the newborn period. Incidence inversely proportional to gestational age and weight. Common in premature infants of diabetic mothers delivered before term, Caesarean section, asphyxia, precipitous delivery, after antepartum haemorrhage.

Pathophysiology

(1) Surfactant (dipalmitoylphosphatidylcholine) deficiency leads to collapse owing to increased surface tension, so there is a failure to maintain functional residual capacity. Surfactant synthesis by Type II alveolar cells increases with foetal maturity. (2) Small alveoli - Diameters of airways up to bronchioles are smaller in prematures, requiring greater force for inflation and larger transpulmonary pressure to keep them from deflating. (3) Weakened compliant chest wall at this time compounds tendency to atelectasis, offering poor resistance.

These factors produce near-atelectasis, dyspnoea and tachypnoea, increased airway resistance and work of breathing, and eventually hypoxia, hypercapnia and acidosis. These events give rise to pulmonary vasoconstriction, maintenance of ductal blood flow and foramen ovale flow in an attempt to perfuse the lungs. Decreased lung flow causes ischemic necrosis of surfactant cells and the vasculature causing effusion of protein-like material into alveolar spaces, producing the hyaline membrane.

Lungs appear liver-like. Microscopically there is extensive atelectasis, engorgement of vessels and lining of alveoli by acidophilic homogenous membrane; membranes are seen only 6-8 hours after birth.

Clinical Features

Signs appear minutes after birth; may require resuscitation. Late tachypnoea is very unusual.

- Rapid shallow respirations increasing to 60 or more per minute.
- Audible grunting (ominous sign).
- Intercostal and subcostal retractions.
- Nasal flare.
- Duskiness with increasing cyanosis poorly responsive to oxygen.
- Breath sounds normal or diminished with harsh, tubular quality, fine crepitations on deep inspiration at lung bases.

Worsening is characterised by increased dyspnoea, air hunger, progressive cyanosis, decrease and then absence of grunting, absent breath sounds despite chest movement, hypothermia, hypotension, irregular breathing, acidosis and apnoea; progresses to death in a few hours. Death is rare after 3 days if an infant survives severity of newborn respiratory distress judged by Anderson and Silverman's score.

Complications

Of the disease

- Hypoxia, hypercapnia, acidosis, respiratory failure.
- Persistence of ductus arteriosus - delayed closure due to hypoxia, acidosis, increased pulmonary pressure, immaturity of the infant and local release of ductal dilators such as prostaglandin E₂ and E₂ causes persistent apnoea, systolic or continuous murmur, increases oxygen dependency, aggravates hypercapnia, cardiomegaly and cardiac failure.
- Intraventricular and pulmonary haemorrhage.

Of intensive care

- Tracheal intubation - Obstruction of tube, cardiac arrest during suction, bleeding and ulceration of nose and throat from trauma, vocal cord avulsion, subglottic stenosis, laryngeal oedema and stridor.
- Umbilical catheterization - Vascular embolism, thrombosis, perforation, ischemic necrosis of viscera, gangrene of legs, haemorrhage after removal of heparinised catheter.
- Oxygen toxicity - Retrolental fibroplasia, bronchopulmonary dysplasia.
- Pneumothorax and pneumoperitoneum (with intubation, respirator)
- Secondary infection.
- Anemia due to frequent blood collections.

Diagnosis

1. Low pO₂ < 50 mm Hg, pCO₂ > 50 mm Hg and acidosis signal respiratory failure.
2. Radiograph chest - Fine reticular granularity of lung fields with air bronchogram seen within 6-12 hours characteristic but not pathognomonic.

OTHER CAUSES OF NEONATAL RESPIRATORY DISTRESS

- a. *Respiratory* - 1. Prenatal, natal meconium aspiration. 2. Intrauterine or postnatal pneumonia, esp. group B streptococcal pneumonia. 3. Pneumothorax,

Table 10: Anderson and Silverman's score

Upper chest	Lower chest retraction	Xiphoid retraction	Alae nasi flare	Expiratory grunt
Gr 0 Synchronised motion	None	None	None	None
Gr 1 Insp. lag	Just visible	Minimal	Minimal	With stetho.
Gr 2 "See-saw" movement	Marked	Marked	Marked	Naked ear

Grade 0–1 for each criterion indicates no distress.

Grade 2 for each criterion indicates severe distress. Applicable 1–2 hours after birth.

pneumomediastinum. 4. Pulmonary haemorrhage. 5. Transient tachypnoea of the full-term newborn (persistence of lung fluid, recovers fully). 6. Wilson-Mikity syndrome (late onset dyspnoea, X-ray shows 'bubbly' lungs, cause unknown). 7. Congenital malformations—Choanal atresia, Pierre Robin syndrome (small chin, cleft palate, tendency for tongue to fall back); laryngeal webs, stenosis, atresia, vascular rings, ectopic goitre, T-O fistula, congenital lobar emphysema, pulmonary agenesis, diaphragmatic hernia, congenital tumours, e.g. cysts, teratomas.

- Cardiovascular** – CHF from any cause, congenital heart disease PDA, coarctation of aorta, cyanotic heart disease, severe anemia, polycythemia, myocarditis, arrhythmias, diabetic offspring.
- Neurological** – Birth asphyxia or injury, intracranial haemorrhage, plexus injuries in breech deliveries, meningitis.
- Metabolic** – Acidosis, uraemia, inborn errors of metabolism (hyperammonaemia), hypoglycemia, hypothermia.

Anderson and Silverman's score for newborn respiratory distress: See Table 10.

Management

Course can be altered by intensive care and supportive therapy.

- Treatment of inadequate gas exchange** – Warm humidified oxygen to keep arterial blood levels from 50 to 70 mm Hg with stable vital signs, while minimising risks of toxicity. Inspired concentration safely kept at 40–70%. If > 50 mm Hg O₂ cannot be achieved, use of continuous positive airway pressure (CPAP) by nasal prongs or head box is used. Persistent apnoea, blood pH < 7.2, pCO₂ > 60 mm Hg, pO₂ < 50 mm Hg, at O₂ concentrations of 70–100% need assisted ventilation (mask and bag resuscitator or variable pressure respirator with endotracheal tube). This may also help in correction of respiratory acidosis.

- Correction of metabolic acidosis** – Sodium bicarbonate 7.5% solution 2 mL/kg slowly IV diluted in 5 times volume of 5% glucose (1 mL NaHCO₃ = 0.9 mEq Na). Formula – HCO₃ [mEq needed = Deficit of HCO₃ × 0.6 × body weight (kg)]. One half of calculated amount given initially. More than 12 mEq/kg/day can aggravate hypernatremia and CHF. Alternatively, THAM 1 mL/kg for each pH unit below 7.4 at rate of 1 mL/min.
- Pharmacological closure of ductus** – If ductus complicates the disease, oral or rectal indomethacin 0.2 mg/kg given thrice at 12 hour intervals. The drug inhibits prostaglandin synthesis. Surgical closure may be necessary. Frusemide 1–2 mg/kg IM/IV and Digitalis 0.02 mg/kg digitalising dose if CHF occurs.
- Antibiotics** – because of frequency of superinfection Ampicillin 200 mg/kg IV 12-hourly with gentamicin 5 mg/kg IV 12-hourly, or Amikacin 15 mg/kg IV 12-hourly.
- Exchange transfusion** – may benefit by improving oxygen carrying capacity of blood.
- Steroids are ineffective and contraindicated.
- General measures** – Prevention and treatment of hypothermia and hypoglycemia, IV fluids not more than 80–100 mL/kg/24 hours. Parenteral nutrition if available. Incubator care. Gentle and minimal handling. Inj. vitamin K 1 mg to prevent haemorrhage IV. Phenobarbitone 20 mg/kg to prevent intra-ventricular haemorrhage. Monitoring of pulse, temperature, respiration, CVP, PaO₂, blood pH, blood HCO₃, Hb, less often serum electrolytes, and blood glucose, ECG.
- Use of artificial surfactant** – 2 varieties available – (i) Bovine (Survanta). (ii) Synthetic (Exosurf). Saline suspension 10 ml intratracheally within first day rapidly reduces oxygen requirement. A single dose produces transient benefit in oxygenation and reduces need for ventilation. Multiple doses may improve prognosis when given within the first 2 days every 12 hrs for 4 doses (rescue therapy).

Prevention

- Prevention of prematurity, unnecessary and poorly timed LSCS, management of high risk pregnancy and labour.
- Assessment of foetal maturity. Foetal head circumference by ultrasound. 'shake test' with amniotic fluid and 1: 2 dilution of 95% ethanol producing complete ring of bubbles at meniscus indicating foetal lung maturity, or determination of amniotic fluid lecithin to sphingomyelin ratio which is 2: 1 by 35 weeks gestation, increasing till term.

3. Antenatal administration to mother, of synthetic steroids in absence of toxæmia, diabetes or renal disease, 24 to 72 hours prior to delivery of foetus at 32 weeks gestation reduces incidence of and mortality from hyaline membrane disease. One or two doses of 6 mg betamethasone acetate and 6 mg of betamethasone phosphate IM.

Croup: It is characterized by acute onset of hoarseness of voice, inspiratory stridor, barking cough and some degree of respiratory distress. It usually occurs due to viral (parainfluenza, RSV), acute laryngotracheobronchitis. There may be mild fever. Chest X-ray reveals subglottic narrowing resembling a Church spire (steeple or pencil point sign). Lateral view of neck shows ill-defined thumb-shaped opacification at site of epiglottitis (Thumb sign). *Treatment:* (a) Nebulised budesonide, corticosteroids. (b) Supportive measures like humidified O₂, or inhalation of mixture of helium and O₂.

INFECTIONS OF THE NEWBORN

Neonates, particularly those born prematurely, are relatively immunocompromised and are, therefore, prone to more infections, more severe disease and infection with unusual organisms. Almost all foetal infections and a significant proportion of those in the neonatal period are caused by organisms acquired from the mother; that is, they are vertically transmitted. Transmissions may be transplacental *in utero*, perinatal during the birth process or post-natal (including transmission via breastfeeding). Neonates also acquire infections horizontally including nosocomial. Several infections including HIV, may be transmitted by more than one of these routes, but because diagnosis and management differ between routes, it is convenient to consider transplacental infections separately from perinatal and postnatal infection.

Transplacental infections of the foetus. Most infections affecting women during pregnancy remain localized (e.g. to GI or respiratory tract). However, if blood stream infection occurs, the foetus may be infected transplacentally.

Clinical Features

Placentitis can occur without infection of the foetus (e.g. tuberculosis, malaria, syphilis, CMV, rubella), but may cause foetal growth retardation. Even in absence of foetal and placental infection, the foetus can be affected indirectly by fever, anoxia, circulating toxins and metabolic derangement. When an embryo or foetus is infected, possible outcome are:

- a. *Embryonic death and resorption.*
- b. *Abortion and stillbirth.*
- c. *Developmental anomalies and teratogenesis* – CMV, rubella and VZV cause developmental anomalies that appear to result at least partly from the ability of these viruses to cause cell death, changes in cell growth and chromosomal damage. In contrast, inflammation and tissue damage appear to be responsible for structural abnormalities caused by congenital syphilis, HSV infection and toxoplasmosis.
- d. *Intrauterine growth retardation* may be a marked feature of foetal and placental infection. Typically, it affects both head and general growth. Most herpes viruses, protozoal infections and rubella can cause this.
- e. *Asymptomatic infection* – When pregnancy progresses to term, most infants with transplacental infection are asymptomatic at birth. However, these children may develop late sequelae, sometimes after years; examples include interstitial keratitis after congenital syphilis, chorioretinitis in toxoplasmosis and late-onset hearing loss in CMV disease.
- f. *Congenital disease*, e.g. rubella, CMV. Symptoms manifest at or soon after birth and consist of growth retardation, congenital defects and inflammatory features including jaundice, hepatosplenomegaly, pneumonia and purpura. The inflammatory symptoms may be self-limiting if controlled by neonatal defence mechanisms, or may progress and result in early death.

Persistent postnatal infection – Certain microbial agents may continue to survive and replicate for years after *in utero* infection. Rubella, CMV, HSV, HIV, syphilis, toxoplasmosis, tuberculosis and malaria can all cause progressive or late-onset disease.

Diagnosis

Tests on the mother – Identification of mothers who are chronically infected with HIV, hepatitis B or C virus, or syphilis can be achieved by prenatal or ideally pre-conceptual serological testing. Serological testing is also used to detect pre-existing immunity (e.g. to rubella), which identifies at risk pregnancies and provides baseline for subsequent serological determination of *in utero* infection should the mother be exposed.

Tests in the foetus (e.g. foetal blood sampling, amniocentesis) are performed only in situations in which there is a high risk of foetal damage and confirmation of foetal infection is likely to result in termination of pregnancy (e.g. in first-trimester rubella), PCR-based tests are used for detection of microbial nucleic acid in blood or amniotic fluid.

Postnatal tests – Detection of organism by culture or by molecular diagnostic methods allows specific and rapid diagnosis. Examples include culture of rubella or CMV from urine sample collected within the first 21 days after birth, which confirms congenital infection, and PCR analysis to diagnose vertically acquired HIV infection (though it should be remembered that false-negative results may occur in first 2 months). Serological tests are sometimes necessary. If IgG titre in an infant is fourfold or greater than that of the mother, a titre that rises over time in the infant, or failure of disappearance of maternal IgG by 12 months is highly suggestive of infection.

Management and prevention – Immunization against rubella is highly successful. Routine antenatal care should detect mothers with chronic infections (e.g. TB, malaria, syphilis) and treatment can restore both the mother's health and protect the foetus. In other cases, asymptomatic infection can be detected in pregnancy on blood tests allowing strategies to protect the foetus (e.g. neonatal hepatitis B prophylaxis, antiretroviral drugs to reduce transmission of HIV).

Perinatal and postnatal infections of the neonate

There are three possible mechanisms by which perinatal transmission of infection can occur:

- Physiological changes before and during labour may promote passage of maternal blood to the foetus, thus transmitting blood borne infection, such as HIV and hepatitis B.
- Ascending infection from the vagina can cause chorioamnionitis and foetal infection. This may occur following rupture of amniotic membranes or invasion of intact membrane by certain organisms (e.g. group B *Streptococcus*).
- Passage through the birth canal exposes the infant directly to maternal blood and vaginal secretions.

Neonatal sepsis. Incidence of infection and sepsis in premature infants is 3–10 fold greater than in full-term infants of normal weight. Other risk factors for neonatal sepsis at any gestation include prolonged (> 18 hours) rupture of amniotic membranes before delivery, chorioamnionitis and UTI in the mother. Neonatal sepsis can be classified into:

Early-onset sepsis manifests at birth or within 48 hours. The causative organisms are always maternally derived; group B *Streptococcus* and *E. coli* are predominant. The disease often has a fulminating course; pneumonia and septicemic features predominate.

Late-onset sepsis (commencing after 48 hours) is usually caused by organisms from the environment and only

Table 11: Clinical features of neonatal sepsis

Early-onset

- Maternal risk factors
- Unexplained birth asphyxia
- Respiratory distress (radiographic appearance of pneumonia may be indistinguishable from that of hyaline membrane disease)
- Poor circulatory status (low BP, cold peripheries)
- Unexplained neutropenia (neutrophil count < 100/mm³)
- Unexplained hypoglycemia
- Rash (consider *Listeria*)
- Hepatosplenomegaly
- Jaundice

Late-onset

- Bradycardia and apnoea
- Poor feeding, vomiting/increasing gastric aspirates/abdominal distension
- Irritability
- Convulsions
- Increasing jaundice
- Increasing respiratory distress and ventilatory requirements
- Unexplained rapid changes in neutrophil and/or platelet counts
- Signs of focal inflammation/infection

occasionally by maternal flora. The onset is often insidious and there is greater likelihood of focal infection, including meningitis and osteoarticular infection. There is a wide range of causative organisms – coagulase-negative staphylococci, Gram-positive cocci, Gram-negative enteric bacilli and fungi.

See Table 11 for the clinical features of neonatal sepsis.

Investigations

Early-onset Sepsis

Blood culture – A minimum of 0.5 mL per blood culture bottle.

Deep-ear culture – Samples collected through a sterile ear speculum, if taken within first 6 hours, should reflect amniotic fluid uninfluenced by passage through the birth canal. This can help confirm the type (if any) of bacteria present in the amniotic fluid before delivery. It may aid the choice of antibiotics when culture results become available.

Maternal cultures – Blood cultures, and placental and high vaginal swabs.

Chest radiograph – for pneumonia and other lung pathology.

Lumbar puncture – CSF for microscopy and culture performed after infant is clinically stable.

Viral serology and PCR analysis – for HSV and enteroviruses if clinically suspected.

Late-onset sepsis – As for early-onset sepsis. In addition, examination of urine (by clean catch methods) and cultures from any indwelling devices, such as endotracheal tube and vascular catheters.

Management

Early-onset sepsis – Intensive care. Combination of benzylpenicillin and gentamicin is the best choice. In non-intensive care setting, cefotaxime can be used as a single agent. When infection with *Listeria monocytogenes* is suspected, ampicillin instead of penicillin or in addition to cefotaxime.

Late-onset sepsis – In ICU, a broad spectrum combination such as Ciprofloxacin and an aminoglycoside should be first-line therapy. In non-ICU setting, combination of ampicillin and cefotaxime. Duration of treatment depends on clinical response but minimum period is 10 days.

General supportive care includes ventilatory support, careful fluid management and circulatory and blood product support. Parenteral nutrition may be required (as in necrotizing enterocolitis).

Fungal infection is most commonly caused by *Candida spp.* Treatment should be commenced with amphotericin, and 5-flucytosine added when CNS, renal or osteoarticular involvement is suspected.

SEPSIS AND MENINGITIS

Common organisms – Gram negatives, group B streptococcus, Staph. aureus.

Symptoms and Signs of septicaemia and convulsions. Bulging fontanelle and neck stiffness may be absent in 75% of cases. Initially may not 'do well' or just 'feed poorly'.

Diagnosis: CSF examination and culture. Other site cultures and blood culture may help. Normal CSF protein as high as 45–100 mg/dL in term baby and up to 120 mg/dl in preterm. Up to 7 cells/ μ L with 50–60% neutrophils. Up to 800 RBCs/cmm normal in newborn and up to 50 in first 7 days. CSF sugar < 50% of blood sugar diagnostic of meningitis.

Complications: Ventriculitis, status epilepticus, neural deficits, deafness, hydrocephalus, blindness, abnormal speech and learning problems later.

Management: *Antibiotics* – Ampicillin 100 mg/kg IV under 7 days, and 200 mg/kg/day in 4 divided doses after

7 days of life, with Gentamicin 7.5 mg/kg/day in two divided doses IV. Must be given for at least 10–14 days or 5–7 days after clinical response in case of sepsis, and at least 21 days treatment for meningitis. Amikacin 15–20 mg/kg IV 12-hourly. (Effective in most infections except pseudomonas). Cefotaxime 100 mg/kg/day IV. Cefotaxime and Amikacin combination works in most cases.

For group B streptococcus – Aqueous penicillin G 100,000 U/kg/day IV 12-hourly if under 7 days, 250,000 U/kg/day in 8-hourly doses after 7 days.

Staphylococcus – Cloxacillin up to 200 mg/kg/day IV in 8-hourly or 6-hourly doses. Vancomycin 15 mg/kg 8–12 hrly for resistant cases.

Pseudomonas – Combination of Gentamicin with Carbenicillin up to 400 mg/kg/day IV in 6-hourly doses or Cef-tazidime 100 mg/kg 8 hourly or Piperacillin 100 mg/kg IV 12 hourly.

Candidiasis – Amphotericin B 0.7–1-mg/day for 3–4 weeks or Fluconazole 3–6 mg/kg/day IV 12 hourly.

For ventriculitis – Gentamicin 2.5 mg intraventrically daily till ventricular fluid sterile in poorly responding patients or Amikacin 5 mg, 2–3 times a week as last resort. CT scan is indicated.

Supportive treatment – For convulsions diazepam 0.2–0.3 mg/kg IV slowly. Restricted IV fluids, blood transfusion. Relief of raised intracranial tension may be necessary. Exchange transfusions have been tried.

UMBILICAL INFECTION (OMPHALITIS)

Causes – Any pyogenic bacteria commonly Staph. aureus. Danger of haematogenous spread or extension to liver and peritoneum. Foul smelling umbilical discharge or failure of cord to separate within normal period of time may provide a clue. General symptoms and signs might be minimal.

Treatment – Appropriate systemic antibiotics. Local application of spirit.

Prevention – Clean cord care. Thrice daily swabbing with spirit or application of triple dye. The cord is best left open, no restrictive binders are necessary.

Viral infections – can be transmitted perinatally through the placenta during labour or directly via blood and secretions swallowed by the infant during delivery.

HSV – Caesarean section within 4 hours of rupture of the membrane reduces risk of transmission. In babies born of a mother with active lesions, IV acyclovir (if swabs from nose, eyes and skin are positive) or baby develops signs of infection.

VZV – Infants at greatest risk are those born to mothers who develop chickenpox within 7 days before or after delivery.

Varicella-zoster – Immunoglobulin is given and acyclovir started at first sign of the disease in the infant.

CMV – Postnatally acquired disease seldom requires treatment except in the immuno-compromised. Children with symptomatic congenital infection may benefit from a 6-week course of IV ganciclovir.

Enteroviruses can cause multisystem involvement in the newborn. Immunoglobulin IV may be helpful.

Hepatitis B is mainly transmitted postnatally. Maternal antenatal screening should identify at-risk pregnancies and prophylaxis with immunization is necessary.

Human papillomavirus causes genital warts. It may be transmitted at birth, and can cause perianal warts in the infant, or occasionally juvenile laryngeal papillomatosis years later.

HIV infection occurs mainly around time of labour or subsequently through breastfeeding. Antiretroviral treatment during short term protocols have been evolved for the developing countries. Pregnancy reduce risk of transmission. The risk might be reduced by avoidance of very prolonged breastfeeding and avoiding subclinical mastitis in the mother.

Short-term Protocols

1. AZT given to pregnant women in the dose of 100 mg 5 times a day from 35 weeks of gestation till delivery followed by IV administration of AZT during labour. AZT is also given to the newborn baby in dose of 2 mg/kg 4 times a day for 6 weeks along with replacement feeding.

This regimen reduces transmission rates by 65%.

2. Second regimen is a single dose of nevirapine 200 mg given to mother at the onset of labour and a single dose of nevirapine in dose of 2 mg/kg given to baby within 48 hrs of birth. This regimen reduces transmission by 50%. This protocol is simple, inexpensive, effective and feasible in our country and adopted as National Policy in India.

Safe delivery: Elective LSCS reduces transmission by decreasing the contact of the baby with infected maternal secretions.

JAUNDICE IN NEWBORN

Aetiology

Normal bilirubin metabolism requires the following factors – (i) Maturity of liver. (ii) Normal load of bilirubin. (iii)

Adequate quality and quantity of glucuronic acid conjugate for conversion of lipid-soluble (indirect) bilirubin to water-soluble (direct) bilirubin for proper excretion. (iv) Normal biliary passages. (v) Patency and motility of intestines.

It is only indirect bilirubin that crosses the immature blood brain barrier causing kernicterus or brain damage.

Varieties

1. *Immature liver* – (a) Jaundice of prematurity. (b) Physiological jaundice.
2. *Increased load of bilirubin* – (a) Rh incompatibility. (b) ABO incompatibility. (c) Hereditary spherocytosis. (d) Glucose-6-phosphate dehydrogenase deficiency. (e) Enclosed haemorrhage cephalhaematoma. (f) Infants of diabetic mother (polycythemia). (g) Polycythemia (SFD). (h) Increased free bilirubin – Decreased serum albumin as in prematurity and neonatal sepsis. (i) Bilirubin displacement from albumin by drugs like sulphonamides, sodium benzoate, injectable diazepam.
3. *Enzyme abnormality* (glucuronyl transferase) – (a) Reduced activity – anoxia, infection, hypothermia, hypothyroidism. (b) Blocking of enzyme action – drugs like vitamin K analogues. (c) Absence or decreased quantity – (i) Genetic type (Crigler-Najjar syndrome). (ii) Prematurity.
4. *Obstructive jaundice* – (i) Intrauterine and neonatal viral infections causing hepatitis. (ii) Congenital atresia of bile ducts. (iii) Choledochal cyst. (iv) Inspissated bile syndrome. (v) Metabolic diseases like galactosaemia, tyrosinaemia. In all these, direct bilirubin is more than 15% of the total.
5. *Other causes* – Congenital familial non-haemolytic jaundice. Breast milk jaundice. Hypertrophic pyloric stenosis.

Clinical Manifestations

1. **Physiological jaundice** – Occurs in about 50% of infants. Appears on about the 4th day and lasts for a few hours to 7 days. Usually not above 12 mg%. Breast-fed babies can have a high level up to 16 mg% which does not require intervention. Stools retain bile pigment. Table 12 gives factors causing exaggeration of physiological jaundice

Clinical Features

Phase 1 – Jaundice appears on about 4th day, and lasts for 5 days in term infants and about 7 days in preterm infants, when there is rapid rise in serum bilirubin to 12 and 15 mg% respectively.

Table 12: Factors causing exaggeration of physiological jaundice

Factor	Association
Bilirubin load on liver	Polycythemia, diabetic mother, delayed cord clamping, extravasated blood, intraventricular haemorrhage
Defective uptake from plasma	Decreased Y protein from caloric deprivation
Defective bilirubin conjugation	Due to decreased UDPG activity, e.g. inhibitors in breast milk, hypothyroidism
Decreased hepatic excretion	Congenital infections
Inadequate hepatic perfusion	Hypoxia, congenital heart disease
Increased enterohepatic circulation	Unfed babies, delayed passage of meconium

Table 14: Causes of jaundice

Increased production
• Rh, ABO incompatibility
• Hereditary spherocytosis
• Non-spherocytic hemolytic anemia: G-6-PD or pyruvate kinase deficiency
• α -thalassemia, vitamin K3-induced haemolysis
• Sepsis
• Increased enterohepatic circulation: pyloric stenosis, large bowel obstruction
Decreased clearance
• Inborn errors of metabolism: Crigler-Najjar syndrome (type I, II)
• Drugs and hormones: Hypothyroidism, breast milk jaundice

Phase 2—A decline to about 2 mg% occurs which lasts for up to 14 days after which normal values are reached. This phase may last for more than one month in preterm infants and those with exclusive breastfeeding. Tables 13 and 14 give mechanism and causes of jaundice in newborn.

2. Pathological jaundice

Features of pathological hyperbilirubinemia:

- Jaundice in first 24 hrs
- Increase in total bilirubin > 0.5 mg/dL/hr or 5 mg/dL/24 hrs.
- Total bilirubin > 15 mg/dL
- Direct bilirubin > 2 mg/dL

Neonatal jaundice of prematurity – is more marked and more prolonged than in full-term infants owing to glucuronyl-transferase deficiency. In the absence of *Rhesus* or ABO incompatibility, this may result from injudicious use of vitamin K analogues, or sulphonamides in premature infants. Jaundice of prematurity is aggravated by birth asphyxia and sepsis.

Table 13: Mechanisms of jaundice

• Increased bilirubin load on liver
Raised erythrocyte volume
Increased enterohepatic circulation of bilirubin
• Decreased erythrocyte survival
Defective uptake of bilirubin from plasma
Decreased ligandin (Y protein)
Increased binding of Y protein by other anions
Decreased hepatic uptake
• Defective bilirubin conjugation
Decreased UDPG activity
Defective bilirubin excretion

3. Haemolytic disease of the newborn –

- Due to ABO incompatibility** – Development of jaundice within first 24 hours (before one expects physiological jaundice to become manifest). Serum bilirubin level exceeds 12 mg/100 mL in first 24 hours. No anemia, liver and spleen do not enlarge. Jaundice disappears in 3–7 days. Rarely the disease assumes greater severity, there is more severe jaundice, anemia and hepatosplenomegaly.
 - Due to Rh-incompatibility** – Jaundice is present from birth or appears within 48 hours. Associated anemia, enlargement of liver and spleen. Severe anemia at birth can cause foetal anasarca (hydrops). Increasing drowsiness, restlessness, head retraction, twitchings and convulsions may develop and indicate kernicterus, the most serious complication due to destruction of basal ganglia, usually fatal in the acute stages. Bile pigments in urine and marked increase of nucleated red cells in circulation.
 - Haemolytic jaundice due to congenitally abnormal erythrocytes** (Hereditary spherocytosis) – When much blood is lysed jaundice may become intense, this depends on intensity of haemolysis and immaturity of liver.
- Obstructive jaundice** – *Congenital atresia of bile ducts* – Jaundice appears 7–10 days after birth and gets progressively worse. Stools clay coloured and urine dark containing bile salts and pigments. Gradual enlargement of liver and spleen, mild anemia. Haemorrhages may occur into the skin or from stomach or intestine. Fatal within 3 to 8 months.
 - Other causes:**
 - Jaundice due to infections** – Septicaemia usually from pyogenic umbilical infection, congenital

Table 15: The congenital hyperbilirubinaemias

Feature	Type			
	Najjar and Crigler	Dubin Johnson	Gilbert	Rotor
Familial	–	+	+	+
Severity	+++ (fatal)	+	+	+
Age-group	Infancy	Any	Any	Any
(usually first noted in childhood)				
Type of bilirubin in serum	Unconjugated	Conjugated	Unconjugated	Conjugated
Bile in urine	No	+	No	+
Histology of liver	Normal	Blackish pigment present	Normal	Normal, same condition as Dubin-Johnson but without pigment
				Bromsulphthalein retention [↑]
				Non-filling gallbladder
Other abnormalities	Kernicterus	Bromsulphthalein retention [↑]		
		Non-filling gall-bladder. Alkaline phosphatase [↑]		

syphilis, generalized herpes simplex infection. Toxoplasmosis and cytomegalic inclusion disease.

- (b) **Congenital hyperbilirubinemia** – of the four forms only Najjar-Crigler courses severe jaundice and has a poor prognosis. *Crigler-Najjar syndrome* – (i) Type I is rare and due to complete absence of hepatic glucuronyl transferase activity. Severe hyperbilirubinemia develops within first 3 days. Treatment is repeated exchange transfusions and phototherapy. Kernicterus and death occurs in half the infants. (ii) Type II disease is more common and benign. Bilirubin levels seldom > 20 mg/dL and kernicterus is rare. It responds to oral phenobarbitone (Table 15).
- (c) **Benign recurrent intrahepatic cholestasis (BRIC)** – Rare familial AR disorder with recurrent attacks of pruritus and jaundice. Episodes can occur at any age. Conjugated bilirubin and alkaline phosphatase raised, benign disorder and does not lead to end stage liver disease.
- (d) **Progressive familial intrahepatic cholestasis (FIC)** – The name is applied to three related syndromes. Type I presents in early infancy as cholestasis and progresses to malnutrition, growth retardation and end-stage liver disease during childhood both FIC 2 and FIC 3 have been described. FIC 3 has high serum levels of γ -glutamyl transferase activity.
- (e) **Hypothyroidism** – Persistent elevation of indirect bilirubin is the first sign of congenital hypothyroidism in neonates. It is due to decreased activity of UDPG for weeks or months after birth. Administration of thyroxine clears the icterus.

SEQUELAE OF UNCONJUGATED HYPERBILIRUBINEMIA

Transient encephalopathy – Suspected by increasing lethargy with rising bilirubin levels. Recovery with exchange transfusion.

Kernicterus (bilirubin encephalopathy) – It is a symptom-complex which results from the fixation of indirect bilirubin to basal ganglia in the brain and other important brainstem nuclei (nuclear staining), notably the cochlear nucleus. It usually occurs when indirect serum bilirubin of more than 20 mg persists for more than 24 hours, but can occur at a lower level in premature babies, hypoxia, and sepsis.

The neurotoxicity depends on the maturity of the newborn and concentration of unbound bilirubin which can cross the blood-brain barrier especially when the level of bilirubin is very high (> 20 mg/dL) and persists for > 24 hours in the first 4 to 5 days of life.

Bilirubin encephalopathy is rare beyond 5–7 days of life as the blood brain barrier (BBB) matures with age and becomes virtually impermeable to unconjugated bilirubin.

Clinical Manifestations

- Appears between 2nd and 6th day
- Lethargy, refusal of feeds, shrill cry
- Bulging fontanelle, ‘setting sun’ sign, opisthotonic fit and later generalized convulsions, poor reflexes

Clinical Stages

- I. Hypotonia, dampened Moro’s reflex, depressed sensorium, vomiting, high-pitched cry

II. Hypertonia progressing to opisthotonus, seizures, fever, oculogyric crisis

III. High-pitched cry, convulsions, death.

Late Sequelae

- Sensorineural deafness
- Cerebral palsy (spastic, athetoid)
- Paralysis of upward gaze
- Mental retardation
- Epilepsy
- Dental dysplasia and brownish staining

Investigation of a Case of Neonatal Jaundice

Aim is to distinguish physiological from pathological jaundice.

History

About neonate

- Time of onset
- Increasing/decreasing
- Colour of urine and stool
- General factors: Feeding difficulties, sepsis if any, breastfeeding or not
- Delivery: Preterm, any drugs, blood transfusion

Maternal

- Previous babies with jaundice or needing exchange transfusion
- Illness suggestive of viral infection
- Drugs, e.g. sulphonamides or antimalarials causing haemolysis in G-6PD deficiency

Family history

- Of jaundice and anemia
- Of neonatal or early infant death due to liver dysfunction suggesting galactosaemia, Crigler-Najjar syndrome or a 1- antitrypsin deficiency

Examination: Signs suggestive of non-physiological jaundice:

- Intrauterine growth retardation
- Stigmata of intrauterine infections, e.g. microcephaly, cataracts, hepatosplenomegaly, chorioretinitis, etc.
- Cephalhaematoma, bruising, signs of intraventricular hemorrhage

Clinical estimation of jaundice - The icterus is first noticed in the face and as the bilirubin level rises, it proceeds to the trunk and extremities.

Table 16: Correlation of dermal zones and levels of bilirubin

Dermal zone	Bilirubin (mg/dl)
Face	5
Upper trunk	10
Lower trunk	12
Extremities	15
Palms and soles	> 15

Correlation of dermal zones and levels of bilirubin
see Table 16

Investigations

- CBC, Hb, reticulocyte count
- RBC morphology
- ABC and Rh grouping of mother and baby
- Coomb's test of mother and baby
- Serum bilirubin, both direct and indirect
- Blood culture if sepsis
- Serum albumin and other LFTs
- Ultrasonography of abdomen and liver scan
- TSH

Management of Jaundice in the Newborn

1. *Send cord blood* for serum bilirubin, haemoglobin, direct Coomb's test, and blood grouping of child and mother when incompatibility is suspected. Bilirubin monitoring every 8–12 hours.
2. *Start phototherapy* when serum bilirubin is higher than 10 mg% or is rising fast (> 0.5 mg/hour). Bilirubin absorbs light maximally in blue range (420–470 nm), converts toxic bilirubin by photoisomerisation into unconjugated nontoxic isomers like lumirubin excreted in bile and urine. Eyes should be kept padded. Complications include loose stools, rashes, exposure hypothermia, and dehydration. Phototherapy to babies with direct jaundice causes the "bronze baby syndrome".
3. *Phenobarbitone* 5 mg/kg day orally to hasten maturation of the liver microsomal enzymes. Not useful after 7 days. Not a substitute for phototherapy. To be avoided as drowsiness due to phenobarb will intervene with correct assessment of onset of kernicterus.
4. *Tin (Sn)-Protoporphyrin* - administration has been tried. Bilirubin levels decline but there is no advantage over phototherapy. It inhibits conversion of biliverdin to bilirubin by haeme oxygenase.

5. *Exchange transfusion* if bilirubin level > 20 mg/100 mL in full term babies, and if > 18 mg/100 mL in preterm babies. It may be carried out at lower levels in premature babies, or if bilirubin level is rising rapidly in presence of evidence of haemolysis, sepsis, asphyxia or acidosis. Rough rule: Exchange level bilirubin = Wt. in gms/100. In Rh disease with Coomb's test positive, cord bilirubin > 5 mg%, cord Hb < 12 gm% are indications for exchange at birth. Exchange done with 160-180 mL/kg of semi-packed cells through catheter in umbilical vein.

Management of Pathological Jaundice

Phototherapy

Mode of action

- Structural isomerization converting bilirubin to lumirubin, which can be excreted into the bile without need for hepatic conjugation.
- Geometric photoisomerisation of unconjugated bilirubin with formation of more soluble form of bilirubin.
- Photo-oxidation - Bilirubin gets oxidised to colourless byproducts which are excreted in urine, the least important mechanism.

Indications

- Serum bilirubin >15 mg% for term infants and 10 mg% for preterm infants or 5 mg or more in first 24 hours.
- Hemolytic disease of newborn, seen after birth (in conjunction with exchange transfusion).
- Prophylactic therapy in extremely low birth weight or severely bruised babies.

Technique

- Light source - 4 blue fluorescent lamps and 4 daylight lights (effective radiance of 11 $\mu\text{m}/\text{cm}^2/\text{nm}$)
- Protection of infant - Eye patches to prevent adverse effects on retina
- Position - Baby lies naked with only diapers on at a distance of about 45 cm from light source.
- Duration - 24-48 hours exposure

Complications

- Increase in body temperature
- Dehydration due to insensible water loss
- Photosensitization resulting in skin rash
- damage
- Bronze baby syndrome - Skin, urine and serum brownish black after several days of phototherapy. Seen more often in neonates with conjugated hyperbilirubinemia. Full recovery after discontinuation of therapy
- Congenital erythropoietic porphyria - A rare condition with features of haemolysis, splenomegaly and pink

urine, and bullous dermal lesions. Contraindication for phototherapy

- Diarrhoea due to high content of photodegradation products in gut

Exchange transfusion - is the standard immediate therapy for severe hyperbilirubinemia to prevent kernicterus and to correct anemia in erythroblastosis foetalis.

Indications

- Serum bilirubin > 20 mg/100 mL in full term babies and > 18 mg/100 mL in preterm babies
- Serum bilirubin rising by 1 mg/100 mL per day
- Severe anemia - Hb < 8 gm%

Exchange at lower levels if sepsis, asphyxia or acidosis, Rh disease with Coomb's test positive, cord bilirubin > 5 mg%, cord, Hb < 11 gm%

- To prevent or improve cardiac failure in hydropic infants.

Type of blood - Blood withdrawn < 72 hrs preferred. In emergency, frozen RBCs reconstituted in saline or plasma can be used. ABO compatible Rh negative blood for erythroblastosis foetalis and O group Rh compatible blood for ABO incompatibility.

Quantity - Rough rule: exchange level: bilirubin wt. in gms/100. 160 ml/kg is used for one exchange transfusion.

Technique - Push and pull method in umbilical vein with a syringe and 4-way stopcock with aliquots of 5-10 mL at each push.

Complications

- Bacterial sepsis
- Bleeding - Thrombocytopenia, deficient clotting factors
- Vascular - Portal vein thrombosis, umbilical or portal vein perforation
- Cardiac - Arrhythmia, cardiac arrest, circulatory overload
- Electrolyte and metabolic - Hypocalcemia, hypoglycemia, hypomagnesemia, acidosis

Pharmacotherapy

Phenobarbitone - reduces serum bilirubin by more than 50% in physiological jaundice, but is effective only if given to the mother before delivery. Dose of 5 mg/kg/day. Hastens maturation of liver microsomal enzymes. Not a substitute for phototherapy.

Tin (Tn) and Zinc (Zn) porphyrins cause decline in bilirubin levels by inhibiting activity of haemoxygenase. Not a substitute for phototherapy.

Others - (a) *Frequent milk feeding* prevents reabsorption of unconjugated bilirubin from the gut reducing enterohepatic circulation. (b) *Agar* - Bilirubin-binding

agent in the gut 125 mg 3 hrly has the same effect. (c) *Albumin infusion* 1 mg/kg of salt-free albumin as an alternative to exchange transfusion in very small babies.

Hemorrhagic Disease of the Newborn

Types of neonatal haemorrhage:

1. *Haemorrhagic disease of the newborn* due to: (i) Low prothrombin level at birth due to deficiency of vitamin K. (ii) Fall of prothrombin on fourth or fifth day after birth. If it falls as low as 15–20% of normal, spontaneous haemorrhages are likely to occur. (iii) Immaturity of liver for formation of vitamin K-dependent factors. (iv) Relatively low concentration of vitamin K in breast milk. (v) Poor endogenous intestinal production until full colonization with intestinal bacteria. Common from day 2 to day 5 of life.
2. *Birth injuries*, e.g. superficial injuries of scalp, intracranial and visceral haemorrhages.
3. *Due to asphyxia or infection* in premature infants leading to DIC.
4. *Secondary to general or local disease*, e.g. syphilis, neonatal infections and septicaemia.
5. *Umbilical bleeding* due to mechanical cause, or after separation of the cord from an umbilical polypus, clotting factor deficiencies (especially factor xiii).
6. *Thrombocytopenia* due to trapping of platelets in big hematomas, intrauterine and neonatal infections, iso-immune.
7. *Rare blood disease*, e.g. haemophilia.
8. *Vaginal haemorrhage*, usually a manifestation of maternal hormone withdrawal, occurs on 5th–7th day, of no consequence.
9. *Swallowed maternal blood*.
10. *Mother on treatment* with coumarin derivatives, dilantin or phenobarbitone.

Symptoms and signs:

- *GI tract* – Haematemesis and melena are the most common manifestations. Sudden onset with passage of dark tarry stool on first or second day after birth. Stools that follow may consist of almost pure blood. Haematemesis occurs in about half the cases and usually follows melena. Infant soon becomes pale and collapsed and may die in a few hours or after 2 to 3 days.

- *Vagina* – may be the only site of bleeding which is usually slight and continues for 2–3 days, withdrawal bleeding seen normally after fifth day.
- *Haematuria* – usually slight loss of blood.
- *Umbilicus* – severe and even fatal bleeding may occur. It often starts in the form of a steady oozing at the end of the first week.
- *Lungs* – Acute haemorrhagic pneumonia may start within a few hours. Rapid pallor and blood stained froth in mouth. Rapidly fatal.
- *Intracranial* – if large, infant is stillborn; if less severe – asphyxia, inability to suck well and to swallow, poor ineffective cry, twitchings or convulsions, intermittent cyanosis, bulging fontanelle, rigidity of limbs. Squint, nystagmus and local paralysis may be present.
- *Adrenal* – may accompany other manifestations of anoxia at birth or later occur rarely as a part of clinical manifestation of haemorrhagic disease.
- *Skin* – Ecchymotic areas at points of pressure.
- *Miscellaneous* – Nose, mouth, conjunctiva and retina.

Management

1. Vitamin K₁ oxide – 1 mg/kg IV or Aqueous preparation of IM Menadione (vit-K₃) thrice, repeat at 8 hourly intervals.
2. Transfusions of fresh whole blood – 20 mL/kg if bleeding continues, or 10 mL/kg of fresh frozen plasma.

Prevention – Administration of vitamin K to the mother in the last months of pregnancy and during labour if mother on phenytoin or coumarin. Elective surgery like circumcision should be postponed till after a week, but if performed, vitamin K should be given parenterally. Vitamin K₁ mg to at risk neonates at birth, particularly prematures and low birth weight, forceps, LSCS and instrumental deliveries.

REGURGITATION AND VOMITING IN THE NEWBORN

Regurgitation is non-forceful expulsion of gastric contents from oesophagus or stomach through the mouth, unaccompanied by nausea or forceful abdominal contractions.

Causes

1. **Physiologic** – in early weeks, referred to as ‘spitting up’. Of no concern if normal weight gain continues. Frequency lessens with age.
2. **Faulty feeding techniques** – Lack of burping, eructation of air when supine, prolonged feeding through small nipple, weak caloric formula, bottle-propping, all these lead to aerophagia.

3. **Gastro-oesophageal reflux** (Chalasia cardia) – Symptoms between 3rd and 10th day. Regurgitation when infant laid supine; prevented if held up for 30 minutes after feeding. Diagnosis by 24 hr. oesophageal pH monitoring with a pH probe.
4. **Congenital oesophageal obstruction** – Oesophageal atresia with or without tracheo-oesophageal fistula. Symptoms soon after birth – excess mucus at mouth, choking, cyanosis. Failure to pass No. 8 to 10 French soft rubber catheter into stomach confirms diagnosis.
5. **Increased abdominal pressure at birth** – Neonatal ascites, bilateral renal masses.

Vomiting – Causes

1. Mechanical causes:

Congenital anomalies of GI tract frequent in newborn – (a) Ileal, jejunal or duodenal atresia. (b) Imperforate anus. (c) Meconium ileus in first 24–36 hours early sign of cystic fibrosis. (d) Meconium plug – inspissation in distal colon. (e) Intestinal stenosis – duodenal, jejunal, ileal, rectal. (f) Malrotation. Duodenum obstructed in first 3 weeks. Midgut volvulus. (g) Pyloric stenosis – initially regurgitation of feeds in first week, vomiting in 2nd or 3rd week, constipation from birth, loss of weight. (h) Stomach torsion. (i) Diaphragmatic hernia. (j) Lactobezoar – obstruction from inspissated milk sugar. (k) Hirschprung's disease. (l) Paralytic ileus – Peritonitis, sepsis, hypokalaemia. (m) Gastric stasis common in proteus infection. Early sign of sepsis.

2. Reflex causes:

(a) *Stimuli from GI tract* – (i) Mucus or meconium gastritis – swallowing of amniotic fluid or meconium could be cause of unexplained vomiting in first 2–3 days. (ii) Gastritis from acute parenteral infection, severe respiratory infections, or bacterial gastroenteritis. (iii) Spontaneous gastric perforation (1st week). (iv) Peptic or duodenal ulcer. (v) Necrotizing enterocolitis of newborn. (vi) Haemorrhagic disease of newborn.

(b) *Stimuli from urinary tract* – (i) Urinary tract infection in newborn. (ii) Uraemia.

(c) *Inborn errors of metabolism* – Amino acid disturbances, organic acidaemias, galactosaemia.

3. **Central causes** – (a) Cerebral oedema – birth injury, asphyxia. (b) Intracranial haemorrhage. (c) Sepsis and neonatal meningitis.

Investigations:

A. HISTORY:

1. *Feeding history* – Time of onset of vomiting, history of frothing, choking, cyanosis, failure to gain weight, antenatal and intranatal events.

2. *Appearance of vomitus* – Gastric aspirate with bile more than 20 mL in newborn suggestive of intestinal obstruction. (i) Biliious – Definite sign of obstruction below ampulla of Vater. (ii) Non-biliious – Obstruction above ampulla. (iii) Uncurdled milk – Oesophageal atresia. (vi) Blood – Peptic or stress ulcer, sepsis, achalasia, haemorrhagic disease, swallowed maternal blood.

3. *History of polyhydramnios* – Oesophageal atresia, other GI obstructions. History of meconium-stained liquor in gastritis.

4. *Site and degree of abdominal distension* – Generalized if jejunal or ileal, epigastric if duodenal.

5. *Stool* – (i) Thick, tenacious meconium – meconium ileus. (ii) Malena – haemorrhagic disease, necrotizing enterocolitis, ulcers. (iii) Whitish stools – atresia distal to ampulla of Vater.

B. EXAMINATION:

1. *Abdominal examination* – pyloric lump, stomach peristalsis in hypertrophic pyloric stenosis, rubbery bowel loops in meconium ileus, scaphoid abdomen in diaphragmatic hernia, absent peristalsis in ileus. PR examination – imperforate anus, meconium plug.

2. *Chest examination* – Mediastinal shift to right with cyanosis suggests diaphragmatic hernia. Shift to the left rarely.

C. INVESTIGATIONS:

1. Radiological features:

- Hyperperistalsis in early stages (on fluoroscopy).
- String sign – A thin streak of barium extending between pyloric antrum and duodenal cap, representing the narrowed pyloric canal.
- Beak sign – An abrupt cut-off of barium column in the pylorus, forming a very small curved point.
- Shouldering – Indentation of barium-filled antrum as a result of hypertrophic pyloric muscle.
- Single large bubble or double bubble in pyloric obstruction.
- Tram track sign – A double track of barium may be observed, outlining hypertrophic mucosa, in the elongated pyloric canal.
- Delay in gastric emptying.

2. *Ultrasonography*.

3. *Urine* – Routine, amino acids, culture.

4. *Blood CBC and culture.*
5. *For sepsis screen.*

Management

1. Stomach wash with sterile water or normal saline helps in mucus gastritis.
2. Small feeds of suitable concentration. Thickening of feeds with cereal in pyloric stenosis.

NECROTIZING ENTEROCOLITIS

Occurs in premature infants under stress in first week of life.

Pathogenesis

Mucosal injury – This is attributed to: (a) *Ischemic damage* to intestinal mucosal barrier, as a result of foetal distress, perinatal asphyxia, respiratory distress syndrome, hypothermia, congenital heart disease or following exchange transfusion for hyperbilirubinemia. (b) *Diarrhoea*. (c) *Bacterial infections* with E.coli, Klebsiella, pseudomonas. Also Clostridia, C. perfringens and C. butyricum. Stasis of intestinal contents favours bacterial overgrowth.

Milk formula feeding – Almost all babies are fed artificially prior to onset of illness. Poor systemic and gastrointestinal and mucosal protection against bacterial infections in preterm infants predisposes them to infection of the gut.

Clinical features: These may be described in three stages:

Stage 1A: Suspected NEC – Unstable temperature, apnoea, bradycardia, lethargy, mild abdominal distension, vomiting.

Stage 1B: Blood in stools. X-ray shows mild intestinal distension.

Stage 2: Clinical features as in stage 1. Bowel sounds diminished. In more severe cases metabolic acidosis. Abdominal X-ray: *Pneumatosis intestinalis* and dilatation of intestines.

Stage 3: In addition to the above, infant has low BP, bradycardia, apnoea, acidosis, DIC and even anuria. There are signs of peritonitis with abdominal tenderness, erythema of abdominal wall and distension. X-ray may show portal vein gas (an ominous sign) and gas under the diaphragm if perforation has occurred.

Management

Stage 1: Conservative stop enteral feeds. Give IV fluids

Stage 2: Conservative + Antibiotic

Stage 3: Antibiotic + Surgery

3. CONGENITAL SYPHILIS

CLINICAL MANIFESTATIONS

1. *Constitutional symptoms* – Anaemia, wasting, fever, fretfulness.
2. *Marasmus* – Infant undersized, puny and marasmic with a wrinkled face and wizened appearance.
3. *Mucocutaneous lesions* –
 - (a) Snuffles – due to rhinitis. It may be present at birth or appear after few weeks.
 - (b) Laryngitis – causing the cry to be hoarse.
 - (c) Skin rashes – (i) Maculopapular, circular, slightly elevated, and does not itch. The rash at first is bright red but gradually fades to a brownish colour. It may involve the entire body or be confined to the face, back and extremities. The rash and subsequent flaking on the soles and palms may give rise to a highly glazed appearance of the skin. (ii) Linear cracks or ulcers radiating from the mouth and anus. They are moist and produce fissuring and bleeding. Condylomata or raised greyish masses close to the anal margin or around the anus and female genitalia. (iii) Syphilitic pemphigus. (iv) Syphilitic onychia.
4. *Hair* – Eyebrows disappear, excess hair on head (syphilitic wig).
5. *Visceral* – (i) Liver usually enlarged, may extend to the umbilicus; firm, smooth and not tender. Jaundice indicates severe infection. (ii) Spleen – slightly enlarged. (iii) Kidneys – occasionally albumin, casts and blood cells in urine, rarely generalized oedema. (iv) Lungs – Pneumonia alba. (v) Orchitis.
6. *Ocular* – Iritis and choroiditis.
7. *Nervous system* – Meningitis.
8. *Bones* – (i) Osteochondritis – Swelling and tenderness at ends of long bones, and in severe cases separation of epiphysis. The condition is so painful that the infant may refuse to move the limb – “pseudoparalysis”. (ii) Periostitis along the shafts of the bones. (iii) Dactylitis occasional. (iv) Skull bones – Craniotabes, Parrot’s nodes, hydrocephalus.

DIAGNOSIS

X-rays of long bones – (a) Periostitis of shafts of long bones gives appearance of double margin or greatly thickened cortex. (b) Eroded areas (moth-eaten appearance) at upper end and inner aspect of tibia. (c) ‘Cat-bite’ deformity

of medial tibial condyle. (d) Widened and serrated epiphyseal lines, separation of epiphyses.

Serology – Treponemal tests positive in mother. Higher titre of baby compared to mother or rising titre after 3 months diagnostic in baby.

LATE CONGENITAL SYPHILIS

1. *Interstitial keratitis* – begins as a small pinkish grey patch near the margin of the cornea (salmon patch) which gradually spreads until the whole cornea is involved.
2. *Neurosyphilis* – Juvenile general paralysis more common than tabes, meningovascular syphilis, optic atrophy.
3. *Teeth* – (i) Hutchinson's teeth – the incisors of the second dentition are broader at the base than at the cutting edge in the centre of which there are notches. (ii) Moon's molars – molars dome-shaped.
4. *Bones* – Sclerosing osteitis and periostitis – sabre tibia, gummata of bones which might break down and leave a discharging sinus. Necrosis of nasal bones and hard palate not uncommon.
5. *Joints* – Painless effusion into the synovial cavities, most commonly the knees (Clutton's joints). Rarely multiple arthritis of smaller joints resembling rheumatoid arthritis.
6. *Visceral changes* – Liver may enlarge up to the umbilicus, surface may be irregular. Ascites and jaundice rare. Splenomegaly. Kidneys – albuminuria, casts and haematuria due to progressive renal fibrosis. Recurrent attacks of paroxysmal haemoglobinuria occur.
7. *Deafness*.

SYMPTOMS ACCORDING TO AGE

At birth... Pemphigus, progeric appearance, syphilitic wig, pneumonia, osteochondritis.

3–4 weeks... Skin eruptions, choroiditis, otitis, haemorrhage from umbilicus, nose or fissures.

3–4 months... Epiphysitis, fissures at lips and anus, condyloma, hepatomegaly and splenomegaly, gumma of testis.

6 months–1 year... Uveitis, bossing of skull.

1–2 years... Dactylitis, mental deficiency.

Late manifestations... Interstitial keratitis, deafness, periostitis of long bones, Clutton's joints, tertiary lesions of skin and mucous membrane, paroxysmal haemoglobinuria, neurosyphilis.

STIGMAS OR HALLMARKS OF PREVIOUS LESIONS OF CONGENITAL SYPHILIS

Mucocutaneous – Rhagades – peribuccal cicatrices radiating from mouth. Mucous membranes – saddle nose, perforation of palate.

Bones and joints – Bossing of head. Sabre shin.

Hutchinson's triad – (i) Eyes – keratic scar, chorioretinitis, pupillary changes, optic atrophy. (ii) Ear – deafness. (iii) Teeth – Hutchinson's teeth, mulberry molars.

Constitutional defects – Syphilitic facies. Dwarfism and infantilism. Mental deficiency.

Treatment: Benzathine penicillin IM daily for 14 days in dose of 50,000 U/kg eradicates CNS involvement.

4. GASTROESOPHAGEAL REFLUX DISEASE

It is now well established that transient lower esophageal sphincter relaxations (TLESRs) are the main mechanisms that underlie gastroesophageal reflux events.

Symptoms and Complications

Regurgitation, vomiting, persistent or sudden spells of crying for no obvious reason, choking, food refusal, anorexia, hiccups, failure to thrive.

Management

- (a) Small, frequent feeds. Thickening of milk feeds (with rice cereal).
- (b) H₂ receptor antagonists, e.g. Ranitidine.
- (c) Proton pump inhibitors, e.g. Lansoprazole 0.2 mg/kg/day.
- (d) Prokinetic agents, e.g. Mosapride 0.1 mg/kg/day.
- (e) Surgery may be required in severe cases.

5. INFANT FEEDING

BIRTH TO 6 MONTHS

Breast milk: The ideal food for human infants is human milk, a complex band of nutrients and immunological and other bioactive substances that nourishes the baby, and helps to confer protection from bacterial and viral infections and assists in adaptation of life outside the womb (Table 17). It is the sole and sufficient source of nutrients from birth to about 6 months and its nutrient composition meets specific nutritional requirements of neonates; for example, the sodium, protein and fatty acid contents of human milk differ fundamentally from cows' milk which

Table 17: Principal advantages of breastfeeding

• Strengthens mother-infant bonding
• Natural and easier
• Helps uterine involution
• Partial contraceptive effect
• Confers protection to infants against infections
Immunoglobulin A
Lactoferrin
Lysozyme
Oligosaccharides
• Reduces risk to infant of GI disturbances
Obesity
Hypocalcemia
Hyponatremia
Hypothyroidism
Cow's milk protein intolerance
• Reduces risk of childhood and adult disease
Sudden infant death syndrome
Cardiovascular disease
Inflammatory bowel disease

is the basis of most bottled milk formulae. The composition of human milk changes during lactation and during a single feed. At the beginning of each feed, the fat content is low, but increases gradually such that most energy-dense milk is secreted at the end of the feed.

Colostrum is secreted by the breast during the first few days of lactation; it contains more protein (about 100 g/litre) than milk produced later (about 10 g/litre). Most of this protein comprises 'protective proteins', which help to defend the infant from GI and respiratory infections (Table 18).

The incidence of GI and respiratory infections is lower in breastfed babies than those receiving formula milk, because there are many protective factors.

'Demand' feeding requires that the mother watch for early feeding cues from the baby, such as rapid eye movements, lip-smacking, rooting or sucking on hands. The mother should put the baby to the breast when she observes these cues, rather than waiting for the infant to cry.

Infrequently allergens to which the infant is sensitised may be conveyed in the milk.

Contraindications:

- Temporary – Fissuring or cracking of nipples, mastitis, acute illness in mother. Feeding should continue or expressed breast milk given.

Table 18: Antimicrobial factors in human milk

• Immunoglobulin A	Protects intestinal epithelium from luminal antigens
• Lactoferrin	Competes with bacteria for iron
• Lysozyme	Antibacterial enzyme lysis cell walls
• Oligosaccharides	Stimulate growth of lactobacilli in colon
• Macrophages	Engulf bacteria
• Lymphocytes	Secrete immunoglobulins (B) and lymphokines (T)
• Protease inhibitors	Inhibit digestion of bioactive proteins in milk
• Complement	Assists in bacterial lysis
• Interferon	Antiviral agent
• B ₁₂ binding	Compete with bacteria for folate-binding these vitamins proteins
• Antistaphylococcus factor	Lipid with antistaphylococcal action

- Permanent – Infants with galactosaemia or congenital lactase deficiency, chronic poor nutrition, debility, epilepsy, severe neurosis or postpartum psychosis, severe diabetes, mother receiving drugs such as anti-thyroid drugs which are secreted in milk, deep breast abscesses. HIV and hepatitis B positive mothers can transmit infection to the baby in 20–25% cases.

6–12 MONTHS

Complimentary feeds should be offered after 4–6 months of age. May have to be given earlier if breast milk is not sufficient owing to poor advice on feeding and lack of stimulation. True lactation failure is very rare. Drugs like Chlorpromazine 25 mg t.d.s. or Metoclopramide 10 mg t.d.s. for 7 days are of limited value for enhancing lactation and cannot substitute for early initiation and frequent feeding. Weight gain, and urine output more than 6 times a day are most reliable indications of adequacy.

EXPRESSED BREAST MILK – can be obtained by hand or by pump. Used in sick infants or preterm infants and fed by cup, spoon or tube. Can be preserved for 6 hrs. at room temperature and 24 hrs. in refrigerator at 4–8°C without contamination. Can be taught to working mothers.

WEANING – For developing countries breastfeeding encouraged up to 2 years. Usually advisable until infant is 6–9 months old. Initially one of the breastfeeds is replaced by artificial feeding. After several days, another breastfeed is replaced and so on until the baby is entirely weaned. The total time required depends on the maternal

Table 19: Nutritional comparison of milks

Milk (per 100 mL)	Human	Cow	Buffalo	Double-toned	Toned (Buffalo)
Protein	1.2	3.5	4	3	3
Fat	4	4	7	1.5	3.5
Carbohydrate (Lactose)	7	4	4	4	4
Calories	67	67	103	40	67

milk supply. Bottle discouraged at all times owing to infection. Protein-rich solids begun after 6 months.

Artificial Feeding

1. *Whole fresh milk* – buffalo, cow. Dilution – 1:1 up to 1 month. 2:1 up to 2 months, undiluted later. Composition – in g/100 mL is shown in Table 19.
2. *Skimmed milk* – Low fat content is preferable for fat intolerance.
3. *Toned milk* – can be used undiluted in first 4–5 months.
4. *Powdered milk:*
 - a. Whole milk powder.
 - b. Skim milk powder.
 - c. Humanised milk powder.
5. *Modified milk powder* – largely used for infant feeding. Animal fat is substituted with vegetable fats, and fortified with iron and vitamins. Reconstituted by adding one level measure (provided with the powder) to 30 mL of water.
6. *Soyabean milk* – used when lactose intolerance is proved. 100 mL reconstituted – 60 cal/100 mL and 2.1 g protein.

Feeding principles – consist of demand feeding.

- The quantum should be judged by the infant's needs and weight gain. 2-hourly breastfeeding during day and 3-hourly at night is recommended for maximal let-down.
- The principle is one of supply and demand encouraged by free interaction of breast and baby without 'an eye on the clock'.
- No check on feeding duration. Allow for up to 20–25 minutes, important for the baby to get "hind-milk" which is 3-fold higher in fat and 1.5 times higher in protein compared to the fore-milk.
- Emptying the breast encourages re-filling.
- Plain water should be avoided as it decreases breast milk intake and poses a risk for infection.
- Complete natural demand feeding is desirable against any schedule.

- Feedingbottles must be avoided. Clean vessel and spoon preferable.
- Breastfeeding should be discontinued latest by 2 years of age.
- No vitamin supplements are necessary up to 6 months in term infants of healthy mothers.
- Breast milk is a poor source of vitamin D containing 20–60 IU per litre which is not enough to protect against rickets. Hence, vitamin D supplement is necessary in exclusively breastfed babies.

In top feeding, the milk is warmed to body temperature. The sterile nipple should be applied without contaminating it. The hole of the nipple should be such that milk will drop slowly. The eructation of air (burping) swallowed during feeding is important for avoidance of abdominal discomfort and of regurgitation. Eructation is facilitated by holding the infant upright over the shoulder with or without gently patting the back. Making the child lie on the abdomen or on the right side also facilitates burping. A feeding may require 5–25 minutes depending on the vigour and age of the infant. In no instance should the baby be urged to take more than it desires.

Change over to solids – Green banana and cereal, mashed vegetable, dal, all introduced one at a time after 4–6 months. Eggs, minced meat gradually after 9 months to one year. Every new item of diet should be offered in small quantity – 1/2–1 teaspoonful at the beginning. If the infant tolerates it well, it can be gradually increased. Not more than one item of diet should be introduced per week.

6. GROWTH AND DEVELOPMENT

It is a process by which the fertilized ovum attains adult size. Growth implies changes in the size or in the values given for certain measurements of maturity. Development encompasses other aspects of differentiation of form or function including emotional and social changes as a result of environmental interaction.

FACTORS AFFECTING GROWTH AND DEVELOPMENT

1. *Genetic* – A legacy of biologic potential influenced by environment.
2. *Hormonal* – Growth hormone and its peripheral action compounds (somatomedins), thyroxine, insulin, sex steroids.
3. *Growth factors* – Nerve growth factor, cartilage factor, fibroblast growth factor and others with undifferentiated action.

- Trauma** - Prenatal or postnatal including infection, chemical or physical trauma or immunologic.
- Nutritional failure** - Antenatal malnutrition leads to IUGR and low birth weight which influences growth potential throughout life. Postnatal PEM (protein energy malnutrition), iron deficiency, trace element deficiency, vitamin deficiency.
- Socio-economic factors** - Closely influence nutrition, infection, developmental stimulation.
- Emotional factors** - modify growth potential. Deprivation leads to "emotional deprivation syndrome" which can stunt physical and psychological development. Position of child in family, interaction of parents and child, child-rearing patterns influence growth.
- Culturopolitical factors** - may limit development potential by establishing conventional behaviour patterns and expectations and alter schedule for acquisitions of motor and intellectual skills.
- Intellectual stimulation and learning.**

GROWTH PARAMETERS

1. Height or length:

Foetus	8 weeks	: 2.5 cm
	12 weeks	: 7.5 cm
	28 weeks	: 35 cm
	Birth	: 50 cm

1 year: adds on 1/2 of birth length 75 cm

2 years: adds on 1/2 of 1st year's growth 87-88 cm

Thereafter till adolescence growth spurt about 6-8 cm per year.

Weech's formula that can be used from 2-12 years.

Age (yr) \times 6 + 77 cm.

2. Weight: Sensitive growth parameter, first to decrease in acute malnutrition.

Foetus	8 weeks	: 1 gm
	12 weeks	: 14 gm
	28 weeks	: 1000 gm

Birth: 2.5-3.7 kg. Less than 2.5 kg considered low birth weight. Weight loss in first 10 days up to 10% body weight. Thereafter, increase of 20 gm per day for first 5 months and about 15 gm per day up to 12 months. Baby doubles birth weight at 5 months, triples at 1 year.

2nd year: gains 2.5 kg

3-5 years: gains 2 kg per year

6-12 years: gains 2-2.5 kg per year.

Approximately 15 kg at 5 years, 25 kg at 10 years, 40 at 15 years.

Weech's formulae for average weight (in kg)

$$3-12 \text{ months } \frac{\text{age (mths)} + 9}{2}$$

$$1-6 \text{ years } \text{age (yrs)} \times 2 + 8$$

$$6-12 \text{ years } \frac{\text{age (yrs)} \times 7 - 5}{2}$$

- Skull circumference:** A good measure of brain growth. Maximal in first year, reaches 90-95% adult size by 4 years. Birth: 32-35 cm (less than 30 cm microcephaly)
First 3 months: 2 cm per month (avg. 39 cm)
4-6 months: 1 cm per month (avg. 42 cm)
6-12 months: 1/2 cm per month (avg. 46-47 cm)
2nd year: 2 cm (48-49 cm)
3rd year: 2 cm (50-51 cm)
4th year: 2 cm (52-53 cm)
Adult: 53-56 cm
Up to 13 months use formula $1/2 \times \text{length (cm)} + 10 \text{ cm} \pm 2.5 \text{ cm}$.

- Surface area:** It bears constant relation to nutritional factors affecting growth. Best calculated from normograms involving average weight and height.

Crude methods are:

$$(\text{m}^2) = \sqrt[3]{\text{wt}^2 (\text{kg}) \times 0.1}$$

Simpler formula:

$$1.5 \text{ kg m}^2 = (0.05 \times \text{kg}) + 0.05$$

$$6-10 \text{ kg m}^2 = (0.04 \times \text{kg}) + 0.10$$

$$11-20 \text{ kg m}^2 = (0.03 \times \text{kg}) + 0.20$$

$$21-40 \text{ kg m}^2 = (0.02 \times \text{kg}) + 0.40$$

- Upper to lower segment ratio:** Upper segment measured from vertex to pubic symphysis. Important in assessment of growth disturbances - proportionate or disproportionate dwarfs. Ratio changes with age and height. Marginal difference between males and females.

Premature > 1.7

Full-term newborn 1.69

1 year 1.54

2 years 1.44

3 years 1.33

4 years 1.27

5 years 1.21

6 years 1.14

7-12 years 1.10-0.98

Ratio retarded for age in hypothyroidism, achondroplasia and other short-limbed dwarfisms, rickets with lower limb deformities.

Table 20: Chronology of dentition

	Primary tooth eruption		Permanent tooth eruption	
	Maxillary	Mandibular	Maxillary	Mandibular
Central incisors	6–8 mths	5–7 mths	7–8 yrs	6–7 yrs
Lateral incisors	8–11 mths	7–10 mths	8–9 yrs	7–8 yrs
Canines	16–20 mths	16–20 mths	11–12 yrs	9–11 yrs
First premolars	–	–	10–11 yrs	10–12 yrs
Second premolars	–	–	10–12 yrs	10–13 yrs
First molars	10–16 mths	10–16 mths	6–7 yrs	6–7 yrs
Second molars	20–30 mths	20–30 mths	12–13 yrs	12–13 yrs
Third molars	–	–	17–25 yrs	

Ratio advanced for age in – Short trunk dwarfisms, acquired spinal diseases with kyphosis or scoliosis, e.g. tuberculosis, hypogonadism (Klinefelter's syndrome), Marfan's syndrome.

- Chest circumference:** Smaller than head circumference by 2–3 cm. Cross-over of head and chest circumferences takes place in Indian children at about 2 years of age (about 1 year in white races).
- Mid-upper arm circumference:** taken at midpoint of acromion and olecranon. Index of malnutrition constant at 1–5 years at 16–17 cms.
Mild PEM 13.5–16 cm
Moderate PEM 12.5–13.5 cm
Severe PEM < 12.5 cm
- Chronology of dentition:** See Table 20.
- Ossification centre appearances in infancy and childhood:**
Birth: Distal femoral, proximal tibial, cuboid.
3 wks: Head of humerus
2–4 mths: Hamate, capitate
4–6 mths: Head of femur
1 year: Distal radial
2 years: Distal tibia and fibula, capitulum of humerus.
3 years: Triquetral bone, heads of metacarpals and phalanges of hand.
4 years: Lunate, navicular of foot, greater trochanter of femur.
5–6 years: Scaphoid, trapezoid, trapezium, lower ulnar epiphysis, upper epiphysis of radius, medial epicondyle of humerus.

Table 21: Sexual maturity

	Boys	Girls
1. Adolescent growth spurt	13–15.5 years	11.5–14 years
2. Average increase in height	20 cm After 18 years 2.5 cms remain	8 cm After 18 years 1–2 cm remain
3. First sign of puberty	Increase in length and colour of pubic hair	Breast bud visible or palpable
4. Age at start of puberty	12–13 years	11–12 years
5. Duration of puberty to adult sex characteristics	4 years	2–2.5 years to menarche May be as long as 6 years

7–8 years: Lower epiphysis of ulna.

9–10 years: Olecranon, trochlea of humerus, pisiform.

11–12 years: Lateral epicondyle of humerus.

- Milestones of development: Importance:** (a) Assessment of step by step age-wise psychomotor and mental development. (b) Early detection of motor disorders, cerebral palsy, mental retardation, speech, auditory and visual defects. (c) Assessment of aetiology of developmental delay – congenital if poor milestones development from beginning, acquired or hereditary/acquired degenerative neuromuscular or CNS disease if arrest occurs after certain stage is reached. (d) Assessment of approximate point in time when pathology began, e.g. age at which malnutrition set in to cause development retardation.

Classification:

- Motor.
- Adaptive – (a) Fine motor. (b) Visual. (c) Auditory.
- Social.
- Language – (a) Perceptive. (b) Expressive.

- Sexual maturity:** See Table 21.

7. PREMATURITY AND LOW BIRTH WEIGHT

Babies born before 37 weeks of gestation are called preterm (PM). Those weighing less than 2500 gm (10th percentile for gestational age) are called low birth weight (LBW) babies. Low birth weight may be due to prematurity or intrauterine growth retardation. The latter group are called small for date (SFD). Premature babies may be small for date also.

CLINICAL FEATURES

1. Length is short (less than 46 cm) in preterm. It is relatively normal for weight in SFD babies.
2. Head appears large compared to the rest of the body, particularly in SFD babies.
3. Only one of the two transverse creases on sole of the foot up to 37–38 weeks.
4. Breast nodule absent up to 33–34 weeks.
5. Scalp hair tends to be short and fuzzy up to 37 weeks.
6. Ear cartilage is poorly developed and the folds of the helix and anti-helix do not stand out till 36 weeks.
7. Testes descends and the scrotal rugae develop after 36 weeks.
8. Sucking and synchronized deglutition develop after 33 weeks.
9. Moro's reflex develops after 32 weeks.
10. Pupillary reaction to light develops after 31 weeks.
11. Blink response to glabellar tap develops after 31 weeks.
12. Strong flexor response to extension of forearm develops after 35 weeks.

COMPLICATIONS

1. *Hypothermia* – because of poor subcutaneous fat insulation, increased surface area compared to weight, immature hypothalamus and lack of brown fat that can be readily burnt for energy.
2. *Infection* – Septicaemia, meningitis and sclerema neonatorum. Baby appears lethargic, becomes pale, hypo- or hyperthermic. Abdominal distension, vomiting and paralytic ileus may develop. Skin becomes thick and adherent to underlying tissue (sclerema neonatorum). Polymorph functions and complement factors are depressed in PM.
3. *Respiratory distress syndrome* – due to hyaline membrane disease in PM, pneumonia and meconium aspiration in SFD.
4. *Apnoeic spells* – due to prematurity, intracranial haemorrhage, intra-pulmonary haemorrhage, hypoglycemia, hypothermia, sepsis.
5. *Hypoglycemia* – Baby becomes lethargic, develops convulsions or cyanosis.
6. *Retinopathy of prematurity (ROP)* – Multifactorial. Primary cause is prematurity, hyperoxia is also important. More sick the child, greater the risk.
7. *Anemia* develops within 4 weeks in preterm, SFD have polycythemia.

8. *Hypocalcemia* more in SFD.
9. *Pathological jaundice* in PM due to liver immaturity.
10. *Intraventricular-periventricular haemorrhage* – More common in PM. Can be spontaneous in babies less than 34 weeks. Aggravated or precipitated by asphyxia. Severe grades die or survive with mental handicap and cerebral palsy. Incidence reduced by gentle handling and thus preventing surges in BP.
11. *Persistent ductus arteriosus* – Higher incidence in PM because of influence of PGE₂ keeping ductus open. Can cause cardiac failure.
12. *Necrotizing enterocolitis* – common in PM with sepsis.
13. *Osteopenia* and rickets may occur in very small preterms.
14. *Oedema* may occur without obvious cause or due to intrauterine pressures.
15. *Late metabolic acidosis* may develop during 2nd or 3rd week especially if fed artificial milks.
16. *Massive pulmonary hemorrhage* may develop with asphyxia, infection or hypothermia, more common in SFD.
17. *Persistent pulmonary hypertension of the newborn (PPHN)* – occurs due to failure of normal drop in pulmonary arterial pressure after birth. Seen in FT or preterm babies. Birth asphyxia and meconium aspiration are common causes.

MANAGEMENT

1. *Warm chain* – A set of interlinked procedures carried out at birth and subsequently – (a) Warm delivery room. (b) Warm resuscitation facilities. (c) Drying the newborn immediately after delivery followed by (d) Skin to skin contact between infant and mother or putting the infant in an incubator or using radiant warmers. (e) Breastfeeding. (f) No baby bath at birth (g) Appropriate clothing and bedding covering the head conserves 2/3 of body Heat. (h) Mother and baby are nursed together. (i) Maintaining rectal temperature at 37°–37.2° in preterm babies.
2. *Feeding* – Feed the infant with a nasogastric tube till good sucking develops. Aim at giving 120 to 150 calories and 120 to 150 mL of fluid per kg of body weight, by the 6th or 7th day of life. Add 20–30 mL/kg extra fluid if on radiant warmer or phototherapy. Feeds should be given in small equally divided quantities every 2–3 hours round the clock. Start feeding early by the 6th hour of life, unless respiratory distress develops. Tube feeding with No. 5 or 6 infant tube if gestational age less than 34 weeks. Sucking

Table 22: Classification of milestones

Age	Motor	Adaptive	Language	Social
Neonatal period (4 weeks)	Prone: Flexed attitude, buttocks high. Supine: Flexed Moro active, grasp, stepping, placing reflexes.	Fixates face in line of vision. Startles with sound.	Cry	Visual preference for human face.
4 weeks	Prone: Legs more extended, buttocks down. Head lift momentary to body plane. Supine: More extended, tonic neck attitude.	Watches person, follows object 45° on one side.	Cry more meaningful, distinguishable hunger, pain	Body movements with social contact. Social smile.
8 weeks	Prone: Extended attitude. Raises head and sustains in line of body. Supine: Tonic neck posture. Head lags, less in traction position.	Follows object 45° on either side of midline.	Coos in response	Smiles on contact
12 weeks	Prone: Lifts head, arms extended, head above body plane. Supine: Tonic neck posture. Moro's, involuntary grasp, walking and placing reflexes go. Early head control with bobbing motion.	Reaches out for object and misses. Slight palm opening. Follows light 180°.	Makes 'aa' vowel sounds. Listens intently to voice. Cannot localise sound.	Sustained social Contact
16 weeks	Lifts head and chest, legs extended, arms outstretched. Symmetrical posture now, head in midline.	Hands in midline, tries to grasp with both hands and misses object. Follows ball rolling on table.	Turns head to sound. Laughs out aloud.	Displeasure if social contact broken, excited at sight of food.
20 weeks	Turns over prone to supine. Lifts up head, half of chest, arms outstretched. Sits with support with rounded back.	Goes out for object with one hand, may miss. Grasps voluntarily if object placed in hand.	Vowel sounds. Pitch variations.	Plays with strangers, demands prolonged contact.
24 weeks	Turns over supine to prone. Sits propped up with straight back momentarily without support. Supports weight on legs.	Grasps object offered, waves it in hand. Attempts to mouth it. Binocular vision develops. Regards mirror image.	Grunts, growls. Says 'ga-ga'.	Responds to name. Initiates contact by making sounds. Knows strangers.
28 weeks	Pivots: squirming movements. Sits on his own with hand support. Bounces when stood up.	Grasps large object with intermediate palmar grip, transfers objects, mouths actively, rakes at small objects.	Polysyllabic vowels. Bubbles at mother.	Enjoys mirror. Pits image. Cries if shouted at.
36 weeks	Sits up alone and well with support with a straight back. Creeps on all fours.	Radial grasp of objects. Assisted pincer grasp. Rakes at small object with index finger.	Monosyllabic consonants – labials 'ma', 'ba'. Can announce his arrival with sounds. Understands 'No'.	Develops fear of strangers. Plays 'peek-a-boo'.
40 weeks	Pulls to standing position. Stands with support. Crawls on fours.	Pincer grasp. Uncovers hidden toy. Retrieves dropped object. Releases objects grasped by others. Looks at picture.	Repetitive Consonants 'mama', 'baba'.	Waves 'bye bye'.
1 year	Walks with one hand held or cruises along furniture.	Unassisted pincer grasp for small objects; releases object on request or gesture.	4 to 5 words. May try to imitate spoken word. Understands commands.	Plays simple ball game. Simple postural adjustments to dressing.

Contd...

Contd...

15 months	Walks alone. Crawls upstairs but cannot come down.	Inserts pellet in bottle. Makes a line with pencil held like dagger. Tower of 2 cubes. Scribbles.	Jargon. Follows simple commands. May name familiar object.	Gives up bottle. Shows needs by pointing.
18 months	Runs stiffly. Walks upstairs one hand held, both feet on step. Explores places. Climbs on chair. Gait broad-based.	Imitates vertical stroke. Dumps pellet from bottle. Tower of 3 cubes.	Vocalises needs 10 words average. Names pictures. Obeys 2 serial commands.	Feeds self. Bowel control.
2 years	Runs well. Walks up stairs alternate feet. Downstairs one step at a time. Opens doors.	Tries to draw circle. Tower of 6 cubes. Folds paper once.	Puts 3 words in a sentence. Relates experiences. Names animals. 200–300 words.	Sphincter control by day. Helps undressing.
2½ years	Climbs down stairs. Kicks. Jumps.	Horizontal and vertical strokes, cannot cross them, closes circular figure. Tower of 18 cubes.	Uses pronoun 'I'. Knows full name. Physiological stammer.	Imitates others. "Parallel play".
3 years	Stands on one foot. Rides tricycle.	Copies circle, forms a cross. Tower of 9 cubes. Forms 'bridge' of 3 cubes.	Knows age and sex. Counts 3 objects well. Full sentences. Uses plurals and prepositions.	Dry by night. Plays with other children.
4 years	Hops. Climbs well. Throws ball over-hand.	Uses scissors. Draws a man with 2 to 3 parts Copies square. Hand dominance.	Tells stories 1600 words, 4 words per sentence. Knows colours.	Social interaction and role-playing. Runs errands.
5 years	Skips.	Names heavier of 2 weights. Copies triangle. Draws man with 3–4 parts.	Sentence of 5 words, counts 10 objects well.	Asks questions about meanings.
6 years	Acquires finer motor skills. Simple gymnastics.	Draws full man with clothes. Adds and subtracts.	2600 words.	Knows time of day. Knows right from left, good from bad.
7 years	—	Copies a diamond.	Most childhood difficulties gone. Speech clear.	Avoids self-exposure. Knows about sex.

and swallowing coordination develops after 34 weeks, when direct cup or spoon feeding of expressed breast milk can be started. Breast milk from the PM infant's mother is preferred as the preterm mother's milk is higher in protein and immunoglobulin with higher sodium content than term infant's mother's milk. Strict barrier nursing observing aseptic technique is imperative, because of proneness to infection.

3. **Vitamins** – Give 1mg of vitamin K IM at birth. Start vitamin C and multi-vitamin drops by 10th day of life. Vitamin E has a role in preventing specific haemolytic anemia. No iron for 4–6 weeks.

Apnoea of prematurity is treated with IV Aminophylline 5 mg/kg bolus followed by 1–2 mg/kg 8–12 hrly. The drug Doxapram is equal in efficacy. CAPP beneficial

Meconium aspiration can be fatal in SFD. Watch for 24 hrs for development of respiratory distress. Add antibiotics only if X-ray chest shows haziness or bilateral emphy-

sema. Meconium is sterile but is a good medium for secondary infection. Ventilatory care.

8. FAILURE TO THRIVE

Failure to gain and often loss of weight in infants (and children) in absence of apparent cause (Table 23).

CLINICAL PICTURE

1. Failure to gain weight.
2. Failure to grow at expected rate.
3. Signs of developmental retardation.
4. Signs of physical and emotional deprivation – apathy, listlessness, lack of interest in surroundings, poor hygiene, withdrawal, intense eye contact with others.
5. Disorders of appetite – Anorexia, voracious appetite, pica.

Table 23: Causes failure to thrive**I. Inadequate intake –****Environmental causes**

- Inadequate food intake due to ignorance and poverty.
- Emotional deprivation including maternal deprivation.
- Environmental disruptions.
- Rumination (controlled regurgitation of feeds).
- Child abuse, withholding of food.
- Psychiatric causes – infantile autism, childhood schizophrenia, anorexia nervosa in adolescence.

Organic causes

- Inability to suck due to prematurity, birth trauma, congenital malformations such as cleft palate and upper GI obstructions, cerebral palsy.
- Chronic vomiting.

II. Lack of digestion –

1. Chronic iron deficiency anemia.
2. Lack of bile in biliary atresia.
3. Pancreatic insufficiency in cystic fibrosis.
4. Chronic active hepatitis.

III. Impaired absorption –

1. Chronic diarrhoea.
2. Chronic infestation, e.g. giardia.
3. Intestinal malabsorption syndromes –congenital disaccharide deficiency, cystic fibrosis, coeliac disease.
4. Structural intestinal defects.

IV. Impaired utilization –

1. Chronic infections – Tuberculosis.
2. Respiratory – Asthma, cystic fibrosis, bronchiectasis
3. Endocrine disorders – Hypothyroidism, hyperthyroidism, hypoadrenalism, growth hormone deficiency, diabetes insipidus.
4. Chronic kidney failure.
5. Congenital heart disease, especially cyanotic.
6. Malignancy.
7. Chronic haemolytic anemia, e.g. thalassemia.
8. Inborn errors of amino acid and carbohydrate metabolism.
9. Collagen diseases.
10. Occult malignancy.

V. Hereditary –

1. Chromosomal disorders – Down's syndrome. Turner syndrome.
2. Primordial dwarfism.
3. Syndromes with premature ageing – progeria.
4. Cerebral malformation, cerebral degeneration.

6. Others depending on aetiology – Fever, polyuria, pallor, chronic constipation, vomiting, diarrhoea, dehydration, bulky foul stools (steatorrhoea), central cyanosis, acidosis, open anterior fontanelle, CNS signs of mental retardation or cerebral palsy, stigmata of chromosomal anomalies.

DIAGNOSIS

1. *History* – especially for environmental causes.
2. *Growth chart* – Identifies point of failure to thrive, may uncover causes, shows response to treatment. Aids diagnosis of constitutional short stature and hypopituitarism.
3. *Physical examination* – points to organ systems, CNS defect, cleft palate. Developmental and psychiatric evaluation.
4. *Investigations:*
 - CBC for infection, anemia.
 - Urine – routine, pH, sp. gravity, culture.
 - Stool – Ova and parasites. Tests for malabsorption – fat globules, 72 hours fat excretion, stool trypsin, stool pH and reducing substances for carbohydrate malabsorption.
 - Biochemistry – BUN, creatinine, electrolytes, sugar, LFT.
 - Radiograph – Chest, abdomen, sonography
 - Mantoux test.
 - Others – Chromosomal analysis, haemoglobin electrophoresis, sweat chlorides, tests of endocrine function.

PROGNOSIS: Non-organic ones eventually attain normalcy. Over half remain emotionally disturbed, have school problems. Small number die suspiciously. In case of organic cause prognosis depends on underlying disease.

MANAGEMENT AND PREVENTION

1. *Temporary change of environment* – Hospitalization may ease tension and cause dramatic improvement in weight gain and social interactions.
2. *Treatment of organic disease.*
3. *Parental education*, birth spacing, family planning, marital counselling.
4. *Early recognition of 'at risk' families* – Immature parents, drug addiction, anti-social behaviour, child dislike, economic and emotional instability, single parent, family tragedy.

5. *Support* – From physician, social worker, family welfare agency, temporary foster care.

9. MALNUTRITION IN INFANTS AND CHILDREN

Malnutrition is the cellular imbalance between supply of nutrition and energy and the body's demand for both of them to ensure normal growth, maintenance and specific tissue functions.

Kwashiorkor and *Marasmus* are classical syndromes of childhood malnutrition. Although their clinical features appear to be distinct, many children have features of both. However, oedema is the only characteristic, other than weight deficit, that must be present for diagnosis of kwashiorkor. Marasmus is simply severe cachexia with weight loss as a result of wasting in infancy or childhood. The cut off point for the severity of wt. loss is 60% of expected wt. for age. Severity of wt. deficit and presence of oedema are the criteria for the Wellcome classification of severe malnutrition in children is given in Table 24. Table 25 gives age-dependant classification of Protein Energy Malnutrition (PEM).

KWASHIORKOR

Literally means 'the neglected one' and describes the young infant (usually from months to 2 years) displaced from the mother's breast by the succeeding infant.

Aetiology and Pathogenesis

- Kwashiorkor develops in those on diets with a low protein: energy ratio. Protein may be a limiting factor on such diets but the view has been challenged. Free radical-induced and possibly other damage to tissues caused by deficiencies of essential nutrients and coexisting infections may be an important reason why some children develop oedema and skin lesions.
- The initial endocrine responses in kwashiorkor are high insulin and low plasma cortisol levels, which promote uptake of amino acids by muscle, diverting them from the liver. As a consequence, there is reduced synthesis of albumin (resulting in hypoalbuminemia,

which causes oedema) and apoproteins which predispose to fatty liver.

- These children have multiple infections, including tuberculosis and gastroenteritis. Infection may divert amino acids for synthesis of acute-phase proteins, thereby further reducing albumin synthesis. Fatty liver may develop.

Dysadaptation therapy – Suggests that children with marasmus are adapted to the deficient protein intake. In such children there was loss of fat and degradation of muscle protein secondary to hormonal responses, i.e. high cortisol and low insulin levels. The protein thus derived was used for generation of proteins including albumin, hence the absence of oedema and hypoalbuminemia. In Kwashiorkor, this adaptation does not occur.

Clinical Features

(a) Anorexia, diarrhoea, anemia (mainly iron deficient), irritability (leave me alone attitude) or apathy. (b) Dystrophic changes in skin and hair – skin becomes dry, thin, shiny or wrinkled (xerosis). The peeling plaques of dermatosis are labelled 'crazy paving' or 'flaky paint' dermatoses. The hair is thin and easily pulled out. During better periods of nutrition, scalp hair may grow normally, but a fresh band of abnormal hair would appear during another period of malnutrition (flag sign). Skin and hair changes are variable and may be accompanied by hypopigmentation. Depigmented hair is possibly mediated by zinc deficiency.

MARASMUS

When dietary energy is limited through chronic inadequate food intake, low insulin and high plasma cortisol levels result in release of amino acids from liver and their subsequent availability for hepatic synthesis protein (particularly albumin). The result is severe muscle wasting with normal plasma albumin levels and, hence no oedema. Absence of oedema in presence of severe muscle wasting in an infant or 1 year old child is characteristic of marasmus. Table 26 gives differentiating features of kwashiorkor and marasmus.

Table 24: Wellcome classification

Wt. for age (% of expected)	Oedema	
50–60	Present	Absent
	Kwashiorkor	Undernutrition
<60	Marasmic Kwashiorkor	Marasmus

Table 25: Age-dependant classification of protein energy malnutrition (PEM)

Nutritional status	% Wt. for age
Normal	> 80
1st degree	70–80
2nd degree	60–70
3rd degree	50–60
4th degree	< 50

Table 26: Differentiating features of Kwashiorkor and Marasmus

<i>Kwashiorkor</i>	<i>Marasmus</i>
Little wasting	Severe wasting
Oedema	No oedema
Subcutaneous fat present	Subcutaneous fat minimal
Serum albumin low	Serum albumin near normal
Enlarged fatty liver	
High prevalence of infection	

Marasmic kwashiorkor. Sometimes an infant or young child presents with features of both marasmus and kwashiorkor (oedema with severe muscle wasting).

Kwashiorkor equivalent - A well-nourished infant is suddenly switched off from all proteins including milk and instead fed carbohydrate rich foods (sugar baby). Since the energy needs are sufficient, the fat is not mobilized but, the protein deficiency results in hypoalbuminemia and oedema. The infant looks plump and pale (due to good subcutaneous fat).

Stunting - Persistent suboptimal food intake associated with recurrent and episodic malnutrition in children can result in short stature. Such children fail to achieve their maximum growth potential for growth, despite 'catch-up' growth during intervening periods of nutritional repletion or when free from infection.

Obesity - It is also a type of malnutrition. WHO has recommended the use of Body Mass Index (BMI = weight in kg/height in m²) as an indicator of obesity. If BMI is in excess of 95th percentile for age and gender between 85th and 95th percentile, it is considered "overweight".

Management of Severe Malnutrition

Immediate treatment includes resuscitation - Correction of fluid and electrolyte disturbances, such as acidosis, hypoglycemia and hypothermia, and treatment of localized or generalized infections (e.g. bronchopneumonia, septicaemia). In kwashiorkor, an acute diarrhoeal illness often compounds. Chronic infections, such as tuberculosis, and chest infections are common.

Principles of management - Two-stage process: stabilization (usually for up to 7 days) followed by rehabilitation.

Stabilization - Correction of hypoglycemia, dehydration (glucose 25% IV 4 mL/kg bolus) and fluid and electrolyte imbalances (e.g. potassium chloride 4-5mEq/kg/day).

Hypothermia dealt with wrapping blankets, radiant warmers to maintain rectal temperature at 37°C. Because malnourished children do not exhibit the classical signs of infection (fever and leucocytosis), routine administration of antibiotics is advisable to control infection.

Refeeding must be initiated gradually. Overfeeding may also provoke acute liver failure. A suitable regimen provides 80 kcal/kg body wt./day and 0.7 g protein/kg body wt/day. Feeds small, every 2-2½ hours by tube if needed. Milk with 2 teaspoons of sugar/100 mL milk forms basis of feeding unless lactose intolerance is documented (stool pH < 6 and Benedict's test on stool > 2+ positive reaction). Banana, rice and dal, vegetable oil for calories. Egg as a flip with milk and water is a good source of first class protein. Dal, rice and buttermilk can be given if lactose intolerance. Micronutrients may be needed in amounts greater than normal daily requirement, to replenish stores and avoid further depletion related to tissue growth. For example as wasted muscle regrows, there are specific needs for potassium, iron, zinc and phosphate to avoid deficiencies (refeeding syndrome). Hypoalbuminemia is not helped by use of a high-protein diet, which can impair renal function.

Nutritional rehabilitation follows when the oedema has resolved and the child has recovered clinically, has a good appetite and begins to gain weight. This may take several weeks.

10. DEFICIENCY DISEASES

RICKETS

Aetiology

Age - From 4 months to 2 years, also in prematures. **Diet** - Less common in breastfed infants, may develop if mother's diet is poor. **Growth** - Rickets will only develop if growth is taking place, marasmic infants are seldom rachitic, but as soon as the infant begins to put on weight rickets is likely to develop. Dark-skinned infants more prone, lack of adequate exposure to sunlight.

Classification of Rickets

- **Dietary deficiency of vitamin D** (inadequate intake of calcium, vitamin D exposure to sunlight).
- **Secondary rickets:** due to malabsorption, e.g. coeliac disease.
- **Resistant rickets:** Resistance to therapeutic doses of vitamin D, e.g. familial hypophosphatemia rickets or Vitamin D dependent rickets.
- **Renal rickets** (Poor conversion of 25 OH-D₃ to 1.25-dihydroxy D₃ - active principle of vitamin D₃) in chronic kidney failure.
- **Malignancy** - Tumour-based rickets.

- *Hereditary forms* – (i) Vitamin D-dependent rickets (VDDR) – deficiency of 1-hydroxylase enzyme, autosomal recessive, low calcium type. (ii) Vitamin D Resistant Rickets (VDRR) – Primary defect is phosphorus wasting by proximal tubule (low phosphorus type). Also called type II rickets due to end organ defect. Inherited as X-linked dominant, autosomal director. Elevated levels of circulating calcitriol.

Clinical Features

1. *Head* – apparently larger than normal in horizontal diameters, forehead prominent (frontal bosses) and occiput and vault flattened out, hot-cross bun appearance, anterior fontanelle larger than normal and closing delayed, posterior portion of the skull in the first year may have demonstrable softening on pressure (ping-pong resilience, craniotabes). Frequent rocking movements of the head common, face appears small upper jaw being narrow, temporary teeth usually appear late. Excessive sweating over forehead.
2. *Thorax* – Beading of ribs at the junction of ribs with costal cartilages, best developed in the 4th, 5th and 6th ribs just external to the nipple – rachitic rosary. Sternum unduly prominent producing a “pigeon breast”. Horizontal depression corresponding to insertion of the diaphragm below which there is a flaring of the ribs (Harrison’s groove), occasionally funnel shaped depression of lower part of sternum.
3. *Spinal column* – Kyphosis due to weakness of muscles, which disappears if child is suspended from armpits. In severe cases after weight bearing scoliosis.
4. *Extremities* – Metaphyseal enlargement at wrists and ankles; knock-knee and bow legs; coxa vara, curving of bones of forearm outwards. Upper to lower segment ratio retarded for age, dwarfism in severe cases. Multiple greenstick fractures in severe rickets. Deformities may occur due to malunion. “Double-malleolus” at ankle.
5. *Ligaments and muscles* – relaxed and weak, hence deformity of spine, late standing and walking and over extension of knee joints – “acrobatic rickets”.
6. *Digestive system* – Pot-belly due to weakness of abdominal muscles, and ptosis of liver and spleen.
7. *Nervous symptoms* – Restlessness at night with rocking of head on the pillow. Predisposition to tetanic convulsions.
8. *Respiratory system* – Adenoid and tonsillar hypertrophy, rhinitis, pharyngitis, bronchitis and bronchopneumonia common. In severe cases, tachypnoea with largely diaphragmatic breathing.

9. *Spasmophilia* – Triad of tetany, laryngismus stridulus, and convulsions may be expected in the low calcium type of rickets. High pitched distressing cry.

Diagnosis

Early signs of rickets – (a) Restlessness and irritability. (b) Sweating of head. (c) Head rolling. (d) Craniotabes. (e) Beading of ribs. (f) Anterior fontanelle noticeably big. (g) Enlargement of metaphyses at the wrists. (h) Delay in dentition.

Radiology

- Loss of zone of provisional calcification and widened growth plate
- Fraying of metaphysis – metaphyseal margins tend to be blurred and indistinct
- Splaying (widening of the metaphysis) and cortical spurs
- Cupping of the metaphysis
- Rachitic rosary
- Bowing of tibia (in long standing cases)

Laboratory

(i) Increased alkaline phosphatase in plasma earliest change. (ii) Low concentration of phosphorus except in late renal osteodystrophy where it may be high. (iii) Calcium level may also fall in tetany though it is usually normal, low in VDDR, can fall with infections, high phosphorus diet, alkali administration, administration of low doses of vitamin D. (iv) Generalized aminoaciduria except in VDDR.

Fig. 1: Rickets. Widened and cupped epiphysis of the lower end of the radius

Management

A. Administration of vitamin D

1. ORDINARY CASE OF RICKETS - 1200-2000 units per day.
 - (a) *Fish oils* - Fish liver oils contain Vitamin D₃. The fat of the oil is a valuable addition to the diet.
 - (i) Cod liver oil - 1 teaspoonful (containing about 400 units of vitamin D₃) three times a day. Some children do not tolerate it well and develop diarrhoea; older children may refuse on account of its taste.
 - (ii) Halibut liver oil - 10 times more potent than cod liver oil.
 - (b) *Vitamin D milk* - (i) Fortified milk. (ii) Irradiated milk standardised to contain 400 IU of vitamin D₃ per quart. The taste of the milk is not affected.
 - (c) *Fortified fish oils* - Calciferol has been added to fish oils to enrich their Vitamin D content. The result is a product rich in both vitamin A and vitamin D. After healing has taken place it is necessary to continue with the dose during the second and third years of life.
 - (d) *Exposure to sunlight* daily for at least 1-2 hours.
 - (e) *Massive doses of vitamin D* (Stoss regime) - 600,000 IU of Vitamin D (15 mg calciferol) in oil solution intramuscularly or by mouth. Best current treatment of deficiency rickets. Advantages of Stoss regime - (i) Treats deficiency rickets with one dose, healing obvious on radiograph of wrist within 15 days. (ii) Differential diagnosis of deficiency and resistant rickets - 3 doses of massive D 15 days apart fail to produce healing in resistant rickets. (iii) Large dose prevents hypocalcemia during treatment.
2. REFRACTORY RICKETS - Vitamin D dependent rickets - 40,000 units daily. Vitamin D resistant (hypophosphataemic) rickets - 400,000 units daily. Administration of neutral phosphate salts along with calciferol is helpful in healing rickets of VDRR type. Cause of refractory rickets should be established and treated.

Hypervitaminosis D (more than 50,000-1,00,000 IU/day) *Symptoms:* Nausea, vomiting, constipation, abdominal cramps, and later muscular weakness or pain and dizziness, excessive thirst, polyuria, irritability, drowsiness, CKF.

Diagnosis: Level of serum calcium and inorganic phosphorus rises and urine may contain calcium casts. X-ray of radius and ulna show deposits of calcium salts. Renal calculi. Metastatication in arteries and kidneys due to hypercalcaemia.

- B. **Calcium** - Not usually necessary except in tetany. In acute convulsions 2 mL/kg calcium gluconate 10% IV. Maintenance 100-150 mg/kg of elemental calcium. Calcium lactate 300 mg = 40 mg (13%) of elemental Ca, calcium gluconate gives 9 mg elemental calcium per ml.
- C. **Use of cereals** - in diet should be restricted because phytate of cereal combines with calcium to form an insoluble compound which is passed out in the faeces. Lactose is antirachitic.

SCURVY

Aetiology

Due to deficiency of vitamin C.

Age - usually from 6 months to 2 years.

Diet - more common in artificially fed infants.

Precipitated by febrile disease, infections, or diarrhoea.

Clinical Features

1. **Onset** - (a) Usually gradual - Fretfulness and increasing pallor, or tenderness of legs which causes child to cry whenever touched, anorexia and loss of weight. (b) Rarely sudden onset, the first symptom being inability of the child to use his legs.
2. **Symptoms due to haemorrhages:**
 - (a) *Under periosteum of long bones* - "pithed-frog posture" with thighs flexed and abducted and knees flexed, sometimes diffuse swelling above or below the knee; in severe cases infiltration of muscles with blood causing oedematous limbs (woody leg); haemorrhage between diaphysis and epiphysis causes separation of epiphysis from shaft.
 - (b) *In the gums* - only if teeth have erupted, common at base of incisors. In mild cases only a narrow line of purple discolouration, but in severe cases gums swell up into large, purple fleshy masses which bleed on touch, and teeth become loose.
 - (c) *Perifollicular hemorrhage*.
 - (d) *Within the orbit* - proptosis with swelling of eyelids.
 - (e) *Haematuria* - May be an early symptom, often only microscopic.
 - (f) *Scorbutic beading of the ribs* - due to backward displacement of sternum and costal cartilages, or sometimes due to haemorrhage at the junction of the ribs and cartilage; in contrast to rachitic rosary is sharp.

3. **Anemia.**
4. **Keratinosis of hair follicles** with 'corkscrew' hair.
5. **Failure of wound healing.**

Diagnosis

(i) Radiography

Acute phase

- Generalized decrease in bone density of shaft and epiphyses (ground glass appearance).
- Pencilled cortex - Cortex is thinned out appearing only as a pencil streak.
- 'White lines of Frankel' - Thickening of provisional zones of calcification at epiphyseal ends of long bones, which become dense and cast heavy transverse shadow at the end of the shaft.
- 'Zone of Trummerfeld' - (a) A radiolucent area proximal to the white line due to atrophy of sub-epiphyseal cortex and spongiosa and which casts a narrow zone of rarefaction. This is a somewhat weak zone and leads to easy fractures and (b) Marginal metaphyseal infarctions, which during stages of healing protrude laterally to form Pelkan's spurs (Corner sign) (Fig. 2).
- Halo sign of Wimberger - due to pencilling effect produced by the epiphysis. Thus, the epiphysis is seen as a rim standing out against a rarefied body with pencilling resembling 'signet rings'.

Fig. 2: Scurvy. Widening of the temporary calcification zone - 'the white line of scurvy'. Note the defect in the spongiosa and the cortex just below the epiphyseal plate. The 'corner sign of scurvy' and the spurs which have formed (Pelkan's spurs)

- Subperiosteal hematomas - Soft tissue densities due to lifting off of the periosteum from the underlying bone (Figs. 3A and B).
- Joint effusions - causing bulging of joint capsule or the flat planes around the joint.
- Subluxation of epiphysis may occur in very severe cases.
- Scorbutic rosary - Step-like subluxation of costochondral joints.

Healing stage

- Cortex becomes thicker and rarefied transverse areas at the end of shafts regain normal density.
- In case of lateral displacement of the epiphyseal cartilage, a new shell of bone on the cortex aligns itself with the displaced epiphysis following treatment and there is no permanent deformity.
- The contour of the shaft returns to normal.

(ii) **Plasma ascorbic acid level** - very low.

Management

Vitamin C - (i) 3 to 4 ounces of fresh orange juice or tomato juice daily. (ii) Ascorbic acid - 100 mg or more orally or parenterally twice or thrice daily. Response dramatic. Pain lessens and alertness increases within 24 hours. X-ray changes take 15-21 days to resolve. Continue treatment for 10-15 days. IV vitamin C is mainly excreted in urine. Only used as test dose for relief of pain.

Figs 3A and B: Scurvy (A) Acute scurvy (tibia). Note white line at metaphysis surrounded by white ring, 'ground glass' appearance of shaft; (B) Healing scurvy (humerus). Club shape due to calcification of periosteal hematoma, and marginal metaphyseal infarction protruding laterally (Pelkan's spurs)

11. INFANTILE DIARRHOEA

Predisposing factors for acute diarrhoea – Infants under 1 year of age, bottle fed infants, poor hygiene, poor economic status.

I. **Infective diarrhoea** See Table 27 for the causative organisms.

Characteristics of diarrhoea caused by rotavirus:

1. Indistinguishable clinically from other causes of infantile diarrhoea.
2. Short incubation period (2-3 days).
3. Abrupt onset – Vomiting often precedes diarrhoea.
4. Illness usually lasts about one week, but usually improves within 2-3 days.
5. Temporary neutropenia may occur.
6. The illness may be very severe.
7. Hospital-acquired infection is common.

Pathophysiology of diarrhoea. See Table 28.

II. **Parenteral diarrhoea** – At onset of any acute infection, e.g. acute otitis media and mastoiditis, infection of respiratory tract, acute pyelonephritis and meningitis. Probably same virus involves both systems as in measles.

III. **Dietetic diarrhoea** – (a) Excessive quantity of food – overfeeding. (b) Excess of carbohydrates – Osmotic diarrhoea: loose, sour smelling stools. Lactase deficiency – Green, frothy, acid stools. (c) Allergy to certain foods or milk intolerance or milk protein allergy (more common with cow's milk). (d) Sucrose deficiency – Acid stools with RBCs.

If diarrhoea persists for more than 5 days, and if there is watery diarrhoea soon after introducing milk feeds, possibility of lactose intolerance, especially if abdominal distension soon after meals associated with perianal excoriation.

Table 27: Causative organisms of diarrhoea

Bacterial	Viral	Parasitic
E. coli (Diff. strains)	Rotavirus	Giardia lamblia
Clostridium difficile	Adenovirus	Entamoeba histolytica
Shigella	Others	Others
Salmonella (non-typhoidal)		
Yersinia		
Campylobacter		
V. cholerae		
Staphylococcal and others		

Symptoms

Mild case – Onset with loose diarrhoeal type of stools with sometimes vomiting. Gradual increase in frequency of stools; greenish, slightly offensive with mucus, varying in number from 2–3 to 10–12 per day. Slight fever.

Severe case – Onset moderately severe with or without vomiting. Stools soon become watery and odourless. Rapid dehydration as evidenced by thirst, dry tongue, depressed anterior fontanelle, loss of elasticity of skin and sunken abdomen. Fever, restlessness, tachycardia and oliguria. Later symptoms of toxæmia – apathy, staring sunken eyes, shallow respirations, uncountable pulse, cyanosis, acidotic breathing. Temperature high or sub-normal. “Cholera infantum” or acute toxic diarrhoea – In a very severe case rice water stools and symptoms of toxæmia. Abrupt onset with high fever and extreme prostration, vomiting, irritability, restlessness and often convulsions, collapse, suppression of urine and finally stupor and coma. Copious watery stool suggestive of toxigenic diarrhoea, small, frequent with tenesmus, blood and mucus in invasive infections – EIEC, Salmonella, Shigella, amoebiasis.

Table 28: Pathophysiology of diarrhoea

Character of stools	Site of pathology	Likely organisms
A. Large volume watery stools, macroscopic or microscopic blood/pus absent	Small intestine (Enteritis)	Viruses E. coli (EPEC, ETEC, EAggEC) V. cholerae Giardia
B. Frequent small volume stools, pus and/or blood present (naked eye/microscopy)	Large intestine (Colitis)	Shigella, E. histolytica E. coli (EHEC) (EIEC) Cl. difficile.
C. Initially large volume watery stools changing to small volume stools (Macroscopic or microscopic blood/pus present)	Small and large Intestines (Enterocolitis)	Salmonella Campylobacter Shigella sonnei
D. Stool type: Bloody	Acute dysentery Intussusception Ischaemic colitis Pseudomembranous colitis	
Nonbloody	Mostly small bowel diarrhoea	Bacterial, viral

Clinical assessment of dehydration in infancy – See Table 29.

Management

1. FLUIDS:

- (a) **Solution used** – (i) Ringer lactate – Full strength 1 ampoule in 500 mL glucose or 1/2 strength. (ii) Isolyte M is suitable rehydrating fluid in infants. (iii) Glucose-saline IV – 1/5th in newborns, 1/3 in older children, use after initial rapid rehydration. (iv) Potassium chloride (1 mL = 2 mEq), add 1 mL of solution to 100 mL IV solution (maximum 2 mL) after patient starts passing urine.
- (b) **Quantity** – (i) *Assessment of fluid loss* – According to grade of dehydration. In a moderately severe case there is a deficit of 100–120 mL per kg body weight. The aim of treatment is to restore the fluid deficit and to provide a maintenance intake according to the table. Volume of fluid lost through urine and stool is added to subsequent intake.

(ii) Assessment of type of dehydration by estimation of serum electrolytes (see Table 31)

ORAL REHYDRATION THERAPY – WHO solution formula (Table 32).

Dissolve in one litre of potable water. Can be given by mouth or by Ryle's tube. Very useful in all cases of childhood gastroenteritis including cholera (Table 33). Based on the concept that glucose stimulated sodium absorption is intact in toxigenic diarrhoea, works in other forms. Contraindicated in severe dehydration with shock, paralytic ileus, persistent vomiting.

Deficit is to be replaced in first 6-8 hours. Mild to moderate vomiting is not a contraindication to successful use. Vomiting can be controlled by Domperidone orally (0.5 mg/kg/day) which has no neurological side effects. Maintenance plus ongoing losses replaced thereafter over 18 hours in proportion of two feeds ORS to one feed milk.

Table 29: Clinical assessment of dehydration in infancy

Loss of wt.	Cl. Fs.
Mild (0.5%)	Thirst Dry mucous membranes Depressed fontanelle Normal pulse
Moderate (5–10%)	Markedly depressed fontanelle Loss of skin turgor Sunken eyes Tachycardia Oliguria
Marked (10%)	Increased severity of above signs Agitation or drowsiness Signs of shock

Table 31: Assessment of type of dehydration

Type	Deficit	
	Sodium	Potassium
Isonatraemic	8–10 mEq/kg	8–10 mEq/kg
Hyponatraemic	10–12 mEq/kg	8–10 mEq/kg
Hypernatraemic	4 mEq/kg	5–8 mEq/kg

Table 33: Use of ORS

Grade of dehydration			
Stool output	Mild	Moderate	Severe
< 1 every 2 hours	50 mL/kg	100 mL/kg	100–120 mL/kg
> 1 every 2 hours	50 mL/kg	Replace at	10–15 mL/kg/hour

Table 30: Maintenance fluid requirements in children

Wt.	Daily requirement
3–10 kg	100 mL/kg
10–20 kg	1000 mL+50 mL for each kg. above 10 kg
> 20 kg	1500 mL + 20 mL/kg for each kg above 20 kg

Table 32: WHO ORS formula

Constituents (g/litre)	
Sodium chloride	3.5 gm
Sodium bicarbonate	2.5 gm
Potassium chloride	1.5 gm
Glucose	2.0 gm
Concentration (mmol/litre)	
Sodium	90
Chloride	80
Potassium	20
Bicarbonate	30
Glucose	110

(Recently sodium bicarbonate has been replaced by 2.9 gm sodium citrate and has better shelf-life).

Sugar-based ORS – 40 g sugar (sucrose) replaces 20 g of glucose. Cheaper and as efficacious.

Rice-based ORS – Amino acids in rice exert separate water and sodium reabsorptive influence. Better than standard ORS by 40% rehydration efficacy.

Amino acid-based ORS (Super ORS) – Addition of dipeptides glycine-glycine or glycine-alanine improves sodium reabsorption.

Home-based ORS – using hand measures or special spoons. 4 glasses of water plus 4 finger scoops of sugar plus 3 finger pinch of salt. Squeeze of lime adds some potassium and flavour. Must taste like tears.

- Diet** – Solid feeds must be given during diarrhoea to prevent PEM. Clear fluids containing electrolytes in first 24 hours. After 24–36 hours, weak milk mixture may be substituted. Homemade butter milk can also be used.
Mashed rice, curds and dal safely given.
- Feeding of breast milk** – must continue.
- Antimicrobial drugs** – Indications – (a) Blood and mucus in stool. (b) Faecal leucocytes 20–25/hpf. (c) High fever. Start with – (i) In newborns – Parenteral Ampicillin 100 mg/kg/day IV 6–8 hourly for 5–7 days, or Gentamycin 5 mg/kg/day 12-hourly or Colistin 6–8 mg/kg/day in 3–4 divided doses for 5 days. (ii) Older children – One of the following for 3 days – Cotrimoxazole – 10 mg/kg/day of Trimethoprim in 2 divided doses. (d) Furazolidone – 6–8 mg/kg/day in 2–3 doses. (e) Ampicillin – 50–100 mg/kg/day in 2–3 doses. (f) Norfloxacin 10 mg/kg/day in two or Ciprofloxacin 20 mg/kg/day in two divided doses. (g) Nalidixic acid – 55 mg/kg/day in 3–4 doses. Excellent response to invasive infections. (h) Erythromycin 40 mg/kg/day for *Campylobacter* infections. (i) For *E. histolytica* – Metronidazole or Tinidazole 40 mg/kg/day in 3 divided doses for 7–10 days. (j) For giardia – Metronidazole 15–20 mg/kg/day for 5 days, or Furazolidone.
- Severe dehydration – *IV fluid therapy* – Ringer's lactate, or if not available N saline. (a) Age < 12 months 30 mL/kg in 1hr followed by 70 mL/kg in 5 hours. (b) 12 months – 5 years: Same quantities in 30 minutes and then after 2½ hrs. Sodium losses in severe dehydration 10–12 mEq/kg. After electrolytes estimation, replace Na⁺ deficit at (Na expected – Na observed) × 0.6 × body wt (kg). This is added to maintenance Na⁺ need of 2–3 mEq/kg/day. Potassium losses 8–10 mEq/

kg in severe dehydration. Start adding K⁺ to drip once urine output is established, can be dangerous and cause paralytic ileus.

- Binding agents and anticholinergic drugs – not recommended. Some secretory diarrhoeas respond to Loperamide or Aspirin (25 mg/kg), the latter has anti-prostaglandin effect. Not to be used routinely in infective diarrhoeas.

Persistent diarrhoea (PD) – Acute diarrhoea which lasts for at least 14 days. The main causes are (excluding conditions such as coeliac disease, metabolic or biochemical disorders):

- Persistent infection with one or more enteric pathogens.
- Malabsorption particularly of carbohydrates and fats
- Rarely dietary protein intolerance.

Complications

Dehydration – if reduced, oral intake. Growth retardation and worsening of malnutrition. It may prove fatal during subsequent diarrhoeal or non-diarrhoeal illness.

Management

Dietary management is the mainstay of therapy.

Infants < 4 months – (a) Exclusive breastfeeding. (b) If only top milk is given, use curds or lactose-free milk formula. (c) From 3rd month onwards, cooked rice can be mixed with milk/curd/lactose-free formula.

Older infants and young children – Breast milk output becomes less and mixed diet should be given.

12. ACUTE GASTROENTERITIS IN CHILDREN

Table 34 gives causes and Table 35 risk factors of acute gastroenteritis in children.

13. PICA

The term 'pica' is derived from a Latin word for magpie a bird known for its eating behaviour. The diagnostic and statistical Manual of Mental Disorders (DSM-IV) defines pica as the persistent eating of non-nutritive substances for a period of at least one month without an association for aversion of food.

Physiological basis for various forms of pica-eating clay (geophagia), ice (pagophagia) or starch (amylophagia) is not well understood.

Table 34: Causes of acute gastroenteritis in children	
<i>Viruses 70%</i>	
<ul style="list-style-type: none"> • Rotavirus • Norovirus (Norwalk-like virus) • Enteric adenoviruses • Calci viruses • Astroviruses • Enteroviruses 	
<i>Protozoa 10%</i>	
<ul style="list-style-type: none"> • Cryptosporidium • Giardia lamblia 	
<i>Bacteria 10–20%</i>	
<ul style="list-style-type: none"> • Campylobacter jejuni • Salmonella spp. Non-typhoid • Enteropathogenic E. coli • C. difficile • Shigella spp. • Yersinia enterocolica • Salmonella typhi and S. paratyphi • Vibrio cholerae 	
<i>Helminths</i>	
<ul style="list-style-type: none"> • Strongyloides stercoralis 	

Table 36: Viral and bacterial gastroenteritis differentiation		
Feature	Viral	Bacterial
Season	Year-round	More common in summer and rains
Reservoir	Primary human	As per species: Human (Shigella, Salmonella), Animal (Campylobacter, salmonella, E. coli), Antibiotic use (C difficile) water (V. cholerae)
Fever	Common with rotavirus, norovirus	Common with inflammatory disorder (Shigella, salmonella)
Vomiting	Can be the only presenting feature in children	Common with bacteria producing preformed toxin
Diagnosis	Enzyme immunoassays for detection of rotavirus and adenovirus	Stool examination for pus cells, RBCs Stool culture on special media
Treatment	Supportive therapy Antibiotics contraindicated	Oral hydration therapy Antibiotics Anti-secretory agent: Racecadotril or Octreotide (single dose)

Table 35: Risk factors for AGE	
<ul style="list-style-type: none"> • Environmental contamination • Immune deficiency • Measles • Malnutrition • Lack of exclusive breastfeeding • Malaria • Zinc and vitamin A deficiency 	

Table 37: Assessment and management of dehydration			
Dehydration	Clinical signs	Pinch test	Management
Nil	None	Normal	Normal diet without breastfeeds
Mild to moderate	2 or more of restlessness, irritability, sunken eyeballs	Slow (Skinfold visible < 2 secs)	Can be managed at home with oral dehydration therapy. If not tolerated then NG feeding or IV fluids
5–10% wt. loss			
Severe > 10%	2 or more of abnormally sleepy, sunken eyes, drinking poorly	Very slow (> 2 secs)	Check acid-base status, urea, electrolytes before IVF. If shock, resuscitate with IVF rehydrate 4–6 hrs. Regular clinical and biochemical review

During infancy, this habit may be a part of oral phase (normal exploration of the environment).

Predisposing factors:

- Mental retardation
- Lack of parental nurturing
- Children with autism
- Brain-behaviour disorder
- Low socio-economic groups
- Iron deficiency
- Lesch-Nyhan syndrome.

Complications of pica include:

- Heavy metal poisoning
- Metabolic abnormalities
- Intestinal obstruction
- Nutritional deprivation
- Worm infections
- Increased risk of Alzheimer’s disease

Substances eaten:

- | | |
|--------------|-----------------|
| Wall plaster | Paint |
| Clay | Ash |
| Earth or mud | Cigarette butts |
| Pencil | Soap |
| Lead | |

Management: Screening for lead poisoning, iron-deficiency anemia, parasitic infestation.

14. INDIAN CHILDHOOD CIRRHOSIS (ICC)

Aetiology: (a) *Incidence* - Disease peculiar to Indian sub-continent with 80% of all cases of cirrhosis in India. Incidence has come down significantly in recent years. (b) *Age* - from 1 to 3 years usually, may occur in older children also. (c) *Sex* - Apparently more common in males, usually first male child after many females. (d) *Familial incidence* - known but definite inheritance not defined. (e) *Community* - Mainly Hindus. Common in Agarwals and Banyas (North India) and Brahmins of South India.

AETIOPATHOGENESIS

Appears to be a response of a genetically inferior liver to viral infection. Theories:

1. *Nutritional* - Seen in traditional vegetarians. Rare in poor and malnourished, commoner in middle income groups. No dietary deficiency appears to contribute. Excessive intake of copper may have a role from use of copper and brass vessels for cooking and storing water.
2. *Viral infection* - appears logical because of febrile onset and leucocytosis. 20% of ICC patients have recent family history of viral hepatitis. Hepatitis B antigen found in 5-20% of cases. However, there is no increased incidence of the disease following epidemics of viral hepatitis.
3. *Genetic* - Siblings can be affected; reported in many generations and in twins. Abnormal palm print patterns have been noted.
4. *Toxic* - Aflatoxin more in urine of patients with ICC and in breast milk of their mothers. Herbal medicines containing toxic levels of arsenic used by mothers in pregnancy "to change sex of child" have been implicated. High levels of copper demonstrated in liver. High copper intake of diet implicated especially in top fed babies where milk is boiled in brass or copper vessels. Patients have been also found to have zinc deficiency.
5. *Immunological* - Could be an autoimmune disease, autoliver antibodies against antigenically altered liver cells by virus. Also evidence of primary defect in cell-mediated immunity has been found.

PATHOLOGY

Liver remains enlarged throughout illness, may shrink slightly in terminal stages. Organ surface finely granular,

hard consistency. On microscopy early changes- ballooning of cells; later stages - necrosis with reticular system collapse, hyaline material (Mallory bodies) seen; no fatty change, "creeping fibrosis", no bile duct proliferation and hardly any regeneration.

CLINICAL FEATURES

Onset - usually insidious. In some, acute onset with fulminant fatal course. The disease ultimately proves fatal within one year of diagnosis.

Early stage - There may be history of infective hepatitis. Child becomes irritable, is off-colour and does not play. Diarrhoea with sticky stools, episodes of low grade fever, flatulence, peevishness, excessive crying and inability to thrive are common complaints. The liver is just palpable and firm with a sharp margin. The spleen may become palpable. These symptoms are referred to as 'pre-cirrhotic symptom complex'.

Intermediate stage - Clinical features more definite. The child looks very ill and may be frankly jaundiced. Abdomen becomes more prominent and dilated superficial veins become visible. A hard liver is always palpable and has a leafy edge and also the spleen owing to development of portal hypertension. Oedema of ankles. Some puffiness of face and ascites may appear.

Terminal stage - The child has deep icterus and the abdomen becomes protuberant with liver enlarged up to umbilicus and spleen becoming hard. Marked ascites. Child may die of hepatic coma, intercurrent infection or bleeding episode.

LABORATORY FEATURES

(1) Leucocytosis. (2) Urinary glycosuria. (3) Increased conjugated bilirubin. (4) Elevated alkaline phosphatase. (5) Decreased serum albumin (later). (6) Increase in gamma globulins, mainly IgM. (7) Decreased serum complement. (8) Impaired tests of cell mediated immunity. (9) Positive Australia antigen in few cases. (10) Increased serum free copper, urinary copper. (11) Miscellaneous - Increased alpha fetoprotein, low alpha-1-antitrypsin, low serum zinc, excess liver copper. (12) Liver biopsy - shows Mallory bodies and increased concentration of copper.

MANAGEMENT

- I. **General** - (1) *Diet* - Balanced diet in compensated state. Salt restriction, protein supplements with additional

glucose in presence of oedema and ascites. Protein restriction (1 g/kg/day) in hepatic coma. (2) *Vitamins* – specially A, D and E orally. Vitamin K 5 mg IM for 3 days if there is bleeding. (3) *Diuretics* – Spironolactone 2 mg/kg/day or Frusemide 2 mg/kg/day if oedema and ascites, with oral potassium chloride. (4) Treatment of hepatic coma – IV glucose, protein restriction, oral neomycin, high bowel washes, treatment of infection. (5) Liver extracts, vitamin B₁₂ of no therapeutic value.

- II. **Specific** – None of the therapies of proved value. (1) *Steroids* – Prednisolone 1–2 mg/kg/day for 2–3 weeks followed by half the dose on alternate days for several months if improvement seen. (2) *Gamma globulin* – 0.1–0.3 mL/kg IM every 3 weeks for 1–2 years has been used with some benefit. (3) *L-tetramisole* – a drug stimulating cell mediated immunity has not proved of value. (4) *Copper chelating agents* – Penicillamine 20 mg/kg/day for periods up to 6 months may bring about reversal of pathological changes in liver. (5) *Zinc therapy* – 30–120 mg/day. Some have claimed improvement.

Prognosis – 45% die in 1 month, 75% in 2 months and 85% in 6 months after diagnosis.

Prevention – Early cases detected by palpating livers of 6 months to 3-year-old siblings of patients. Penicillamine in these cases is not effective because the fibrosed liver has poor capacity for regeneration. Avoid use of copper and brass vessels.

15. WHEEZING INFANT

Wheeze is a symptom and not a diagnosis. It is quite common in children and a number of them have commonly experienced recurrent episodic wheezing. Wheezing results from widespread peripheral airway narrowing.

RISK FACTORS

- In infants, wheezing may be due to exposure to environmental tobacco smoke during foetal life and post-natally
- Viral infection
- Atopy may be implicated in children with severe disease
- Brief or no breastfeeding during the first few weeks of life increase the risk of wheezing in infancy, possibly because of reduced protection against viruses.

Pathogenesis – Acute episodes of wheezing in infancy are characterized by hyperinflation and an increase in airway resistance. In infants, there is little bronchodilator

Table 38: Uncommon causes of chronic or recurrent wheezing in infants

Developmental anomalies

- Bronchomalacia (localized or generalized) and tracheal anomalies
- Bronchial compression syndromes (e.g. vascular anomalies, bronchial or pericardial cyst)
- Congenital heart disease (left-right shunts)
- Tracheal granuloma, stricture or polyp (after mechanical ventilation)

Host defence defects affecting the airways

- Cystic fibrosis
- Ciliary dyskinesia
- Defects of immunity

Postviral syndromes

- Obliterative bronchiolitis
- Airway stricture or granuloma

Recurrent aspiration

- Gastro-oesophageal reflux
- Disorders of swallowing (neuromuscular disease)
- Tracheo-oesophageal fistula
- Laryngeal cleft

Perinatal inflammatory lung disease

- Chronic lung disease of prematurity
- Congenital infection

response to β_2 -agonists given by aerosol. As β_2 -agonists block the action of nebulized bronchoconstrictor agents during bronchial challenge in infants.

CLINICAL FEATURES

There are two main patterns:

- Acute episodic wheeze and cough are commonly associated with respiratory viral infection and punctuated mainly by symptom free intervals. Rhinoviruses, RSV, coronaviruses and metapneumovirus are commonly implicated.
- Chronic symptoms include day-to-day wheeze and troublesome, dry night-time cough. Acute episodes may also occur. There may be atopic features.

DIFFERENTIAL DIAGNOSIS

- Perinatal respiratory disease or neonatal symptoms
- Extreme prematurity
- Vomiting, possetting or dysphagia

- Inspiratory noises or expiratory noises other than wheeze. Other features that indicate alternative diagnosis or major complications include:
 - Persistent failure to thrive
 - Hypoxia between episodes
 - Focal signs on auscultation
 - Inspiratory wheeze or stridor
 - Abnormal voice or cry

INVESTIGATIONS

- Chest radiograph
- CT scan to exclude structural disorders such as airway compression
- Bronchoscopy if bronchial stricture or foreign body is suspected
- Sweat test if cystic fibrosis is suspected
- 24-hour oesophageal pH study for GER
- Oximetry to monitor arterial O₂ saturation during acute episodes. SaO₂ < 92% during quiet sleep, or a quiet awake state suggests airway obstruction requiring hospitalization.

MANAGEMENT

(a) Avoidance of trigger factors, cigarette smoke being the most important. (b) Overcrowding in presence of older siblings in day nurseries increases risk of viral infections in infancy. (c) Breastfeeding reduces risk of wheeze. (d) Drug treatment - (i) Bronchodilators - inhaled β₂ agonists may be more effective when given by metered dose inhaler and spacer than by jet nebulizer. (ii) Corticosteroids - Infants with chronic symptoms (between and during viral episodes) benefit from long-term prophylaxis with inhaled corticosteroids. (e) Mechanical ventilation may be needed, if exhaustion or a gradual increase in oxygen requirement occurs. PaCO₂ is seldom used as a single indicator of the need for ventilatory support in infancy. The efficacy of treatment increases with age and when inter-current symptoms accompany acute wheezy episodes.

16. BRONCHIOLITIS AND BRONCHOPNEUMONIA

Bronchiolitis and Bronchopneumonia are the most serious respiratory illnesses in childhood involving the airways because of (a) Smaller airways which easily get obstructed by inflammatory oedema or secretions. (b) Airway resist-

ance. (c) Marked chest wall recession. (d) Immature respiratory muscles leading to rapid muscle fatigue.

Bronchiolitis is an inflammation of the bronchioles caused mainly by viruses, the most common being respiratory syncytial virus, but also human parainfluenza virus type 3, and some adenoviruses.

Predisposing factors - Weak and marasmic children, rickets, or infective fevers like measles and whooping cough. Viral bronchitis occurs in healthy children 3 months to 9 months old. In children with allergic diathesis, any respiratory infection can trigger off bronchiolar spasms.

PATHOGENESIS

Acute bronchiolitis - in the first 6 months of life is an inflammatory disorder characterized by a massive influx of neutrophils into the lung.

Bronchopneumonia - The interalveolar connections (pores of Kohn and canals of Lambert) are poorly developed in small infants so that contiguous spread to nearby areas is not possible. Hence, infection reaching the alveolus can produce localized exudation and consolidation but is unable to spread to the adjacent alveoli; as a result, confluent areas of consolidation cannot develop and bronchopneumonia and not lobar pneumonia is the usual feature in infants.

SYMPTOMS

1. Onset - Acute with fever, and often vomiting and convulsions; or after preceding nasal or pharyngeal inflammation or tracheobronchitis.
2. Fever - rises rapidly to 39°C (103°F) or more and may remain continuously high in bronchopneumonia. In bronchiolitis, fever may be minimal and in allergic bronchitis, it may be totally absent. More often gradual rise with a tendency to remittance may be of "saw tooth" variety. In debilitated children, normal or subnormal temperature. Fever falls by lysis. Remissions and relapses may carry the disease over a period of 3-4 weeks.
3. Dyspnoea - constant symptom. Very acute and progressive and with sudden subsidence with bronchiolitis. Bronchopneumonia is progressive if untreated, bronchiolitis may reverse with simple measures.
4. Cough and wheeze - since the bronchus and smaller airways are infected, there is irritation of the airways. Hence, a dry cough is a predominant symptom accompanied by wheezing in bronchopneumonia. Children under 4 years cannot expectorate.

5. Cyanosis – may be an early symptom.
6. Prostration – to some extent in all cases, in bad cases, child lies exhausted with half open eyes.
7. Gastrointestinal symptoms – common in infants, vomiting occasional or repeated. Diarrhoea may occur at onset.
8. Neurological – Convulsions may occur at onset or later may indicate meningitis. General restlessness and delirium. Insomnia, or apathy and stupor, or even coma.

SIGNS

1. *Respiration* – Respirations are rapid and shallow and often accompanied by a respiratory grunt. The accessory muscles of respiration are used actively so that there is suprasternal and subcostal indrawing with inspiration.
 2. *Chest* – In bronchiolitis, physical findings in the severe case are those of generalized obstructive emphysema. Cyanosis may be striking and often there is extreme pallor. The percussion note is hyperresonant. There may be prolonged expiration with wheeze, but may have no signs at all except decreased air entry bilaterally. Liver and spleen palpable due to diaphragm being pushed down. Coarse crackles are heard all over in bronchopneumonia.
 3. *Dehydration* – may be relatively severe due to excessive loss of water through hyperventilation.
 4. *X-ray* – examination may reveal generalised obstructive emphysema of varying degree with or without evidence of scattered parenchymal infiltration in acute bronchiolitis. In bronchopneumonia lesions diffuse and are bilateral. Diffused lesions mimic miliary TB. Confluent areas of bronchopneumonia may simulate lobar pneumonia. Staphylococcal – breaking down and cavitory lesions seen which heal as thin-walled sacs (pneumatocoeles) which persist quietly for a year.
4. *Antibiotics* – Crystalline penicillin 1.4 lakh unit's kg/IV 6-hourly, or Ampicillin 100 mg/kg/day, in divided doses 6–8 hourly. Amoxicillin clavulanic acid combination – Amoxicillin 30–40 mg/day in 3 divided doses, IV cephalosporins (2nd and 3rd generation) very useful. If due to staphylo. cloxacillin 100–200 mg/kg IV 6-hourly. The course of virus disease will not be altered but secondary infection will be controlled. Vidarabine 10 mg/kg/day IV is useful for treating RSV infections in high-risk groups, such as cyanotic heart disease.

5. Symptomatic treatment –

- (a) *Bronchodilators* – Salbutamol aerosol 0.03 mL/kg empirically. Nebulized racemic epinephrine 1 mL/kg diluted with normal saline more effective.
- (b) *Cyanosis* – Humidified oxygen, with blood gas monitoring. Sodium bicarbonate if significant metabolic acidosis.
- (c) *Fever* – Paracetamol may be used.
- (d) *Fluids* – Parenterally if respiratory rate more than 60/minute. Weaned off to oral feeds with decreasing distress. Necessary to correct dehydration due to tachypnoea and prevent aspiration.
- (e) *Steroids* – Value not proven in bronchiolitis. Not to be used in bronchopneumonia.

17. ACUTE RHEUMATIC FEVER

Acute rheumatic fever is initiated by group A streptococcal pharyngitis. This is followed by a latent period of 2–6 weeks, after which the clinical syndrome of acute rheumatic fever evolves characterized by:

- Polyarthrits
- Carditis
- Chorea
- Erythema marginatum
- Subcutaneous nodules

These features may occur singly or in any combination.

MANAGEMENT

1. *Nursing* – Good nursing essential to conserve child's energy.
2. *Diet* – should be as normal as child will accept.
3. *Sedatives* – to be used judiciously, may be indicated if restlessness is distressing but this may be due to hypoxia which only a high concentration of O₂ will relieve. Best sedative to control excessive crying and exhaustion which will not cause respiratory depression is Chloral hydrate 50 mg/kg.

AETIOLOGY

Predisposing causes – Age – 5–15 years. Sex – equal incidence, later in boys. Chorea more in females. Also MS more in females. AR in males. *Genetic factors* – Familial incidence known. *Social and economic factors* – Dampness, overcrowding and undernutrition greatly increase the incidence. *Idiosyncrasy* – is presumably a factor, since only 3% of people involved in streptococcal epidemics develop rheumatic fever. These susceptible individuals include a

significantly higher proportion of non-secretors of ABC blood groups. HLA associations being shown along with other immune markers to explain susceptibility.

PATHOGENESIS

Rheumatic fever is invariably preceded by infection with a group A beta-haemolytic streptococcus of specific M-types. Serum from patients with ARF contains antibodies to an antigen in the membrane of the organism, the type 5 streptococcal in protein, which cross-reacts with myocardial tissue. Similarly between streptococcal cell wall antigen and endogenous antigens in cardiac tissue, synovium, cartilage and brain lead to immunologic attack by the host antibodies and manifestations of acute rheumatic fever.

CLINICAL FEATURES

- (a) *Prodromal phase* - Tonsillitis or sore throat 1-4 weeks prior to onset of acute rheumatic fever. Vague prodromata include "Growing pains", anorexia, pallor, fatigability and nervous irritability, and low grade febrile attacks.
- (b) *Latent period* - when antibodies to the preceding streptococcal infection are produced. May vary in length from a few days to several weeks.
- (c) *Phase of onset* - of acute rheumatic fever.

MODES OF ONSET -

- (i) Arthritis and fever 2-3 weeks after infection. (ii) Cardiac symptoms 3-6 weeks after infection may be the first to draw attention, e.g. pain of pericarditis, or palpitation, or symptoms of cardiac failure. (iii) Abdominal symptoms - abdominal pain and tenderness, nausea, vomiting, fever and leucocytosis simulating an acute abdomen. (iv) Pyrexia of unknown origin. (v) Typhoid or influenzal mode of onset with fever, toxæmia and vague abdominal or respiratory symptoms. (vi) Chorea may be the first and only evidence 6 months-1 year later. (vii) Latent valvular disease without previous history of rheumatic fever. (viii) Nodules, or skin lesions, or epistaxis may rarely be the first symptoms.

SYMPTOMS AND SIGNS

1. **Polyarthritis** - Pain disproportionate to objective joint findings. Joints most subject to stress and strain first affected. Migratory or flitting signs of acute inflammation but no suppuration Polyarthritic form is divided into -
 - (a) *Monocyclic* - single cycle of fever for 10 to 15 days, each joint inflamed for 4 to 6 days, recovers and is not again affected.

- (b) *Polycyclic* - joints which have recovered again get involved. Recurrence of arthritis and fever as soon as influence of drug wears off.
- (c) *Continuous form* - persistence of some evidence of active infection often varying in intensity from time to time.

Jaccoud's arthritis - is a rare sequel to repeated attacks of acute rheumatic fever. The features are - (a) Hands and feet are affected. The typical deformity of hands is of marked ulnar deviation of ring finger and slight ulnar deviation of other fingers. (b) Absence of pain. (c) Periarticular fibrosis. (d) Effusions rare, when present seen in metacarpal heads. (e) Tests for rheumatoid factor negative and ESR normal.

2. **Fever** - is usually low grade and never the presenting symptom. Almost always present. Types -
 - (i) Irregular but well-marked. The temperature may rise to 101-103°F, shows daily variations of 1-3°F. Duration variable, may last from a few days in mild cases to a few weeks in severe attacks. (ii) Continuous low grade fever. (iii) Continuous low grade fever with acute exacerbations during relapses. (iv) Hyperpyrexia may rarely occur with delirium, convulsions, and coma.
3. **Carditis** - Rheumatic carditis is an acute inflammatory process that may involve the endocardium, myocardium or pericardium and frequently a combination of all three.

Endocarditis - or valvulitis is indicated by the presence of a significant heart murmur not previously noted - (a) *Systolic murmur* of mitral regurgitation may be heard early in the course of the illness. (b) *Carey Coombs murmur* - Mid-diastolic murmur localized at the apex due to acute mitral valvulitis. It may be transient. (c) *Basal diastolic murmur* of aortic regurgitation due to acute involvement of aortic valve may be heard. The murmur of MR is more likely to disappear whereas the murmur of acute AR usually persists. A mitral stenotic murmur develops only some years after acute episode of rheumatic fever. Tends to be seen earlier in Indian populations. Order and frequency of valvular involvement - commonest mitral, then aortic, tricuspid and pulmonary.

Myocarditis - is suggested by - (a) Tachycardia disproportionate to the fever. (b) Decrease in intensity of 1st heart sound indicating first degree A-V block. (c) Diastolic gallop rhythm or early signs of failure (such as tachypnoea and shortness of breath).

Pericarditis - occurs in patients with severe carditis and is indicated by a friction rub. Large pericardial effusion is uncommon.

4. **Chorea** can occur alone (pure chorea) or in association with carditis. The latent period between the streptococcal infection and onset of chorea is characteristically long (2–6 months), this accounts for the normal ESR and antistreptolysin-O (ASO) titres that are usually found in patients with chorea. Chorea is more common in girls than in boys and usually occurs at the age of 8–12 years. The symptoms lasts for 3–4 months, sometimes longer.

Emotional liability requires a high index of suspicion. School teachers and parents may observe that the child prefers to be alone, is mildly depressed, has a short attention span and is easily provoked.

Involuntary movements principally involve the face and may be unilateral.

5. **Skin** –

- *Erythema marginatum* – most characteristic lesion. May occur 3 weeks after infection. Pale-centred ringlets with pink margins, over trunk and flexure surfaces of joints. There may be few lesions or many, usually evanescent. As a rule, it is recurrent and may appear from time to time long after other manifestations have subsided.
- *Erythema multiforme* – fairly common.
- *Erythema nodosum* – Nodular eruptions usually on the legs. The lesions are tender and warm. Cropping of the lesions is common.
- *Purpuric eruptions* may rarely occur.
- *Sudaminal eruptions* due to marked sweats is an early manifestation along with arthritis.

6. **Subcutaneous nodules** – (i) Painless, translucent, non-pruritic, conical or rounded nodules just under the skin, varying in size from a pinhead to about 2 cm in diameter. Appear in crops on extensor surface of elbows, dorsum of hand or foot, skull, scapula and other bony prominences. Sign of virulent process. Occur relatively late (6 weeks to 6 months) in the course of the disease and remain for several weeks. (ii) Rheumatic tendinitis, tenosynovitis, myositis and bursitis may seldom occur. Nodules indicate chronicity, and are associated with significant heart disease.

7. **Respiratory** – (i) Epistaxis may be an atypical manifestation. (ii) Rheumatic pneumonia – uncommon and almost always occurs in patients with severe carditis. Chest X-ray may show changing areas of pulmonary infiltration which do not respond to antibiotics but respond dramatically to steroid therapy.

8. **Gastrointestinal** – (i) Mild gastroenteritis may be one of the prodromal features. Occasionally signs of acute

appendicitis due to inflammatory changes in the right rectus abdominalis muscle, or to inflammatory changes in the mesentery, or to enlargement of abdominal lymph glands. (ii) Repeated vomiting spells.

LABORATORY FINDINGS

1. EVIDENCE OF PRECEDING STREPTOCOCCAL INFECTION – Antistreptolysin-O (ASO) determination useful in 80 per cent of cases. Titre < 250 considered normal, 250–320 borderline elevated. Eighty per cent of rheumatic fever patients have higher than 250 units/litre, of which 60% are above 500 units. Serial rises more significant. Antistreptozyme test (ASTZ) – Tests for 5 streptococcal enzymes antigenically more accurate diagnostically. The titre usually rises within 1–2 weeks and increases until a maximal level is reached 3–5 weeks after infection, returns to normal in 8–16 weeks.
2. ACUTE PHASE REACTIONS – not specific for rheumatic fever. (a) *ESR* – elevated. (b) *C-reactive protein* – reflects rheumatic activity more precisely than ESR. (c) *Serum proteins* – Significant elevation of serum haptoglobin common in acute phase.
3. MISCELLANEOUS:
 - (a) *Anaemia* – mild to moderate. Persistence of anaemia is often a sign that rheumatic inflammation is still present.
 - (b) *ECG* – (i) Disturbance of conduction – Prolonged PR interval or more severe grades of heart block. (ii) Changes associated with myocarditis. (iii) Abnormalities secondary to pericardial involvement.
 - (c) *X-ray chest* – Cardiac enlargement may help to confirm diagnosis of carditis in equivocal cases.

Table 39: Revised Jones criteria

Major criteria	Minor criteria
Carditis	<i>Clinical:</i>
Polyarthritis	Fever
Erythema marginatum	Arthralgia (esp. if there is major arthritis).
Chorea	Previous rheumatic fever or RHD.
Subcutaneous nodules	<i>Laboratory:</i>
	Raised – ESR,
	leucocytes, C-reactive protein.
	Prolonged PR interval on
	ECG (not if there is major carditis).

Two major manifestations or one major with two minor manifestations in the presence of evidence of previous streptococcal infection makes the diagnosis of rheumatic fever highly probable.

WHO Recommendations

- Chorea and indolent carditis do not require evidence of antecedent Group A streptococcus infection or other major criteria.
- First episode as per Jones criteria
- Recurrent episode:
 - In a patient without established RHD, as per first episode
 - In a patient with established RHD requires two major manifestations plus evidence of antecedent Group A streptococcus infection as per Jones criteria.

WHO criteria can be used for both first episode and recurrent episodes of acute rheumatic fever. Supporting evidence of preceding streptococcal infection also includes positive rapid antigen test for Group A streptococci on sore throat.

Chorea alone, insidious or late onset carditis with no other explanation can be indicative of disease without evidence of preceding streptococcal infection. In those with documented rheumatic heart disease, presence of one criterion, or of fever, arthralgia or elevated acute phase reactants is presumptive diagnosis of recurrence.

DIFFERENTIAL DIAGNOSIS

1. *Juvenile rheumatoid arthritis* - (Still's disease) - may present with acute arthritis with history of preceding sore throat. Points in favour of Still's disease are high swinging, intermittent temperature as compared with the more persistent or remittent fever in rheumatic fever, rash and later more persistent joint changes, aspirin response dramatic in rheumatic fever.
2. *Acute osteomyelitis* - There may be no leucocytosis at the start and X-ray changes take two weeks or more to develop. With osteomyelitis of upper end of humerus, there may be pain on movements of both shoulder and elbow, thus simulating rheumatic fever acute arthritis. Child is likely to be more acutely ill.
3. *Henoch-Schonlein purpura* - may present with acute joint pains but often there is, in addition, relative painless swelling over the back of hands or of eyelids; there may also be bowel symptoms. More diagnostic is the maculopapular rash over buttocks and lower limbs, which turns haemorrhagic.

4. *Acute poliomyelitis* - Acute limb pain on movement for a day or two before paresis or obvious changes in reflexes develop.
5. *Acute leukaemia* - Acute pain and swelling of joints from periarticular inflammation, rarely haemarthrosis.
6. *Streptococcal tonsillitis* - followed by limb pain. The pain may be worse on movements of the limbs and maximal in relation to joints. The condition subsides rapidly with adequate treatment of throat infection.
7. *Sensitivity reaction* - to drugs, serum sensitivity and certain food allergies may cause migratory polyarthritis similar to rheumatic fever. Often associated with urticaria.
8. *Collagen diseases* - Polyarthritis can occur early in the course of polyarteritis nodosa, lupus erythematosus and dermatomyositis. The arthritic symptoms are usually mild and other characteristic features are either present or emerge as the patient is observed.

MANAGEMENT

1. **Rest and nursing care** - Rest in bed (Table 40). Speed of ambulation should be varied according to the severity and course of the rheumatic attack. In patients with polyarthritis without carditis, prolonged bed rest is not necessary. Patients with definite myocarditis and valvulitis should be kept in bed until: (i) the intensity of heart murmur has diminished or has become stabilized, (ii) heart sounds are of good quality, (iii) sleeping pulse rate is below 100 per minute, (iv) haematocrit is rising or normal and the CRP is negative and (v) there is a true weight gain. Convalescence may often take 6 months or longer.
2. **Diet** - Aim is to maintain nutrition. Only fluids if moderate or high fever. Vitamins and minerals.
3. **Drugs** - control acute exudative manifestations.
 - (a) **ANTIBACTERIAL AGENTS** - Benzathine penicillin 1.2 million units IM followed by phenoxymethylpenicillin 500 mg b.d. for 10 days. If sensitive to penicillin Erythromycin 40-50 mg/kg for 10 days.

Table 40: General acceptable rules for bed rest

Status	Rest	Ambulation
No carditis	2 weeks	Gradual 2 weeks
Carditis, no cardiomegaly	4 weeks	4 weeks
Carditis with cardiomegaly	6 weeks	6 weeks
Carditis with CHF	Until criteria in text fulfilled	3 months

(b) ANTI-INFLAMMATORY AGENTS

- *Salicylates* - in the form of Aspirin 100 mg per kg body weight per day in 3-4 divided doses taken in milk or after meals. Continued for 2 weeks, then scaled down to 75 mg/kg for 4-6 weeks for both arthritis alone, and/or carditis with or without cardiomegaly. Signs of aspirin toxicity are - vomiting, tinnitus, and hyperpnoea. If these occur, the drug should be discontinued for one or two days and then restarted in a lower dose.
 - *Steroids* - should be given with first signs of carditis. They suppress the activity and allow digitalis and diuretics to work, and if there is only potential failure, risk of development of failure is minimised. Rebound phenomena (reappearance of clinical or laboratory signs of rheumatic activity) may occur when steroid medication is stopped or the dosage reduced. Dosage - Prednisolone 2 mg/kg/day in divided doses for 2 weeks, gradually decreased over another 2 weeks. Aspirin should be started after 2 weeks of steroids and continued for 4 weeks beyond to prevent steroid rebound.
4. **Symptomatic treatment** - (i) Local treatment - Cradle to lift bed clothing from affected joints. (ii) Cardiac failure - Digitalis - 0.03-0.05 mg/kg total dose orally, 3/4 this dose if parenteral digitalisation necessary. Give 1/2 dose stat, 1/4 after 8 hours, 1/4 after another 8 hours. Daily maintenance 1/4th-1/5th total dose. Furosemide 2 mg/kg/day with oral pot. chloride, oxygen. (iii) Pain and restlessness - Codeine for chest pain and cough. (iv) Anaemia - Iron by mouth.
 5. **Convalescence** - Physical activity not undertaken until clinical and laboratory evidence of rheumatic activity have been absent for at least 2 weeks after stopping of salicylates. Restriction of physical exertion is not necessary where there is satisfactory compensation, and moderate degree of physical activity is desirable, but exercise should be increased gradually.

PREVENTION AND PROPHYLAXIS

1. Immediate treatment of every suspected case of sore throat or streptococcal infection with penicillin or erythromycin for 10 days.
2. Change of environment and improvement of nutrition.
3. Antimicrobial prophylaxis - Oral phenoxymethylpenicillin 200,000 units twice daily, or benzathine penicillin G 1.2 million units IM once every 3 weeks. For patients sensitive to penicillin, Erythromycin 40 mg/kg/day can be used. Prophylaxis must be continued till

the patient is 25 years old, or for 5 years from the last attack of rheumatic fever whichever is longer. Preferably life-long in patients with carditis as adults can get recurrences after many years. Must be used even in chorea.

RHEUMATIC CHOREA (SYDENHAM'S CHOREA, ST. VITUS' DANCE)

Aetiology: Age - maximum incidence at 10th year, rare after puberty. Sex - twice more common in girls. *Predisposing factors* - Mental strain, e.g. overwork at school, fright or shock, or pregnancy in young females. *Exciting cause* - Majority due to acute rheumatic fever. Rarely, diphtheria, encephalitis, chickenpox. Chorea is regarded as a diffuse meningo-encephalitis affecting the basal ganglia, cerebral cortex and pia arachnoid.

Clinical features: *Triad* - of emotional instability, hypotonia and semipurposeful movements.

Onset - Chorea may appear several weeks or months (usually more than 6 months) after an attack of acute rheumatic fever, or it may be the initial symptom of a rheumatic episode. The onset is usually gradual. The child becomes increasingly nervous, tends to drop things and stumbles frequently. Speech becomes indistinct and characteristic purposeless movements of arms and legs develop.

1. Involuntary movements

- Face - constant bizarre grimacing.
- Tongue - when protruded it may be impossible to hold it quietly (Jack-in-the-box or chameleon tongue) and its undulating jerky movements are described as those of a bag of worms. When asked to show the tongue, the child puts it out rapidly and may bite it to keep it out, or may jerk it back rapidly with reptilian speed. When talking, the tongue produces a clucking sound.
- Ocular muscles may rarely participate in the involuntary movements.
- Extremities - Movements appear first in hands, when arms are outstretched in front, the posture is one of flexion at the wrist and hyperextension at the metacarpophalangeal joints. Choreic hands or spooning of hands on shaking hand with the child, there is intermittent squeezing (milk-maid grip). If the upper limbs are held above the head, the palm faces outwards (pronator sign).
- Lower extremities less affected. Gait may be clumsy.
- Muscles of abdomen and neck may be involved.

- Respiration - alteration in rhythm. Breath is taken rapidly, held for some time, and let go with a sigh. Involuntary grunting noises common.
 - Choreic movements are intensified by voluntary effort and excitement, and banished by sleep.
2. **Weakness of voluntary movements** - In mild cases, little or no impairment of power, but in severe cases the choreic movements may become less marked but the limbs progressively weaken.
 3. **Associated movements** - incoordinated and exaggerated. The hand grip is characteristic, pressure is not steadily maintained but waxes and wanes as stated above. When patient clenches his fist, movements may occur in the face, trunk and limbs. When the hands are extended the wrist often flexes and the fingers hyperextended giving a so-called 'dinner fork' deformity.
 4. **Psychiatric disturbances** - Emotional instability, meaningless laughing or crying; in severe cases, delirium. Eventually normalcy is regained.
 5. **Muscular hypotonia** - It gives rise to characteristic dinner-fork deformity of the wrist and to pronation of the elevated hand.
 6. **Reflexes** - Cutaneous reflexes often very brisk. Pendular knee jerk characteristic. If a chorea jerk coincides with testing the knee reflex, it will cause 'hung up' jerk. In severe cases deep reflexes may be absent. Ocular phenomena - pupils often dilated, hippus may be present.
 7. **Speech** - Hesitating, distorted and monotonous, words spoken in a whisper or explosively. In severe cases, speech may be so severely affected as to be completely lost, and swallowing may be difficult.
 8. **Rheumatic manifestations** - In 20-25% of cases, rheumatic heart disease develops. Pericarditis, arthritis and nodules are rarely associated with chorea and there is no fever.

COURSE - Chorea is a self-limited condition lasting on an average for 3 months, and usually there is complete recovery from the emotional and neuromuscular abnormalities. Recurrence occurs in about a third of patients and as many as five to six attacks may occur. It is unlikely 2 years after the first attack. Symptoms are less severe and duration shorter.

Varieties of Rheumatic Chorea

1. Hemichorea - movements confined to one side of body.
2. Paralytic chorea, limp chorea or chorea mollis - complete flaccidity of muscles and hypotonia. It is preceded by usual symptoms of chorea or rarely may be the first noticeable symptom.
3. Chorea gravidarum - rare but severe variety occurring chiefly in young women during earlier months of pregnancy. Chorea may recur with successive pregnancies.

Management

1. **General measures** - Bed rest indicated in most patients. If chorea is severe, change of environment may help and hospitalization is therefore better. Attention to fluids and nutrition of children unable to feed themselves.
2. **Sedatives** - Phenobarbitone 5 mg/kg/day. Alternatively chlorpromazine 2-3 mg/kg/day or haloperidol 0.2 mg/kg/day.
3. **Antistreptococcal treatment** - 10-day course of penicillin followed by prophylaxis.
4. **Suppressive drugs** - Salicylates or steroids may be indicated in patients with signs of an active rheumatic inflammatory process.
5. **Rheumatic penicillin prophylaxis.**

18. TUBERCULOUS MENINGITIS

AETIOLOGY

Age - highest incidence from 6 months to 3 years. Very rare before age of 3 months. **Sex** - equal incidence. **Primary infection** - usually in lungs or mediastinal glands, or bowel and mesenteric glands. Tubercle bacilli carried in the blood stream produce caseous foci called Rich's focus in brain, meninges, spinal cord. It is only when these rupture into the cerebrospinal fluid that meningitis results.

PATHOLOGY

Meningitic and encephalitic component.

Meninges - Rich's focus. Meningeal exudate at base of brain from optic chiasma anteriorly to mid-pons posteriorly. Exudate and later organizations and adhesions responsible for communicating and obstructive hydrocephalus, cranial nerve palsies, arterial compression and inflammation.

Brain - (a) Border zone encephalitis - Contiguous areas to meningeal inflammation show perivascular inflammation and softening. (b) Cerebral oedema and encephalopathy - Diffuse neuronal oedema due mainly to vascular damage and partly to hypersensitivity reaction to tuberculin. (c) Infarcts in distribution of arterial territories. (d) Ventricular dilatation - Hydrocephalus common to all cases. (e) Tuberculoma, mainly cerebellar, single or multiple. Can cause cerebellar signs, focal convulsions and raised ICT.

Blood vessels – Main arteries compressed or inflamed – middle cerebral, internal carotid or siphon, anterior cerebral. Rarely posterior cerebral and basilar.

CLINICAL FEATURES (CLASSICAL)

- Prodromal stage of sensory irritability** – (i) Onset insidious, rarely acute with high fever. (ii) Change in temperament – irritability, restlessness, disinclination to play combined with periods of drowsiness. (iii) Headache; older children may complain of it, younger children may indicate their pain by screams and by putting their hands to head. (iv) Anorexia and vomiting. (v) Constipation often severe. (vi) Temperature normal or only slightly raised. This stage lasts for a week or more.
- Stage of meningeal irritation** – (i) Convulsions. (ii) Evidence of meningeal irritation – child lies curled upon side, stiffness of neck, positive Kernig's and Brudzinski's signs. (iii) Tense anterior fontanelle and separation of cranial sutures. When anterior fontanelle is closed, separation of sutures gives rise to 'cracked-pot' resonance on tapping skull (Macewen's sign). (iv) Exaggeration of deep reflexes. (v) Grinding of teeth. (vi) Muscular twitchings. (vii) Squint usually internal, and ptosis. (viii) Temperature usually raised to 101-102°F, sometimes high throughout the illness. (ix) Disturbances of consciousness.
- Terminal stage of coma** – (i) Irritability – replaced by coma, child lies on back with eyes staring vacantly and dilated pupils. (ii) Rapid loss of weight and dehydration. (iii) Tachycardia and irregular pulse. (iv) Respiration irregular, often Cheyne-Stokes. (v) Tremors of limbs and occasionally choreic movements. (vi) Terminal hyperpyrexia. This stage also lasts approximately one week. (vii) Child may lie in position of decerebrate rigidity for many weeks. Stage 2 may be missed, stages 2 and 3 may be concomitant.

Fundoscopy – may reveal choroid tubercles especially when there is associated miliary tuberculosis. Papilloedema with raised ICT or optic nerve compression. Later secondary optic atrophy.

VARIATIONS

- Sudden onset, absent prodromal symptoms, and brief course.
- Initial manifestation may be hemiplegia or some other localising symptom, and meningeal symptoms occur later.
- Coma without meningeal manifestations.

- Temporary improvement or remission without treatment.
- Typhoid-like onset.
- Onset with status epilepticus.
- Tumour onset.
- Bronchopneumonic onset with respiratory symptoms.
- GI onset with vomiting, abdominal pain.
- With chronic head enlargement.
- Precipitation following head trauma.
- Hypersensitivity manifestations
 - Phlyctenular conjunctivitis
 - Erythema nodosum
 - Poncet's disease - Arthralgia and affections of large joints such as knees
 - Fever - High grade fever without definite evidence of progression of primary complex.

CSF – Clear or slightly opalescent. Pressure increased. Cells 50-500/cmm. mainly lymphocytes, initially polymorphs. Protein increased (above 50 mg per 100 mL). Sugar reduced (below 50 mg per 100 mL) in majority of early cases, a finding which excludes virus meningitis. The chloride content falls too late in the disease to be of much diagnostic importance. Direct examination of the fluid may reveal acid fast bacilli in centrifuged deposit or in the pellicle (cob-web) which forms when it is allowed to stand overnight. CSF may be normal or show Froin's syndrome if there is spinal subarachnoid block, rarely mimics pyogenic meningitis in the early stages. Newer serological techniques for acid fast bacilli, TB antibody by ELISA technique. Molecular DNA technology may help in near future for accurate diagnosis by identifying mycobacterial DNA by PCR (polymerase chain reaction) analysis.

CT Scan – will show cerebral oedema, basal exudates, areas of infarction and hydrocephalus.

See Table 41 for the complications and sequelae of TBM.

DIFFERENTIAL DIAGNOSIS

- Viral encephalitis* See Table 42.
- Other types of meningitis:* (Refer).

MANAGEMENT

- GENERAL –
 - Nursing-care of mouth and skin.
 - Fluids – 1300-1400 mL/m², restricted to prevent cerebral oedema. Nasal feeds if child cannot take by mouth, chiefly milk and high-protein preparations.

Table 41: Complications and sequelae of TBM

Table 43: Antitubercular RNTCP regimes

Tr. category	Type of patient	Intensive phase	Continuing phase
New	Sputum +ve	2H3 R3Z3E3	4H3R3
	Sputum -ve Extrapulmonary		
Previously treated	Smear +ve relapse	2 I3 R3Z3E3S3	5 H3R3
	Smear +ve failure Smear +ve Treatment	IH2R3Z3E3	

Prefix indicates months of therapy and subscript indicates frequency of drugs to be given per week. Continuation phase in TBM is 7 months.

3. Multivitamin syrup
4. Indwelling catheter for retention of urine
5. Enema every 3rd or 4th day if constipation

Treatment under RNCTP is under two categories. New case and previously treated case. First line TB drugs. (Revised National Tuberculosis control program).

Note: In DOT an observer watches and supports the child in taking the drugs.

Steroids – by mouth may reduce inflammatory reaction and thereby decrease the incidence of spinal or ventricular block and release the tubercle bacilli from the fibrinous exudate so that they are more exposed to the action of drugs. It also produces rapid improvement in the general condition of the patient. Initial therapy with 0.5 mg/kg IV dexamethasone for increased intracranial tension, repeat at 0.2 mg/kg dose every 6–8 hours. Oral steroids: prednisolone 1–2 mg/kg/day for 4–8 weeks, followed by gradual discontinuation over 2–4 weeks.

Table 42: Differentiating features between viral encephalitis and tuberculous meningitis

Characteristic	Viral encephalitis	Tuberculous meningitis
Fluid	Clear	Clear, may have fibrin web on standing
Pressure	Normal or increased	Normal or increased.
Protein	Normal or increased	Increased. May be over 100 mg per cent.
Glucose	Rarely below 40 mg per cent. May be above 80 mg per cent. CSF/Blood ratio about 2/3.	Usually in region of 20–25 mg per cent. Rarely if ever above 45 mg per cent. CSF/Blood ratio <1/2.
Cells	May be normal. When increased usually of lymphocytes to 50–200/c.mm. Some polymorphs in first week.	Increased. In first few weeks polymorphs.
Organism	Isolated	M. tuberculosis may be seen on direct microscopy. Culture may be positive in 6–10 weeks
Antibodies	Antibody to particular virus may rise with serial samples.	Gamma globulin increased.

Table 44: Antitubercular drugs RNTCP regimes

Drugs	Daily	Intermittent thrice weekly	Main adverse effects
Isoniazid	5 mg/kg	12–17 mg/kg	Hepatotoxicity, Polyneuritis
Rifampicin	10 mg/kg	15 mg/kg	Hepatotoxicity, red-coloured body secretions
Pyrazinamide	25 mg/kg	35 mg/kg	Hepatotoxicity
Streptomycin	15 mg/kg	15 mg/kg	Vestibular damage
Ethambutol	15 mg/kg	30 mg/kg	Retrolbulbar neuritis

CHEMOPROPHYLAXIS

Asymptomatic children under 6 years of age, exposed to an adult with infectious TB from within the same household are to be given 6 months of INH (10 mg/kg daily), irrespective of Mantoux's test and BCG vaccination status.

Patientwise Boxes (PWB)

These boxes have standardized drug therapy ready to use. For the purpose of treatment, paediatric population is divided into four weight based: 6–10 kg, 11–17 kg, 18–25 kg, and 26–30 kg. These boxes are given to the patients and supervised.

II. SYMPTOMATIC -

1. Convulsions - (i) Phenobarbitone 5-10 mg/kg IM stat, then 5 mg/kg once daily, or (ii) Diazepam 0.25-0.3 mg/kg slowly IV.
2. Irritability and increased tension - (i) Lumbar puncture. (ii) Mannitol IV 2.5-3 mL/kg one dose. (iii) Dexamethasone - mainstay of treatment for raised ICT. (iv) Acetazolamide 25-75 mg/kg daily for prevention of progressive hydrocephalus.
3. Fever - If above 39°C (102°F) antipyretics like paracetamol every 4 hours. Ice compresses to forehead and Eau de Cologne compresses to abdomen.
4. Constipation - Glycerine suppository or glycerine syringe.
5. Dehydration - 1/3 or 1/2 glucose saline.

III. SURGICAL - Insertion of ventriculoatrial or ventriculoperitoneal shunt in cases with severe hydrocephalus not responding to early medical treatment. Maybe life-saving, but makes child shunt-dependent for life.

Complications - Infection, block, displacement.

- *Increased intracranial pressure* - Tumour, hydrocephalus, Reye's syndrome.
 - *Degeneration of brain* - Cerebrovascular degeneration, storage disorders.
 - *Malformations of brain.*
 - *Tumors of brain* - Astrocytoma, medulloblastoma, leukemic deposits.
3. **Encephalopathies** -
 - *Hypertensive* - Acute and chronic nephritis, congenital abnormalities of kidneys with renal rickets.
 - *Toxic* - Lead encephalopathy, convulsant drugs, e.g. camphor, phenothiazine, steroids; kernicterus.
 - *Allergic* - Vaccine sensitivity.
 - *Collagen disease* like SLE.
 4. **Epilepsy.**
 5. **Metabolic** - Hypoglycemia, hypocalcemia, hypomagnesemia, alkalosis, hyponatremia, hypernatremia, pyridoxine deficiency and dependency, phenylketonuria and other inborn errors of metabolism.
 6. **Anoxia** - Asphyxia neonatorum, breath holding spasms, whooping cough, Adam-Stokes syndrome, Fallot's tetralogy, suffocation, near-drowning, poisoning.

7. **Tetanus.**

19. INFANTILE CONVULSIONS

CAUSES

1. **Febrile** - Commonest type in childhood. Temperature of more than 38°C in absence of demonstrable CNS infection, e.g. upper respiratory tract infections, measles, pneumonia, pyelonephritis, otitis media. Seen between 6 months and 5 years.

TYPES: *Simple typical* - is generalized clonic, lasts for less than 15 minutes, does not recur again within 30 minutes, recovers fully after 1/2-1 hour without neurological deficit. Drowsiness but no loss of consciousness following the seizure. Simple seizures may lead to epilepsy in 1% of children. *Complex or atypical seizure* - lasts longer than 15 minutes, may go into status, may be focal, may have residual neural deficit. Risk of epilepsy is about 10%.

Febrile seizures can be familial.

2. **Intracranial** -

- *Traumatic* - Birth injury, subdural haematoma.
- *Vascular* - Cerebral arterial embolism or thrombosis, intracerebral haemorrhage, cortical thrombophlebitis, Sturge-Weber syndrome.
- *Infection* - Encephalitis, meningitis, cerebral abscess, parasitic brain disease.

DIAGNOSIS AND INVESTIGATION

History:

1. AGE -

Newborn - Intracranial birth injury, perinatal asphyxia, intracranial hemorrhage, tetanus neonatorum, tetany of newborn, hypoglycemia, kernicterus, sepsis and meningitis, inborn errors of metabolism, brain malformations, polycythemia.

First 6 months - CNS infections, perinatal asphyxia, tetany, other metabolic defects.

6 months to 3-4 years - Febrile convulsions, CNS infections, metabolic disorders, sequelae of perinatal asphyxia, early neurodegeneration, idiopathic epilepsy.

3-10 years - Idiopathic epilepsy, febrile convulsions up to 5 years, residual cerebral damage from early trauma, infection, brain tumour, acute nephritis and certain degenerative diseases of the brain, lead poisoning.

2. RECURRENT OR NON-RECURRENT-

Table 45 gives causes of convulsions.

3. BIRTH INJURY - History of previous convulsions and any difficulty experienced by mother or baby in the perinatal period.

Table 45: Causes of convulsions**Acute or nonrecurrent convulsions:**

- Intracranial infections
- Intracranial haemorrhage
- Toxic
- Anoxic
- Metabolic disturbances
- Acute cerebral oedema
- Cerebral thrombosis

Chronic or recurrent convulsions:

- Febrile convulsions
- Epilepsy
- Hydrocephalus
- Tetany
- Hypoglycaemic states
- Uraemia
- Subdural hematoma
- Cardiovascular dysfunction
- Parasitic disease of brain
- Intracranial tumours
- Cerebral degeneration
- Migraine
- Lead poisoning

4. **FAMILY PREDISPOSITION** – in idiopathic epilepsy and in febrile convulsions.
5. **RECENT IMMUNIZATION PROCEDURES** – Convulsions occasionally occur after vaccination against pertussis and very exceptionally may be evidence of post-vaccination encephalitis.
6. **HEAD INJURY** – Past history may suggest chronic subdural hematoma.
7. **POISON INGESTION** or toxin exposure.
8. **RELATION TO MEALS** – Tendency for convulsions in early morning hours or at the end of a long interval between meals suggestive of hypoglycemia.
9. **HISTORY OF PAST ENCEPHALOPATHY** – Children who have recovered from tuberculous meningitis or encephalitis may develop convulsions at a later date.
10. **HISTORY OF OTHER SYSTEMIC DISEASE** – such as cardiovascular, nephritis, bleeding disorder, collagen disease.

EXAMINATION

1. *Loss of consciousness* – absent in tetany, tetanus and rare in simple febrile seizures.
2. *Unilateral attacks* – Vascular thrombosis (commonest in TBM), brain tumour, cerebral abscess, focal encephalitis, tetany and lead poisoning.

3. *Fever* – Otitis media, pharyngitis, pneumonia, pyelonephritis, meningitis, sinus thrombosis. If clinical findings are negative and the child is less than 5 years of age, consider possibility of febrile convulsions.
4. *Blood pressure* – measurement to rule out hypertensive encephalopathy.
5. *Tautness or bulging of the fontanelle*, and rigidity or objection to flexion of neck.
6. *Stridulous breathing* – in an infant with rachitic bone changes should raise question of tetany.
7. *Pronounced asymmetry of face and/or cranium* – may provide outward evidence of cerebral agenesis, a facial naevus of intracranial haemangioma, superficial pigmented areas of neurofibromatosis, and facial adenomata with butterfly distribution of tuberous sclerosis.
8. *Localising signs* – in the central nervous system. Sixth nerve palsy (false) suggests raised intracranial pressure.
9. *Ophthalmological examination* – changes in discs in uraemia, cerebral tumour (not if infratentorial) and meningitis. Phakomas in tuberous sclerosis. Macular degeneration or cherry red spot in degenerative disorders.

INVESTIGATIONS

1. *Urine* – to exclude causal renal factor.
2. *CSF* – for diagnosis of meningitis, encephalitis.
3. *Imaging* – Radiograph – (i) Long bones – Lead line in lead poisoning. (ii) Skull – evidence of increased intracranial tension. (iii) Sutural separation. (iv) Angiography. (v) Brain scan. (vi) CT scan. (vii) MRI scan.
4. *EEG*.
5. *Blood chemistry*.

MANAGEMENT**A. Of an attack**

1. Loosen the child's clothes. Turn the child on one side and keep the airway patent. Prevent tongue biting by placing a mouth gag between the jaws, not made of metal.
2. Take temperature, if there is fever – (a) Tepid water compresses to head and body. (b) Eau de Cologne compresses to abdomen.
3. Anticonvulsants – (a) Diazepam or Lorazepam – 0.25–0.5 mg/kg very slowly IV without dilution. Danger of respiratory depression if bolus is given.

Repeated every 20 minutes if necessary. Action within 30 seconds. 1 mg/kg can be given rectally in an emergency. Treatment of choice. (b) Dilantin sodium - 10 mg/kg IV stat, then 5-8 mg/kg/day in two divided doses orally. Diazepam followed by IV bolus of Dilantin will control 90% of acute seizures. (c) Phenobarbitone sodium - 8-10 mg/kg IM stat, then 5 mg/kg in divided doses 12-hourly IM for 2-3 days for adequate blood levels, then 5 mg/kg orally once daily. (d) Intranasal Midazolam 0.2 mg/kg or IM is safe and equally effective.

4. CSF - to rule out meningitis.
5. Sodium bicarbonate for acidosis, oxygen and suction.

B. Treatment of special types of convulsions

1. *Febrile convulsions* - (a) Paracetamol at start of fever. 10-15 mg/kg/every 4 hours. (b) Tepid sponging or ice cap. (c) Rectal diazepam at start of fever in dose of 1 mg/kg useful in simple febrile convulsions. No prolonged prophylaxis necessary.
2. *Atypical febrile convulsions* - Family history of epilepsy or neurologically abnormal child needs prophylaxis with phenobarbitone 3-5 mg/kg/day once at night, or valproate 15-20 mg/kg/day in 2-3 divided doses up to 5 years of age.
3. *Acute infection* - Antibiotic and antipyretic therapy.
4. *Tetany* - 2 mL/kg 10% calcium gluconate IV Oral maintenance 50-100 mg/kg elemental calcium (Calcium lactate has 13% elemental calcium).
5. *Hydrocephalus* - Repeated ventricular punctures or surgical procedures. Acetazolamide 50-75 mg/kg/day until surgery.
6. *Hypertensive encephalopathy* - Lumbar puncture to rule out intracranial infection. IV Mannitol 2.5-3 mg/kg 1-2 doses.
7. *Epilepsy*
8. *Seizures recurring without explanation especially seen after birth* - despite anticonvulsant therapy may be due to pyridoxine deficiency and respond to pyridoxine 50 mg IM or 50-100 mg by mouth.
2. Anterior fontanelle normally closes at about 18 months. Most posterior fontanelles are closed at birth, or close by 3-6 months.

In disease

1. *Unduly large head or macrocephaly* - Hydrocephalus, subdural hematoma, intracranial tumour, rickets, achondroplasia, megalencephaly, gigantism, storage disorders.
2. *Microcephaly* - Cranium abnormally small in congenital microcephaly, chromosomal anomalies, craniospina, intrauterine infections, drugs and radiation, postnatal cerebral damage following birth asphyxia.
3. *Abnormal delay in closure of anterior fontanelle* - Rickets, hypothyroidism, hydrocephalus, osteogenesis imperfecta, cleidocranial dysostosis, malnutrition.
4. *Craniotabes* - Isolated areas of thinness and softness of the skull, especially the parietal areas, which indent with pressure of the fingers like a ping-pong ball. Causes - congenital, rickets, hydrocephalus, congenital syphilis, osteogenesis imperfecta.
5. *Hydrocephalus* - Globular shape, forehead bulges forwards and parietal bones bulge laterally above the ears. The anterior fontanelle may stretch from ear to ear and extend backwards to the posterior fontanelle. As the head enlarges, the child may have difficulty in holding it up. Associated with "sun-setting" of eyes.
6. *Skull of rickets* - Craniotabes commonest early sign. Central parts of frontal and parietal bones often harder and thicker, forming frontal and parietal prominences or bosses which give the skull a box-like appearance. If these prominences are separated by deep grooves, which correspond to the sutures of the skull bones, a "hot-cross bun" skull may develop.
7. *Anencephaly* - Osseous vault of cranium defective and brain underdeveloped.
8. *Cranioostenosis* - Premature closure of sutures of skull resulting in deformities of head and frequently damage to the brain and eyes - (a) *Oxycephaly* - Premature closure of coronal sutures resulting in tower head, pointing in the region of anterior fontanelle. (b) *Scaphocephaly* - Skull narrowed in anteroposterior diameter but elongated in coronal diameter due to premature fusion of coronal suture. (c) *Dolichocephalic* - Anteroposterior elongation due to premature closure of sagittal suture. (d) *Mixed forms* of various syndromes.
9. *Hypertelorism* - Abnormally large distance between the eyes, and broadening of the roof of the nose due to overdevelopment of lesser wings of sphenoid bone.

20. SKULL

CHANGES IN HEALTH AND DISEASE

In health

1. Rate of increase in circumference of the head (See section on growth and development).

10. *Lacunar skull* – Defects in the vault in the form of shallow depressions or deep cavitations extending to the outer surface and occurring mainly in the frontal or parietal areas. X-ray of skull shows irregular patches of rarefaction or lacunas. Often associated with meningocoele.

21. HYDROCEPHALUS

Hydrocephalus is an accumulation of fluid in the head. It is usually caused by disturbance of the flow or absorption of CSF. Table 46 lists causes of hydrocephalus.

TERMS USED IN HYDROCEPHALUS

Communicating hydrocephalus: Paraventricular enlargement with communication between the ventricles and subarachnoid space.

Non-communicating or obstructive hydrocephalus: Obstruction in the ventricular system or at the outlets of fourth ventricle.

Low, normal or intermittently raised pressure hydrocephalus: Chronic hydrocephalus, either communicating or non-communicating, presenting with gait disturbance, slowing of mentation/dementia and urinary incontinence (Hakim's triad).

Arrested hydrocephalus: Apparently stable ventriculomegaly despite a non-functioning shunt and with no apparent neurological sequelae, but deterioration and even death may occur unpredictably.

External hydrocephalus: Self-limiting absorption deficiency of infancy and early childhood with raised pressure, enlarged subarachnoid space and insignificant enlargement of ventricles; the condition usually resolves within 1 year.

CLINICAL MANIFESTATIONS

1. *Infants with mild or severe head enlargement at birth* – who subsequently exhibit progressive hydrocephalus due to congenital malformation.
2. *Infants born with normal head circumference* – who develop abnormally rapid growth of the head; hydrocephalus develops 2 or 3 months later. Due to milder forms of congenital malformations, sequelae of meningitis and birth trauma, particularly intraventricular haemorrhage in the premature.
3. *Heterogenous group* – Infants in whom hydrocephalus has resulted from inflammation and haemorrhage, neoplasm, skull deformities, etc.

Table 46: Causes of hydrocephalus

1. Obstruction to CSF flow within the ventricles:
<i>Congenital:</i>
Aqueduct stenosis, forking or atresia
Dandy-Walker syndrome (atresia of foramina of Luschka and Magendie)
Hind-brain abnormalities, spina bifida
Vein of Galen aneurysm
<i>Space-occupying lesions:</i>
Acquired aqueduct stenosis
Colloid and arachnoid cysts
Thalamic glioma
Intraventricular tumours
Posterior fossa tumours
Tentorial herniation
<i>Ventricular haemorrhage</i>
Prematurity
A-V malformation
2. Defects of flow in subarachnoid space:
(leptomeningeal inflammation)
<i>Infections:</i>
Pyogenic
Tuberculous, fungal
<i>Haemorrhage:</i>
Subarachnoid haemorrhage
Trauma
<i>Meningitis carcinomatosis</i>
<i>Foreign matter</i>
3. Defects of absorption of CSF at the arachnoid granulations:
Congenital deficiency of arachnoid granulations (uncommon).

4. *Normal pressure hydrocephalus* – Skull large, ventricles dilated, pressure normal.

Signs

1. *Enlargement of head* – Speed of enlargement is generally proportional to the elevation of the intracranial pressure. In proportion to the rapid expansion of the head, the face remains small. The downward displacement of the orbital plate pushes the eyeballs portion of the sclera. This together with a marked divergent squint and paralysis of upward gaze gives a very characteristic facial expression (“setting-sun” sign).
2. *Separation of sutures* – and widening and fullness of the anterior fontanelle.

3. *Veins of scalp* – may become prominent as a result of increased drainage of the blood from intracranial structures through the emissary veins to the superficial circulation.
4. *Wasting* – is common with progression of the hydrocephalus.
5. *Cracked pot resonance* – on percussion of the skull.
6. *Physical and mental development* – lag behind and in advanced stages deterioration of the acquired functions takes place. In long lasting and severe hydrocephalus, weakness and spasticity of all extremities eventually occur. Blindness may occur in terminal stages. Corticospinal signs in lower limbs and ataxia may be early signs.
7. *Epileptic manifestations* – commonly occur in one or another stage of the disease.

INVESTIGATIONS

Imaging

1. *Radiography of skull* – seldom required. (a) Evidence of raised intracranial pressure – thinning of skull, separation of sutures, wide fontanelle. (b) Aqueduct stenosis, small size of the posterior fossa and marked expansion of the vault of the skull. (c) Dandy-Walker malformation may be recognised by unduly prominent occipital region and calcification may indicate tumour or toxoplasmosis.
2. *CT scan* – Ventricular enlargement is easily seen and its extent can be assessed, possible site of block, malformations and thinness of cerebral mantle can be judged.
3. *Transfontanelle ultrasonography* – is useful in neonates because it is non-invasive and repeatable.
4. *MRI* – is helpful in complex cases to define multiple congenital lesions and anatomy at the foramen magnum. Dynamic MRI can image the pattern of pulsatile CSF flow.

Intracranial pressure monitoring – Saline-filled catheter or catheter-tipped transducer is inserted into lateral ventricle, brain or subdural space records a pulsatile pressure of 0–10 mm relative to the foramen of Munro when patient is lying flat. As the ventricles enlarge, the mean arterial pressure rises and spontaneous periodic waves become more pronounced.

Quantitative assessment of CSF circulation – Infusion of mock CSF into the ventricles or lumbar sac combined with CSF pressure monitoring enables measurement of outflow resistance, CSF production rate and stiffness of the brain.

Cognitive testing – both before and after shunting is helpful. Cognitive decline is a useful index of true shunt dysfunction in a headache-prone child.

MANAGEMENT

1. *Treatment of cause* – Failing this obstruction to CSF outflow should be relieved. Patients requiring long-term CSF diversion can be treated with shunt or with endoscopic third ventriculostomy.
2. *Endoscopy* – In case of non-communicating hydrocephalus caused by obstruction distal to the third ventricle, an endoscope is inserted into the third ventricle, via a frontal burr hole. The thinned-out floor is visualized and a hole is made through this allowing CSF to drain into the basal cisterns.
3. *Drugs* – Acetazolamide 50–75 mg/kg/day decreases CSF production and in conjunction with corticosteroids or diuretics helps to control hydrocephalus in premature infants until they are well enough to undergo surgery.
4. *Hydrocephalus shunts* – CSF is usually drained from the ventricular system via a ventricular catheter (a valve with reservoir mechanism and distal catheter) into the peritoneal cavity. Lumboperitoneal shunts are used to drain fluid from lumbar subarachnoid space to the peritoneal cavity in some patients with communicating hydrocephalus. Complications—Shunt malfunction, shunt infection, overdrainage causing subdural hematoma, underdrainage, slit ventricles, multilobulated hydrocephaly, seizures, abdominal complications (peritoneal pseudocysts, bowel perforations, hernias).

In some cases of hydrocephalus complicating TB meningitis where insertion of shunt would result in shunt blockage caused by shunt infection, a temporary external ventricular drainage tube (EVD) is placed to drain the CSF for a few days.

22. CEREBRAL PALSY (LITTLE'S DISEASE)

Non-progressive central motor deficit due to prenatal or perinatal causes. Distinct from mental retardation.

CAUSES

1. Perinatal asphyxia (hypoxic-ischemic encephalopathy).
2. Birth injury.
3. Congenital malformations of the brain.
4. Kernicterus.
5. Inborn errors of metabolism.
6. Prenatal infective or vascular insults.

CLINICAL PICTURE

Clinical types:

1. *Spastic CP* – Quadriplegia, hemiplegia, paraplegia or monoplegia. Hyper-excitability, persistence of neonatal reflexes (such as exaggerated Moro's reflex or persistent asymmetric tonic neck reflex), arching of the back, scissoring of the legs, brisk deep jerks, swallowing difficulties and drooling of saliva.
2. *Extrapyramidal CP* – Choreoathetosis or dystonia. Hypotonia in early life, choreoathetosis in later life. Choreoathetosis with weakness seen with kernicterus.
3. *Atonic CP* – (a) Atonic diplegia, characterised by hypotonia, severe mental retardation and brisk tendon reflexes or rarely (b) congenital cerebellar ataxia. Cerebellar signs develop by second year of life. Mental retardation mild.

PREVENTION

Good antenatal and perinatal care. Proper management of premature and jaundiced babies.

MANAGEMENT

Team approach by paediatrician, neurologist, psychologist, physiotherapist, occupation therapist, orthopaedic surgeon, and speech therapist. Positive prenatal approach is helpful. Prognosis will depend upon the extent of brain damage and facilities available. Injection of Botulinum toxin to reduce spasticity. Surgery in carefully selected cases to reduce spasticity.

23. BREATH-HOLDING SPELLS

A conduct disorder in children from age of 6 months to 5 years.

TYPES

Cyanotic - Precipitated by anger or frustration. After a bout of crying, most of the air in the lungs is exhaled but there is no inspiratory effort and the vocal cords which were narrowed during crying, close. Breath is held for a few seconds in expiration and the child turns blue. If hypoxia continues, there is rigidity and opisthotonus, the child may lose consciousness and convulsions may occur. Child recovers consciousness but becomes limp for some time. In some cases if the child is given a painful stimulus it will take another breath and begin a fresh bout of crying and the impending attack may be aborted.

An attack could be aborted by a strong physical stimulus such as a pinch at the onset of the spell. Reassurance to parents about benign nature of the episodes. Purposeful neglect of the child after it recovers.

Acyanotic or *pallid* are not true breath holding spells but a type of brief reflex asystole following unexpected painful stimulus. Child may become rigid and may develop clonic seizures. Attempts to abort an attack by painful stimulus are contraindicated.

24. CHILDHOOD ENURESIS

Bed-wetting by children beyond the age when control of urinary bladder should have been acquired, due to delay in the maturing of physiological reflex bladder control.

Aetiology – More common in boys, first born children, children who have experienced stress in early life, lower social classes.

TYPES

- *Intermittent* – Only occasional dry night.
- *Primary or true* – Child has never had a single dry night (rare over age of 5 years).
- *Secondary or acquired* – Enuresis develops at the age of 5 in a child who has been previously dry at night for at least 12 months.

CAUSES

- *Genetic factors* – A boy with intermittent nocturnal enuresis has 75% chance of having a first degree relative who also wets the bed after age of 5 years.
- *Delay in establishment of bladder control* – due to maturational delay, chronic illness, improper or inadequate training, or small functional bladder capacity.
- *As a symptom of organic illness* –
 - (a) Neurological – Epilepsy, spina bifida, cerebral palsy, nutritional deficiency.
 - (b) Endocrine – Polyuria in diabetes mellitus, diabetes insipidus.
 - (c) Urinary – Pyelonephritis, TB, congenital malformations, calculi, chronic nephritis, ectopic ureter.
 - (d) Genitalia – Balanitis, meatal ulcer, vulvo vaginitis, threadworms.
 - (e) Post-operative anxiety, trauma- induced.
- *As a symptom of psychological ill-health* and without evidence of organic disease.

INVESTIGATIONS

- *Urine* – for glucose, albumin and blood. Microscopy and culture to exclude UTI.
- *Ultrasound or other radiological investigation* – if urinary tract infection or history suggesting anatomical abnormality of urinary tract (e.g. straining on micturition or persistent dribbling of urine).

MANAGEMENT

1. CONFIDENCE AND TRAINING – Aim is to treat the bed-wetter not the bed-wetting. Scolding and punishment should be avoided. Child should empty bladder before going to bed. For some time child may be awakened 2–3 hours after sleep and made to evacuate bladder, and again in the early morning. Restriction of fluid in latter part of day. Bladder capacity training in daytime by holding of urine for progressive increase of time before voiding.
2. CORRECTION OF PHYSICAL DEFECTS and improvement of general health.
3. CONDITION THERAPY –
 - (a) *Dry bed training* – requires skilled therapist and maximum compliance by the family.
 - (b) *Enuresis alarms* – depend on the completion of an electrical circuit when urine is passed and then an alarm goes off. The child then has to get out of bed, switch off the alarm, and go to the toilet before setting up the system again.
Types of alarms – (i) Pad and bell – The sensor pad is a plastic mat imprinted with electric current. (ii) Body-worn alarm – A tiny electrical sensor is attached to the child's thigh or pants and is connected to a minialarm worn on the shoulder or in the pocket of the pyjama jacket.
4. DRUGS – can be used when conditioning therapy is inappropriate, or to achieve dryness quickly, e.g. temporary period during a school trip or holiday.
 - (a) *Antidiuretics* – Desmopressin – given as metered-dose aerosol intranasally, starting with 20 mg last thing at night and increasing to maximum of 40 mg.
 - (b) *Oxybutynin* – 2.5 mg at bed time.
 - (c) *Tricyclic antidepressants* – Imipramine 25 mg at night increased to 50 mg or 75 mg depending on size of the child.

25. DOWN'S SYNDROME (MONGOLISM)

AETIOLOGY

Chromosomal abnormality. Majority born to elderly mothers, have trisomy 21 due to nondisjunction at meiosis due to ageing of the oocyte. A small percentage born to young mothers, have translocation of the chromosomes in the D group with 21.

CLINICAL FEATURES

1. *Mental retardation* – of moderate to severe degree. Pleasant temperament.
2. *Skull* – small, brachycephalic. Excessive skinfolds at back of neck.
3. *Eyes* – Orbits small, mongoloid slant of the eyes. Epicanthic folds. Blepharitis, strabismus, speckling of the iris (Brushfield spots).
4. *Ears* – Small low set. May be deformed.
5. *Tongue* – protruded, fissured (scrotal tongue).
6. *Nose* – short with flattened bridge.
7. *Teeth* – Delayed eruption, protruded lower jaw.
8. *Generalized hypotonia* – causing protuberant abdomen, diastasis recti, and umbilical hernia.
9. *Extremities and phalanges* – short, hands and feet appear broad and square. Fifth finger is short and tends to be incurved due to atretic second phalanx. Wide space between first and second fingers and toes (sandal gap). Single transverse palmar crease.
10. *Bony pelvis* – Broad ilia, smaller acetabular angles and elongated ischia.
11. *Congenital cardiac defects* – most commonly endocardial cushion defects, ASD or VSD.
12. *Genitalia* – poorly developed.
13. *Prone to skin and respiratory infections.*
14. *Others* – Incidence of leukaemia, GI malformations such as duodenal atresia and Hirschsprung's disease, and hypothyroidism higher as compared to general population.

DIAGNOSIS

Diagnosis by karyotyping (trisomy 21). Young mothers also have to be karyotyped to rule out translocation. In nondisjunction recurrence risk in most children less than 1%, with translocation can vary from 10 to 15%.

MANAGEMENT

1. Multidisciplinary approach to mental handicap.
2. No drugs effective.
3. Genetic counselling.
4. Prenatal diagnosis by USG, chorion villus biopsy or amniocentesis. Maternal serum alpha-fetoprotein is lowered considerably if

Table 47: IAP immunization time table 2011

Age (completed weeks/months/years)	Vaccines
Birth	BCG OPVO HepB 1
6 weeks	DTwP1/DTaP1 OPV1*/OPV1 + IPV1 Hib1 HepB2 Rotavirus 1*# PCV 1

*OPV alone if IPV cannot be given

*# Rotavirus vaccine (2/3 doses (depending on the brand) at 4–8 weeks' interval)

** The third dose of Hepatitis B can be given at 6 months

\$ The second dose of MMR vaccine can be given at any time 4–8 weeks after the first dose

\$\$ Varicella (2nd dose may be given any time 3 months after the 1st dose)

Typhoid revaccination every 3 years

& Tdap preferred to Td, followed by repeat Td every 10 years

^ Only females, three doses at 0, 1-2 and 6 months

foetus has Down's syndrome, indication for prenatal testing. Maternal infections known to damage the foetus are – Rubella, cytomegalovirus, HIV, toxoplasmosis, varicella zoster, human parvovirus, herpes simplex, Treponema pallidum.

Table 48: IAP recommended vaccines for adolescents (10 years to 18 years)

Vaccine	Schedule
Tdap/Td&	10 years
HPV^	10 to 12 years

&Tdap preferred to Td, followed by repeat Td every 10 years (Tdap to be used once only)

^ Only females, three doses at 0, 1 or 2 (depending on the vaccine used) and 6 months

Table 49: IAP Recommendations for catch up Immunization in adolescents

Vaccine	Schedule
MMR	2 doses at 4–8 weeks interval@
Hepatitis B	3 doses at 0, 1 and 6 months#
Hepatitis A	2 doses at 0, 6 months (prior check for Anti HAV IgG may be cost effective)##
Typhoid	1 dose every 3 years**
Varicella	2 doses at 4–8 weeks interval

@ one dose if previously vaccinated with one dose

Combination of Hep B and Hep A may be used in 0, 1, 6 schedule

** A minimum interval of 3 years should be observed between 2 doses of typhoid vaccine

Table 50: IAP Recommendations for adolescent Immunization in special circumstances

Vaccine	Age recommended
Influenza vaccine	One dose every year
Japanese encephalitis	Vaccine Catch up to 15 years@
PPSV23 (Pneumococcal) vaccine	2 doses 5 years apart*
Rabies vaccine 0, 3, 7, 14, 28 day	As soon as possible after exposure

@Only in endemic area as catch up;

* Maximum number of doses–Two

26. IMMUNIZATION IN CHILDREN

IMMUNIZATION OF ADOLESCENTS

Adolescence should be considered an appropriate age for catch up immunization as well as for administration of certain vaccines which may not have been available earlier. Preferred age for administration is at 10–12 years but catch up may be done till 18 years. Vaccines to be considered for adolescents if not received earlier include.

PRECAUTIONS AND CONTRAINDICATIONS TO IMMUNIZATION

(a) Antigens should not be given in the presence of severe respiratory or other infections, can be given in presence of minor respiratory or GI infection. (b) Antigens should

Table 51: IAPCPI recommendations for immunization of HIV infected children

Vaccine	Asymptomatic	Symptomatic
BCG	Yes (at birth)	No
DTwP/DTaP/TT/Td/Tdap	Yes as per routine schedule at 6w, 10w, 14w, 18m and 5 years	
Polio vaccines	IPV at 6, 10, 14 weeks, 15–18 months and 5 years If indicated IPV to household contacts If IPV is not affordable, OPV should be given*	
Measles vaccines	Yes, at 9 months	Yes if CD4 count \geq 15%
MMR vaccine	Yes, at 15 m and at 5 y	Yes if CD4 count \geq 15%
Hepatitis B	Yes, at 0, 1 and 6 months	Yes, four doses, double dose, check for seroconversion, regular boosters Hib Yes as per routine schedule at 6w, 10w, 14w and 18m
Pneumococcal vaccines	Yes as per routine schedule at 6w, 10w, (PCV and PPV 23) 14 w and 15 m	
Inactivated Influenza	Yes as per routine schedule beginning vaccine at 6m, revaccination every year	
Rotavirus vaccine	Insufficient data to recommend	
Hepatitis A vaccine	Yes	Yes, check for seroconversion, boosters if needed
Varicella vaccine	Yes, two doses at 4–12 weeks' interval	Yes, if CD4 count \geq 15% two doses at 4-12 weeks' interval
Vi typhoid vaccine	Yes as per routine schedule at 2 y and every 3 years	
HPV vaccine	Yes (females only) as per routine schedule 3 doses at 0, 1–2 and 6 m and at 10 years	

* OPV has been found to be generally safe in HIV infected especially in early stages.

be injected deep subcutaneously or intramuscularly. (c) A history of frequent repeated convulsions with possibility of epilepsy would contraindicate giving of pertussis vaccine in combined prophylaxis, or the child should be given phenobarb 6 mg/kg for 2 days prior and 2 days after giving the vaccine. (d) History of personal or family allergy exemplified by infantile eczema is not a contra-indication

unless the first dose of combined vaccine produced an exacerbation. In such an instance, it is advisable to give the antigens separately; if a further reaction occurs after a particular antigen, its use should be discontinued. (e) Vaccination should not be done in the presence of eczema or skin infection, and the site of vaccination should be covered lightly, if at all.

BCG VACCINATION

BCG vaccine is made from a live attenuated strain of bovine tuberculosis bacilli. A preliminary Mantoux or other tuberculin test should be done to eliminate positive reactors for whom vaccine is contraindicated.

Indications:

1. Tuberculin negative persons at any age. It is quite safe to vaccinate newly-born babies. They react with as high a percentage of positive results as adults.
2. Non-reactors in homes where there are tuberculous patients.
3. Persons constantly exposed to infection such as medical students, nurses, hospital and sanatoria personnel.
4. All Mantoux-negative young adults.

Method – Intradermal injection of 0.1 mL of freeze-dried BCG vaccine with disposable or heat-sterilised syringe and needle or dermojet usually into the skin over the left deltoid. About a week after the injection, the local reaction starts as a small red papule which develops into a vesicle and breaks down into a small sore over the next few weeks. Use of the vaccine causes long-lasting or permanent conversion of the tuberculin reaction from negative to positive in almost all cases.

Ill-effects – rare. 1. Occurrence of abnormally large sore or local abscess which can be treated by antibiotics. Disseminated tuberculosis (very rare) often in infants and children with pre-existing immunological defects. 2. Large axillary lymphadenopathy. Can be excised, given a trial with 10 days of Erythromycin; if still enlarging antituberculous treatment.

OTHER VACCINES

Cholera

Oral cholera vaccines – Efficient method of eliciting intestinal mucosal immune response.

1. Killed VC vaccine with CTB subunit
2. Killed VC vaccine without CTB (subunit)
3. Reformulated killed VC vaccine without CTB subunit (Shanchol) contains both 01 and 0139 serotypes.

It is administered as two-dose regimen and does not require an oral buffer. It also gives herd protection.

Rotavirus Vaccine

Rotavirus is a major cause of diarrhoea related morbidity and mortality in children. Rates are similar in both the developed and developing world and in children of all socio-economic status.

Generally two live oral vaccines are licensed and marketed worldwide.

1. Human monovalent live vaccine derived from human Rotavirus strain 89.12 grown in vero cells and contain G1P1 (8) strain administered orally in 2 dose scheduled to infants of approximately 2–6 months of age.
2. Human Bovine pentavalent live vaccine is a Human Bovine reassortant vaccine and consists of five reassortants between the bovine WC3 strain and human G1, G2, G3, G4 and P1A (8) rotavirus strains grown in vero cells and administered orally in a three dose schedule at 2, 4 and 6 months. Both vaccines have shown excellent protective efficacy against rotavirus gastroenteritis.

HPV Vaccine for Protection against Cervical Cancer

There are 2 types of vaccines

1. Bivalent vaccine is a mixture of L1 proteins of HPV serotypes 16 and 18
 2. Quadrivalent vaccine is a mixture of L1 proteins of HPV serotypes 16, 18, 6 and 11
- Both are equally safe. Should be stored at 2 to 8°C
Dose is 0.5 ml intramuscular in deltoid
Bivalent vaccine is given 0, 1 and 6 months
Quadrivalent vaccine is given 0, 2 and 6 months
Vaccine is advocated from 10 years to 45 years in all females.

ADDENDUM

Pointers to Organic Cause

- Pain – (a) Localized in non-paraumbilical region. (b) Referred pain. (c) Sudden onset of severe pain. (d) Pain awakens child from sleep.
- High fever
- Dysuria
- Jaundice
- Anorexia/weight loss
- Abnormal physical findings
- Reduced activity of the child

Table 52: Acute abdominal pain in children

Medical	Surgical
Child < 2 years	
• Gastroenteritis	• Volvulus
• Lower lobe pneumonia	• Malrotation
• Acute pyelonephritis	• Intussusception
• Hepatitis	• Incarcerated inguinal hernia
• Subacute bacterial peritonitis	• Appendicitis
• Mesenteric adenitis	• Necrotizing enterocolitis
Child > 2 years	
• Acute non-specific pain	• Appendicitis
• Gallstones	• Intestinal obstruction
• Inflammatory bowel disease	• Meckle's diverticulitis
• Pancreatitis	• Peritonitis
• Urinary tract infection	• Cholecystitis
• Mesenteric lymphadenitis	• Incarcerated inguinal
• Henoch-Schonlein purpura	• Hernia
• Lead-poisoning	• Trauma-induced
• Primary peritonitis	• Splenic rupture/hematoma
<i>Chronic or recurrent</i>	
< 2 years	> 2 years
• Colic	• Functional (non-organic)
• Malabsorption	• Giardiasis
• Milk allergy	• Constipation
• Rotational defects	• Intra-abdominal abscess
• Hirschsprung's disease	• Lead-poisoning
• Oesophagitis	• Abdominal migraine/epilepsy
	• Urolithiasis

Investigations

History

- Pain – Time of onset, location, radiation, character
- Other symptoms – Anorexia, nausea, vomiting, diarrhoea
- Systemic symptoms
- Family history

Table 53: Normal average BP

Age	Systolic	Diastolic
1–3 months	75 ± 5	50 ± 5
4–12 months	84 ± 5	65 ± 5
1–8 years	95 ± 5	65 ± 5
9–14 years	100 ± 5	65 ± 5

Examination

- General: Activity of child, ill appearance, lethargy, rolling in bed in discomfort.
- Abdomen: Diastasis, tenderness, organomegaly, abdominal mass, bowel sounds (paralytic ileus), hernial sites.
- Systemic examination

Normal BP in Children**Differentiation between breath holding spells and epileptic seizures****Breath-holding spells**

Precipitating factors

Blue at beginning

Crying precedes episode

No tonic/clonic phase

Duration 1 min.

Seizures

Usually no ppt. factors in such as anger or fright

Blue at late stage

No crying before seizures

Tonic/clonic phase of convulsions

Can last for any duration

Causes of chronic cough

- Bronchial asthma
- Recurrent normal infections
- Prolonged infection
- Aspiration
- Habitual cough
- Cigarette smoke (passive action)
- Intra-bronchial foreign body
- Suppurative lung disease
- Congenital abnormalities

Serous meningitis

A few children with suspected TB meningitis and CSF pleocytosis recover without any treatment, an early meningitis undergoing natural cure is an immune competent child.

Characteristics of diarrhoea caused by rotavirus

1. Indistinguishable clinically from other causes of infantile diarrhoea.
2. Short incubation period (2–3 days).
3. Abrupt onset – Vomiting often precedes diarrhoea.
4. Illness usually lasts about one week, but usually improves within 2–3 days.
5. Temporary neutropenia may occur.
6. The illness may be very severe.
7. Hospital-acquired infection is common.

Maternal infections known to damage the foetus

Rubella

Cytomegalovirus

Toxoplasmosis

HIV

Varicella zoster

Human parvovirus

Treponema pallidum

Herpes simplex

Foetal nuchal translucency

In the foetus, fluid collecting behind the neck can be detected as nuchal translucency by ultrasound scanning, and it can be measured. The more the fluid has accumulated, the greater the risk of an abnormality being present. Chromosomal abnormalities, e.g. Down's syndrome can cause fluid accumulation.

VACTERL association

It is an association of birth defects:

- Vertebral anomalies
- Anal atresia
- Cardiac defect, most often ASD
- Tracheoesophageal fistula
- Renal (kidney) abnormalities
- Limb abnormalities (most often radial aplasia)

Psychiatry

1. INTRODUCTION

Psychiatry, also known as Psychological Medicine, is that branch of medicine which deals with the diagnosis, treatment and prevention of mental disorders.

Psychology is the science which studies the structure and functions of the mind.

Mind: According to psychoanalytic theory, the human mind consists of two parts: (a) The Conscious or the strata of mind within one's awareness; which forms only a small portion. (b) The Preconscious or the strata of mind between the conscious and the unconscious that serves as a boundary or water-shed between the two helps to mediate information between these two parts.

Psychoanalytic theory postulates that an individual's mind comprises of three components, namely - (a) Id - contains instinctual and repressed impulses and is unconscious. (b) Ego - The reality based part the mind that regulates and channelizes instinctual desires and impulses; this component is partly conscious and partly unconscious. (c) Superego - decider of which instinctual impulse to be permitted an outlet, "rewarding and punishing" aspect of self, produces guilt when disobeyed. This component is partly conscious and partly unconscious.

Personality: *Definition:* Unique characteristics of an individual which differentiate one person from another. Depending on the dominant personality traits various kinds of personalities can be described.

1. *Aggressive* - dominating and assertive.
2. *Anxious* - worrying over trivial and minor things, highly strung, irritable and panicky.
3. *Hypomanic* - always happy and cheerful, happy-go-lucky type, witty and jovial, extroverted.
4. *Histrionic* - exhibitionistic and dramatizing, attention seeking, immature, highly suggestible.
5. *Avoidant* - shunning responsibilities, diffident.
6. *Melancholic* - depressed and sad, pessimistic outlook and philosophy.

7. *Obsessive* - rigid in habits and outlook, perfectionist, conscientious, fond of cleanliness, regularity and punctuality.
8. *Paranoid* - extremely suspicious.
9. *Psychopathic or antisocial* - antisocial traits like lying, stealing, etc., nonconformist; not observing the codes of ethics, culture, etc.; very little feelings of shame and guilt, cannot evolve stable emotional relationship.
10. *Schizoid* - shy, reserved, asocial, poor mixers, have very few friends, introverted.
11. *Dependant* - Unduly compliant to wishes of others, fears abandonment, allowing others to make decisions for self.

Knowledge of individual's personality helps in - (a) Understanding behaviour of normal persons. (b) Diagnosing the patient's psychological problems. (c) Predicting the response to treatment. (d) Rehabilitating the patient after recovery from illness.

Causes of mental disorders: The development of psychiatric disorders depends upon an interaction between predisposing and precipitating factors.

Predisposing factors: These determine an individual's vulnerability to develop psychiatric disorders. Many of these operate from early life. Some of the predisposing factors are: (a) *Biological factors* - heredity, constitution, metabolic and biochemical abnormalities, physical defects and illnesses.

(b) *Psycho-social factors* - personality traits, faulty parent-child relationships, psychologically traumatic experiences during early years, socioeconomic conditions, adverse life events.

Precipitating factors: These are events that occur before the onset of a psychiatric disorder and appear to have induced its onset. These could be: (i) *Physical* - Puberty, pregnancy, childbirth, menopause, systemic disease, drugs, etc. (ii) *Psychological* - Disturbed interpersonal relationships, marital disharmony, financial difficulties, occupational maladjustments, etc. (iii) *Environmental* - Calamities: War, famine, earthquakes, cyclones, etc.

(iv) *Sociocultural factors* – Sexual discrimination, racial discrimination, migration, etc.

Dynamics of mental illnesses – The predisposing factors determine an individual's susceptibility to mental illness. Individuals who are less susceptible can bear a greater severity of stress. Their capacity to handle tension (i.e. the emotional counterpart of unresolved conflicts or dilemmas) is high and their threshold to tolerate stress is high. Individuals who have a low threshold to tolerate stress are more susceptible to the development of mental disorders. Any stress – Physical, physiological and/ or psychological – acting as “the last straw on the camel's back”, exacerbates this tension and can result in the onset of a psychiatric disorder which may manifest as disturbances in physiological, psychological and/or social functioning.

2. DIAGNOSIS AND INVESTIGATION OF A PSYCHIATRIC PATIENT

The diagnosis of a mental disorder is arrived at by carrying out the following:

1. History:
 - a. Chief complaints with their origin, duration and progress.
 - b. Associated symptoms related to physical or psychological dysfunction (disturbances in sleep, appetite, bowel functions, etc.).
 - c. Past history of similar illness or any other mental and/or major physical illness.
 - d. Family history of mental disorders.
 - e. Personal history – regarding information about stressful situations during childhood, adolescence, school and college life; occupational, social, marital and psychological difficulties.
 - f. Clinical assessment of dominant personality traits. (Premorbid personality)
2. Psychiatric examination – to detect disturbances in thinking, emotion, behavior, orientation, perception, memory, intelligence, insight and judgment.
3. Physical examination.
4. Investigations –
 - a. *Laboratory investigations* – Blood, urine, stool examination, radiological studies, ECG, liver and kidney function tests, etc. to rule out physical disorders.
 - b. *Brain imaging* – CT, MRI scan, SPECT, MR angiography. EEG, Brain Electrical Activity mapping (BEAM), PET.

c. *Special investigations* –

- *Social or environmental investigations* done by the Psychiatric Social Worker through interviews with the patient, relatives, friends and employers, held either in the hospital or by paying a visit to the home or the place of work. The aim is to study the milieu or the environment in which the patient has lived before becoming sick. An attempt is made to understand the role of various factors like cultural and religious background, family and social relationship, childhood experiences, school and college life, occupational adjustments, financial problems, marital and sexual difficulties, etc. in the development of the individual's personality and his illness.
- *Psychological investigations* done by the clinical psychologist with the help of standardised tests.

TYPES OF PSYCHOLOGICAL TESTS

1. *Intelligence tests* – (Verbal and performance tests) to assess intelligence. The commonly used tests are Kamat-Binet test, Bhatia's test, Goddard form board, Raven's progressive matrices, Wechsler's Intelligence Tests for adults and children.
2. *Personality tests* – to assess the pre-sickness personality traits, the psychological conflicts and the nature of personality disturbance. Commonly used tests are Rorschach test, Thematic Apperception test, Minnesota Multiphasic Personality Inventory and Eysenck Personality Inventory.
3. *Aptitude tests* – to find out the natural likes and dislikes of the patient and his proficiency in any particular field. This information helps in vocational and educational guidance and rehabilitation of the patient, e.g. DAT (Differential Aptitude Test).
4. *Neuropsychological tests* – to assess an individual's higher mental functions. Tests used for this purpose include Wechsler's Memory Scale, Bender-Gestalt visual motor co-ordination test, etc.
 - Observations by an Occupational Therapist are sometimes necessary to get an objective evaluation of the (a) patient's mental state, particularly behaviour, and (b) progress in the recovery of the patient undergoing treatment.
 - Observations by a psychiatric nurse on the patient's ward behaviour.

Rating scales – to quantify the psychopathology observed, e.g. Brief Psychiatric Rating Scale (BPRS), Scale for assessment of negative symptoms (SANS), Scale for assessment of positive symptoms (SAPS), Hamilton Depression Rating Scale (HDRS).

3. DELIRIUM, DEMENTIA, AMNESTIC AND OTHER COGNITIVE DISORDERS

DELIRIUM

Delirium is a transient condition of disordered consciousness with global impairment of cognitive function. It is a syndrome and not a disease with most of its causes lying outside the CNS. It is seen in 10–30% of patients in medical settings and may be seen more in intensive care cases.

Clinical Features

Delirium may develop acutely or subacutely, and normally lasts less than 7 days. It is characterized by a fluctuating level of consciousness ranging from extreme drowsiness to intense arousal, with motor restlessness, disorientation and disorders of perception. Patients are often frightened and irritable, with disturbed thinking and memory, as well as illusions; they may also experience vivid visual and, less often, auditory hallucinations. There is normally associated diffuse slowing of EEG, except in delirium tremens when increased fast activity may be observed.

Causes

Causes of delirium are listed in [Table 1](#).

Management

- Diagnosis and treatment of the cause. Sometimes the cause of delirium is known when the patient presents (e.g. withdrawal from alcohol, or with rapidly deteriorating hepatic function). However if there is no known cause, since the patient's ability to give an accurate history is limited, an account from someone who knows the patient should include inquiries about presence of any known illness, use of any prescribed or illicit drugs and an account of the events at the time the current symptoms developed. Physical examina-

Table 1: Causes of delirium

• Effects of exogenous toxins (e.g. alcohol)
• Infection
• Metabolic effects of renal or hepatic failure
• Hypoxia
• Hypoglycemia
• Drugs – Antiparkinsonian medications, overdose of psychotropic drugs
• Electrolyte disturbances
• Stroke, epilepsy, demyelinating diseases, brain tumors, head injury

tion and investigation must be guided by the knowledge that delirium may be developed as a result of many different conditions. Knowing the cause is very important as delirium may be reversed once the cause is ameliorated.

- Symptoms of delirium tend to be worse at night and may be minimized by measures such as a calm, constant environment with some light still present at night. Medical management is principally treatment of the underlying cause, however pharmacological treatment may be required to control some of the acute symptoms (e.g. neuroleptics to limit excessive restlessness and agitation).

DEMENTIA

Dementia is chronic brain disorder in which there is progressive decline in acquired intellect, behaviour and personality.

Causes

Causes of dementia are listed in [Table 2](#).

Normal pressure hydrocephalus – A clinically useful division of dementia-producing pathological status is made into two types:

- Progressive or fixed*, or irreversible such as Alzheimer's disease
- Arrestable or reversible*, such as chronic subdural hematoma or myxoedema.

Investigations in a Case of Dementia

Laboratory tests

- Complete blood count
- Biochemistry profile: Renal and hepatic functions, detect presence of diabetes, and electrolyte abnormalities
- Serum B₁₂ levels and folate
- Thyroid stimulating hormone
- Serological tests for syphilis
- HIV testing

Brain imaging

CT scan and MRI – demonstrated large ventricular enlargement, critical sulcal widening and reduced temporal lobe volumes in a significant number of patients with AD.

SPECT – Patients who have bilateral hypoperfusion defect in temporoparietal lobes are more likely to have AD.

Alzheimer's disease is a dementing illness characterised histologically by intracellular neurofibrillary tangles and intracellular amyloid plaques accompanied by neuronal cell loss in certain areas of the brain. There is cerebral atrophy with flattened cortical sulci and enlarged ventricles.

Table 2: Causes of dementia

Parenchymatous brain disease
• Alzheimer's disease (AD)
• Pick's disease
• Huntington's chorea
• Progressive supranuclear palsy
• Lewy body dementia
Vascular causes
• Multi-infarct dementia
• Subcortical vascular dementia
Toxins
• Drugs
• Alcohol
• Analgesics
• Anticonvulsants
• Psychotropic drugs
Infections
• Viral encephalitis
• Neurosyphilis
• Cryptococcus
• Creutzfeldt-Jakob disease
• HIV infection
• Subacute sclerosing panencephalitis
Metabolic
• Chronic hepatic encephalopathy
• Uremia
• Dialysis dementia
• Wilson's disease
Endocrine
• Thyroid, parathyroid, pituitary, adrenal dysfunction
Deficiency
• Pernicious anemia
• Pellagra
• Folic acid and B ¹² deficiency
• Thiamine deficiency
Neoplastic: Brain tumors and other intracranial space occupying lesions
Traumatic
Subdural hematoma, head injury

Aetiology

Age – After 65 years of age, the incidence approximately doubles for every 5-year increase in age; at least until age 90 years. The incidence is similar in men and women but the prevalence is greater in women, reflecting their greater longevity.

Genetics – The risk is about three-fold greater in the first degree relatives of patients with AD. A number of mutations to the early form of AD (before age of 65, presenile AD) have been described in three genes (amyloid precursor protein [APP], presenilin-1 and presenilin-2).

In AD developing after 65, evidence suggests that presence of one copy of the *ApoE E₄* is associated with a three-fold increased risk of AD, and two copies with a nine-fold increased risk.

Pathogenesis

Plaques are relatively large extracellular structures known as amyloid or amyloid precursor protein (APP). It is a normal protein that plays an essential role in the growth and maintenance of neurons. But in AD, it accumulates abnormally in the brain and interferes with normal brain cell functioning.

Neurofibrillary tangles – Tangles are made of neuronal proteins known as tau proteins, play an essential structural role in holding neurons together. In AD, the proteins break loose from the neurons and form twisted tangles. Findings that tau is heavily phosphorylated and that microtubules are lost in AD have led to a search for regulatory mechanisms of tau phosphorylation as possible cause.

Chemical – Disturbances in cholinergic abnormalities are seen with depletion of acetylcholine as transmitter. Aluminium toxicity is another hypothesis. A gene has been located on chromosome 21.

Clinical Features

Cognitive symptoms – Memory loss is the most common, and usually the presenting complaint – Patients have difficulty learning and retaining new information. Later in the disease, remote memories are also affected. Other cognitive defects include anomia, aphasia, apraxia, agnosia and executive planning.

Cognitive deficits relate more clearly to disease progression leading to use of cognitive scales such as Mini-Mental State Examination or Clock Draw Test.

Non-cognitive symptoms – A wide range can occur including disorders of thought content (delusions of theft, infidelity and abandonment, persecutory ideation), disorders of perception (auditory, visual and other hallucinations) and misidentification.

Disorders of affect and behaviour – include depressive symptoms, hypomania, aggression, wandering, agitation, stereotypes, hypersexuality, hypermorality and hyperphagia.

Diagnostic Criteria for Alzheimer's Disease

Probable Alzheimer's disease

- Dementia established by clinical examination and documented by Mini-Mental State Examination or other standard screening test.
- Deficits in two or more areas of cognition.
- Progressive worsening of memory and other cognitive functions.
- No disturbance of consciousness.
- Onset at 40–90 years.
- Absence of systemic disorders or other brain diseases that could account for the progressive deficit memory and cognition.

Possible Alzheimer's disease

- Onset, presentation or clinical course different from that above, but patient has no other disorder sufficient to cause dementia.
- Patient has a systemic or brain disorder sufficient to produce dementia, but this is not considered to be the cause of dementia.

Recognition of Alzheimer's disease

- Loss of memory
- The person might forget what he/she was doing 5 minutes ago and repeat the same thing several times.
- Forgetting words while communicating or finding difficulty in naming objects such as a flower or a dog.
- Difficulty in carrying out daily activities such as dressing, cooking and washing, how to use a knife, open the door, etc.
- Inability to carry out movements despite muscle power and coordination, e.g. tying shoe laces, turning a tap on, fastening buttons or switching on a TV.
- Difficulty in speaking and understanding spoken language. Using language which is difficult for others to understand.
- Inability to recognize people.
- Using a fork instead of a spoon and a knife instead of a pencil
- Personality change. Aggressive and ill-mannered behaviour.
- Frequent mood changes.
- Wandering during day and night, inability to identify time and space.
- Physical change: Weight loss can occur as a result of the person forgetting to chew or swallow.

Management

Cognitive symptoms

1. Cholinesterase inhibitors

Donepezil: Reversible long-acting selective piperidine inhibitor of acetylcholinesterase (AChE). Not an inhibitor for butyrylcholinesterase (BuChE). Dose - Initial 5 mg o.d. increased if necessary to 10 mg after 4–6 weeks. Pro-cholinergic side effects.

Rivastigmine - Carbamate which is pseudo-irreversible and intermediate acting. Selective inhibitor for AChE over BuChE but also for AChE in cortex and hippocampus which are most affected in AD. Dose - 1.5 mg b.d. initially, can be increased to 6 mg b.d. over 4–6 weeks and then can be increased to 12 mg b.d. depending on clinical response. Side effects - Nausea, vomiting, diarrhoea, headache, dizziness, abdominal pain, fatigue, malaise, anxiety and agitation.

Galantamine - Dual mechanism of action - Cholinesterase inhibitor with direct nicotine action causing AChE release. Dose - Initial 4 mg b.d. for 4 weeks, then 8 mg b.d. for at least 4 weeks and then can be increased to 12 mg b.d. depending on clinical response. Side effects - Nausea, vomiting, diarrhoea. Contraindicated in patients with hepatic, renal impairment.

2. **Memantine hydrochloride** - Acts by attaching to NMDA receptors in the brain and regulating activity of glutamate, helping to ensure that the right amount of glutamate is available by allowing calcium to flow in the nerve cell for the brain to process, store and retrieve information, resulting in learning and memory. Can be given in combination with donepezil for maximum benefit. Dose - 1st week 5 mg o.d., 2nd week 5 mg b.d., 3rd week 10 mg morning, 5 mg evening, 4th week 10 mg b.d. Side effects - Dizziness, confusion, headache, constipation.

Non-cognitive symptoms: Non-pharmacological treatment, particularly if symptoms not severe. (a) Assessment of clear precipitants (e.g. suboptimal prompting, personal care or toileting), social interaction, activity, exercise. (b) Use of specific drugs is based on psychiatric treatment in younger patients and avoidance of drugs with marked anticholinergic properties.

Depressive symptoms: Non-tricyclic antidepressants (e.g. selective serotonin re-uptake inhibitors, trazodone, escitalopram).

Psychotic symptoms: Atypical antipsychotics (e.g. risperidone, olanzapine).

Aggressive symptoms: Atypical antipsychotics, non-tricyclic antidepressants or anticonvulsants (e.g. carbamazepine, valproate).

Agitated behaviours: Atypical antipsychotics, non-tricyclic antidepressants or, in severe cases, short-acting benzodiazepines.

ORGANIC AMNESTIC SYNDROME

Clinical features: Memory impairment due to organic cause, consciousness intact and unlike dementia, no disturbance of attention or of global intellectual function, abstract thinking or personality. Impairment of memory is both for recent or long-term memory. Immediate memory is not disturbed.

Diagnosis (ICD-10)

- Recent memory impairment; anterograde and retrograde amnesia
- No impairment of immediate retention and recall, attention, consciousness and global intellectual functioning
- Historical or objective evidence of brain disease or injury (especially with bilateral involvement of diencephalic and medial temporal structures).

Transient global amnesia is a syndrome with abrupt onset with loss of memory probably due to transient cerebral ischemia involving posterior cerebral circulation.

Causes:

- Thiamine deficiency most commonly due to chronic alcoholism (Wernicke-Korsakoff syndrome)
- Lesion involving inner core of limbic system bilaterally, e.g. head injury, hypoxia, bilateral posterior cerebral artery infarction, herpes simplex encephalitis, neoplasm in region of 3rd ventricle, bilateral temporal lobectomy.

Management – Supportive care and treatment of causative condition.

COGNITION AND COGNITIVE TESTING

Cognition is the acquisition and manipulation of knowledge and is a cardinal function of the human brain. Cognitive function can be assessed using a problem-oriented approach (e.g. specific language tasks in suspected aphasia), or a non-problem oriented number of screening tests. Ideally, both methods should be used to assess cognitive disorders.

Non-problem oriented screening has the advantage of providing a numerical score that allows comparison with other patients and monitoring of progress. The Folstein Mini-Mental state examination is the most common

bedside cognitive test (Table 3). It gives a score out of 30; 24 or less is generally considered abnormal and is highly suggestive of a cognitive disorder.

Table 3: Folstein Mini-Mental state examination

Orientation	Maximum score
• Can you tell me today's date, month and year? (accept date if correct to within 2 days)	5
• Which day of the week is it today?	
• Can you also tell me which season it is?	
• What city/town are we in?	5
• What county and country?	
• What building are we in, and on what floor?	
Anterograde memory	
• I would like you to remember three objects (name three common objects, e.g. ball, car, man)	3
• Can you repeat the words I said? (score 1 for each word, repeat up to six trials until all three are remembered, record number of trials needed)	
Attention and calculation	
• Starting with 100, keep subtracting 7 (stop after 5 answers - 93, 86, 79, 72, 65; do not penalize for sequential errors - e.g. 92, 85, 78, 71, 64 scores 4) or Spell word backwards ('drlow' scores 4, 'dw' scores 2)	5
Recall	
• What were the three words I asked you to say earlier? (omit this test if the patient failed to remember all three objects during the registration test)	3
Language	
Naming	
• Name these objects (show a watch, show a pencil)	2
Repeating	
• Repeat the following: "No ifs, ands or buts"	1
Repeating	
• Read this sentence and do what it says (show card or write 'close your eyes')	1
Writing	
• Now can you write a short sentence for me? (it must contain a subject, verb and object)	1
Three-stage command	
• Can you take this piece of paper in your left (or right) hand, fold it in half, and put it on the floor?	3
Visuospatial	
• Can you copy this drawing? (both pentagons must have five sides and must be interlocked; do not penalize for poor artistic quality)	1
Total score	30

Problem-oriented Screening

History – Much information can be gained from spontaneous conversation with the patient. Non-fluent, effortful speech punctuated by frequent pauses may suggest a Broca's-type aphasia. If fluent but vacuous and circumlocutive as in Wernicke's aphasia or the fluent anomia accompanying Alzheimer's disease.

Episodic memory can be anterograde (acquisition of new memories) or retrograde. It is useful to recount their own medical and social history, including dates and locations of home, schooling, employers, marriages and births of children.

Orientation and attention – Recent onset of severe disorientation (details of time, place and person) is typical of metabolic encephalopathy and examiner should check for asterix ('metabolic flap').

Digital span is a simple assessment of attention; normal individuals have a forward span of at least six digits, and reverse span of one or two fewer. Digits must be presented individually, by reading the string to be repeated at a rate of one digit per second.

Ability to preserve at a given task is another means of assessing attention. Patient is asked to recite the months of the year in reverse order or to copy a design.

Language Dysfunction is an early feature of AD that manifests particularly in naming tasks. This results in circumlocutive language, e.g. when shown a drawing of a kite, a patient may reply: 'that's a thing that flies'. Wernicke's and Broca's aphasia are seen after stroke.

Memory: Long-term memory may be divided into personal recollections (episodic memory) and shared knowledge of the world (semantic memory). Testing semantic memory, in terms of knowledge of famous people and events. Breakdown in semantic memory also manifests as an inability to name objects or drawings, and to make broad, superordinate responses (e.g. 'animal' for 'elephant').

Knowledge of recent news events (after disease onset) provides an insight into retrograde memory function. Three trials of a name and address followed by a 5-minute recall condition also assesses efficiency of registration. Increased forgetting after a 5-minute delay is highly suggestive of amnesic syndromes (e.g. AD).

Visuospatial – Hemispatial neglect is demonstrated by 'sensory extinction or clock-drawing' and is usually a feature of non-dominant parietal lesions.

Executive function concerns high-order brain function (e.g. problem solving, reasoning, mental abstraction) that

rely on the dorsolateral prefrontal lobes. Frontal lobe disorders are also associated with impulsivity and failure to persevere with tasks.

Tests – Letter fluency test – Patients are given 1 minute to produce as many words as they can beginning with a single letter. Normal individuals usually produce 15 or more words. Patients with disorders of executive function struggle to produce many words.

'Go-on-go' test assesses impulsivity. Patient is asked to tap the table once if the examiner does so, but not at all if the examiner taps twice. Patients with frontal pathology are often unable to stop themselves tapping under both conditions.

4. PSYCHOSIS

Psychosis is a mental disorder in which a person's mental capacity, emotional responsivity, capacity to recognise reality and to communicate and relate to others is sufficiently impaired so as to interfere with his or her ability to deal with the ordinary demands of life.

TYPES OF PSYCHOTIC DISORDERS

See Table 4.

- I. *Organic psychosis* (Organic brain disorders).
- II. *Functional psychosis*:
 1. Schizophrenia
 2. Schizophreniform disorder
 3. Brief psychotic disorder
 4. Schizoaffective disorder
 5. Delusional disorders

ORGANIC PSYCHOSIS

Clinical Manifestations

Symptoms of organic brain disorders can be divided into:

1. *Mandatory or essential symptoms* which are seen in every case of organic psychosis.
2. *Obligatory or accessory symptoms*, which are dependent on certain factors peculiar to the individual patient, i.e. his/her personality, emotional conflicts and stresses, environmental situation and interpersonal relationships.

Mandatory Symptoms

1. *Impairment of orientation in time, place and/or person.*
2. *Impairment of memory* – Memory for recent events is impaired first, while memory for remote events may be unaffected until an advanced stage of the disease process.

Table 4: Differences between organic and functional psychosis

Organic	Functional
<ul style="list-style-type: none"> Caused by or associated with impairment of brain tissue function; evidence for systemic diseases involving brain, liver, kidney, endocrine glands, etc. present. 	<ul style="list-style-type: none"> Caused usually by psychological factors. No clearly systemic cause or structural change in brain or defined other viscera.
<ul style="list-style-type: none"> Disturbances of consciousness common. 	<ul style="list-style-type: none"> Disturbances of consciousness are rare.
<ul style="list-style-type: none"> Disturbances of orientation, memory and intelligence present. 	<ul style="list-style-type: none"> Disturbances of orientation, memory and intelligence absent. (Pseudo disturbances which arise because of patient's non-cooperation and lack of attention or interest may be present).
<ul style="list-style-type: none"> Disturbances of perception, viz. hallucinations are of visual variety. 	<ul style="list-style-type: none"> Disturbances of perception, viz. hallucinations are usually of auditory variety.
<ul style="list-style-type: none"> Disturbances of emotions are usually of the "labile" type, i.e. patient fails to hold back emotional expressions – "emotional incontinence". 	<ul style="list-style-type: none"> Emotional incontinence is rare.
<ul style="list-style-type: none"> Confabulation common. 	<ul style="list-style-type: none"> Confabulation rare.
<ul style="list-style-type: none"> Physical examination of the patient reveals clinical features of systemic diseases. 	<ul style="list-style-type: none"> Physical examination of the patient usually reveals no abnormality which can explain the mental symptoms.
<ul style="list-style-type: none"> Psychological tests like Bender-Gestalt test positive. Marked difference between verbal and non-verbal tests of intelligence. 	<ul style="list-style-type: none"> Bender-Gestalt test negative. No marked difference between verbal and non-verbal tests of intelligence.
<ul style="list-style-type: none"> Laboratory and radiological investigations as well as electroencephalography help in determining the etiological factors responsible for the psychosis. 	<ul style="list-style-type: none"> Laboratory and radiological investigations as well as electroencephalogram reveal no specific abnormality.

- 3. Impairment of intellectual functions** – A variety of intellectual functions may be disturbed, e.g. calculation, comprehension, general fund of information, ability to learn new tasks and ability to understand the meaning of verbal language (vocabulary).
- 4. Impairment of consciousness** of varying degree, ranging from stupor, clouding of consciousness to coma.
- 5. Altered emotionality-emotional lability**, i.e. patient shifts rapidly from one emotion to another or he may lose contact over his emotions – emotional incontinence.

Obligatory or accessory symptoms – Anxiety, depression, psychotic symptoms, avoidance of situations, denial of cognitive defects, jocularity, confabulation, circumstantiality, excessive orderliness.

Investigations

- 1. Laboratory** – Haematological, bio-chemical, serological tests, mainly to confirm clinical diagnosis of systemic disease.
- 2. Radiological** – X-ray studies, isotope scanning, CT scan, angiography, MRI.
- 3. Others** – EEG, CSF analysis.
- 4. Neuropsychological tests** – to assess higher mental functions – Wisconsin card sorting test, Bender-Gestalt visual motor-coordination test; Wechsler memory scale and intelligence tests. In the latter the score on performance or non-verbal sub-tests is lower than score on verbal sub-tests by at least 15 points.

Types of Organic Brain Disorders

Acute: Characterised by: (a) Sudden onset with rapid development of impairment of orientation, memory, intellectual functions, judgment and affect. (b) Delirium, stupor or coma may be present. (c) It is caused by temporary, reversible and diffuse disturbance of brain tissue function. (d) Patient may recover without any residual defect, or may progress to the chronic type. The clinical course usually progresses over months or years and the syndrome may end with death.

Chronic: Characteristics are: (a) Onset is usually insidious. (b) Gradual deterioration of higher mental functions. (c) It is caused by an irreversible, permanent and diffuse alteration of brain tissue function. (d) The clinical course usually progresses over months or years and the syndrome may end with death. Although the causative factor can be identified and eliminated at times, some permanent alteration in higher mental functions may remain.

2. FUNCTIONAL PSYCHOSIS

A. Schizophrenia

Kraepelin in 1896 recognised this form of illness and coined the term "Dementia Praecox" (premature deterioration of mental faculties). Bleuler in 1911 introduced the term schizophrenia (splitting of mind) to identify the same illness.

Histopathological studies of the brains of patients of schizophrenia have revealed cytoarchitectural changes consistent with impairment of neurodevelopment at an

early age. Minor physical anomalies (e.g. malformed ears, hands or palate), representing alterations in ectodermal development as a result of early neuronal deviance are also more common in schizophrenia.

Risk Factors

Genetic factors – Lifetime risk of developing schizophrenia rises from less than 1% in the general population to about 10% in first-degree relatives of patients with the disease, and up to 48% in the children of two schizophrenic patients. Risk of schizoaffective disorder, schizotypal personality disorder and affective psychosis is also greater in relatives of schizophrenics. If one parent has it then the child has 16% chance.

Early environmental factors – Obstetric complications appear to be important in mothers of schizophrenics (e.g. during pregnancy, pre-eclampsia, antepartum hemorrhage), and difficulties during labour (e.g. protracted labour, asphyxia, low birth weight) than normal controls and patients with other psychiatric disorders. Epidemiological studies have found an association between maternal exposure to influenza epidemics in the second trimester and increased rate of schizophrenia in offspring.

Precipitating factors – The first psychotic breakdown often follows an adverse life event, or drug abuse and dependence.

Neurochemistry – Dopaminergic overactivity was originally proposed as the neurochemical substrate for schizophrenia, based on the mode of action of antipsychotic drugs which block post-synaptic dopamine (D_2) receptors. In view of serotonergic ($5HT_2$) receptor blocking properties of the newer atypical neuroleptic drugs, serotonergic system have also been implicated.

Clinical Presentation

Acute schizophrenia

Delusions – are the most common symptoms. They may be persecutory, grandiose, religious or hypochondriacal, and occasionally extremely bizarre.

Passivity phenomena – Sufferers believe that impulses, actions, emotions or sensations they experience are not their own but imposed on them by external forces.

Hallucinations – are usually auditory. The duration of hallucinations is as important as their content or form, because the duration tends to be longer in patients with schizophrenia than in other psychoses.

Thought disorders – occur in about 20%. Speech may appear odd; patients may give apparently irrelevant answers to direct questions, may jump from one theme to another with no cohesive link (loosening of associations), and occasionally use ordinary words in new way (paraphasia) or invent new words (neologisms). Sometimes speech is totally incomprehensible, comprising a jumble of unrelated words ('word salad').

Mood – Patients may feel that the world around them has changed in some way (perplexity, delusional mood), or may show flattening of emotional response (blunted effect), or incongruity of mood. Depressive or manic symptoms may also occur.

Catatonic phenomena (e.g. mutism, stupor, strange postures or movements) are uncommon.

Chronic schizophrenia – In this type, symptoms are present for a continuous prolonged period of more than 2 years. The predominant symptoms are 'negative' or non-productive. These include lack of initiative and drive, poverty of speech, social withdrawal and blunting of emotional expression. Depression is a common feature. Acute psychotic episodes can recur from time to time, precipitated by withdrawal of medication or stressful life events.

Diagnosis – Schneider's first-rank symptoms are incorporated in the current definitions in WHO International Classification of Diseases (ICD-10) which requires:

- Clear evidence of past or present psychosis
- Absence of prominent affective symptoms
- Minimum duration of illness at least 1 month.

Schneider's First-rank Symptoms of Schizophrenia

- Auditory hallucinations
 - Third person talking or arguing about the patient
 - Third person commentary on patient's actions

Audible thoughts

- Thought withdrawal or insertion
- Thought broadcast
- Somatic passivity
- Feelings or actions experienced as being under external control
- Delusional perception

Note: First-rank symptoms occasionally occur in mania, drug-induced psychosis.

Subtypes of Schizophrenia (ICD-10), see Table 5.

Table 6 gives the differential diagnosis of schizophrenia.

Table 5: WHO international classification of diseases subtypes of schizophrenia

Subtype	Main characteristics
• Paranoid	Prominent delusions and hallucinations Personality well preserved
• Hebephrenic (Disorganised)	Thought disorder, affective changes, mannerisms, early onset, poor prognosis
• Catatonic	Psychomotor disturbance (e.g. posturing, stupor)
• Undifferentiated	No early predominant symptoms
• Post-schizophrenic depression	Depressive episode arising in aftermath of schizophrenic illness
• Residual	Clear progression from earlier psychotic stage to defect state of negative symptoms
• Simple	Progressive deterioration and eccentricity in absence of overt psychosis

Table 7: Prognostic factors in schizophrenia

Good	Bad
Older age at onset	Younger patient
Married	Single, separated, widowed, divorced
Short duration	Long duration
No family history	Family history of schizophrenia
Good social relationships	Social isolation
Stable work record	Poor work record
Good psychosexual adjustment	Poor psychosexual adjustment
No previous psychiatric history	Previous psychiatric history
Known precipitating cause	No obvious precipitating cause
Acute onset	Gradual onset
Prominent affective symptoms	No affective symptoms
Catatonic symptoms	Paranoid symptoms
Initiative and drive preserved	Loss of initiative and drive
No neurological signs	Presence of 'soft' neurological signs
Minimal negative symptoms	Predominant negative symptoms
Prompt treatment	Delayed treatment

Prognosis

Prognostic factors in schizophrenia are given in Table 7.

Management

Antipsychotic drugs – In the early acute phase, treatment has a dual purpose – control of agitated or aggressive behaviour (achieved by the sedative action of the drug

Table 6: Differential diagnosis of schizophrenia

Organic	Functional
<ul style="list-style-type: none"> • Temporal lobe epilepsy • Drug-induced states (amphetamines, cocaine, LSD, cannabis) • Alcoholic hallucinosis • Cerebral tumour • Encephalitis • Head injury 	<ul style="list-style-type: none"> • Affective disorder • Schizoaffective disorder • Atypical psychoses and other paranoid states • Personality disorders

within minutes or hours), and alleviation of psychotic symptoms (within days or weeks).

Once patient is stabilized, maintenance therapy to prevent development of further symptoms is continued with an oral or depot formulation. Maintenance treatment should be continued at the lowest possible dose for at least 1 year after the first schizophrenic episode. In recurrent episodes, maintenance therapy can be continued indefinitely. Failure to respond to medication may require ECT therapy. However with the advance of new medication, the need for ECT is reduced.

Certain forms of psychotic therapy may be beneficial to the patient in the recovery phase along with occupational therapy and vocational help.

Psychological and social management – Family intervention has been shown to reduce risk of relapse associated with high levels of expressed emotion. New cognitive behavioural techniques can be used effectively with drugs to reduce distressing symptoms (e.g. auditory hallucinations) or to help patients develop an insight into their illness.

5. MOOD DISORDERS

The mood disorders are so called because their main feature is an abnormality of affect on mood. Episode of clinically disturbed mood can be divided into manic and depressive phases. Over a patient's lifetime, the two types may occur in varying patterns. There is therefore a 'lifetime diagnosis' to be made in recurrent disorders, in addition to diagnosis of each individual episode.

DIAGNOSIS OF EPISODE

Manic episode – is almost the opposite of depression. Mood is often euphoric or elated to a degree disproportionate to the patient's circumstances, and can be irritable, hostile or aggressive. Energy levels are raised, and many feel they do not need to sleep. There are grandiose

ideas and frank delusions. They often become involved in sexual or financial indiscretions and fail to accept the likely consequences of actions.

Depressive episode – Clinical features include symptoms that almost always occur (e.g. depressed mood, loss of interest and pleasure, reduced energy) and other symptoms. Within this general depressive syndrome, some symptoms (termed ‘biological’, ‘somatic’ or ‘vegetative’) have special significance – they indicate the presence of ‘endogenous’ or ‘melancholic’ depression. These symptoms include anhedonia (complete inability to take interest or pleasure in anything, leading to a flat or unvarying mood), some psychomotor symptoms (retardation, agitation) and marked loss of appetite, weight and libido.

Symptoms of depression (see Table 8) – The episode can vary from mild to severe, depending on the number and severity of symptoms and on the disturbances they cause to work and family commitments. Depression is commonly associated with symptoms of anxiety or with coexisting anxiety disorders such as agoraphobia or social phobia.

Hallucinations and delusions may occur in severe cases when these symptoms are present, the illness is termed ‘psychotic depression’.

Depression can generally be distinguished from other syndromes when four or more symptoms of a depressive episode are present.

CRITERIA FOR A DEPRESSIVE EPISODE

A to D must all apply

Table 8: Symptoms of depression	
General	Somatic
• Hopelessness	• Appetite disturbance
• Helplessness	• Weight change
• Low mood	• Constipation
• Low self-esteem	• Amenorrhoea
• Reduced energy	• Low libido
• Suicidal thoughts	• Sleep disturbance
• Loss of interest	
• Poor concentration	Anxiety
• Guilt	• Tension
• Pessimism	• Apprehension
• Depersonization	• Phobias

A

At least 5 or more of the following symptoms (including 1 or 2) present for at least 2 weeks, representing a change from previous functioning.

1. Depressed mood almost every day for most of the day.
2. Markedly reduced interest or pleasure in all, or almost all activities almost every day for most of the day.
3. Significant weight loss or weight gain when not dieting, or increased or decreased appetite almost every day.
4. Insomnia or hypersomnia almost every day.
5. Agitation or retardation almost every day.
6. Fatigue or loss of energy almost every day.
7. Feelings of worthlessness or excessive or inappropriate guilt almost every day.
8. Reduced ability to think or concentrate or indecisiveness almost every day.
9. Recurrent thoughts of death or suicide.

B

1. No organic cause
2. Not caused by bereavement

C

No delusions or hallucinations in absence of mood symptoms for as long as 2 weeks during the course of the illness.

D

Not superimposed on schizophrenia or other psychoses.

‘Atypical’ depression – Definition of a depressive episode includes some symptoms representing changes in function that are opposed to the ‘typical’ somatic symptoms. When these dominate, the syndrome is termed ‘atypical’ depression. Such patients suffer from an increase in appetite and weight (often with carbohydrate craving), hypersomnia, fatigue and a reversed diurnal variation in mood, which is at its worst later in the day. This pattern of symptoms is often found in patients with a winter pattern in their illness (seasonal affective disorder).

Masked depression – Patients with a depressive disorder may present with somatic symptoms (e.g. headache, backache), sometimes they appear to be unaware of being depressed, even when they have a complete set of somatic symptoms with no physical cause.

Lifetime diagnosis – Over the patient’s lifetime episodes of mood disorder occur in one of three broad patterns:

Bipolar disorder – Here patients suffer from episodes of depression and of mania at various times. Progression of the disorder may be regular, cyclical or periodic, but is

usually irregular, each bout striking 'out of the blue' with no clear pattern. Both manic and depressive episodes can be triggered by life events. Recurrent depressive disorder that may be predictable (e.g. in seasonal affective disorder) or irregular. Symptoms may be similar in each episode or may vary over the years.

Recurrent depressive disorder - Recurrent episodes that may be predictable (e.g. in seasonal affective disorder) or irregular symptoms may be similar in each episode or vary over the years. Also referred to as Major depressive disorder - Recurrent.

Persistent mood disorder - In cyclothymia, mood swings occur for much of the time but are milder than manic depression. In dysthymia, patients experience persistent low grade depression.

Secondary mood disorders - The illnesses described above are assumed to be primary; they are not caused by another illness. Mood disorders thought to result from a physical illness (e.g. Cushing's disease, carcinoma) or a previously identified psychiatric illness (such as schizophrenia or alcoholism) are termed secondary mood disorders.

AETIOLOGY

Genetic factors - play a major role in mood disorders and their effect is stronger in patients with more severe biological symptoms. In twin studies of bipolar disorder, average concordance rate is 65% in monozygotic twins and 14% in dizygotic twins. An inherited factor, not an environmental one, determines the high rates seen in first degree relatives.

Social factors - Events associated with depression are generally 'loss events' such as loss of a job, relative or friend, money, health or status. Other factors that adversely affect the response to the events can be - A working class background, lack of confiding relationship with a spouse, unemployment, loss of a parent before 11 years of age. The presence of significant symptoms before onset of depressive illness occurs with somatic symptoms as much as those without. Thus the so called endogenous depression does not necessarily occur 'out of the blue'.

Biological markers for depression - show strong associations, particularly with the somatic (endogenous) syndrome. False-positive results occur in the presence of various medical disorders.

Dexamethasone suppression test - is the most important biological marker. A small dose of the drug is given postoperatively in the evening and plasma cortisol is

measured at the same time the next day. Failure to suppress endogenous cortisol secretion below a given reference point is associated with endogenous depression, particularly in patients with weight loss. This abnormality reflects underlying hyperactivity of the hypothalamo-pituitary-adrenal axis.

Abnormal α_2 receptors of the hypothalamus - Failure of clonidine (an α_2 -agonist), to provoke secretion of growth hormone is a consistent finding in depressed patients. The response returns temporarily with antidepressant treatment, but subsequently becomes abnormal again. This suggests that patients who have been depressed have an enduring abnormality in the α_2 receptors of the hypothalamus. This test is abnormal only in patients with endogenous depression.

5-HT challenge test - Tryptophan, taken orally, releases prolactin and growth hormone by increasing the activity of serotonergic system. The response is reduced in depression.

Circadian rhythms and related markers - have also been found abnormal in depression. This is suggested by the diurnal variations in mood, early morning waking and the sometimes periodic course, for example, yearly attacks of illness. Abnormalities of circadian rhythms of cortisol and melatonin have been reported, and sleep EEG reveals that the first phase of rapid eye movements sleep occurs earlier than expected.

Psychological factors - Repeated trauma, stressful life events and disturbed marital and interpersonal relationships.

MANAGEMENT

Pharmacotherapy - Severe type mood disorders are more responsive to physical treatment.

Antidepressants - are used in all phases of the treatment of major depression, acute management, continuation therapy and maintenance or prophylactic treatment.

Tricyclic drugs - increase recovery rate significantly, but have a wide range of side effects. These lead to non-compliance and limit usefulness in illnesses of mild to moderate severity. The dose of tricyclics should be initially low and increased gradually.

Selective serotonin re-uptake inhibitors (SSRIs) are effective drugs and are better tolerated at therapeutic doses than other compounds.

Table 9: Drugs for treatment of mood disorders

Drug	Indications
<i>Antidepressants</i>	
<ul style="list-style-type: none"> • Tricyclics • Selective serotonin re-uptake inhibitors • Monoamine oxidase inhibitors 	Acute treatment, Continuation therapy and maintenance of major depression Atypical vegetative symptoms of depression
<i>Antipsychotics</i>	
Conventional (haloperidol) Atypical (olanzapine)	Acute treatment of mania
<i>Mood stabilizers</i>	
Lithium Carbamazepine Valproate Lamotrigine Gabapentin	Acute treatment of mania Prophylaxis of bipolar disorder Treatment of resistant depression

Table 11: Adverse effects of selective serotonin re-uptake inhibitors

GI	CNS
<i>Common</i>	<i>Common</i>
Nausea	Headache
Appetite loss	Insomnia
Dry mouth	Dizziness
Diarrhoea	Anxiety
Constipation	Fatigue
Dyspepsia	Tremor
<i>Uncommon</i>	<i>Uncommon</i>

<i>Common</i>	<i>Uncommon</i>
Sweating	Rash
Delayed orgasm	Pharyngitis
Anorgasmia	Serum sickness
	Hyponatremia
	Alopecia

DRUGS USED IN TREATMENT OF MOOD DISORDERS

See Table 9.

Mechanism of action – All these drugs can potentiate the activity of noradrenaline and/or 5-HT in the CNS, usually by inhibiting re-uptake of these amines into the nerve endings. Though pharmacological effect is apparent a few hours after starting treatment, but most patients require a

Table 10: Adverse effects of tricyclic antidepressants

Pharmacological action	Adverse effects
Anticholinergic	Dry mouth, tachycardia, blurred vision, glaucoma, constipation, urinary retention
α -adrenergic blockers	Drowsiness, postural hypotension, sexual dysfunction, cognitive impairment
Histamine H ₁ receptor blockade	Drowsiness, weight gain
Membrane stabilizing properties	Cardiac conduction defects, arrhythmias, epileptic seizures
Others	Rash, oedema, leucopenia, elevated liver enzymes

couple of weeks before the effect of antidepressant treatment is fully apparent.

Efficacy – In most depressed patients the drugs mentioned are equal in efficacy. In more severely depressed patients drugs that cause potentiation of both 5-HT and noradrenaline neurotransmission (e.g. amitriptyline, clomipramine, venlafaxine, citalopram) are the most efficacious. In patients with depressive psychosis, antidepressants are usually not effective as a sole treatment, and should be given with an antipsychotic. ECT is an alternative approach.

Adverse effects – Most tricyclic antidepressants are potent antagonists of muscarine, histamine H₁ and α_1 -adrenoreceptor, and have characteristic side effects (Table 10). Some antidepressants (trazodone, mirtazapine) have a sedative effect in absence of anticholinergic properties.

The acute pharmacological action of SSRIs is essentially confined to blockade of 5-HT uptake and is associated with side effects such as anxiety, insomnia and sexual dysfunction different from those with tricyclics. Adverse effects of selective serotonin re-uptake inhibitors are listed in Table 11.

Long-term treatment – Continuation of antidepressant drugs for 4–6 months after resolution of symptoms is associated with significantly lower rate of relapse.

Discontinuation symptoms – Abrupt cessation of tricyclic antidepressants can provoke withdrawal symptoms like abdominal pain, nausea and diarrhoea, fragmented sleep and nightmares. Discontinuation symptoms can also occur 24–72 hours after sudden cessation of SSRIs particularly paroxetine; common withdrawal symptoms are dizziness, nausea, lethargy and headache.

Monoamine oxidase inhibitors (MAOIs) have the major disadvantage of adhering to a tyramine-free diet to avoid the hypertensive crisis of the so-called cheese reaction. Principal MAOIs in use are phenelzine (45–90 mg) and tranylcypromine. (These are not available in India). Side effects are similar to those of tricyclics; postural hypotension can be troublesome. They are selectively useful in patients with the atypical vegetative symptoms of depression.

Reversible MAOIs such as moclobemide are less likely to cause cheese reaction.

Mood-stabilizing drugs

Lithium is used in treatment of several conditions:

- First-line agent in acute treatment of mania (often in combination with antipsychotic drugs in severe illness) and in long-term prophylaxis of bipolar disorder.
- Prophylaxis of recurrent unipolar depression though agent of first choice is tricyclic or a newer antidepressant.
- Useful antidepressant action when added to the antidepressant drug treatment of patients who have failed to show a satisfactory response to them.
- In patients with learning disabilities, lithium decreases aggressive behaviour towards self or others.

Monitoring of lithium levels is necessary because renal lithium clearance varies widely between individuals, and the dose required for optimal therapeutic effect is only slightly less than that resulting toxicity; permanent renal and cerebral damage can occur if toxicity is unrecognised (see Table 12). Several drugs, e.g. diuretics, NSAIDs, ACEIs, metronidazole can raise lithium levels and cause toxicity.

Plasma levels of lithium (12 hours after the final dose) necessary for prophylaxis should be in the range of 0.5–0.8 mmol/L. Some patients require levels similar to those for acute management (0.9–1.2 mmol/L) for adequate prophylaxis.

Side effects – Lithium has a wide range of side effects and hence compliance for the drug is poor. Patients most often complain of tremor, thirst, memory difficulties, weight gain and tiredness.

Abrupt cessation of lithium in bipolar patients is associated with increased risk of affective relapse.

Carbamazepine – Many patients with bipolar disorder or mixed affective states do not respond satisfactorily to lithium. Carbamazepine may produce good mood-stabilizing effects when given alone or with lithium. The drug can be useful also in acute treatment of mania, and can be combined with lithium or antipsychotic drugs. Dose 400–1200 mg daily. Adverse effects. Carbamazepine levels can be increased by erythromycin, SSRIs and nefazodone.

Sodium valproate is effective in patients with acute mania and in those with mixed affective symptomatology. An advantage of valproate in acute mania is the possibility of rapid dose increase, resulting in rapid onset of therapeutic effect in 2 days with loading dose of 20 mg/kg/day.

Antipsychotic drugs – Despite the availability of mood-stabilizing drugs, antipsychotics continue to be used because of their ability to produce rapid sedation and control of overactivity and aggression. As in the treatment of schizophrenia, current practice is to use lower doses of antipsychotics to treat mania (e.g. haloperidol 5–10 mg daily).

Table 12: Adverse effects of lithium, carbamazepine and valproate

	<i>Lithium</i>	<i>Carbamazepine</i>	<i>Valproate</i>
Neurological	Tremor, weakness, dysarthria, ataxia, impaired memory	Dizziness, weakness, drowsiness, ataxia, headache, visual disturbance	Tremor, sedation
Renal / fluid balance	Increased urine output with decreased urine-concentrating ability, thirst, oedema	Low sodium states, oedema	
GI/hepatic	Altered taste, anorexia, nausea, vomiting, diarrhoea, wt. gain	Anorexia, nausea, constipation, hepatitis	Anorexia, nausea, vomiting, diarrhoea, wt. gain, hepatitis
Endocrine	Decreased thyroxine with increased TSH, goitre	Decreased thyroxine with normal TSH	Menstrual disturbances
Haematological	Leucocytosis	Leucopenia	Low platelet count, abnormal platelet aggregation
Dermatological	Acne, exacerbation of psoriasis	Erythematous rash	Hair loss
CVS	ECG changes (usually benign)	Cardiac conduction disturbances	

Patients with bipolar illness are commonly given longer-term antipsychotic medication because this may help prevent swings in mood. The risk of tardive dyskinesia is less likely with clozapine and olanzapine.

ECT – is an effective and fast-acting treatment for severe mood disorders, but its use is generally reserved for patients unresponsive to antidepressant drugs or when the need for clinical response is particularly urgent.

Indications for ECT

- Major depression not responding to antidepressant drugs with:
 - Psychotic symptoms
 - Failure to eat and drink
 - Depressive stupor
 - High risk of suicide
- Schizoaffective depression
- Mania not responding to drug treatment
- Postpartum affective psychosis

Duration of treatment and maintenance therapy – Usually 6 to 10 ECTs are effective in resolving acute depression or mania. Once the course of treatment is completed appropriate prophylactic drug treatment should be given to prevent relapse. Some patients with frequent relapses that respond to ECT can be considered for maintenance ECT, in which treatment is given every 2 weeks or monthly.

Psychological treatments – These can be used in patients with ‘real’ problems such as threatened redundancy or a relationship difficulty. Many depressed patients perceive imagined problems and here techniques used in cognitive psychotherapy can be useful.

6. PSYCHONEUROSIS OR NEUROSIS

(Anxiety disorders, somatoform disorders, dissociative disorders)

A group of mental disorders which are sometimes described as “minor” or “benign”. The patient’s symptoms do not interfere with his capacity for insight and judgement, his ties with reality are intact, and his mental dysfunctions are comparatively of a milder form in contrast to psychosis. As in functional psychosis, in these disorders also, there is no clearly defined structural change in brain tissue function to account for the symptoms. See Table 13 for the differences between psychosis and neurosis.

ANXIETY DISORDERS

Anxiety is a normal response to threat or stressful events, and is usually short-lived and controllable. It probably functions as an ‘alarm mechanism’ to prepare an individual for a physical response to perceived danger (the ‘fight-or-flight’ response). Anxiety symptoms are considered clinically significant when they:

- Are abnormally severe
- Are unusually prolonged
- Occur in absence of stressful circumstances
- Impair physical, social or occupational functioning

Features of anxiety – Anxiety symptoms may be a feature of some physical conditions (e.g. caffeinism, drug withdrawal, hyperthyroidism, hypoglycemia, paroxysmal tachycardia, complex partial seizures, pheochromocytoma) and these must be excluded when features in the history or physical examination suggest their presence. See Table 14 for the classification of anxiety features.

Generalized anxiety disorder – is characterized by inappropriate or excessive anxiety and worrying that is persistent (more than 6 months) and not restricted to particular circumstances (i.e. it is ‘free-floating’). Common features are listed in Table 15.

Differential diagnosis – Most important is depressive illness, for this patient is questioned about symptoms such as loss of interest and pleasure, loss of appetite and weight, diurnal variation in mood and early morning waking.

A distinction is also made between patients with and without panic attacks.

- Panic attacks may accompany any anxiety disorder, but a specific diagnosis of panic disorder can be made if they occur frequently and unexpectedly.
- Phobic disorders are divided into specific (simple) phobias, agoraphobia and social phobia.
- Obsessive compulsive neurosis is a distinct entity, but at present is grouped with other neurotic, stress-related and somatic disorders.

Management – Definitive need for treatment depends on severity of symptoms, degree of personal distress, level of occupational and social impairment.

- a. Benzodiazepines are effective anxiolytic drugs but can cause sedation and have potential for dependence. They should be given in short courses.
- (b) Other drugs include certain tricyclic antidepressants (e.g. imipramine 50–300 mg/d), buspirone (5-HT_{1A} partial agonist) (15–45 mg/d) and venlafaxine (serotonin-noradrenaline re-uptake inhibitor 75 mg/d), sertraline

Table 13: Differences between psychosis and neurosis

	<i>Psychosis</i>	<i>Neurosis</i>
<i>Aetiology:</i>		
Biological factors	More important	Less important
Environmental factors	Less important except in reactive psychosis	More important
<i>Psychopathology:</i>		
Personality disintegration	Severe	Partial
<i>Clinical manifestations:</i>		
1. Touch with reality.	Lost	Not lost
2. Insight into the illness	Lost (Patient believes that he is all right but family members and relatives are sick)	Not lost (Patient complains of illness but family members and relatives believe that the patient is not sick)
3. Judgement (i.e capacity to discriminate between right and wrong, good and bad, ethical and unethical).	Lost	Not lost
4. Social relationship and behaviour.	Affected	Not affected
5. Personal hygiene.	Neglected	Not neglected
6. Disturbances of mental functions like thinking, emotion and behaviour.	Gross	Minor
7. Disturbances of intelligence, memory, attention, consciousness and orientation.	Common in organic psychosis	Rare
8. Disturbances of thought (viz. delusions) and perception (viz. illusions and hallucinations).	Common	Rare
<i>Course and prognosis</i>	More malignant than benign. Difficult to treat. Recovery may not be always possible or complete. Relapses are common.	More benign than malignant. Easier to treat. Recovery is complete. Relapses are common.
<i>Management</i>		
1. ECT	Very useful	Contraindicated
2. Abreactive therapy	Not useful	Useful
3. Drugs	Neuroleptics commonly used.	Anxiolytics and antidepressants
4. Psychotherapy		
a. Supportive	Useful	Useful
b. Analytical	Not useful	Useful
5. Case work	Useful	Useful

(selective serotonin re-uptake inhibitor, 5 mg/day) none of which have the same potential for psychological or physical dependence.

- b. Behaviour therapy in the form of relaxation training, systemic desensitization and cognitive therapy. Psychotherapy and family education is a must.

Panic disorder and agoraphobia – Panic attacks are discrete episodes of paroxysmal severe anxiety and are characterized by severe and frightening autonomic symptoms (e.g. shortness of breath, palpitations, excessive perspiration), dizziness, faintness and chest pain – many

patients believe they are in imminent danger of death or collapse and seek urgent medical attention. Panic disorder can occur with or without *agoraphobia*.

TYPICAL FEATURES OF PANIC ATTACKS

- Sudden onset
- Short duration (typically a few minutes)
- Rapidly escalating physical and psychological symptoms

Table 14: Classification of anxiety features*Psychological*

- Fear and apprehension
- Inner tension and restlessness
- Irritability
- Impaired ability to concentrate
- Increased startle response
- Increased sensitivity to physical sensations
- Disturbed sleep

Physical

- Increased muscle tension
- Tremor
- Sweating
- Palpitations
- Chest tightness and discomfort
- Shortness of breath
- Dry mouth
- Difficulty swallowing
- Diarrhoea
- Frequency of micturition
- Loss of sexual interest
- Dizziness
- Numbness and tingling
- Faintness

- Incapacitating symptoms of breathlessness and/or palpitations
- Fear of impending death, collapse or loss of control
- Rapid escape (if possible) from situation where attack occurred
- Sometimes panic attacks are labelled nocturnal when they occur at night only.

'Co-morbidity' is common in individuals suffering from panic attacks or panic disorder. Compared with those with 'pure' panic disorder, patients with co-morbid panic and depression are more severely ill, more functionally impaired at home and at work.

DIAGNOSTIC GUIDELINES FOR PANIC DISORDER

- The individual experiences recurrent panic attacks that are not consistently associated with specific situation or object and that often occur spontaneously; these

Table 15: Common features of generalized anxiety disorder

- Apprehension
 - Worries about future misfortune
 - Inner tension
 - Difficulty in concentrating
- Motor tension
 - Restlessness
 - Tremor
 - Headache
- Autonomic anxiety
 - Excessive perspiration
 - Dry mouth
 - Epigastric discomfort
 - Muscle tension and pain/stiffness

attacks are not associated with marked exertion or exposure to dangerous or life-threatening situations.

- A panic attack is characterized by all of the following:
 - A discrete episode of intense fear or discomfort
 - Starts abruptly
 - Reaches maximum intensity within a few minutes
 - Lasts at least several minutes
 - At least four symptoms are present (including at least one autonomic symptom)
 - The attack is not caused by a physical disease, an organic mental disorder, or another condition such as schizophrenia, mood disorder or somatoform disorder.

MANAGEMENT

- Psychological* – Helping patients to understand that their symptoms are not caused by serious physical ailment. Relaxation training can be helpful, but severely ill patients are more likely to benefit from cognitive behaviour therapy. Exposure therapy can be performed under supervision of a behaviour therapist.
- Drugs* – High dose benzodiazepines (e.g. alprazolam) are effective but can cause substantial depression and should be prescribed in severely ill patients who have not responded to other treatment approaches. The antidepressant drugs (imipramine, clomipramine and selective serotonin re-uptake inhibitors (e.g. Paroxetine) are as efficacious in reducing anxiety symptoms, lessening agoraphobia and minimizing overall impairment.

Specific (isolated) phobias – Characteristic feature is a single, discrete fear of an object (e.g. a particular animal), a situation (e.g. flying) or an individual (e.g. a dentist). This fear causes significant emotional distress, and is often accompanied by marked avoidance.

Management – Behaviour therapy. Patients with a specific fear of blood or bodily injury tend to develop bradycardia and hypotension, and require tension exercises in addition to exposure therapy. Relaxation therapy may be useful. This may be coupled with behaviour therapy methods like systematic desensitization, exposure methods and modelling or flooding and implosion.

Social phobia (Social anxiety disorder) – Characteristic feature is an intense and persistent fear of being scrutinized or evaluated by others. The feared situations may be relatively discrete (e.g. public speaking) or diffuse. The disorder is more common in women and highest in those from low socioeconomic status.

Diagnostic guidelines for social phobia

- Marked fear of being the focus of attention, or fear of behaving in a manner that will be embarrassing or humiliating.
- Marked avoidance of fear situations
- Anxiety symptoms are restricted to, or predominate in, feared situations or are a contemplation of these
- In addition to more typical anxiety symptoms, at least one of the following is present:
 - Blushing or shaking
 - Fear of vomiting
 - Urgency or fear of micturition or defecation
- The symptoms cause significant emotional distress.

Agoraphobia – can occur as an isolated condition (or with panic attack) in which the individual experiences anxiety about being in places or situations from which escape might be difficult or embarrassing. Typical fears include being outside the home, being in a crowd, standing in a queue and using public transport. These feared situations are avoided or endured with marked distress, which is often lessened by the presence of a trusted friend involving almost all social situations outside the family circle ('generalized' subtype).

Differential diagnosis – The generalized subtype can be confused with panic disorder (Table 16).

Management – (a) β -blockers in management of performance anxiety. (b) Monoamine oxidase inhibitors, moclobemide and several selective serotonin re-uptake inhibitors like sertraline and paroxetine have been found efficacious. (c) Cognitive behaviour therapy (individually or in groups) is useful.

Obsessive-Compulsive Disorder (OCD)

A disorder in which there is persistent intrusion of unwanted thoughts, urges or actions that the patient is unable to stop.

Aetiology – OCD is widely accepted to result from genetic vulnerability and/or chemical changes in some areas of the brain. The precise pathogenesis is not completely understood.

Neurobiology – OCD patients have shown abnormalities in orbitofrontal cortex, cingulate cortex and caudate nucleus. In some children and adolescents, OCD develops after β -hemolytic streptococcal infection, an autoimmune reaction similar to that of rheumatic fever.

Genetic factors – Twin studies show concordance rates as high as 87% in monozygous twins compared with 47% in dizygous pairs.

Psychological theories – In cognitive behavioural theory, obsessions are considered anxiogenic. OCD patients cannot escape this anxiety and therefore develop compulsion in an attempt to reduce or prevent the feared consequences. Reduction of anxiety reinforces the compulsive behaviour.

Clinical features – Symptoms can arise acutely or insidiously.

Obsessions are frequent and persistent thoughts, impulses or images that are normally experienced as intrusive and senseless. They are usually accompanied by marked anxiety. Common obsessional themes are contamination, aggression, and sexual or religious ruminations.

Compulsions are repetitive behaviours, e.g. hand washing, checking, ordering or mental acts (e.g. counting, repeating words silently). It may involve repeating acts for a fixed number of times.

Table 16: Panic disorders

	<i>Social phobia</i>	<i>Panic disorder</i>
Panic attacks	Restricted to feared social situations	Occur unexpectedly in social encounters and when alone
Types of fear	Appearing foolish or awkward	Losing control or death
Company	Enjoy social encounters when accompanied by a trusted friend	Presence of a friend makes little difference

DIAGNOSTIC CRITERIA FOR OCD

- Obsessional thoughts, compulsive acts or both should be present on most days for at least 2 weeks
- They are recognized by patients as their own

- Patients have tried to resist unsuccessfully at least one obsessive thought or compulsive act
- The thoughts and acts are not pleasurable
- The thoughts, images, impulses and acts are unpleasantly repetitive

DIFFERENTIAL DIAGNOSIS

Anankastic (obsessive-compulsive) personality is often confused with OCD. Excessive cleanliness, checking and orderliness are not uncommon among healthy individuals, but they do not interfere with normal functioning.

Other anxiety disorders – Such as phobic disorders, generalized anxiety disorder and post-traumatic stress disorders have some features common with OCD.

Depressive disorder – Depression and OCD often occur together. In many patients OCD must be treated to alleviate depression.

Psychotic disorder particularly schizophrenia. It is necessary to differentiate obsession from thought insertion, which is an important feature of schizophrenia.

Tic disorders – Features of OCD are present in many patients with Tourette's disorder, and incidence of tics is greater in OCD.

Anorexia nervosa – has many features in common with OCD, but obsessive behaviour is limited to achieving weight loss.

Other disorders – such as body dysmorphic disorder and impulse control disorders (e.g. trichotillomania, kleptomania, pathological gambling) are (with tics and anorexia nervosa) considered by some to be OCD-spectrum disorders.

Brain damage, learning disabilities and autism may be associated with development of obsessions and rituals.

MANAGEMENT

- Selective serotonin re-uptake inhibitors or tricyclic drugs.**
- Cognitive behaviour therapy** – The main approach in OCD is graded exposure and self-imposed response prevention. This requires patients to face their feared obsessions without 'undoing' them with their compulsions. Exposure should be of sufficient duration to be effective. An effective method known as thought stopping may also be used.

Drug treatment – Clomipramine 150–300 mg/d. SSRIs are effective in both OCD and depression, but must be given in higher doses, e.g. fluoxetine or paroxetine 60 mg/day.

Combined therapy – Combination of cognitive behaviour therapy and medication can be more effective than either alone.

Psychosurgery – is reserved for patients with severe illness that has not responded to multiple therapies. Selective operations separating areas of frontal cortex from deep limbic structures (e.g. cingulotomy, capsulotomy) can lead to improvement in 25–30% of such patients. ECT may be used in resistant cases.

Post-traumatic Stress Disorder (PTSD) and Acute Stress Disorder (ASR)

PTSD is a common, potentially disabling condition that affects all age groups and may have a lifelong, relapsing course if untreated.

Prevalence – Of individuals who experience combat disasters or personal tragedy (e.g. torture, accidents, abuse, rape) 30–35% suffer PTSD.

Vulnerability – Predisposing factors can be past history of psychiatric disorder, a 'neurotic' anxiety prone personality, exposure to previous traumatic experiences (including childhood abuse). Women are more likely to develop PTSD following interpersonal violence.

Co-morbidity – 'Pure' PTSD syndrome is uncommon, the condition is often complicated by concurrent affective disorder (particularly major depression, generalized anxiety and panic disorder), and by alcohol and drug abuse.

Behavioural effects – Dysfunctional behaviour is common in patients with PTSD and may be the presenting feature. Occupational instability, antisocial behaviour are also common. Those with PTSD are also likely to make negative life-course decisions.

Biology of PTSD – Abnormalities of the hypothalamo-pituitary-adrenal axis have been reported, these include hypocortisolaemia, and enhanced adrenocorticoid sensitivity to the effects of dexamethasone suppression ('super-suppression'), which is proportional to the clinical severity of PTSD. This suggests that the sensitivity of central glucocorticoid receptors is increased in PTSD, and distinguishes PTSD from other psychiatric disorders.

Other neurochemical findings include evidence of increased central catecholamine activity. High-resolution MRI reveals reduced hippocampal volume.

Functional neuroimaging studies have shown similarities between PTSD and OCD that distinguishes these conditions from other neurotic disorders. In both single-photon emission tomography reveals significant abnormalities of regional blood flow, predominantly affecting the basal ganglia and orbitofrontal cortex. These findings suggest that PTSD and OCD may have a common pathophysiology.

DIAGNOSTIC CRITERIA FOR POST-TRAUMATIC STRESS DISORDER

- A life-threatening event outside normal human experience
- Re-experiencing the trauma
 - Intrusive memories
 - Dreams or nightmares
 - Flashbacks with a sense of reliving the event
 - Distress at exposure to events resembling the trauma
- Avoidance of stimuli associated with the trauma
- Evidence of increased arousal
 - Sleep disturbances
 - Irritability
 - Hypervigilance
 - Exaggerated startle response

Duration >1 month

Prevention - (a) *Primary prevention* includes preparing those at risk of experiencing trauma (e.g. emergency service workers, soldiers). Stress-inoculation programmes are used to prepare high-risk occupational groups for trauma. (b) *Secondary prevention* - Measures to reduce long-term psychiatric morbidity following trauma include counselling, of which 'critical incident' and 'psychological debriefing' are the most widely used.

Management

Psychological therapies - Cognitive techniques and exposure-based behavioural interventions are effective. In audiotape desensitization, the patient writes a detailed description of trauma (including feeling, sights, sounds and smells) which is recorded on to audiotape. Repeated listening to the audiotape reduces symptoms of hyperarousal within 2-3 weeks.

Drugs - are most effective following acute PTSD. Drugs acting on central serotonergic transmission have the most beneficial effect e.g. tricyclic antidepressants (e.g. imipramine), monoamine oxidase inhibitors (e.g. phenelzine) and SSRIs (e.g. fluoxetine). Generally drugs are given in higher doses and for longer duration than in the treatment of depression.

SOMATIFORM AND DISSOCIATION DISORDERS

Types of Hysterical Disorders

1. **Conversion disorder** - (Hysterical neurosis, conversion type). Here the special senses or voluntary nervous

system are affected causing symptoms such as blindness, deafness, paralysis, akinesias, etc. for which there is no organic basis. Often the patient shows an inappropriate lack of concern ("la belle" indifference) about those symptoms which may actually provide secondary gains by winning sympathy. There is often a presentation with symptoms that are unexplained medically or physiologically.

2. **Dissociative disorder** - (Hysterical neurosis, dissociative type). Here alterations may occur in the patient's state of consciousness or in his identity to produce such symptoms as amnesia, somnambulism, fugue and multiple personality.

Aetiology

There is sufficient evidence to suggest that the symptoms are psychogenic and that the environmental factors are the important etiological factors.

1. **Age** - The peak incidence is between the ages of 20 to 35 years.
2. **Sex** - Incidence is higher in females.
3. **Intelligence** - People with low intelligence are more likely to develop this disorder.
4. **Personality** - Commonest is histrionic personality (characteristics - dramatizing and exhibitionistic, attention seeking, immature, having shallow and superficial emotional relationships).
5. **Marital status** - More common in unmarried, widows and divorcees.
6. **Sociocultural factors** - More common in primitive, developing and less sophisticated or cultured societies.
7. **Psychoanalytical theories** - Hysterical symptoms are viewed as symbolic representations and distorted expressions of unresolved intrapsychic conflicts about one's sexual drive (libido). When the libidinal energy manifests itself as somatic symptoms through the ego-defence mechanism of conversion, the resulting disorder is known as conversion disorder. When the libidinal energy manifests as psychological symptoms through the defence mechanism of dissociation, the resulting disorder is labelled dissociative disorder.

Clinical Manifestations

1. **Symptoms of conversion disorder** - These arise because of the involvement of voluntary neuromuscular system.
 - a. **Motor symptoms** - These are of two types: (i) *Akinesia*, e.g. paresis or paralysis involving a part of the body like monoplegia, hemiplegia, paraplegia, etc. (ii) *Hyperkinesia* and dyskinesia, e.g. tremors, torticollis, convulsions or fits.

- b. *Sensory symptoms* – These can be in the form of anaesthesia, hypoaesthesia, hyperaesthesia and paraesthesia. This disturbance can affect all the general sensations. Special organs of sense, like those for sight, hearing, smell and taste can also be disturbed resulting in blindness, deafness, etc.
 - c. *Visceral symptoms* – Common ones are hiccoughs, vomiting, dyspnoea, dysphagia, aphonia, etc.
2. **Symptoms of dissociation disorder** –
- a. Somnambulism and somniloquy.
 - b. Amnesia – usually circumscribed and covers up the psychologically traumatic event.
 - c. Trance – An altered state of consciousness lasting for a few minutes to a few hours, during which the patient appears to be oblivious of the surroundings.
 - d. Fugue – An altered state of consciousness wherein the patient travels long distances over a period of days and subsequently has amnesia for the entire episode.
 - e. Multiple personalities like those of Dr Jekyll and Mr Hyde.
 - f. Ganser's syndrome, a rare disorder characterised by giving of "approximate answers", somatic or psychological hysterical symptoms, hallucinations and an apparent clouding of consciousness. Possession states where the soul of God or Goddess enters into one's body commonly seen in rural India during religious festivals.

Characteristics of Hysterical Symptoms

- Absence of organic basis for symptoms.
- They serve both primary gain (resolution of intrapsychic conflicts) and secondary gain (obtaining sympathy and attention).
- In conversion disorder – Symptoms seldom occur when patient is alone, on the other hand, symptoms are exaggerated in presence of other persons. Patient is often indifferent to the symptoms even though they may appear to be incapacitating (la belle indifference). There is a stressful factor or event that will trigger or maintain symptoms. Symptoms change in quality and severity over a period of time.

Prognosis is determined by the following factors:

1. Intelligence – low intelligence usually associated with relapses.
2. Associated physical defects and physical illnesses – presence of these carries poor prognosis.
3. Personality – Histrionic personality does not carry a good prognosis. Even with adequate treatment, relapses are

more frequent. 4. Possibility of environmental change – change in the environment relieves stress, ameliorates symptoms and ensures long lasting recovery.

Management

1. *Isolation of the patient* – from the pathogenic environment is very necessary in the acute attack. The patient may have to be hospitalized and no visitors be allowed to meet the patient.
2. *Placebo therapy* – sometimes help in relieving the symptoms because these patients are very suggestible.
3. *Drugs* – Anxiolytics, as in treatment of anxiety disorders, orally or parenterally help in some resistant cases by: (i) reducing secondary gain and (ii) by relieving stress.
4. *Narcoanalysis* – using subanaesthetic doses of sodium pentothal may be beneficial in some cases by providing an opportunity to the patients to discharge emotional conflicts.
5. *Hypnosis* – helps in relieving the symptoms by its value of suggestibility.
6. *Psychotherapy* – Supportive psychotherapy gives good results in most cases. Deep, analytical psychotherapy may benefit few patients. Family or marital therapy may be useful to correct associated maladjustments in family and marital units respectively.
7. *Relaxation therapy*.

SOMATIFORM DISORDERS

Somatization Disorder

A chronic syndrome characterised by multiple somatic symptoms for which no organic cause can be found and associated with psychological distress and persistent medical help-seeking. There are patients who have medically explainable symptoms but all investigations reveal no abnormality.

Aetiology – (a) *Age of onset* – before 30 years. (b) *Sex* – Much more common in women. (c) *Social status* – More common among the poor, uneducated and poorly employed persons. (d) *Family history* – More common in relatives of somatization disorder patients. (e) *Sociocultural factors* – Parental attitudes and teaching, cultural and ethnic traditions could be the reasons why some individuals 'learn' to somatise.

Clinical Features

1. Long history of multiple somatic complaints and long complicated medical histories.

2. Symptoms usually referable to any organ symptoms of the body but, nausea (or vomiting), pain in the extremities, shortness of breath in absence of exertion, amnesia, difficulty in swallowing, painful menstruation and burning sensation in sexual organs or rectum are among the most common symptoms.
3. Interpersonal problems and emotional distress. Anxiety, depression and strong suicidal ideation are common.
4. Patients tend to be exhibitionistic, self-centred, attention-seeking and manipulative. They tend to describe their symptoms in a dramatic and exaggerated manner. It is a bodily expression of inner psychological pain or stress. (Refer to conversion disorder).

Management - Optimum management depends on identifying psychosocial and physical symptoms early in the evolution of the disease.

Simple reassurance is sufficient in some patients when symptoms occur in the context of anxiety or depressive illness. However, a relevant explanation is preferable to bland reassurance.

A Technique Called 'Reattribution' is Useful

1. Make the patient feel understood by drawing on findings at assessment, and by acceptance and interest
2. Broaden the agenda to involve discussion of previously elicited psychological and social factors
3. Make the link between symptoms and psychological problems, using the following techniques:
 - Link to anxiety (e.g. overbreathing causing muscular tension and chest pain)
 - Demonstrate generation of symptoms (e.g. muscular pain from sustained contraction)
 - Link to life events
 - Link to another key individual's symptoms (e.g. response of his/her mother to stress).

Factitious disorders - These are characterized by physical or psychological symptoms that are feigned to assume a 'sick role'. Most patients are women, and more than half of them work in medically related occupations.

Munchausen syndrome is an uncommon, dangerous subtype of factitious illness characterised by lying, deliberate use of self-induced symptoms to gain hospitalization, and admission to numerous hospitals.

Differential diagnosis - (a) Malingers produce symptoms to achieve a goal (e.g. to avoid court proceedings). The motivation of factitious disorder is obscure. (b) Somatoform disorders - Symptoms or signs with no organic explanation, but not produced deliberately. Patients with

factitious disorder know they are producing symptoms, though they are unclear about their motives.

PAIN DISORDER

The disorder is similar to somatization disorder but here the predominant symptom is severe and prolonged pain for which there is no medical explanation.

Aetiology - (a) *Age* - More common between 30-50 years. (b) *Sex* - More common in females (c) *Occupation* - Manual and blue-collar workers are more prone. (d) *Family history* - Familial tendency. (e) *Psychoanalytical theories* - Pain is seen as a symbolic method of obtaining love, a punishment for wrong doing or atoning for one's guilt. (f) *Learning theories* - Pain is a learned response especially when pain is regarded or reinforced in some way. For example pain may become more intense when following increased attention by others, monetary benefits or by the successful avoidance of unpleasant activities.

Clinical features - (a) Severe and continuous pain of at least six months duration, which completely preoccupies the patient. (b) No organic basis for pain on physical examination. (c) In presence of related organic pathology, pain or the resulting impairment in functioning is grossly in excess of what could be expected from physical findings. (d) Long history of medical and surgical consultations and history of multiple and varied range of medications.

Management - 1. Supportive psychotherapy the objective being to rehabilitate the patient. 2. Drugs - Tricyclic antidepressants and selective serotonin re-uptake inhibitors, as in treatment of depressive disorders are effective in some cases.

HYPPOCHONDRIASIS

A disorder characterised by an excessive concern about being afflicted with a disease and by a preoccupation with one's health.

Aetiology - (a) *Age* - More common in 30-50 age group although all age groups can be affected. (b) *Sex* - Equal incidence. (c) *Family history* - More common in relatives of patients with hypochondriasis. (d) *Psychoanalytical theories* - Aggressive and hostile impulses towards other people are transferred into physical complaints. The latter are viewed as a defence against guilt or expression of low self-esteem. (e) *Sociocultural factors* - Hypochondriasis is seen as an admission of the sick role made by a person who is facing an apparently insurmountable situation. The sick role offers an excuse for the patient to avoid unpleasant obligation and postpone onerous duties.

Clinical features - 1. Unrealistic interpretation of symptoms and sensations leading to a preoccupation with the fear of suffering from a serious disease. 2. Physical examination does not reveal any organic basis for the physical symptoms. 3. Persistence of the fear that one has a serious illness in spite of medical reassurance. 4. Anxiety and depression may accompany hypochondrial symptoms. 5. Symptoms are of at least 6 month's duration and involve multiple organ systems.

Management - 1. Supportive psychotherapy (to provide emotional support to patient and offer reassurance). 2. Treatment of accompanying anxiety or depression with anxiolytics and antidepressants respectively.

7. ANTIPSYCHOTIC DRUGS

Antipsychotic drugs - are now classified as 'typical' and 'atypical' (Table 17).

Typical antipsychotic effects are thought to be mediated by post-synaptic blockade of dopamine (D_2) receptors in the mesolimbic area of the brain.

Atypical antipsychotics can be divided into three groups.

ANTIPSYCHOTICS

Depot Injections

1. Risperidone (Risperdal): 25–37.5 mg IM every 2 weeks
2. Fluphenazine decanoate: 12.5–25 mg IM every 2–4 weeks
3. Zuclopenthixol: 200–400 mg IM every 2–4 weeks
4. Flupenthixol: 20–40 mg IM every 2–4 weeks
5. Haloperidol decanoate: 50 mg IM every 4 weeks

Note: Clinically, 'atypical' simply refers to drugs with fewer or no side effects.

Therapeutic use - With the exception of clozapine, there are no major differences between typical and atypical antipsychotics in primary efficacy against the positive symptoms of schizophrenia. Atypicals may be more effective against negative symptoms, which are characteristically less amenable to treatment. Well-tolerated atypical antipsychotics must be used as a first-line treatment to improve compliance. Use of clozapine is restricted to schizophrenia unresponsive to or intolerance of conventional antipsychotics, because of the potential fatal side-effect of agranulocytosis. It is the treatment of choice for treatment resistant schizophrenia.

Contraindications - For typical antipsychotics cautions include cardiovascular, renal and liver disease,

Table 17: Antipsychotic drugs

Antipsychotic	Chemical group	Dose (mg/ day p.o.)
A. Typical		
Chlorpromazine		25–100
Thioridazine	Phenothiazine	25–600
Trifluoperazine		10–50
Haloperidol	Butyrophenone	1–20
Flupenthixol	Thioxanthene	3–18
Sulpiride	Substituted benzamide	400–2000
Pimozide	Diphenylbutyl piperidine	2–8
B. Atypical		
Risperidone		2–16
lloperidone		2–12
Quetiapine		25–800
Olanzapine		5–20
Amisulpride		400–1200
Ziprasidone		20–50
Amisulpride		10–15
Clozapine		25–900

glaucoma and Parkinson's disease and epilepsy. Atypical drugs are contraindicated in pregnant and breastfeeding women.

Side effects

Typical antipsychotics

- Extrapyramidal side effects caused by nigrostriatal D_2 receptor blockade (e.g. acute dystonia, akathisia, parkinsonism)
- Tardive dyskinesia following prolonged use
- Anticholinergic effects (dry mouth, blurred vision, urinary hesitancy or retention, constipation)
- Anti-adrenergic effects (e.g. postural hypotension, inhibition of ejaculation)
- Sedation as a result of D_2 , H_1 and α -receptor antagonism
- Cardiovascular effects: Tachycardia, arrhythmias, myocarditis, widening of QRS complex and prolonged QT interval
- Hyperprolactinaemia due to hypothalamo-pituitary D_2 receptor blockade causes amenorrhoea and galactorrhoea
- Skin and eye: Allergic and phototoxic skin reactions; long term use may cause skin pigmentation and corneal and lens deposits

- Haematological: Leucopenia, agranulocytosis
- Hepatic: Cholestatic jaundice, minor abnormalities of LFTs
- Neuroleptic malignant syndrome: A rare idiosyncratic reaction characterised by hyperthermia, muscular rigidity, autonomic instability, alteration in level of consciousness and elevated serum creatine phosphokinase (CPK)
- Others: Weight gain, hypothermia, agitation, anxiety, nausea.

Atypical antipsychotics

Clozapine: Sedation, hypersalivation, anticholinergic effects, weight gain, postural hypotension. Agranulocytosis. Lowered seizure threshold. Myocarditis in rare cases.

Olanzapine: weight gain, sedation, dizziness, anticholinergic effects

Risperidone and Amisulpride: Insomnia, anxiety, agitation.

8. PSYCHOLOGICAL FACTORS AFFECTING MEDICAL CONDITIONS

PSYCHOSOMATIC DISORDERS

Disorders characterised by the manifestation of physical or somatic symptoms which are thought to be caused by emotional factors. The symptoms are referable to dysfunction of a single organ system which is under autonomic nervous system innervation. In this respect, psychophysiological disorders differ from conversion disorders in which the primary involvement is of the voluntary neuromuscular system. There are problems when there is an underlying pathology and medical disorder which is exacerbated or relieved by psychological factors, e.g. an attack of bronchial asthma before an examination.

Clinical Manifestations

The commonly recognised psychosomatic conditions classified according to the organ system involved are:

1. *Gastrointestinal* – Peptic ulcer, ulcerative colitis, anorexia nervosa, irritable bowel syndrome.
2. *Cardiovascular* – Hypertension, myocardial infarction.
3. *Respiratory* – Bronchial asthma.
4. *Urogenital* – Menstrual disorders like amenorrhoea, dysmenorrhoea, menorrhagia, metropathia haemorrhagica.
5. *Dermatological* – Urticaria, hyperhidrosis, psoriasis, neurodermatitis, rosacea.
6. *Endocrinal* – Thyrotoxicosis, diabetes.
7. *Musculoskeletal* – Rheumatoid arthritis, tension headache.
8. *Vasomotor* – Migraine.

Etiological theories – Emotional disturbances could be responsible as predisposing, precipitating and perpetuating factors in these illnesses.

1. *Neuroendocrinal theory* – Based on the role played by the autonomic nervous system. The autonomic nervous system influences and is influenced by both, other parts of the nervous system like the limbic system, the neocortex, etc. and the endocrine glands like the anterior pituitary, the adrenal cortex, the adrenal medulla, etc. Complex inter-relationships of these various structures have been postulated to explain the translation of the conflicts arising from the problems of every day living into abnormal physiological functions and the tissue damage. The hypothalamus being the centre for the sympathetic and the parasympathetic activities is of central importance in these feedback circuits. Emotional disturbances acting through the hypothalamus affect the sympathetic and the parasympathetic systems, resulting in alterations in the functions of the viscera which these systems innervate. The end result of all these chain reactions would be the “devitalisation” of the organ, a process which would render the organ more susceptible to external or internal stimuli, both physical and physiological.

2. *Psychoanalytical theory* – The basic underlying defect is weakness of the ego, which is that aspect of the self which helps an individual to face realities of life. The development of both the ego and the personality of the individual takes shape mainly during the first few years of life. The future patterns of behaviour are laid down during these formative years. It has been suggested that in individuals who suffer from psychosomatic disorders, certain ‘infantile residues’ persist in later years. Whenever such individuals are faced with stresses of later life which they cannot cope with adequately, there occurs a psychological and/or physiological regression to these infantile or immature patterns of functioning resulting in the development of psychosomatic illnesses.

It must be borne in mind that psychological factors are not the only responsible agents but genetic, constitutional, endocrinal and metabolic disturbances also contribute to the development of these conditions. In an individual case, one or more of these factors may be of greater importance than the others. It is the complex interactions of all

these varied etiological factors which result in a psychosomatic condition. This view has a very important bearing in the treatment procedures of these diseases.

Management – Psychiatric treatment of the underlying emotional and personality factors may necessitate the use of psychotropic drugs, psychotherapy, behaviour therapy, biofeedback, etc. Treatment of the organic dysfunction by appropriate methods should be undertaken concurrently.

9. PERSONALITY DISORDERS

The presence of certain personality traits makes some individuals more vulnerable to develop behavioural abnormalities when faced with stressful events. With this degree of vulnerability, abnormal behaviour occurs only in response to environmental stress. In certain other personalities, unusual behaviour occurs even in the absence of stressful events. The latter group is referred to as personality disorders. See Table 18 for various personality disorders.

Diagnostic guidelines for specific personality disorders

- Markedly disharmonious attitudes and behaviours, involving usually several areas of functioning, e.g. affectivity, arousal, impulse control, ways of perceiving and thinking, and style of relating to others.
- The abnormal behaviour pattern is enduring, of long standing, and not confined to episodes of mental illness.
- The abnormal behaviour pattern is pervasive and maladaptive to a broad range of personal and social situations.
- The above manifestations appear during childhood or adolescence and continue into adulthood.
- The disorder leads to considerable personal distress but may only become apparent late in its course.
- The disorder is usually, but not invariably, associated with significant problems in occupational and social performance.

SUBTYPES OF PERSONALITY DISORDERS

- I. **Paranoid Personality Disorder.** Evidence of at least three of the traits and behaviours:
 1. Excessive sensitiveness to setbacks.
 2. Tendency to bear grudges persistently.
 3. Suspiciousness and pervasive tendency to distort experience by misconstruing neutral or friendly actions of others as hostile or contemptuous.

Table 18: Personality disorders (PD) clusters

1. Cluster-A (odd and eccentric)

- Paranoid PD
- Schizoid PD
- Schizotypal PD

2. Cluster B (dramatic, emotional and erratic)

Personality disorders thought to be on a 'psychopathic continuum'

- Antisocial PD
- Histrionic PD
- Narcissistic PD
- Borderline PD

3. Cluster C (Anxious and fearful)

Personality disorders characterised by 'introversion'

- Avoidant PD
- Dependent PD
- Obsessive-compulsive PD

4. Others like Anxious Personality Disorder and Passive Aggressive Personality Disorder

4. Combative and tenacious sense of personal rights, out of keeping with the actual situation
5. Recurrent suspicions without justification regarding sexual fidelity of spouse or sexual partner.
6. Tendency to experience excessive self-importance, manifest in a persistent self-referential attitude.
7. Preoccupation with unsubstantiated 'conspiratorial' explanation of events, both immediate to the patient and world at large.

Patient may get involved in litigation on small issues

Management – Individual psychotherapy and supportive psychotherapy along with symptom based pharmacotherapy.

- II. **Schizoid Personality Disorder.** Evidence is usually required for presence of at least three of the traits or behaviours given in the clinical description:
 1. Few, if any activities, provide pleasure.
 2. Emotional coldness, detachment or flattened activity.
 3. Limited capacity to express either warm, tender feelings or anger towards others.
 4. Apparent indifference to either praise or criticism.
 5. Little interest in having sexual experiences with another person (taking age into consideration).
 6. Almost invariable preference for solitary activities
 7. Excessive preoccupation with fantasy and introspection.

8. Lack of close friends or confiding relationships (or having only one) and of desire for such relationships.
9. Marked insensitivity to prevailing social norms and conventions.

Feature of this disorder may overlap with paranoid and schizotypal personality disorders. Psychotic features are absent. It is more common in men, and has an early onset in childhood.

Management - (a) Individual psychotherapy. (b) Psychoanalysis. (c) Involvement in group psychotherapy at a later stage.

III. Schizotypal Personality Disorder. A disorder characterized by eccentric behaviour and anomalies of thinking and affect, which resemble those seen in schizophrenia. At least three or four of the following should be present continuously or episodically for a period of at least 2 years:

1. Inappropriate or constricted affect (the individual appears cold and aloof).
2. Behaviour or appearance that is odd, eccentric or peculiar.
3. Poor rapport with others and tendency for social withdrawal.
4. Odd beliefs or magical thinking, influencing behaviour and inconsistent with subcultural norms.
5. Suspiciousness and paranoid ideas.
6. Obsessive ruminations without inner resistance, often with dysmorphic, sexual or aggressive contents.
7. Unusual perceptual experiences including somatosensory (bodily) or other illusions, depersonalization or derealization.
8. Vague, circumstantial, metaphorical, over-elaborate or stereotyped thinking, manifested by odd speech or in other ways, without gross incoherence.
9. Occasional transient quasi-psychotic episodes with intense illusions, auditory or others, and delusion-like ideas, usually occurring without external provocation.

It is more common in individuals related to schizophrenics and is believed to be part of the genetic 'spectrum' of schizophrenia. Its onset, evolution and course are usually those of a personality disorder, and it runs a chronic course.

Management - (a) Psychoanalysis. (b) Individual psychotherapy. (c) Drugs: Antipsychotics help in brief psychotic episodes. Response to treatment is usually poor.

IV. Antisocial/Dissocial Personality Disorder. For diagnosis clear evidence is required for at least three of the

traits or behaviours given in the clinical description. The disorder is synonymous with psychopathy and sociopathy.

1. Callous concern for the feelings of others.
2. Gross and persistent attitude of irresponsibility and disregard for social norms, values and obligations.
3. Incapacity to maintain enduring relationships, though having no difficulty in establishing them.
4. Very low tolerance to frustration and a low threshold for discharge of aggression, including violence.
5. Incapacity to experience guilt and to profit from experience, particularly punishment.
6. Marked proneness to blame others, or to offer plausible rationalizations, for the behaviour that has brought the patient into conflict with society.

There is no clear *aetiology*, several genetic, environmental and biological factors are associated such as more than normal prevalence of antisocial personality disorder in father, presence of inconsistent and impulsive parents, presence of soft neurological signs, non-specific EEG changes, and presence of conduct and/or attention deficit disorder in childhood.

Management - (a) Individual psychotherapy. (b) Psychoanalysis. (c) Group psychotherapy and self-help groups. (d) Drugs are of little value.

V. Histrionic Personality Disorder. For diagnosis evidence is required for presence of at least three of the traits or behaviours given in clinical presentations:

1. Self-dramatization, theatricality, exaggerated expression of emotions.
2. Suggestibility, easily influenced by others or by circumstances.
3. Shallow and labile affectivity.
4. Continual seeking for excitement, appreciation by others, and activities in which the person is centre of attraction (*attention-seeking attitude*).
5. Inappropriate seductiveness in appearance or behaviour.
6. Overconcern with physical attractiveness.

Associated features may include egocentricity, continuous longing for appreciation, feelings that are easily hurt, and persistent manipulative behaviour to achieve own ends. Tantrums, anger outbursts are common. The disorder is more common in females. There is an attempt to look charming and seductive.

Management - Psychoanalysis and psychoanalytic psychotherapy is helpful in removal of few symptoms.

VI. **Narcissistic Personality Disorder** is characterized by:

1. Ideas of grandiosity and inflated sense of self-importance
2. Preoccupation with fantasies of unlimited success.
3. Attention seeking, dramatic behaviour, wants constant praise, and unable to face criticism.
4. Lack of empathy with others, with exploitative behaviour.
5. Shaky self-esteem, underlying sense of inferiority, easily depressed by minor events.

Management – Individual psychotherapy may help.

VII. **Borderline Disorder**. is a disorder in which there is a marked tendency to act impulsively without consideration of the consequences, together with affective instability.

Types:

Impulsive type – Emotional instability and lack of impulse control. Outbursts of violence or threatening behaviour common, particularly in response to criticism by others.

Borderline type – Emotional instability, in addition the patient's own self-image, aims, and internal preferences (including sexual) are often unclear and disturbed. Characteristics of borderline personality disorder:

1. Significant and persistent disturbance of identity of self, e.g. 'who am I'? Marked uncertainty about major issues in life.
2. Unstable and intense interpersonal relationship patterns.
3. Impulsivity
4. Unstable emotional responses, with rapid shifts. Anger outbursts may occur.
5. Chronic feelings of boredom or emptiness with inability to stay alone.
6. Deliberate self-harm is common in the form of self-mutilation, suicidal gestures or accident-proneness.

Borderline personality disorder includes ambulatory schizophrenia and pseudoneurotic schizophrenia, which were earlier thought to be subtypes of schizophrenia.

Management – (a) Psychoanalytic psychotherapy. (b) Supportive psychotherapy. (c) Drugs: Major depressive episode if it occurs needs antidepressants with or without ECT. When aggressive and impulsivity are prominent use of antipsychotics, lithium and carbamazepine.

VIII. **Anxious Avoidant Personality Disorder**. For diagnosis clear evidence of presence of at least three of the traits or behaviours given in clinical description:

1. Persistent and passive feeling of tension and apprehension.

2. Belief that one is socially inept, personally unappealing, or inferior to others.
3. Excessive preoccupation with being criticized or rejected in social situations.
4. Unwillingness to become involved with people unless certain of being liked.
5. Restrictions in lifestyle because of need to have physical security.
6. Avoidance of social or occupational activities that involve significant interpersonal contact because of fear of criticism, disapproval or rejection.

This disorder is an epitome of what is often called 'inferiority complex'. Secondary depression is common.

Management – (a) Individual psychotherapy. (b) Group psychotherapy. (c) Behaviour therapy in particular social skills and assertiveness training.

IX. **Dependant Personality Disorder**. For diagnosis clear evidence for presence of at least three of the traits or behaviours given in clinical description:

1. Encouraging or allowing others to make most of one's important life decisions.
2. Subordination of one's own needs to those of others on whom one is dependent, and undue compliance with their wishes.
3. Unwillingness to make even reasonable demands on people one depends on.
4. Feeling uncomfortable or helpless when alone, because of exaggerated fears of inability to care for oneself.
5. Preoccupation of being abandoned by a person with whom one has close relationship, and of being left to care for oneself.
6. Limited capacity to make everyday decisions without an excessive amount of advice and reassurance from others.

Associated features may include perceiving oneself as helpless, incompetent, and lacking stamina. There may be overlap with avoidant and passive-aggressive personality disorders. Some exhibit masochistic character.

Management – (a) Individual psychotherapy. (b) Group psychotherapy. (c) Behaviour therapy in the form of assertiveness training. Response to therapy is very good.

X. **Obsessive-Compulsive (Anankastic) Personality Disorder**. Diagnostic guidelines: Evidence required for presence of at least three of traits or behaviours given in clinical description:

1. Feeling of excessive doubts and caution.
2. Preoccupation with details, rules, lists, order, organization or schedule.
3. Perfectionism that interferes with task completion.

4. Excessive conscientiousness, scrupulousness and undue preoccupation with productivity to the exclusion of pleasure and interpersonal relationships.
5. Excessive pedantry and adherence to social conventions
6. Rigidity and stubbornness.
7. Unreasonable insistence by the patient that others submit to exactly his or her way of doing things, or unreasonable reluctance to allow others to do things.
8. Intrusion of insistent and unwelcome thoughts or impulses.

The disorder is more common in males. Major depressive episodes are common. Psychodynamically the disorder is believed to result from fixation at anal sadistic phase, with employment of 'reaction formation' as a defence mechanism.

Management - (a) Psychoanalysis. (b) Group therapy. (c) Medication as in OCD.

XI. **Passive-Aggressive Personality Disorder** is characterised by following clinical features:

1. Significant and persistent passive resistance to demand for adequate social and occupational performance.
2. Stubbornness, intentional inefficiency, procrastination, unjustified protests, forgetful and/or dawdling are used to achieve the purpose.

Passive resistance is viewed as expression of 'covert anger' or 'retroflexed anger'. This behaviour is often chosen in spite of the fact that a more direct and active way of showing an opinion and/or resisting was possible.

Management - (a) Supportive psychotherapy. (b) Behaviour therapy. (c) Group therapy. (d) Drugs: Antidepressants if secondary depression.

10. SEXUAL AND GENDER PERSONALITY DISORDERS

A. Gender identity disorders

1. **Transsexuality** - Some individuals feel so unhappy in the gender of their birth and so much 'in sympathy' with the opposite sex that they seek full gender reassignment, hoping they will be happy in their new sex.

Types

Primary transsexualism. Onset in childhood with a stable course over time. *Types:* Male-to-female, or female-to-male.

Secondary transsexualism. Onset later in life. This category includes effeminate homosexuals, transvestites who secondarily become transsexuals. *Treatment:* (a) Reconciliation with the anatomic sex by psychotherapy and behaviour therapy (e.g. aversion therapy) may help in secondary transsexuals. (b) Sex change to the desired gender by sex reassignment surgery.

Necessary routine before sex reassignment surgery

- Confirmation of primary, stable long-standing transsexualism
- Possibility of stress-induced transsexualism is considered and eliminated
- Psychotherapy for at least 6 months prior to surgery
- Experimental trial in the new gender role to assess patient's ability to adjust in the 'new role'

2. **Cross dressing** is GID if transient and stress-related. Some men dress in female garments to enhance their sexual arousal. Other men feel a compulsion to dress as a female, and describe a sense of relief, relaxation and well-being when they do so. This is termed '*transvestism*'.

Less commonly some females wear clothes of the opposite sex (*dual-role transvestism*) but without a desire for a permanent sex change and without any sexual excitement as is seen in fetishist cross-dressing.

Management - Psychiatric help may be sought if cross-dressing causes problems in the family relationship. In such cases, marital or family therapy can be helpful.

3. **Gender-identity disorder of childhood.** It is similar to transsexualism with age of onset between 2 and 4 years.

Clinical features

- Persistent and strong urge to be of the opposite gender
- Distress regarding the anatomic sex with strong denial of such sex (in contrast to transsexualism)
- Involvement in usual activities, sports and clothing style of the perceived gender
- Onset before puberty

Management - Similar to transsexualism. When anatomic sex and gender-identity are opposing, treatment is based on gender-identity of the individual. Supportive and psychodynamic psychotherapy are a must.

4. **Inter-sexuality.** Presence of gross anatomical or physiological aspects of the opposite sex. These can be in:
 - External genitals, e.g. pseudo-hermaphroditism
 - Gonads, e.g. ovotestes

- Internal sex organs, e.g. true hermaphrodite
- Hormonal disturbances, e.g. testicular feminization syndrome, congenital adrenal hypoplasia
- Chromosomes, e.g. Turner's syndrome, Klinefelter's syndrome
- CNS disorder, e.g. temporal lobe affection (rare)

B. **Psychological and behavioural disorders associated with sexual development and maturation.**

1. **Sexual maturation disorder.** Usually starts in adolescence with uncertainty about gender identity or sexual orientation (heterosexual, homosexual, or bisexual). This often leads to anxiety and depression.
2. **Ego dystonic sexual orientation.** The individual desires to change the orientation because of psychological symptoms or distress. The disorder is seen commonly in homosexuality.

Homosexuality is sexual relationship between individuals of the same sex. It is a disorder only when it is the predominant, significant and persistent mode of sexual relationship for that person and is dystonic (e.g. causes significant distress to the individual). Female homosexuals are labelled 'lesbians'.

Types of homosexual disorders

1. **Obligatory homosexuality**
 - Only homosexuality
 - No heterosexuality
2. **Preferred homosexuality**
 - Predominant homosexuality
 - Occasional heterosexuality
3. **Bisexuality:** Almost equal homo- and heterosexuality
4. **Situational homosexuality**
 - Predominant heterosexuality
 - Occasional homosexuality
5. **Latent homosexuality**
 - Only heterosexuality
 - Fantasies of homosexuality

Management - is offered under certain conditions:

- a. Self-referral by a homosexual person for seeking a change in sexual orientation towards heterosexuality.
- b. Self-referral for removal of distress associated with homosexuality but not for a change in sexual orientation.
- c. Referral by parents, or relatives or others

For seeking a change in sexual orientation:

- (i) Psychoanalytical psychotherapy (especially when associated with neurotic symptoms or traits).
- (ii) Behaviour therapy: Aversion therapy, covert

desensitization (especially if there is a phobia of heterosexual relationship). (iii) Supportive psychotherapy. (iv) Occasionally androgen therapy.

- *For seeking removal of distress only:* (i) Psychotherapy: Psychoanalysis and supportive depending on personality character. (ii) Drugs: Antidepressants and/or benzodiazepines for associated depression and anxiety.
- d. *Referred by others.* Information regarding normal sexuality and homosexuality in detail leaving the ultimate decision of choosing the sexual orientation to the individuals. The person's motivation and presence of significant distress are important factors in therapy.
 3. **Sexual relationship disorder.** The gender identity disorder of sexual preference leads to difficulties in establishing and/or maintaining sexual relationships. In this case both diagnoses are justified.
- C. **Paraphilias (Disorders of sexual preference)** - Paraphilias are disorders in which sexual arousal occurs persistently and significantly in response to objects which are not connected with normal sexual arousal (e.g. non-human objects, suffering or humiliation of self and/or sexual partner, children or non-consenting person). Following are such disorders:

1. **Fetishism** (Fetishism means magical). Here sexual arousal occurs either solely or predominantly with a non-living object, generally intimately associated with the human body such as shoes, underpants, bras, stockings, etc. It occurs exclusively in males and is often associated with masturbation.
2. **Fetishistic transvestism** occurs exclusively in heterosexual males. There is cross-dressing for sexual arousal. The disorder may be associated with fantasies of other males approaching the individual who wears a female dress. Masturbation or rarely coitus is associated with cross-dressing to achieve orgasm.
3. **Sexual sadism.** Here the sadist is sexually aroused by physical and/or psychological humiliation, suffering or injury of the sexual partner (the victim). Methods used range from restraining by tying, beating, burning, cutting, stabbing, to rape and even killing.
4. **Sexual masochism** is the reverse of sexual sadism. Here the person is sexually aroused by physical and/or psychological humiliation, suffering or injury inflicted on self by others (usually sadist). Most often the masochist is a female. Sexual sadism and sexual masochism are often seen in the same individual and are hence classified as *sadomasochism*.

5. **Exhibitionism** is a persistent or recurrent way of sexual arousal by exposure of one's (usually male) genitals to an unsuspecting stranger (usually female or child). This is followed by masturbation to achieve orgasm.
6. **Voyeurism** is a persistent or recurrent tendency almost always by male to watch unsuspecting individuals (usually of the opposite sex) naked, disrobing or engaged in sexual activity. This is followed by masturbation to achieve orgasm without the observed person being aware.
7. **Frotteurism** is a persistent or recurrent habit of touching or rubbing against an unsuspecting, non-consenting person (usually of the opposite sex). It is often indulged in crowded places, e.g. trains or buses. This is often observed in adolescent males.
8. **Paedophilia** is a persistent or recurrent involvement of an adult in sexual activity with prepubertal children, either heterosexual or homosexual. This may be associated with sexual sadism. The paedophilic behaviour may be either limited to incest or spread outside the family.
9. **Zoophilia** (Beastility), a persistent involvement in sexual activity with animals is very rare. Occasional or situational zoophilia is more common.
10. **Other paraphilias** include sexual arousal with urine (urophilia), faeces (coprophilia), enemas (klismaphilia), corpses (necrophilia), etc.

Management – (a) *Psychoanalysis* helpful if patient is psychological minded and has good ego strength. (b) *Behaviour therapy*: Aversion therapy, treatment of choice in severe, distressing paraphilia. (c) *Drugs*: Antipsychotics for severe and dangerous aggression associated with paraphilias. Antiandrogens (e.g. medroxyprogesterone) in presence of excessive sexual activity. (d) *Psychosurgery* (amygdalotomy) occasionally in dangerous, aggressive sexual behaviour if persistent or recurrent.

D. Sexual problems

Sexual dysfunction can cause much distress for individuals and couples. It is necessary to take a clear and sensitive psychosexual history based on a knowledge of sexual physiology, and distinguish between problems involving loss of sexual desire, the arousal phase and orgasm.

Male problems

1. Loss of libido

Causes

- Hypogonadism
- Marital conflict
- Alcohol abuse

- Physical illness
 - Depression
 - Work stress and tiredness
2. **Erectile dysfunction** is an inability to achieve or maintain an erection, making intercourse difficult or impossible. The cause may be primary but is more often secondary, the incidence increases steeply with age.

Organic causes

- Vascular disease (most common cause of erectile dysfunction in middle-aged and elderly men)
- Neuropathy, e.g. diabetes mellitus, multiple sclerosis
- Abnormal veins draining the penis (can cause primary erectile failure)
- Nerve damage (through injury or pelvic surgery)
- Local penile deformities (e.g. Peyronie's disease)
- Tobacco, alcohol
- Drugs (e.g. β -blockers, thiazide diuretics, certain antidepressants, major tranquillizers, anticonvulsants, H_2 -receptor blockers)

Psychological factors can cause, perpetuate and complicate erectile dysfunction. Performance anxiety due to life events, stress, organic factors or relationship factor leads to initial failure, doubt and worry followed by 'spectatoring' in which self-critical monitoring of the body's performance leads to repeated failure, such that the situation becomes chronic.

Management – Ideally, methods of treatment are recommended according to the predominant cause of the problem, but in clinical practice treatment depends largely on which method the man and his partner find most acceptable.

1. *Behavioural treatment* for the couple (e.g. Masters and Johnson's sensate focus therapy) is effective in treating performance anxiety, but are less successful when organic disease is present.
2. *Intracavernosal injections* of vasoactive drugs (e.g. papaverine, phentolamine) is effective in most patients other than those with severe vascular disease.
3. *Mechanical devices* (e.g. vacuum pumps with constriction rings) are simple to use and are effective in all types of erectile problem, but patients may find them intrusive and expensive.
4. *Oral medication* – Sildenafil, vardenafil and tadalafil are phosphodiesterase (PDES) inhibitors that selectively inhibit the breakdown of vasoactive substances in penile tissue, enhancing and prolonging the erectile response once the process of arousal has begun, but is less effective when severe physical causes (e.g. advanced diabetic neuropathy) are present.

Contraindications - (a) Those who have suffered myocardial infarction, stroke or life threatening arrhythmia during last 6 months. (b) Presence of cardiac failure or unstable angina. (c) Hypotension or hypertension. (d) Patients taking nitrates for angina. Dosage: Sildenafil 50 mg one hour before sexual activity tadalafil 10-20 mg. Based on effectiveness and tolerance dose can be increased to 100 mg or reduced to 25 mg. Most persons report only mild and transient side effects (e.g. facial flushing).

3. Premature ejaculation - is a problem when ejaculation regularly occurs before or within seconds of penetration.

Management - (a) Behavioural therapy programmes such as the 'stop-start' and 'squeeze' techniques teach ejaculatory control but depend on a cooperative sexual partner and involve masturbatory exercises that some men find unacceptable. These techniques require patience and motivation, and because these conditions can be difficult to meet, drug therapy may sometimes be considered. (b) Drugs: Some antidepressants (e.g. clomipramine, selective serotonin re-uptake inhibitors such as paroxetine and sertraline) have the side effect of delaying ejaculation. Although this effect does not last when the drug is discontinued, the resulting increase in confidence may be of benefit.

4. Retarded or absent ejaculation is less common and has several possible organic causes. However it may be caused entirely by psychological or emotional factors that are amenable to behaviour therapy, couple therapy or individual psychotherapy.

Female problems

1. Loss of libido (Frigidity) is characterized by loss of desire for sexual activity which is not secondary to other causes like premature ejaculation or dyspareunia. Contributory factors may include fear of pregnancy, unsatisfactory past sexual experiences, marital disharmony or fatigue.

Treatment - Hormone regimes using oestrogen and progesterone, singly or in combination, can restore feelings of general wellbeing in postmenopausal women, but are disappointing in established loss of libido. Loss of libido in women is also dependent on testosterone, which has been used successfully. Mechanism of action is unclear; it may act centrally via the hypothalamus, or peripherally by causing growth and enhanced sensitivity of the clitoris. There is a risk of side-effects (e.g. hirsutism), and not all women respond. Most women report reduced libido in later stages of pregnancy and while lactating, principally

in response to high levels of prolactin. These high levels are temporary, but the problem can become chronic if complicating factors like postnatal depression are present.

2. Dyspareunia

Vaginismus is a spasm of the perianal muscles that circle the entrance to the vagina. It can be intensely painful and is often accompanied by phobic anxiety about vaginal penetration, which can lead to fears and panic when penetration is attempted. In *primary* cases, vaginismus can be associated with an excessively strict and negative upbringing regarding sex, or there may be history of sexual abuse as a child. The problem can also develop *secondarily* after sexual assault, clumsy vaginal examination, painful vaginal infection or complication of episiotomy. Sometimes there is no obvious cause.

Treatment - Most patients benefit from combined approach of supportive counselling and behaviour therapy, often with relaxation training and use of graded sizes of vaginal dilators; this allows the women to develop confidence and control of perineal muscles. Ideally, the woman's sexual partner is involved in therapy from an early stage; by working with his partner, he can overcome any fear of hurting her. Other causes of dyspareunia include insufficient vaginal lubrication. It may result from insufficient or poor quality foreplay, or may be a side effect of drugs such as b-blockers.

3. Anorgasmia: Inability to experience orgasm may need education about importance of foreplay and the role of the clitoris in female sexual pleasure. Treatment programmes based on relaxation, masturbation training and enhancement of pleasure using fantasy are available for women with persistent difficulties.

Secondary anorgasmia may be caused by conflict within a relationship or by pelvic surgery.

11. PERINATAL PSYCHIATRY

Perinatal psychiatry deals with mental illnesses associated with childbearing. It is also concerned with associated psychiatric problems in fathers and the special needs of parents who are psychiatrically ill and have young children.

COMMON PSYCHOLOGICAL PROBLEMS FOLLOWING CHILDBIRTH

- Low mood
- Anxiety

- Tiredness
 - Ambivalence about the baby
 - Feelings of inadequacy
 - Reduced or absent sexual interest
 - Anger and bitterness
1. **Postnatal blues.** In first few days after childbirth, many women experience anxiety, lack of self-confidence, unpredictable mood swings, tearfulness, difficulty concentrating and a general feeling of confusion.
Risk factors – History of premenstrual syndrome.
Management. – Understanding, and support of professionals, family and friends. There is no indication for drug therapy in such a brief, self-limiting disorder.
 2. **Puerperal psychosis** is an uncommon affective disorder akin to manic-depressive illness. There is pronounced disturbance of mood, which can be consistently low or high, or can fluctuate unpredictably between the two. Delusions and/or hallucinations are also present. It usually begins in the first week after delivery.

PREDISPOSING AND PRECIPITATING FACTORS

- Previous family history of psychosis, particularly puerperal
- First pregnancy
- Perinatal death
- Alcohol or drug abuse
- Poor marital relationship
- Poor social support

Management. – Antipsychotic and possibly antidepressant medication. In breastfeeding women, antipsychotic, e.g. haloperidol. Hospitalization is usually necessary.

3. **Postnatal depression** is the most common major complication (physical or psychiatric) of the postnatal period, with a peak after about 3–4 weeks. Many of the features occur in the normal puerperium. The mood is generally low, she may lose interest, feels hopeless, helpless, guilty or inadequate, has loss of appetite and difficulty sleeping. Many of these features occur in normal puerperium, but postnatal depression is differentiated by the pattern of symptoms and the severity and consistency with which they occur.

Management – Fluoxetine 20 mg, or if the woman is breastfeeding imipramine increased from 25 mg to 75 mg over a few days. Response occurs after 2 weeks.

Treatment should be continued for at least 3 months after remission. Good supportive and interpersonal psychotherapy.

12. SUBSTANCE USE DISORDERS

Many substances are taken to alter the mental state of the user. Such substances can be classified according to whether their major effect is to alter perception, or to stimulate or depress the CNS, though there is some overlap between groups.

ROUTES OF SUBSTANCE ABUSE

Ingestion is convenient, but absorption is relatively slow and the impact of the drug on the brain is correspondingly decreased, unless large quantities are taken. Drugs taken by ingestion to alter the mental state include anticholinergic drugs and plant preparations, benzodiazepines, clomethiazole, ethanol, opioid analgesics and sympathomimetics.

Inhalation allows more rapid absorption of cannabis, cocaine, nicotine, opiate analgesics, organic nitrites (e.g. isobutyl nitrite) and volatile substances. Volatile substances are usually ‘bagged’ (sprayed into a plastic bag and inhaled until the individual loses consciousness) or ‘huffed’ (sprayed into a cloth held to the mouth).

Absorption through mucous membrane (‘snorting’ or ‘snuffing’) is the method most commonly used with cocaine. The drug is stuffed into the nostrils, where it is absorbed.

Injection subcutaneously (‘skin popping’) or iv (‘mainlining’) is the fastest method of delivering drugs to the brain in high concentrations and is the route preferred for the more potent opioid analgesics.

HAZARDS OF ABUSE

- Because substance abuse is usually illegal, even seriously ill individuals may not be referred for immediate medical help and thus irreversible brain damage may result.
- Contaminants – Some complications result from deliberate addition of substances to dilute (‘cut’) the drug before it is sold. In other cases, preparation of the drug for injection (e.g. passage through cigarette filters, cotton wool) introduces contaminants. Particulate contaminants cause long-term progressive granulomatous pulmonary lesions.
- Other hazard include:
 - Infection with hepatitis B, C and D virus and HIV
 - Injection site abscess caused by infection or leakage of drug into the tissues

- Bacterial infection of veins and heart valves
- Candidiasis
- Inadvertent intra-arterial injection leading to digital gangrene

Body-packing is the practice of smuggling drugs in small packets (using condom, foil and cellophane) are swallowed for later retrieval from vomit or faeces, or are inserted into the vagina or rectum. Acute intestinal obstruction may result, and overdose is a hazard if a packet bursts.

TYPES OF DRUG USE DISORDERS

1. **Acute intoxication** is a transient condition following intake of alcohol or other psychoactive substance, resulting in disturbance in level of consciousness, cognition, perception, affect or behaviour, or other psychophysiological functions and responses.

The intensity of intoxication decreases with time, and effects eventually disappear in absence of further use of the substance.

Indications to suggest any associated complications

- Uncomplicated (Symptoms of varying severity particularly at high dose levels)
 - With trauma or other bodily injury
 - With other medical complications (e.g. inhaled vomitus, hematemesis)
 - With delirium
 - With perpetual distortions
 - With coma
 - With convulsions, and
 - Pathological intoxication (only with alcohol)
2. **Withdrawal state** - is characterized by a cluster of symptoms, mostly specific to the drug or substance used, which develop on total or partial withdrawal of the drug, usually lasts for few hours to few days. Withdrawal state is further divided into uncomplicated, with convulsions and with delirium.
3. **Dependence syndrome** is a cluster of physiological, behavioural, and cognitive phenomena in which the use of a substance or a class of substances takes on a much higher priority for a given individual than other behaviours that once had greater value.

An important feature of dependence syndrome is the desire (often strong, sometimes overpowering) to take psychoactive drugs, tobacco or alcohol (Table 19).

Table 19: Drugs or substances likely to produce dependence

Drug or substance	Route
• Alcohol	Oral
• Opioids	Oral, parenteral, smoking
• Cannabis (marihuana)	Smoking, oral
• Cocaine	Inhalation, smoking
• Amphetamine	Oral, parenteral
• LSD	Oral
• Barbiturates, benzodiazepines	Oral, parenteral
• Volatile solvents	Inhalation
• Phencyclidine	Smoking, inhalation, oral, parenteral

DIAGNOSIS OF DEPENDENCE

At least three of the following have been experienced or exhibited at some time during the previous year:

- Strong desire or sense of compulsion to take the substance.
- Difficulties in controlling substance-taking behaviour in terms of its onset, termination or levels of use.
- A physiological withdrawal stage when substance use has stopped or reduced, as evidenced by the characteristic withdrawal syndrome for the substance; or use of the same (or a closely related) substance with the intention of relieving or avoiding withdrawal symptoms.
- Evidence of tolerance, such that increased doses of the psychoactive substance are required in order to achieve effects originally produced by lower doses (e.g. in opiate and alcohol dependent individuals).
- Progressive neglect of alternative pleasures or interests because of psychoactive substance use, increased duration to obtain or take the substance or to recover from its effects.
- Persisting with substance use despite clear evidence of overtly harmful consequences, e.g. liver injury from excessive drinking, depressive mood states from heavy substance use, or drug-related impairment of cognitive functioning.

Types of dependence: Dependence can be: (a) *Psychological*: Development or craving for a substance because its effects are perceived as pleasurable. (b) *Physical*: which implies occurrence of a physiological or biochemical change produced by drugs or substances which the body requires continuous presence of, if a withdrawal syndrome is to be avoided after discontinuation of the same.

4. Harmful use – Abuse is characterized by:

- Continued drug use in spite of awareness of harmful medical and/or social effect of the drug being used, and/or
- A pattern of physically hazardous use of drug (e.g. driving during intoxication).

ALCOHOL USE DISORDERS

Etiological explanations of alcohol dependence:

- Alcoholism is simply caused by drinking too much
- Alcoholism is a result of self-medication for life-stresses
- Alcoholism is caused by depravity of temperament
- Alcoholism is hereditary

Personality and psychological factors – Two types of alcoholism have been suggested:

- *Milieu-limited*: Later onset (after 25), less severe, only slight heritability, high avoidance, reward dependence
- *Male-limited*: Early onset, greater severity, associated with criminal behaviour, highly heritable, novelty-seeking may be an important determinant of substance abuse, rather than alcohol dependence, and this may be partly associated with genetic variants at the dopamine receptor 4 (DRD₄).

Hereditary factors. Most twin studies of alcohol dependence have demonstrated that the concordance rate is greater in monozygotic twins than in dizygotic twins, confirming that this clustering is partly caused by genetic factors. Adoption studies have indicated that sons of alcohol-dependent biological parents who are adopted by other families are at greater risk of developing the disorder.

Aldehyde dehydrogenase gene. One of the clearest demonstrations that a single gene can profoundly affect drinking behaviour and alcohol dependence is the 'protection' conferred by a variant of the gene responsible for alcohol metabolism in the liver. Following absorption, alcohol is metabolized to acetaldehyde by alcohol dehydrogenase. The toxic products (acetaldehyde) is then metabolized by aldehyde dehydrogenase 2 (ALDH2). If ALDH2 activity is inhibited, acetaldehyde accumulates and the individual experiences flushing, palpitations and nausea following ingestion of small quantities of alcohol. About 40% of Orientals carry an inactive variant of ALDH2 (the gene differs by a single base), which causes the adverse symptoms. Individuals carrying the gene for inactive ALDH2 are less likely to become alcohol dependent.

Other genetic markers. Other than the association of alcohol dependence and a genetic marker at the dopamine receptor 2 gene, two genome-wide scans using a genetic linkage approach in families have implicated several chromosomal regions in alcohol dependence. These include chromosome 11 close to the DRD₄ receptor and tyrosine hydroxylase genes, chromosome 4 and chromosomes 1 and 7.

ACUTE ALCOHOLIC INTOXICATION

Clinical features

CNS depression. Ethanol is a CNS depressant which, in small quantities interferes with cortical processes, and may in larger doses, depress medullary function. The effects of ethanol on CNS are generally proportional to blood ethanol concentration (Table 20).

Vasodilation. Ethanol is a peripheral vasodilator and may cause hypothermia and hypotension in severely intoxicated individuals.

Hypoglycemia. Inhibition of hepatic gluconeogenesis may result in hypoglycemia, particularly when poisoning follows fasting, exercise or chronic malnutrition. Typically alcohol-induced hypoglycemia occurs within 6–36 hours after ingestion of a moderate to large amount of alcohol.

Table 20: Features of acute alcoholic intoxication

Blood ethanol (mg/litre)	Features
<500	Talkativeness, subjective feeling of well-being
500–1000	Inebriation Slurred speech Emotional instability Incoordination Loss of sensory perception
1000–5000	Intoxication <ul style="list-style-type: none"> • Loss of sensory perception • Muscular incoordination • Ataxia, blurred or double vision • Coma • Convulsions
>5000	Very severe intoxication <ul style="list-style-type: none"> • Coma • Hyporeflexia • Hypothermia • Respiratory depression • Poor airway protection

Note: Habitual drinkers may have few symptoms, even at high blood concentrations, whereas inexperienced drinkers may be comatose at blood ethanol concentrations of 1000 mg/litre.

The patient is often comatose and hypothermic; the usual features of hypoglycemia (e.g. flushing, sweating, tachycardia are often absent).

Lactic acidosis. Usually mild is uncommon but potentially serious complication and occurs particularly in patients with severe liver disease, pancreatitis or sepsis.

Alcoholic ketoacidosis may develop in alcoholics who have recently taken to heavy drinking; it results from a combination of dehydration, glucopenia, increased lipolysis and ketogenesis. Onset of ketoacidosis is usually preceded by an ethanol-free interval with frequent vomiting; ethanol may be undetectable in blood.

Other features. While intoxicated, patient may have suffered an injury, for example to the head or a peripheral nerve. Amnesia is common, and a hangover often results in individuals not habituated to alcohol.

MANAGEMENT

Supportive measures particularly protection of airway. In more severe cases acid-base balance should be determined 2-hourly. Blood sugar hourly and rate of i.v. glucose adjusted accordingly.

Lactic acidosis – Correction of hypoglycemia, hypovolemia and circulatory insufficiency, if present but also infusion of sodium bicarbonate.

Alcoholic ketoacidosis is corrected by infusion of 5% glucose alone.

Haemodialysis if blood alcohol concentration exceeds 7500 mg/L and/or metabolic acidosis not easily corrected by above measures.

Naloxone and flumazenil may improve consciousness (even in patients who have not ingested an opiate or benzodiazepine with ethanol) but routine use is inappropriate.

CHRONIC ALCOHOLISM

See Table 21 for complications of alcohol dependence.

Withdrawal syndrome. Chronic alcohol consumption (alcohol dependence syndrome) results in the development of withdrawal symptoms when alcohol intake ceases.

Pathophysiology. Ethanol appears to act at the benzodiazepine g-aminobutyric acid (GABA) chloride receptor complex. On withdrawal from alcohol, the receptor complex is devoid of the potentiating effects of ethanol on chloride flux; there is a subsequent decrease in the efficacy of GABA, resulting in CNS 'disinhibition'.

Table 21: Complications of alcohol dependence

Physical

Gastrointestinal

- Periodontal disease and caries
- Oral infections, leukoplakia and malignancy
- Alcoholic gastritis and hematemesis
- Alcoholic enteropathy and malabsorption syndrome
- Colonic malignancy

Hepatobiliary and pancreatic

- Hepatomegaly: Fatty liver, alcoholic hepatitis and fibrosis
- Acute and chronic relapsing pancreatitis
- Malabsorption syndrome
- Overt expression of latent genetic hepatic porphyrias

Cardiovascular

- Cardiac arrhythmia
- Cardiomyopathy
- Hypertension
- Hypercholesterolemia

Neurological

- Giddiness, tremors
- Stroke
- Cerebral dementia, cerebellar degeneration
- Demyelinating syndrome – Central pontine myelinolysis, Marchiafava-Bignami syndrome
- Neuropathy: Sensory, motor, mixed, autonomic
- Nutritional deficiencies
- Wernicke-Korsakoff syndrome
- Pellagra
- Tobacco-alcohol amblyopia

Voluntary muscle and skeletal

- Proximal metabolic myopathy, principally affecting type II
- Neuromyopathy secondary to motor nerve damage
- Atrophy of smooth muscle of GI tract leading to motility disorders
- Osteopenia
- Gout
- Avascular necrosis (e.g. femoral head)
- Fractures (malunion)

Genitourinary and reproductive

- IgA nephropathy
- Renal tubular acidosis
- Renal tract infections
- Subfertility
- Impotence
- Spontaneous abortion
- Foetal alcohol syndrome

Contd...

<i>Dermatological</i>
• Skin stigmata of liver disease
• Skin infections bacterial, fungal, viral
• Local cutaneous vascular effects
• Psoriasis
• Discoid eczema
<i>Haematological</i>
• RBCs – Macrocytosis, anemia due to blood loss, folate deficiency and malabsorption
• WBCs – Neutropenia, lymphopenia
• Platelets – Thrombocytopenia
<i>Social</i>
• Family problems
• Marital discord
• Road accidents, driving offences
• Employment (e.g. absenteeism, poor performance, redundancy)
• Children's problem (e.g. stress, behavioural problems)
<i>Psychological</i>
• Anxiety (particularly social phobia), depression
• Personality change
• Misuse of other drugs
• Cognitive impairment
• Social phobia

Alcohol withdrawal syndrome is characterised by sympathetic nervous hyperactivity leading to sweating, tachycardia, hypertension and tremor. Clinical features (e.g. fatigue, weakness, hypertension, mental confusion, depression) may be partly related to, or a consequence of the excessive corticoid concentrations observed during withdrawal.

Clinical features. Marked variations in symptoms from one alcohol episode to the next, even in the same patient. However, individuals who have previously suffered from delirium tremens or seizures are likely to develop these again in subsequent withdrawal episodes.

Minor withdrawal: Features appear within a few hours after blood ethanol concentration declines sharply – weakness, faintness, sweating, irritability, catecholamine-induced hypertension, insomnia and tremors. Full recovery occurs within 24-72 hours.

Intermediate withdrawal: In addition to above features, patients may develop (a) Hallucinations (auditory or visual in nature), often with an unpleasant or threatening content. (b) Convulsions – Fits of the uncomplicated grand mal type. (c) Dysrhythmias are uncommon and probably occur secondary to hypokalaemia, hypomagne-

semia and acid-base disturbances; they include paroxysmal atrial fibrillation, supraventricular tachycardia and ventricular tachycardia.

Major withdrawal: Delirium tremens – *Characteristic features:*

- Disorientation in time and space
- Hallucinations visual and sometimes auditory
- Extreme fear and apprehension leading to aggressive, destructive and suicidal behaviour
- Autonomic disturbances with tachycardia, fever, sweating, hypertension and pupillary dilatation

Management

Drug therapy – (a) *Benzodiazepines* – e.g. Chlordiazepoxide, lorazepam (b) *Carbamazepine* is useful in treating withdrawal features and seizures.

Other measures – Correction of electrolyte and acid-base disturbances, treatment of concomitant infection, adequate calories. B vitamin for Wernicke's encephalopathy.

Neuropsychiatric complications of chronic alcohol abuse

Wernicke's encephalopathy is an acute reaction to chronic thiamine deficiency.

Clinical Features

- *Ocular signs* – Combination of diplopia and strabismus (bilateral abducens and vertical and horizontal gaze palsies). Pupillary changes. Retinal haemorrhages and papilloedema can occur causing visual impairment.
- *Higher mental function disturbances* – Disorientation, confusion, recent memory lapses, poor attention and distractibility.
- *Others* – Polyneuropathy, ataxia are common. Marked malnutrition.

Neuropathology – Neuronal degeneration and hemorrhage in thalamus, hypothalamus, mammillary bodies and midbrain.

Korsakoff's psychosis – Wernicke's encephalopathy is often transformed into a relatively restricted Korsakoff amnesic state, characterized by gross disturbances of memory with confabulation and often impairment of insight. Main neuropathological lesion is in dorsomedial nuclei of thalamus and mammillary bodies. Changes also occur in periventricular and aqueductal grey matter, cerebellum and brainstem.

Marchiafava-Bignami disease – An uncommon disorder characterized by disorientation, fits, ataxia, dysarthrial hallucinations, spastic paresis and personality and intellectual deterioration. Dementia of subacute onset accompanied by prominent grasping and sucking reflexes.

Detection of Problem Drinkers

1. Questionnaires can be used; questions designed to reveal pattern of consumption as well as an estimate of the amount
2. CAGE questionnaire
 - Have you ever felt you should Cut down on your drinking?
 - Have people Annoyed you by criticizing your drinking?
 - Have you ever felt bad or Guilty about your drinking?
 - Have you ever had a drink first thing in the morning to steady your nerves or to get rid of a hangover (Eye-opener)?

Any single answer is probably significant; two positive answers almost certainly indicate alcohol dependence.
3. The AUDIT questionnaire performs better but is cumbersome.

Prevention of relapse in chronic alcoholism

1. **Alcoholic Anonymous** (AA) and the 12-Step Approach
For the course of an individual's life to change, not only commitment to change is required, but at least one of the following conditions must be established:
 - A substitute for the dependency
 - Powerful new sources of self-esteem and hope
 - A new stable relationship

THE 12-STEP PROGRAMME

The language is couched in religious terms; seven of the steps mention God or a higher power and the programme has a spiritual quality:

1. Admitted we were powerless over alcohol that our lives have become manageable
2. Came to believe that a power greater than ourselves could restore us to sanity
3. Made a decision to turn our will and our lives over to the care of God as we understood him.

The remaining steps are reconcerned with faith, resignation, confession and spiritual reawakening. Referral to AA is simple - individuals may call the AA helpline or just attend a meeting. It is not necessary to be an 'alcoholic', the only requirement for membership is to stop drinking. Those who are unable to achieve stable recovery by merely attending meetings may be referred to a professional treatment programme, many of which are designed to help individuals affiliate with A.

PHARMACOTHERAPIES

Alcohol-sensitizing Agents

Disulfiram

Mechanism of action - Disulfiram inhibits aldehyde dehydrogenase, which is involved in the breakdown of ethyl alcohol. If alcohol is consumed, potentially toxic blood levels of acetaldehyde are produced, leading to facial flushing, tachycardia, hypotension, nausea and vomiting, difficulty in breathing, syncope, blurred vision and physical discomfort.

The intensity of the reaction varies with the amount of disulfiram and alcohol taken. Small amounts produce discomfort, but those who consume large amounts of alcohol experience severe, life-threatening symptoms which may last for many hours.

Contraindications - Pregnancy, severe cardiac disease.

Dose: 250-500 mg daily

Anticraving agents

Naltrexone - Mechanism of action: Alcohol consumption is reinforced by an interaction with the endogenous opioid system, and blocking opioid receptors with specific antagonists lessens the pleasurable effects of alcohol, thereby weakening the behavioural reinforcement and decreasing drinking. Side effects - headache and anxiety.

Dose: 50 mg/day.

Acamprosate - Mechanism of action - The drug is structurally similar to the amino acid taurine and acts as a GABA-receptor agonist.

Dose: 1332-1998 mg/day. Side effects: Diarrhoea.

Selection of pharmacotherapy - Disulfiram is usually reserved for individuals who have undergone several unsuccessful treatments and have suffered multiple relapses. The ideal patient for treatment with disulfiram is motivated for abstinence and willing to accept supervised administration of medication.

Naltrexone and acamprosate appear to be most effective in patients whose relapses are strongly related to alcohol craving and are effective in preventing relapses in alcoholics who return to drinking after achieving abstinence. The 'ideal' patient is one who has a strong craving for alcohol, is taking medication.

Detoxification for severely dependent patients requires hospital admission. **Indications** for in-patient detoxification are:

- Severe dependence
- History of fits

- History of delirium tremens
- Severe concurrent physical or mental illness, unsuccessful attempts at out-patient detoxification. Inadequate social support.

(For volatile substance abuse, see acute poisoning)

Opiate Abuse and Dependence

Opioid derivatives

- a. *Natural alkaloids of opium*: Morphine, codeine, thebaine, noscapine, papaverine (b) *Synthetic derivatives*: Heroin, nalorphine, hydromorphone, methadone, pethidine, cyclazocine, levorphanol, diphenoxylate.

Heroin is more addicting than morphine in form of injection. In addition to parenteral use, heroin can also be smoked (or chased) often in the impure form (brown sugar or 'smack'). It can cause dependence after a brief period of use.

Clinical features include euphoria, apathy, psychomotor retardation, drowsiness, slurred speech, impairment of attention and memory.

Complications: (a) Due to contaminants: Parkinsonism, polyneuropathy, degenerative changes in globus pallidus, transverse myelitis, amblyopia. (b) Due to i.v. use: Skin infections, thrombophlebitis, endocarditis, septicæmia, HIV infection. (c) Social complication: Drug peddling and involvement in criminal activities.

Opiate withdrawal syndrome – Features include lacrimation, rhinorrhoea, pupillary dilatation, piloerection, sweating, diarrhoea, abdominal cramps, tachycardia, fever and insomnia.

ESTABLISHING DIAGNOSIS – Tests: (a) Naloxone challenge test to precipitate withdrawal symptoms. (b) Urinary opioid estimation by radioimmunoassay (RIA), free radical assay technique (FRAT), thin layer chromatography (TLC), enzyme-multiplied immunoassay technique (EMIT), etc.

Management

1. *Of opioid overdose* (see poisoning)
2. *Detoxification* – Techniques:

Use of substitute drugs, e.g. (a) Methadone, which is less addicting, with longer half-life and milder withdrawal symptoms. (b) Clonidine an α -2 agonist which inhibits release of norepinephrine at the synaptic receptors. Dose 0.3-1.2 mg/day initially, and then slowly reduced. Side-effects are sedation and postural hypotension. (c) Naltrexone and clonidine: Naltrexone, a narcotic antagonist causes withdrawal symptoms which can be countered by simultaneous use of clonidine for about 2 weeks, after which clonidine is stopped and naltrexone continued. Dose 100mg p.o. on alternate days.

Other drugs – LAAM (levo-alpha-acetyl methadol), propoxyphene, buprenorphine, phenoxylate and lofexidine.

3. *Maintenance therapy* – (a) Methadone 20–50 mg/day to shift the patient from 'hard' drugs, thus decreasing i.v. use. (b) Naltrexone 100 mg on Mondays and Wednesdays and 150 mg on Fridays. The drug combined with clonidine is very effective. (c) Other methods include individual psychotherapy, psychotropic drugs, behaviour therapy, family therapy and group therapy.

Cannabis

Preparations of cannabis are: Hasish/charas, gangja, bhang and hash oil (which is 25 times more potent than bhang). All the active ingredients of cannabis are labelled as marijuana (or marihuana).

Chronic abuse

1. *Transient disorders*: Acute anxiety, acute psychosis, hysterical fugue-like states, suicidal ideation, hypomania, schizophrenia-like state.
2. *Amotivation syndrome*: Lethargy, apathy, indolence, reduced drive.
3. *Cannabis psychosis* (Hemp insanity): Features similar to acute schizophrenic disorder with confusion and disorientation.
4. *Others*: Memory impairment, relapse in mood disorder or in schizophrenia, COPD, lung cancer, decreased immunity, diminished testosterone levels and spermatogenesis, anovulatory cycles, blocked gonadotrophic releasing hormone. Risk to the foetus during pregnancy.

Management is supportive and symptomatic. Antipsychotic drugs for psychiatric symptoms. Psychotherapy and family therapy.

CNS stimulants and Dependence

Cocaine can be taken orally, intranasally, by smoking or parenterally. It acts by inhibiting the uptake of dopamine along with that of norepinephrine and serotonin. A typical pattern of cocaine runs (binges) followed by cocaine 'crashes' from use interruption. Cocaine is at times used in combination with heroin ('speed ball') or with amphetamine.

Chronic abuse may lead to depression, memory loss, mania or paranoid psychosis. Myocardial fibrosis, cardiomyopathy, cerebral vasculitis, facial dystonic movements, preterm labour and foetal death have also been reported. Chronic intranasal use may cause perforation of nasal septum and CSF rhinorrhoea as a result of thinning of cribriform plate.

Withdrawal syndrome. Delirium, excessive fatigue, disturbed sleep, and increased dreams. A triphasic withdrawal syndrome ensues after an abrupt stoppage of chronic cocaine use (Table 22).

Complications: Acute anxiety reaction, uncontrolled compulsive behaviour, psychotic episodes (with persecutory delusions, and tactile and other illusions), and delirium. High doses of cocaine can induce fits, cardiac arrhythmias, respiratory depression, ischemic heart disease, lung damage, GI necrosis, foetal anoxia and nasal septum perforation.

MANAGEMENT. Before commencing therapy, coexisting psychiatric and/or physical disorder must be ruled out.

13. CHRONIC FATIGUE SYNDROME (CFS)

It is a syndrome of severe fatigue associated with other somatic symptoms and considerable disability, but no clear-cut biomedical diagnosis.

RISK FACTORS

- CFS is more common in individuals who have had previous psychiatric illness
- Encephalitic illnesses, and perhaps other causes of CNS damage may predispose
- Lack of physical fitness (an important variable in previously fit individual who are forced into inactivity) may have a role in perpetuating CFS.

CLINICAL FEATURES

- Fatigue is central rather than peripheral in origin, neuromuscular function is usually normal.
- Cognitive dysfunction – Most memory functions are normal, though there are problems in selective attention. CFS may be associated with a disorder of effortful cognition, rather than any defects in recall.

COGNITIVE AND BEHAVIOURAL FACTORS IN CFS

Inactivity – Rest reduces activity tolerance, and has profound effects on cardiovascular and neuromuscular function. With time more symptoms and greater level of fatigue occur at lower levels of exertion.

Inconsistent activity. Typically, prolonged rest is followed by a burst of activity that is often ‘too soon’. This often leads to complain of CFS sufferers that any activity must be ‘paid for’ later by pain and fatigue.

Table 22: Withdrawal syndrome phases

Phases	Cl. Fs.	Duration
I (crash phase) Substage 1 Substage 2 Substage 3	Agitation, depression, Anorexia, craving+++ Fatigue, depression, sleepiness, craving + Exhaustion, hyper-somnia with intermittent awakening, hyperphagia, craving±	9 hrs. to 5–7 days 4–7 days
II Substage 1 Substage 2	Normal sleep, improved mood, craving ± Anxiety, anergia, anhedonia, craving ++	4–7 days
III (Extinction phase)	No withdrawal symptoms, increased risk of relapse	After 7–10 days

Illness beliefs and fears about symptoms can influence disability, mood and behaviour. In CFS unhelpful illness beliefs include fear that: (a) any activity that increases fatigue is damaging, (b) over-exertion causes permanent muscle damage, (c) CFS is irreversible or untreatable.

Symptom focussing. Increased concern leads to increased awareness, selective attention and ‘body-watching’ which can intensify and increase frequency of symptoms.

Emotional consequences. In some patients with CFS, depression may arise during the illness, with anxiety, frustration and boredom. Depression and anxiety are associated with fatigue and muscle pain, impaired memory and reduced activity.

Management – (a) Drugs: Various antiviral drugs and agents acting on the immune system have been tried. (b) Nutritional supplements. (c) Antidepressants for patients with depressive symptoms. (d) Rehabilitation remains the mainstay of treatment.

14. DELIBERATE SELF-HARM

AETIOLOGY

Sex and age – Self-harm occurs principally in young adults, more in females.

Social factors – (a) Incidence high in lower socioeconomic status and inhabitant of urban with socioeconomic deprivation and poor social integration. (b) A major argument or separation from the partner is the most common preceding event. (c) Unemployment and increased risk among individuals with epilepsy, particularly men. (d) Break-ups in relationship and problems in relationship with their parents (among teenagers).

Psychiatric disorder – Most common are depression, alcohol and drug abuse, anxiety and eating disorders. Also personality disorders, particularly of borderline and dissocial type. Some have psychotic disorders.

NATURE OF THE ACT

Self-poisoning is most common with psychotropic drugs, paracetamol, organophosphates, other pesticides and naturally occurring poisons.

Self-injury is usually by self-cutting, particularly of the wrist or forearm. Violent forms include gun-shot wounds, hanging, jumping in front of moving vehicles, severe lacerations.

Table 23 gives the risk of repetition of self-harm.

POTENTIAL PROBLEMS IN SUICIDAL PATIENTS

- Relationship with partner, spouse or other family members particularly with young children
- Employment or studies
- Finances
- Housing
- Legal
- Social isolation (relationship with friends)
- Alcohol or drugs
- Psychiatric disorder
- Personality disorder
- Physical illness
- Sexual adjustment
- Bereavement or impending loss
- Exam failure and failed love affairs in teenagers.

Deliberate self-harm following a recent separation or major argument is less often associated with eventual suicide. The ability of patients to cope can be assessed by asking: (a) who they turn to for help, (b) how they coped with past stressful events, (c) what they think they can do to overcome present difficulties.

After care. Psychiatric disorders require treatment by the usual approaches. Psychotropic medicine may be dangerous in overdose and should be used only when genuinely necessary. SSRIs may prevent repetition of self-harm in those with history of previous episodes. Neuroleptics may help some 'chronic repeaters' and long-term individual and group therapy may benefit some with borderline personality disorders who self-harm frequently. Provision of emergency excess to advise and help at times of future crisis may be helpful in some patients.

Table 23: Risk of repetition of self-harm

Factors associated with increased risk

Previous self-harm
Personality disorder
Alcohol abuse
Previous psychiatric treatment
Unemployment
Low social caste
Drug abuse
Criminal record
History of violence
Age 25–55 years
Single, divorced or separated

Risk of suicide

Factors suggesting serious suicidal intent

Act performed in isolation
Act timed such that intervention is unlikely
Precautions taken to avoid discovery
Preparations made in anticipation of death (e.g. making a will, organizing insurance)
Active preparations made for the act (e.g. saving tablets)
Telling others about intention before the act
Extensive premeditation (more than 3 hours)
Leaving a suicide note
Failure to alert potential helpers during or after the act
Admitting the act was intended to cause death

15. EATING DISORDERS

The term 'eating disorders' refers to a group of psychiatric disorders characterized by abnormal eating behaviour that is not caused by obvious organic disease. The two major eating disorders are anorexia nervosa and bulimia nervosa; a third is binge eating disorder.

ANOREXIA NERVOSA

The primary feature is weight loss.

- *In the restricting type*, patients achieve weight loss by eating restraint alone.
- *In the binge-eating/purging type*, patients may combine calorie restriction with other means of weight control such as self-induced vomiting and abuse of laxatives or diuretics.

Excessive exercise may also be used. Such patients often also binge eat.

Amenorrhoea probably occurs secondary to weight loss. In children, the disease may present often as a reduction in the expected rate of weight increase.

Epidemiology. Although eating disorders usually develop in adolescence and young adulthood, they can occur in the elderly and in children. Anorexia nervosa is more common in occupational groups such as dancers, models, and athletes, among whom thinness is highly valued.

Aetiology - is multifactorial, involving both biological and psychological factors. Twin studies suggest that genetic factors may predispose, and certain personality traits (e.g. perfectionism, emotional restraint, low self-esteem) also have a role. Sociocultural factors are important - anorexia nervosa is more common in industrialized nations than in the developing world.

Psychopathology. Patients are overconcerned about their body size and shape. Even when they know they are significantly underweight, they often feel fat and ugly; this is termed 'body image disturbance'. Fear of complete loss of control of eating if the rigid dietary restraint is relaxed is also more common in anorexia nervosa. Depression is common.

Diagnostic criteria

- Refusal to maintain body weight at or above a minimally normal weight for age and height (e.g. weight loss or failure to make expected weight gain during periods of growth, leading to body weight < 85% expected)
- Intense fear of gaining weight or becoming fat, even though underweight
- Disturbance in perception of body weight or shape, undue influence of body weight and shape on self-evaluation, denial of the seriousness of the current low body weight.
- Amenorrhoea in post-menarchal women.

Physical Complications

See Table 24.

Investigations

- Full blood count
- Urea and electrolytes
- Calcium, magnesium, phosphate
- LFTs and serum proteins
- ECG

Additional Investigations

- Vitamin B₁₂ and folate
- RBC transketolase (thiamine)
- Dual-energy X-ray-absorptiometry

Table 24: Physical complications of anorexia nervosa

Gastrointestinal	Metabolic and nutritional
Dental erosion	Hypokalaemia
Parotid enlargement	Metabolic alkalosis
Oesophagitis	Hyponatremia
Mallory-Weiss tears	Hypochloreaemia
Acute gastric dilatation on refeeding	Hypocalcemia
Abnormal LFTs	Hypomagnesemia
Pancreatitis	Hypophosphatemia
Delayed gastric emptying	Zinc deficiency
Constipation	Thiamine deficiency
Gastric and oesophageal perforation	Impaired renal concentration ability
	Refeeding oedema
Cardiovascular	Haematological
Bradycardia	Neutropenia
Hypotension	Anemia
Arrhythmia	Thrombocytopenia
ECG changes (prolonged QT, ST-T changes, decreased QRS amplitude)	Musculoskeletal
	Osteoporosis
Cardiac failure on refeeding	Proximal myopathy
	Endocrine
	Amenorrhoea
	Low testosterone
	High cortisol
	Skin
	Lanugo hair
	Dry skin
	Hypercarotenemia

Management

a. Out-patient

No form of individual psychotherapy has been shown to be superior to any other, and mostly an electric approach including elements of psycho-education is adopted. Medication has little role.

b. In-patient

Treatment is aimed at restoring normal weight while simultaneously addressing the underlying psychological problem. Refeeding programmes are designed to achieve a weight increase of 0.5–1 kg/week.

Indications for inpatient - (i) Very low weight or rapid weight loss. (ii) Serious physical complications. (iii) Severe psychiatric co-morbidity. (iv) Failed out-patient treatment. (v) Lack of out-patient facilities. (vi) Need for separation from family.

TREATMENT OF PHYSICAL COMPLICATIONS – (a) Osteoporosis may lead to pathological fractures, replacement oestrogen therapy or calcium supplementation preparations can be prescribed. (b) Amenorrhoea usually resolves following restoration of normal weight.

BULIMIA NERVOSA

Aetiology. (a) It is likely that young women who develop bulimia nervosa are responding to similar cultural pressures, and the disorder commonly follows a period of attempted eating restraint. (b) About 30% suffered sexual abuse as children. (c) Genetic factors appear to be less important than in anorexia nervosa, but there is evidence of a role for the 5-HT neurotransmitter system, which is involved in the regulation of appetite.

Diagnostic criteria

- Recurrent episodes of binge eating
- Recurrent inappropriate compensatory behaviour to prevent weight gain
- Binge-eating and inappropriate compensatory behaviours occurring on average, at least twice weekly for 3 months
- Self-evaluation unduly influenced by body shape and weight
- The disturbance does not occur exclusively during episodes of anorexia nervosa

An episode of binge eating is characterized by:

- Eating in a short period of time (e.g. 2 hours) an amount of food larger than most individuals would eat during similar circumstances
- A sense of lack of control of eating (e.g. amount, type of food)

Physical complications

- Hypokalaemia
- Metabolic alkalosis
- Dental erosion
- Parotid enlargement
- Hyperamylasaemia
- Mallory-Weiss tears of oesophagus

Investigations

- Full blood count
- Urea and electrolytes
- Calcium, magnesium, phosphate
- ECG

Management – Cognitive behaviour therapy which requires 10–12 sessions of treatment. Admission to hospital may be required in patients with complicated types of the disorders (e.g. multi-impulsive). Fluoxetine 40–60 mg/day reduces the urge to binge in a good number of patients, and can be used as an adjunct to psychological treatment.

BINGE-EATING DISORDER

It is characterized by repeated binge-eating without the compensatory behaviours seen in bulimia nervosa. Consequently, most patients are overweight, and may represent a specific subgroup of the obese. These individuals have a higher level of general psychiatric morbidity. Some patients may benefit from psychological interventions. It is more common in obese and over-weight individuals.

16. CHILD PSYCHIATRY

ASSESSMENT OF PSYCHIATRIC DISORDERS IN CHILDREN

A psychiatric disorder can be defined as behavioural or emotional symptoms so prolonged or severe that they cause suffering to the child or to others, social restriction or impairment of development. Some symptoms (e.g. fire-setting in the home when others are asleep, delusions, deliberate self-harm) are so extreme that they are considered abnormal when they occur only once. Most symptoms, however are considered abnormal only if they persist, are seen in several situations and lead to impairment. Table 25 gives principal disorders in children.

Type of disorder. Different components of the child's problems are recorded separately using multi-axial classification:

- Axis 1 Clinical psychiatric syndrome
- Axis 2 Specific developmental disorders
- Axis 3 Intellectual level
- Axis 4 Medical conditions
- Axis 5 Abnormal psychosocial situations
- Axis 6 Severity of impairment

Assessment process

- Family interview* to determine how the parents respond to the child's communications (e.g. sympathetically, critically), whether parents have difficulties in their own relationship.

Table 25: Principal disorders in children

Emotional disorders
Anxiety
Depression
Somatization
Obsessive compulsive disorders
Behavioural disorders
Conduct disorders
Hyperkinetic disorder
Mixed disorders of conduct and emotion
Other disorders
Autism and related disorders
Schizophrenia
Enuresis and encopresis
Mental retardation
Learning disability
Academic backwardness
Epilepsy and its consequences
Brain injury in childhood
Disorders due to situations in the family

- b. *Interview with the child.* Area to be assessed include general behaviour, dress and appearance, emotional responsiveness, habitual mannerisms, mood, pre-occupations, speech, attention, activity level and cognition.
- c. *Other sources of information* particularly the school.

MENTAL RETARDATION

Sub-average general intellectual functioning which originates in the developmental period and is associated with impairment of adaptive functioning.

Diagnosis of intellectual defect – Mental retardation should be suspected if any of the following are present in an individual:

- Clinical findings** – (a) History of mental deficiency in the family. (b) Home environment which hampers the development of mental potentialities due to inadequate intellectual, social and personality forming influences. (c) Evidence of anomalies of skull such as microcephaly, oxycephaly, hydrocephalus, asymmetry of skull and face, malformations of external ear, eye and nose; thickness of lips, protruding mandible, ill-formed teeth and deformities of palate. (d) Delay in physiological, psychological or social development, i.e. delay in the milestones. (e) Defect in articulation of

speech and vocabulary. (f) Poor scholastic performance like repeated failures in examinations. (g) Short span of general information and practical knowledge. (h) Inefficiency in work and poor economic achievements.

- Intelligence Quotient (IQ) tests** – These tests are standardised and their reliability and validity indices fall within an accepted range. However, a patient's cooperation is necessary for proper assessment of these tests. Verbal and non-verbal (performance) items comprise the IQ tests from which the mental age of a patient can be determined. The IQ can then be calculated as follows:

$$IQ = \frac{\text{Mental age} \times 100}{\text{Chronological age}}$$

Average IQ = 90–110. IQ of 70 to 90 constitutes borderline mental retardation.

Grades of Retardation:

- Mild: IQ 50–70
- Moderate: IQ 35–49
- Severe: IQ 20–34
- Profound: IQ below 20

Aetiology: Several factors are incriminated, but in majority of cases, no cause can be found (idiopathic or subcultural). The factors could operate before, during or after birth, but before complete mental development is attained (Table 26).

Management

- Piracetam* – 40 mg/kg/day in divided doses, a nootropic drug is postulated to improve concentration and learning abilities of retarded children. No drugs, however, are available to increase the level of intelligence.
- Psychotropic drugs* – for associated behavioural abnormalities.
- Counselling of parents.*
- Education and training in schools* for the mentally handicapped.
- Appropriate rehabilitation* depending on each individual's level of intelligence and aptitude.
- Management of behavioural problems* by appropriate medication and behaviour therapy.

EMOTIONAL DISORDERS IN CHILDREN

- Anxiety disorders** are often exaggerations of normal development trends. Onset is usually during the developmentally appropriate age period. For example, it is normal for infants to show anxiety over separation

Table 26: Aetiology of mental retardation

<p>1. Prenatal factors</p> <p>a. Chromosomal abnormalities like Down's syndrome, Klinefelter's syndrome, Turner's syndrome.</p> <p>b. Inborn errors of metabolism – e.g. phenylketonuria, galactosaemia, mucopolysaccharidosis, Tay-Sachs disease, Gaucher's disease, etc.</p> <p>c. Cranial malformations – Hydrocephaly, microcephaly.</p> <p>d. Gross brain disease – Tuberosus sclerosis, neurofibromatosis, cerebral palsy.</p>
<p>2. Perinatal factors</p> <p>a. <i>Infections</i> – Rubella, cytomegalovirus, toxoplasmosis, syphilis.</p> <p>b. <i>Intoxications</i> – Certain drugs, lead, bilirubin (kernicterus).</p> <p>c. <i>Physical causes</i> – Injury, hypoxia, radiation.</p> <p>d. <i>Placental dysfunction</i> – Toxaemia, nutritional growth retardation.</p> <p>e. <i>Endocrine disorder</i> – Hypothyroidism</p> <p>f. <i>Birth trauma</i></p> <p>g. <i>Prematurity</i>.</p>
<p>3. Postnatal factors</p> <p>a. <i>Infections</i> – Meningitis, encephalitis.</p> <p>b. <i>Head injury</i> – Accidental, child abuse.</p> <p>c. <i>Intoxication</i> – Lead, carbon monoxide.</p> <p>d. Adverse family and sociocultural factors – Low socioeconomic status, poverty, poor housing, malnutrition, unstable family environment.</p>

from those to whom they are attached – it is only when this anxiety causes impairment or persists into later childhood or adolescence, that separation anxiety disorder is diagnosed.

Aetiology – (a) Genetic factors: Children who are constitutionally 'slow to warm up' and inhibited are at greatest risk. (b) Anxious parents behaving overprotectively. (c) Some cases (particularly those caused by specific fears) are precipitated by stress.

Management – Reduction of stress, behavioural treatment of specific symptoms (e.g. graded exposure to the feared situation) and general treatment (e.g. relaxation). Anxiolytics are helpful in severe cases, but should not be prescribed for long periods.

2. Depressive disorders are uncommon in prepubertal children. Main clinical features are the same as in adult depression, but depressed children suffer more somatic complaints and anxiety than adults. Infants who have been severely deprived or abused sometimes show a state of withdrawal retarded development (anaclitic depression).

Children with depressive disorders tend to have parents who are depressed. About 50% of depressed children also have an anxiety disorder, and 20% have a conduct disorder.

Management – comprises reducing adversity, behaviour therapy (to children > 10 years of age) and /or family support. SSRIs (e.g. fluoxetine, paroxetine) may be useful in severe cases. Supportive psychotherapy and family therapy is the key to effective therapy.

3. Somatization. Unexplained physical symptoms such as abdominal pain and headaches are associated with emotional disturbances, but most of the children are not otherwise psychologically disturbed. They tend to come from families in which there are health problems and high academic expectations. In many cases, the child is in a predicament from which there is no other means of 'escape'. Pre-existing physical problems in the child or in a relative may determine the type of symptomatology. Many children may develop these symptoms as an excuse to avoid exams and school after a long vacation.

Management – involves close liaison between psychiatrist and paediatrician, changing the family focus from physical to psychological issues, and an emphasis on the child leading as normal a life as possible (e.g. returning to school).

4. Obsessive compulsive disorder. Obsessions are a normal part of child development. In middle childhood, obsessional acts such as avoidance of stepping on cracks in the pavement are common, in late childhood, obsessive collection of objects (e.g. stamps). The most common presenting obsessions are fear of dirt, fear that something terrible will happen, and fear of disorder. The most common compulsions are washing rituals, repeating rituals and checking.

Obsessive-compulsive symptoms are often found in conjunction with other emotional disorders. Onset tends to be earlier in boys than in girls. Childhood onset OCD is associated with basal ganglia disease, a family history of disorder or tics, and family stress.

MANAGEMENT – Behavioural interventions such as response prevention, and SSRIs (e.g. fluoxetine) or clomipramine.

5. School attendance problems. Some form of emotional disorders are often present, but the most common reason for failure to go to school is truancy, in which absence of school is concealed from parents. School refusal can be a symptom of any form of emotional disorder, particularly separation anxiety. Complaints of illness are often used, and abdominal pains may occur on school days (periodic syndrome).

Management depends on the cause. Close liaison with the school and educational welfare service are important.

6. Enuresis and encopresis

Table 27: Components of hyperactivity**Attention deficit**

- Fails to give attention
- Does not listen
- Easily distracted
- Forgetful
- Does not copy notes completely
- Loses things in the school

Hyperactivity

- Excessive movements
- Fidgety
- Has difficulty playing quietly
- Talks excessively

Impulsivity

- Often acts without thinking
- Reckless
- Difficulty taking turns
- Interrupts others

Childhood enuresis (*see* diseases of children)

Encopresis is involuntary passage of faeces into clothing after the age at which bowel control is usual and in absence of a known organic cause.

Aetiology: (a) Poor toilet training. (b) Environmental stress, e.g. following birth of younger sibling, conflict between parents illness of parent.

Encopresis like enuresis could be present from birth (primary) or could appear after a sustained period of continence (secondary).

Management: (a) Counselling regarding faulty toilet training. (b) Behaviour therapy to encourage child to remain continent. Medication may be needed when aggression is very high. Supportive psychotherapy and family therapy essential.

BEHAVIOURAL DISORDERS IN CHILDREN

1. **Conduct disorders** – are characterized by repetitive antisocial behaviour that lasts for at least 6 months. In young children, the clinical picture is dominated by markedly oppositional behaviour such as defiance, hostility and disruptiveness. In older children behaviours such as stealing, truancy, lying and running away are seen. In the most severe cases, fire-setting or cruelty to animals may occur.

AETIOLOGY – (a) Twice more common in boys. (b) Strong link with family dysfunction, particularly discordant intra-family relationships. (c) Genetic factors role is unclear,

Table 28: Differential diagnosis of hyperkinetic disorders1. **Normal developmental variation**2. **Co-morbid conditions**

- Conduct disorder
- Pervasive developmental disorders (e.g. autism)
- Specific developmental disorder (e.g. language disorder)
- Mental retardation

3. **Disorders affecting activity level or attention**

- Anxiety disorders
- Mood disorders (e.g. mania, depression)
- Substance abuse
- Attachment disorders

though temperamentally ‘difficult’ babies seen to be at a greater risk.

MANAGEMENT – Parenteral skills training encouraging the parent to monitor child’s behaviour, to become more involved with the child, to discipline the child more effectively, and to encourage pro-social behaviour. Severely disturbed children may benefit from placement in a special school or other residential setting.

2. **Hyperkinetic disorders** are characterized by early onset of overactive behaviour, impulsiveness and marked inattention (Table 27). The disorder is four times more common in boys.

Aetiology. Brain dysfunction resulting from genetic processes or early brain damage is important. Hyperkinesis may occasionally result from early social deprivation. It is also associated with family discord.

Several other abnormalities are associated with the disorder, including conduct disturbances and learning difficulties. See Table 28 for the differential diagnosis of hyperkinetic disorders.

Management

1. *Biological factors* (a) Environmental manipulations such as starting fulltime school. (b) Behaviour modification programmes that encourages the child to concentrate for increasingly lengthy periods. Modifying the child’s diet may help.
2. *Stimulant medication* (e.g. methylphenidate) in a dose of 5–10 mg/day for 1 week initially, increasing to 20–40 mg/day depending on response. Dexamphetamine can be used as an alternative in children under 6 years of age. Side effects – Long-term effects on growth are uncertain, dysphoria, tics and poor sleep. Newer drugs like Atomoxetine 10–40 mg/day may be used in some cases.

3. *Mixed disorders of conduct and emotion* are characterized by a mixture of emotional and behavioural problems. About 20% of children also have conduct disorder ('depressive conduct disorder'). Treatment is symptomatic.

LEARNING DISABILITY

Learning disability is defined as a significant impairment of intelligence and social functioning acquired before adulthood.

Aetiology

- It is more common in males. Some affected family members have psychiatric disorder without learning disability.
- Metabolic causes (e.g. phenylketonuria)
- Infections (e.g. cytomegalovirus, rubella, measles, AIDS) are important causes in perinatal period
- Injury in childhood may cause permanent brain injury
- No identifiable cause
- Co-morbid conditions including increased prevalence of epilepsy, psychiatric disorders, hearing and visual impairment, autism.
- Two main characteristics are manifested in the developmental period
- No known medical cause is required

CO-MORBIDITY - Epilepsy in about one third with severe learning disabilities, often presenting at puberty. Depression is common in adults with learning difficulties, but may remain undiagnosed because of atypical presentation (e.g. irritability, aggressive outbursts, loss of interest, with or without disturbance of sleep or appetite).

MANAGEMENT - (a) Regular health checks to exclude sensory problems, thyroid disease, depression and other co-morbidity conditions. (b) Multidisciplinary assessment advisable.

AUTISM

Diagnostic Criteria

- Qualitative impairment in social interactions
- Qualitative impairment in verbal and non-verbal communication
- Restrictive, repetitive and stereotyped patterns of behaviour, interests and activities

Social impairment comprises limited eye contact and little use of body language and facial expression. Autistic children often lack any interest in social activities. If they

do try to make friends with children of their own age, they are usually rebuffed because of social ineptitude.

Communication impairment - Many autistic children with low IQ do not develop useful speech. Language development is usually delayed and they do not use non-verbal gestures in compensation (unlike deaf children, with whom they may be confused initially).

Behaviour - The behaviour of autistic children is stereotyped, and lacks imagination. Many such children flap their hands or spin when excited or upset. Others have bizarre preoccupation with the feel, taste or smell of certain objects such as sand, water or metal.

Intelligence - 75% of autistic individuals have an IQ of < 70, and of these, two-thirds < 50. Typically, non-verbal abilities are considerably better than verbal skills.

Pervasive developmental disorders. In addition to the core syndrome, the ICD-10 classification includes conditions that are autistic-like (termed pervasive developmental disorders, PDDs) including Asperger's syndrome. Typically PDDs are less severe than autism, and social communication deficit is usually the main clinical feature. Asperger's syndrome may be indistinguishable from high-functioning autism, but lacks a significant delay in cognitive and language development. Motor clumsiness and circumscribed interests dominate the clinical picture.

Aetiology: Autism is a strongly heritable disorder and the genetic predisposition is polygenic but none of the genes have been identified. Mild impairment of social communication skills is more commonly found in first-degree relatives, affecting upto 10%, particularly males. Viral hypothesis as well as biological factors and vaccine-related side effects have been proposed as causative factors.

Investigations. In addition to IQ and formal language skills, EEG, screening for fragile X and chromosomal anomalies and a brain scan may be necessary.

Associated disorders. Risk of autistic-like symptoms is increased in tuberous sclerosis, and may be increased in some genetic anomalies (e.g. fragile X syndrome, certain structural anomalies of chromosome 15q, Turner's syndrome). Some children develop seizures in infancy (usually infantile spasm).

Differential Diagnosis of autism includes hearing problems, receptive-expressive language disorders and global intellectual delay. However children with these conditions do not have difficulties in making social relationships, and do not engage in repetitive behaviours or rigid routines to the same extent as those with autism.

Management. (a) Developing communication: Education provision should aim to maximize social, communicative and intellectual functioning. In some cases, behavioural interventions to reduce repetitive, stereotyped, self-injurious and challenging behaviours. (b) Medication: Neuroleptics (e.g. haloperidol) for stereotyped behaviours and hyperactivity. Risperidone to relieve anxiety, aggression and repetitive behaviour. SSRI (fluoxetine) could ameliorate autistic symptomatology.

17. DRUG-INDUCED PSYCHIATRIC DISORDERS

CLASSIFICATION

1. Behavioural toxicity

- Drowsiness* – Benzodiazepines, neuroleptics, antihistaminics, antidepressants, antihypertensives.
- Behavioural changes* – consisting of irritability, aggressive outbursts and a generalised hostile attitude: Benzodiazepines, barbiturates, levodopa, neuroleptic drugs, alcohol, drug-withdrawal states. Some tricyclic antidepressants, selective serotonin uptake inhibitors.

2. Delirium (Acute organic psychosis)

- Cardiovascular drugs – Digitalis, diuretics, propranolol, pindolol, oxprenolol. (b) Anticholinergics – atropine, homatropine, scopolamine, antiparkinsonian drugs, tricyclic antidepressants. (c) Tranquillizers and hypnotics – barbiturates, benzodiazepines, antidepressants, phenothiazines, bromides. (d) Antituberculous drugs – Isoniazid, rifampicin, cycloserine. (e) Anticonvulsants – Phenytoin, sodium valproate. (f) Miscellaneous drugs – Corticosteroids, insulin, disulfiram, cimetidine, chloroquine, aminophylline, oral hypoglycaemic agents. (g) Drug withdrawal – Barbiturates, benzodiazepines, chlormethiazole, dextropropoxyphene, alcohol, opiates, phencyclidine.

3. Affective states –

Depression – (a) Antihypertensive agents – reserpine, alpha methyl dopa, clonidine, propranolol, pindolol. (b) Corticosteroids. (c) Psychoactive drugs – phenothiazines, neuroleptics, benzodiazepines. (d) Antiparkinsonian agents – Levodopa. (e) Analgesics – Indomethacin, pentazocine. (f) Hormones – Oestrogens, oral contraceptives. (g) After withdrawal of CNS stimulants – amphetamines, cocaine. (h) Miscellaneous drugs – Ethanol, antineoplastic agents,

disulfiram, tetrabenazine, phenytoin, phenobarbitone, theophylline, digoxin, danazol, cimetidine, chloroquine, cycloserine.

Elation – (a) Antidepressants. (b) Corticosteroids. (c) Anti-parkinsonian agents – benzhexol, procyclidine, levodopa, bromocriptine. (d) CNS stimulants – amphetamines, cocaine, methylphenidate. (e) Miscellaneous – Isoniazid, aminophylline, cyclizine, yohimbine, salbutamol, clonidine withdrawal.

4. Psychotic states –

- Hallucinogens – LSD, cannabis, phencyclidine. (b) CNS stimulants – Cocaine, amphetamines. (c) Appetite suppressants – Phenmetrazine. (d) Sympathomimetics – Ephedrine, pseudoephedrine, phenylephrine. (e) Alpha-adrenergic agonists – phenylpropanolamine. (f) Beta-adrenergic agonists – Salbutamol. (g) Beta-adrenergic antagonists – Propranolol, oxprenolol. (h) Dopaminergic drugs – Levodopa, dopamine, bromocriptine. (i) Narcotic analgesics – Pentazocine. (j) Corticosteroids. (k) Non-steroidal anti-inflammatory agents – Indomethacin. (l) Anti-depressant drugs. (m) Anticholinergic drugs. (n) Miscellaneous – Disulfiram, anti-tuberculosis drugs, cimetidine, antihistaminics, digoxin, methyl dopa, phenytoin.
5. *Pseudodementia* – Benzodiazepines and barbiturates, major tranquillizers, anti-hypertensives, diuretics, antiparkinsonian drugs and digoxin in the elderly, and overdose of antiepileptic drugs in some epileptics. Chronic hypoglycemia due to oral hypoglycaemic drugs or insulin.
6. *Neuropsychiatric states* – Combinations of psychiatric and neurological symptoms and signs. Phenytoin can induce a paranoid-hallucinatory psychosis or delirium with cerebellar signs and symptoms. Neuroleptics can produce extra-pyramidal reactions like akathisia, pseudo-parkinsonism, acute dystonias and tardive dyskinesia.

18. TREATMENT METHODS IN PSYCHIATRY

I. Psychotherapies

Psychotherapy is an effective primary treatment for many psychiatric disorders. A range of different psychotherapies is now available that can be matched to the illness and personality of the individual patient (Table 29).

Assessment – Despite the overlap between different psychotherapies, assignment of patients to an appropriate therapy is a central psychotherapeutic task.

Table 29: Psychiatric disorders and their psychiatric treatment

Schizophrenia
• Cognitive behaviour therapy for delusions and hallucinations
• Family intervention to reduce expressed emotion
Depressive disorders
• Cognitive behaviour therapy, interpersonal therapy or brief dynamic therapy for mild-to-moderate depression
• Supportive psychotherapy or psychoanalytical psychotherapy for chronic dysthymia
Anxiety disorders
• Behaviour therapy
Obsessive compulsive disorders
• Behaviour therapy
Eating disorders
• Family therapy
• Cognitive behaviour therapy
• Psychoanalytical psychotherapy
Borderline personality disorder
• Psychoanalytic psychotherapy
• Dialectical behaviour therapy
• Supportive psychotherapy
Post-traumatic stress disorder
• Cognitive behaviour therapy
Abnormal grief reactions
• Guided mourning
Learning difficulties
• Creative therapies
Somatoform disorders
• Cognitive behaviour therapy

The dynamic loop – The mind can be considered to maintain a dynamic equilibrium, both internally and in relation to the environment. There is a hierarchy of interlocking psychological structures and mechanism comprising basic assumptions about the world, expectations about relationships ('object relations') and manifest behaviour connected via feedback loops that exist between individuals and their intimates. Psychotherapies aim to intervene at a number of points in this chain, hoping that changing one part will have an effect through the whole system.

Counselling – Compared with formal psychotherapy, counselling tends to be time-limited and less intense, and is undertaken at the level of primary rather than secondary services.

Main Groups of Psychotherapies

1. **Psychoanalytic psychotherapy** – is particularly appropriate to patients with borderline personality disorder or repeated relationship difficulties, or some psychosexual disorders, and sometimes in those with chronic mild depression.

TECHNIQUES – Psychoanalysis attempts to recreate and so reveal the unconscious assumptions, attitudes and desires that motivate patients, and which have led to their difficulties. The main vehicle for such revelation is the transference relationship with the therapist. The process is slow, and working through insights takes time, particularly in the highly disturbed patients to whom the therapy is usually offered.

2. **Brief dynamic therapy** (focal therapy). Here the therapist is more active than in psychoanalytic psychotherapy, often initiating and guiding sessions rather than waiting passively for the patient to reveal material.

Indications – Patients with circumscribed disorders (e.g. mild-to-moderate depression, anxiety states), who are well motivated, and are not actively suicidal or abusing drugs or alcohol. Although improvements in brief dynamic therapy tend to be maintained for upto 1 year, some patients require continuous treatment because relapse rate is high.

3. **Behaviour therapy**

Indications – Phobic disorders such as agoraphobia, specific phobias, social phobia and panic disorder. Standard treatment (often with clomipramine) for obsessive compulsive disorder, learning difficulties, severely disturbed patients.

Technique – ABC principle of:

- Antecedents
- Behaviour
- Consequences

Treatment comprises:

- Teaching the patient anxiety reduction techniques (e.g. deep relaxation)
- Graduated exposure to the feared stimulus, usually using positive reinforcement in the form of encouragement from the therapist, who maintains an uplifting attitude.
- Occasionally, negative reinforcement (e.g. snapping a rubber band on the wrist whenever an unwanted thought intrudes into the mind).

- Active collaboration between therapist and patient, in which patients are encouraged to become 'scientific observers' of their difficulties by recording their behaviour, and are set 'homework' aimed at modifying it. Contingency is a useful technique in behavioural family work, e.g. patients might be offered a reward in return for getting out of bed at an agreed time.
4. **Cognitive behavioural therapy (CBT)** – Techniques used in cognitive behaviour therapy are problem-oriented, aimed at changing errors or biases in cognition by appraisal of situations and stresses, and may modify assumptions about self, the world and the future. See Table 30 for the indications for cognitive behaviour therapy.

Cognitive therapies are two groups of skills: (a) *General therapeutic skills* are the basis. They are probably essential for engaging patients in treatment and maintaining the relationship and include setting a common agenda for therapy, (ii) eliciting feedback frequently, (iii) developing understanding and empathy, (iv) demonstrating interpersonal effectiveness, (v) maintaining collaboration, (vi) pacing and efficient use of time. (b) *Conceptualization, strategy and techniques* are more specific to cognitive behaviour therapy, e.g. patients can benefit from reading relative supporting literature, or from undertaking tasks to explore their problems further (e.g. completing diary sheets about panic attacks).

5. **Systemic (family/marital) therapies** are concerned with:
- How power is distributed between parents and children, and between men and women (e.g. do all have an equal voice, or are only certain family members heard?)
 - How communication occurs and between whom (e.g. are communication 'routed' through one family member or is there free flow?)
 - How close or detached are individual family members?
 - What 'skeletons should be left in the cupboard'.
 - Family work is increasingly used in schizophrenia and can help reduce relapse rates in high 'expressed emotion' families.
6. **Creative ('humanistic') therapies** – constitute a heterogeneous group of therapies including psychodrama, art, music and movement therapies and Gestalt therapy. Their common themes include:
- Creative expression as a means of restoring self-esteem

Table 30: Indications for cognitive behaviour therapy

• Depression (particularly long-standing)
• Panic disorder
• Physical symptoms of 'unknown' origin including chronic fatigue syndrome
• Bulimia nervosa
• Obsessive-compulsive disorder
• Personality disorder
• Schizophrenia

- Doing rather than talking (e.g. in Gestalt therapy, who is expressing anger towards a patient might be encouraged to 'put' that parent in an empty chair and speak to him or her as if present)
 - An emphasis on here and now rather than past experiences.
 - Creative therapies are particularly helpful in patients for whom verbal expression is problematic because of alexithymia (inability to put feelings into words).
7. **Integrative therapies** – Because patients often have a range of different problems (e.g. agoraphobia and marital difficulties), it can be helpful to combine or integrate therapeutic strategies.

'*Conversational model*' is a brief expressive therapy that has been used effectively to treat chronic functional bowel disease, depression and chronic non-psychotic psychiatric outpatients.

Interpersonal therapy is a ten-session course of therapy combining cognitive, marital and dynamic therapeutic approaches. It is effective in treating neurotic disorders, mild depression and bulimia nervosa. It focuses on the patient's current life situation and relates difficulty to unresolved grief, 'transitions' (e.g. leaving home, retirement), relationship conflicts with partners, and social skill deficits. Each is tackled using an appropriate technique.

Cognitive analytic therapy is a 16-session therapy combining a dynamic focus on the relationship with the therapist, a 'formulation' based on the idea that neurotic patterns are self-perpetuating, and a cognitive emphasis including keeping a mood diary and self-rating target problems.

Dialectical behaviour therapy combines cognitive behavioural approaches with a Zen Buddhist technique that helps patients maintain 'attentional focus' and thus be less tempted to self-harm.

8. **Group therapies** – 'Group analysis' combines psychoanalytic and sociological thinking. Therapeutic factors in groups include:

- Mutual support and challenge of fellow sufferers
- Seeing one's own problems from the outside, through the eyes of, or enacted by another
- Reduced isolation and stigmatization (I am not the only one)
- A sense of belonging
- The power of the group matrix to hold and tolerate one's disturbance
- Identification of both strengths and weaknesses.

Groups may be long-term or short-term, closed or 'slow-open', analytic, behavioural or humanistic.

9. **Supportive psychotherapy** is integral to routine psychiatric practice, and covers at least three different types of therapies:

- Brief counselling and support given to patients who are in crisis, often associated with bereavement or trauma
- Non-intensive psychoanalytical therapies (psychoanalytical psychotherapy)
- Formal but non-intensive therapy, often for highly disturbed patients who can be 'held' in supportive psychotherapy but are unsuitable for other forms of therapy.

10. **Hypnosis** – is a psychotherapeutic technique in which the person either by himself or with professional help, achieves a stage of concentration (hypnotic trance), characterized by high degree of focal attention with diminished awareness about the surroundings resulting in highly receptive state to suggestions.

Changes during hypnotic trance

- The individual under hypnosis becomes highly suggestible to the commands of the hypnotist not understanding their nature.
- Dissociation of a part of the body or emotions from the remainder may occur
- Partial or complete amnesia for events during hypnotic trance
- Ability to produce or remove symptoms, perceptions and/or movements
- Suggestion given soon after the trance are followed by the hypnotized person.

Assessment of hypnotic capacity, suggestibility and cooperation for the procedure – Eye roll sign: Those who have an impressive capacity to roll their eyes upwards

while closing them are highly hypnotizable. Also those who are suggestible and willing to cooperate for the procedure can be easily hypnotized.

Indications

- Hysteria
- Psychosomatic disorders
- Phobic disorders
- Somatoform disorders (e.g. chronic pain)
- Habit disorders (e.g. smoking)

Contraindications – Suspicious and paranoid patients, since it can flare up the psychosis.

II. **Psychopharmacology:** (*see* antipsychotic drugs)

III. **Electroconvulsive therapy (ECT)** includes induction of seizures by passing an electric current through electrodes passed across the scalp.

Mechanism of action. It is postulated to be due to changes in neuro-transmitter metabolism and in the permeability of the blood-brain barrier that result from the passage of the electric current. ECT possibly affects the catecholamine pathways between diencephalon (site from where seizure generalization occurs) and limbic system (responsible for mood disorder), also involving the hypothalamus. ECT also causes downregulation of B₁ receptors in cortex and hippocampus.

Indications

- Major depression
- Not responding to antidepressant drugs
 - With psychotic symptoms
 - With failure to eat and drink
 - With depressive stupor
 - With high risk of suicide
- Schizoaffective depression
- Mania not responding to drug treatment
- Catatonia
- Postpartum affective psychosis

Suggestive indications

- Organic mental disorder, e.g. organic mood syndrome, organic hallucinosis, organic delusional disorder and delirium
- Medical disorders (e.g. organic catatonia, hypopituitarism, intractable seizure disorder, neuroleptic malignant syndrome, Parkinsonism)

Contraindications

Absolute: Raised intracranial pressure

Relative:

- Recent myocardial infarction
- Severe hypertension
- Cerebrovascular accident
- Severe lung disease
- Pheochromocytoma
- Detachment of retina

Pre-treatment evaluation

1. Informed consent from patient, guardian or relatives
2. Physical fitness
3. Laboratory investigations: Hb, total blood count, ESR, urinalysis, ECG, chest radiograph

Patient preparation

1. Overnight starvation
2. Bladder (and bowel) should be emptied
3. Removal of dentures and loose teeth if any
4. Removal of tight clothing and metallic objects from the body

Technique

1. Inj. atropine (0.6 mg) i.m. 1/2 hr. before ECT
2. Anaesthesia: Thiopental sodium 5 mg/kg body wt. followed by:
3. Muscle relaxant: Succinylcholine 1 mg/kg body wt.
4. Mouth gag between the teeth to prevent tongue and lip bite

ECT - Two electrodes are placed bifrontotemporally on the scalp, 100–140 volts current is passed through the electrodes for 0.6–0.8 seconds from the ECT machine.

Seizure activity lasts for about 25–30 seconds.

Patient recovers consciousness with 15–30 minutes.

Number and spacing of treatment is determined by the clinical response. On an average 6–10 ECTs are required. Treatment is given 2 or 3 times a week.

Adverse Effects

- *Due to general anaesthesia*, succinylcholine (in patients with deficiency of pseudo-cholinesterase) and drug interactions. Memory disturbances (both antegrade and retrograde) are usually mild and recovery occurs within 1-6 months.

Post-treatment

- Postictal confusion
- Transient cardiac arrhythmias
- Prolonged apnoeic state
- Complications due to seizures (tongue bite, backache, fracture)

Drug interactions - It may be more difficult to induce effective seizures in patients taking drugs that elevate the seizure threshold (e.g. benzodiazepines, anticonvulsants). Antidepressant drugs such as tricyclics and SSRIs can lower the seizure threshold and prolong the duration of convulsions. If lithium is given during the course of ECT, the blood levels should be maintained at the lower end of the therapeutic range.

Duration of treatment and maintenance therapy - The number of ECT treatments is usually six to ten. ECT is effective in resolving acute depression or mania, but appropriate prophylactic drug treatment must be given once the course of treatment is completed. Relapse rates are high in patients who have received what would be considered adequate antidepressant drug treatment before ECT and who are maintained on same drug regimen. Hence, another class of antidepressant or lithium prophylaxis should be considered if it has not been tried previously. Some patients with frequent relapses that respond only to ECT can be considered for maintenance ECT in which treatment is given every 2 weeks or monthly.

IV Magnetic field to externally stimulate brain cells*Indications*

1. Major depressive disorder
2. Treatment resistant depression
3. Auditory hallucinations
4. Schizophrenia
5. Bipolar disorder
6. Obsessive compulsive disorder
7. Eating disorder such as anorexia and bulimia

Advantages

- a. Few or side effects
- b. Quick onset of therapeutic effect (2 to 4 weeks)
- c. Painless procedure
- d. Non-invasive
- e. No anaesthesia required
- f. Outpatient therapy

V Psychosurgery is a surgical intervention to sever fibres connecting one part of the brain to another, or to remove, destroy or stimulate brain tissue, with the intent of modifying behaviour, thought or mood disturbances for which there is no underlying organic pathology (i.e. the disturbance is functional).

Aim of psychosurgery is to produce surgical lesions in selected sections of the limbic system or its connecting fibres. One major section of the limbic

system, believed to play an important role in emotional reactions is *Papez circuit* within which lies the limbic system, connecting cingulate bundle, hippocampus, anterior thalamus, mammillary bodies, fornix and septum.

Indications

1. Conditions which have failed to respond to all available treatments:
 - Chronic, severe, incapacitating depression
 - Chronic, severe, incapacitating OCD
 - Chronic, severe, incapacitating anxiety disorder
2. Schizophrenia with severe depressive component.
3. Severe, pathological and uncontrolled aggressive behaviour associated with a psychological or neurological affection (e.g. temporal lobe epilepsy).

Techniques used are stereotactic methods

1. *Stereotactic subcaudate tractotomy* for severe depression or anxiety, OCD and schizoaffective disorder.
2. *Stereotactic limbic leucotomy*. In addition to a lesion in cingulate bundle, a small subcaudate lesion is also made. It is used for treatment of OCD and schizophrenia.
3. *Amygdalotomy* is employed for severe, pathological, uncontrolled and intractable aggression associated with neuropsychiatric disorders.

Assessing the confused patient

Confusion may be a symptom of:

- Physical illness with metabolic disturbances that disturb brain function
- Systemic or brain infections
- Psychiatric disease
- Neuropsychological testing

A core feature of acute confusional states is disturbed selective attention, in which the patient is distracted by irrelevant environmental stimuli. Poor attention interferes with short-term memory and may be demonstrated by poor performance on digit span tests.

Disorientation in time and space is more common, disorientation for person is less common. Profound fluctuation in performance may occur across the whole range of cognitive testing.

Biofeedback – is the use of an electronic instrument which provides immediate feedback to the patient regarding his physiological activities normally not available to the conscious mind, e.g. ECG, EEG, pulse rate, BP, EMG, galvanic skin response. The feedback helps the patient to

control these responses. Relaxation is easily achieved by this method.

Other uses of biofeedback – Treatment of enuresis, migraine or tension headaches, incontinence, essential hypertension, cardiac arrhythmias, uncontrolled generalized tonic clonic seizures and for neuromuscular rehabilitation.

Interpersonal social rhythm therapy (IPSRT) – Bipolar I disorder is associated with persistent deficits in functioning over time, and for many patients psychosocial functioning remains markedly impaired. IPSRT is a novel, present-focused inter-personal psychotherapy in which the core deficit in bipolar disorder is considered to be instability, and disturbed biological rhythms are thought to arise from disruptions of social routine. IPSRT appears to be beneficial in reducing the time to recovery in bipolar depressive episodes, but this form of psychotherapy has not been useful in preventing relapse.

Omega-3 fatty acids – Eicosapentaenoic acid (EPA) and docosahexaenoic acid supplements, used as maintenance therapy, improve symptoms in patients with bipolar disorder.

Vagus nerve stimulation (VNS) involves stimulation of the left vagus nerve at the cervical level. The vagus nerve is anatomically linked to structures in the brain that are related to mood disorders. Available data suggest a sustained antidepressant effect in moderately medically resistant major depression.

VI **Psychoanalysis** denotes the following:

1. A psychological theory of mind and personality development based mainly on the concept of intrapsychic 'conflict'.
2. A procedure for the investigation of unconscious physical processes, otherwise inaccessible.
3. A therapeutic method of treating psychiatric disorders by psychological means.

ADDENDUM

Acute Confusional State

A core feature of acute confusional states is disturbed selective attention, in which the patient is distracted by irrelevant environmental stimuli. Poor attention interferes with short-term memory and may be demonstrated by poor performance on digit span tests.

Disorientation in time and space is more common, disorientation for person is less common. Profound fluctuation in performance may occur across the whole range of cognitive testing.

Psychiatric Disorders in the Elderly

Organic

- Acute confusional states (delirium)
- Chronic confusional states (dementia)

Functional

Affective disorders

- Depression
- Mania
- Anxiety (generalized, phobic)

Schizophrenia-like

Adjustment disorders

- Bereavement

Abreaction is a procedure which brings to the awareness, for the first time, unconscious conflicts and associated emotions.

Abreaction methods:

With medication – 5% amytal or pentothal 500 mg in 10 mL normal saline infused at the rate of 1 mL/min.

Indications for amytal interview: (a) Abreaction (e.g. in hysteria). (b) Mute patient. (c) Diagnostic test in catatonic syndrome. (d) Differentiating test in stupor (for differential diagnosis of depression, schizophrenia, hysteria and organic brain disorders).

Contraindications: (a) Airway disease. (b) Severe renal or hepatic dysfunction. (c) Hypotension. (d) Porphyrinuria. (e) Barbiturate dependence. (f) Psychosis (not catatonia or stupor).

Other uses of biofeedback – Treatment of enuresis, migraine or tension headaches, incontinence, essential hypertension, cardiac arrhythmias, uncontrolled generalized tonic clonic seizures and for neuromuscular rehabilitation.

Interpersonal social rhythm therapy (IPSRT) – Bipolar I disorder is associated with persistent deficits in functioning over time, and for many patients psychosocial functioning remains markedly impaired. IPSRT is a novel, present-focused inter-personal psychotherapy in which the core deficit in bipolar disorder is considered to be instability, and disturbed biological rhythms are thought to arise from disruptions of social routine. IPSRT appears to be beneficial in reducing the time to recovery in bipolar depressive episodes, but this form of psychotherapy has not been useful in preventing relapse.

Table 31: Clinical specialities and Munchausen's syndrome

Orthopaedics	Low back pain
Obstetrics and gynaecology	Pelvic pain, premenstrual syndrome, vaginal discharge
Otorhinolaryngology	Tinnitus
Neurology	Headache, dizziness
Cardiology	Atypical chest pain, palpitations
Pulmonary	Hyperventilation, dyspnoea
Dentistry	Temporomandibular joint syndrome
Rheumatology	Fibromyalgia (aches and pains)
Internal medicine	Chronic fatigue
Gastroenterology	Irritable bowel, functional dyspepsia

Psychoeducation – In treatment of bipolar I and bipolar II disorder, group psychoeducation reduces the number of patients who relapse and the number of recurrences per patient, and increases the time to depression and to manic, hypomanic and mixed occurrences.

Epidemiology of autistic spectrum disorder (ADS) – Recently autism has been conceptualized as a spectrum of related diagnostic categories (ASD).

Schizophrenia – Suicide is the principal cause of premature death in patients with schizophrenia. Suicidal behaviour is significantly less in patients treated with clozapine or olanzapine.

Cannabis might increase the risk of schizophrenia by 30%.

Brain stimulation techniques

ECT – National Institute of Clinical Excellence (NICE) has recommended that ECT should be used only in patients suffering severe depressive illness, catatonia or a severe or prolonged manic episode, and then only after an adequate trial of other treatments have been ineffective and/or the condition is considered potentially life-threatening.

FDG-PET and Dementia

The distribution of FDG reflects cerebral glucose metabolism.

Diagnosing early Alzheimer's disease can be difficult using traditional clinical criteria and MRI. FDG-PET is able to diagnose early AD by identifying areas of hypometabolism in parietal and temporal regions.

Acute Poisoning

1. DIAGNOSIS OF ACUTE POISONING

History

Circumstantial evidence:

- Suicide note.
- Circumstances under which found, e.g. empty containers, tablets or capsules nearby.

Physical Signs

See Table 1 for the common clusters of diagnostic signs in poisoning.

Table 1: Common clusters of diagnostic signs in poisoning

Feature cluster	Likely poisons
<ul style="list-style-type: none"> • Coma, hypertonia, hyperreflexia extensor plantar responses, myoclonus, strabismus, mydriasis, sinus tachycardia, skin hot and dry 	Tricyclic antidepressants; less commonly or phenadrine, thioridazine, antihistamines
<ul style="list-style-type: none"> • Coma, hypotonia, hyporeflexia, plantar responses flexor or non-elicitable, hypotension 	Barbiturates, benzodiazepines and alcohol combinations, severe tricyclic antidepressant poisoning
<ul style="list-style-type: none"> • Coma, miosis, reduced respiratory rate 	Opioid analgesics
<ul style="list-style-type: none"> • Nausea, vomiting, tinnitus, deafness, sweating, hyperventilation, vasodilatation, metabolic acidosis 	Salicylates
<ul style="list-style-type: none"> • Restlessness, agitation, mydriasis, anxiety, tremor, tachycardia, convulsions, arrhythmias 	Sympathomimetics
<ul style="list-style-type: none"> • Hyperthermia, tachycardia, delirium, agitation, mydriasis 	Ecstasy
<ul style="list-style-type: none"> • Blindness (usually with other features) 	Quinine, methanol
<ul style="list-style-type: none"> • Miosis and hypersalivation 	Organophosphorus and carbamate insecticides, nerve agents

Note: Skin blisters are common in poisoned patients, and sufficiently uncommon in patients unconscious from other causes, to be of some diagnostic value.

Diagnostic Trial of Antidotes

- Naloxone for opioid poisoning
- Flumazenil for benzodiazepine

Toxicological investigations

Measurement of concentration of a specific toxin in the blood or toxicological screening of blood or urine can be used to establish a diagnosis of poisoning.

Poisons for which emergency measurement of plasma or serum concentration is essential are listed in Table 2.

Non-toxicological investigations

a. Inspection of blood

- Chocolate-coloured blood suggests methemoglobinemia caused by drugs such as dapsone, ingestion of nitrates and nitrites.
- Pink plasma suggests hemolytic poisons, e.g. sodium chlorate.
- Brown plasma points to presence of circulating myoglobin secondary to rhabdomyolysis.

Table 2: Measurement of plasma or serum concentration in poisoning

• Carboxyhaemoglobin
• Ethanol (when monitoring treatment in ethylene glycol and methanol poisoning)
• Ethylene glycol
• Iron
• Lithium
• Methanol
• Paracetamol
• Salicylate
• Theophylline

b. Inspection of urine

- Brown discoloration may be due to presence of haemoglobin (if intravascular haemolysis), myoglobin secondary to rhabdomyolysis or metabolites of paracetamol.
 - Crystals after overdose with primidone or ingestion of ethylene glycol.
- c. *Haematology* is of little diagnostic value, though – prolongation of PT may be secondary to ingestion of anticoagulants or may be due to liver necrosis in paracetamol poisoning.
- d. *Biochemistry*: Usefulness of biochemistry in various poisons is depicted in Table 3.

Radiology

It can be used to confirm ingestion of button batteries, or globules of metallic mercury. Sustained release iron salts may show in plain abdominal X-ray.

ECG

Sinus tachycardia with prolonged PR and QRS intervals in an unconscious patient should point to tricyclic antidepressant overdose. Overdosing with cardiac glycosides or potassium salts also induces characteristic ECG changes.

Clinical features and complications of poisoning

Biochemistry	Poisoning
• Serum sodium	Hyponatremia in ecstasy poisoning
• Serum potassium	Hypokalaemia in theophylline poisoning Hyperkalaemia in digoxin poisoning, rhabdomyolysis, haemolysis
• Plasma creatinine	Renal failure in ethylene glycol poisoning
• Blood sugar	Hypoglycemia in insulin poisoning, hypoglycemia and hyperglycemia in salicylate poisoning
• Serum calcium	Hypocalcemia in ethylene glycol poisoning
• Serum ALT and AST	Increased in paracetamol poisoning
• Serum phosphate	Hypophosphatemia in severe para- cetamol induced renal tubular damage
• Acid-base disturbances, including metabolic acidosis	Salicylate poisoning
• RBC cholinesterase activity	Organophosphorus insecticide and nerve agent poisoning
• Whole blood methaemoglobin concentration	Nitrite poisoning

The toxicity of a substance, and therefore the features of poisoning can be predicted from:

- Its physiochemical properties
- Its pharmacological/toxicological actions
- The route of exposure
- The dose

2. PRINCIPLES OF MANAGEMENT

- A. *Admission to hospital*: If cardiorespiratory depression or other complications.
- B. *Reducing absorption*:

REMOVAL OF UNABSORBED POISON

- a. *Induced vomiting* – should be attempted only if patient is fully conscious and co-operative; in a drowsy or semiconscious patient there is risk of aspiration into respiratory tract. Contraindicated in corrosive poisoning because of risk of oesophageal rupture. Methods– (a) Ingestion of hypertonic saline solution. (b) Syrup of ipecac – 15 mL by mouth followed by large amounts of water. Although syrup of ipecacuanha is an effective emetic, there is little evidence that its use prevents significant absorption of toxic material.
- b. *Gastric lavage* – by nasogastric intubation with nasogastric tube and flushing the stomach with large quantities of fluid.

Indications: (a) Patient drowsy or unconscious. (b) Patient conscious but uncooperative as in suicidal attempt.

Contraindications: (a) Corrosive poisoning because of danger of rupture of oesophagus. (b) Kerosene poisoning because aspiration of even small quantity into respiratory tract may cause pneumonia. Precautions – Gastric lavage is most helpful if performed within 4 hours after ingestion of poison. Due precautions should be taken to prevent aspiration in unconscious patient such as head low position, turning the head to one side and suction of nasopharynx after the procedure. Lavage fluid – Warm water serves the purpose, in babies saline. Special solution should be used in opium poisoning (potassium permanganate), glutethimide (castor oil), and iron poisoning (desferrioxamine). After lavage all fluid should be removed except in iron poisoning.

- c. *Adsorbents* – must be administered within one hour of ingestion of the poison. Refined, activated charcoal single doses of 25–100 g by mouth prevents significant absorption of many drugs (e.g. aminophylline, aspirin,

carbamazepine, digoxin, paracetamol, phenobarbital, phenytoin, theophylline).

Toxins poorly absorbed by activated charcoal are acids and alkalis, cyanide, ethanol, ethylene glycol, iron, lithium and methanol.

- d. *Whole bowel wash* – with normal saline or polyethylene glycol electrolyte solutions, can serve the same purpose as cathartics. Whole bowel irrigation may be considered following potentially toxic ingestion of sustained-release or enteric-coated drugs.

FURTHER MANAGEMENT

Hypothermia: A core temperature below 35°C, measured in the rectum or ear, may be recorded in deeply unconscious patients who have been exposed, particularly in cold weather, for several hours. Hypothermia is best treated by placing the patient in room with moistened air at a temperature of 27–29°C and covering him or her with a foil space blanket to minimize heat loss. Local radiant heat should not be used.

Convulsions: Caused by, for example, tricyclic antidepressant drugs can usually be controlled with intravenous diazepam, once hypoxaemia and acidosis have been corrected. Rarely, muscle relaxation and mechanical ventilation are required, together with an anti-epileptic drug such as phenytoin.

Fluid, acid-base and electrolyte balance: Patients who are vomiting should be given fluids intravenously to replace gastrointestinal losses. Severe and clinically significant hypokalaemia (e.g. that caused by theophylline or β_2 -agonist poisoning) should be corrected by infusing potassium to prevent arrhythmias.

Metabolic acidosis is a common complication of many poisons (Table 4) and, after correction of hypoxia, infusion of sodium bicarbonate may be necessary. Hypoglycemia may follow an overdose of insulin, sulphonylureas or ethanol, and may occur in paracetamol-induced liver fail-

ure. It is corrected by infusing 10% dextrose, if necessary, after a bolus injection of 50% dextrose, 50 mL.

Hypertension: A few drugs (e.g. monoamine oxidase inhibitors) when taken in overdose may produce severe systemic hypertension, and there may be risk of arterial rupture, particularly intracranially. To prevent this, an α -adrenergic blocking agent (e.g. phentolamine, 5–60 mg i.v. over 10–30 minutes) should be administered.

Pain: Patients who have ingested a corrosive substance usually suffer severe pain, which can be relieved with an opioid.

Nursing care: Unconscious patients should be turned from side to side at least every 2 hours. Bullous lesions should be left intact until they burst, to reduce the risk of infection. De-roofing should be performed when the blister bursts; a non-adhesive dressing is then applied.

C. Increasing elimination:

Urine alkalinization – increases elimination of salicylates, phenoxyacetate herbicides, phenobarbitone and barbitone. Alkalinization of urine is more important than a large i.v. fluid load. A diuresis of more than 500 mL/h for long periods may be harmful.

However, with exception of salicylate poisoning, urine alkalization is the first-line monotherapy for poisoning with these agents. Before commencing urine alkalization, it is important to correct plasma volume depletion, electrolytes (administration of sodium bicarbonate exacerbates pre-existing hypokalaemia) and metabolic abnormalities.

Multiple-dose activated charcoal: Use of MDAC involves repeated administration of oral activated charcoal to increase elimination of drug that has already been absorbed into the body. Elimination of drugs with small volume of distribution (<1 litre/kg), low pKa (which maximizes transport across membranes), low binding affinity and prolonged elimination half-life following overdose is particularly likely to be enhanced by MDAC (Table 5). MDAC also improves total body clearance of the drug when endogenous processes are compromised by liver and/or renal function.

Table 4: Toxins causing metabolic acidosis

• Carbon monoxide
• Cyanide
• Ethylene glycol
• Iron salts
• Isoniazid
• Methanol
• Salicylate
• Paracetamol
• Tricyclic antidepressants

Table 5: Drugs whose elimination is increased by MDAC

• Carbamazepine
• Quinine
• Dapsone
• Theophylline
• Phenobarbital

Dose: Initial 50–100 g and then at a rate not less than 12.5 g/hr, preferably via nasogastric tube. Smaller initial doses (10–25 g) can be used in children. If the patient has ingested a drug that induces vomiting (e.g. theophylline), i.v. ondansetron is effective as an emetic and thus enables administration of MDAC.

Haemodialysis and haemoperfusion – are indicated for patients with a combination of severe clinical features and high plasma toxin concentrations. Haemodialysis enhances elimination of salicylate, lithium, methanol, isopropanol, ethylene glycol and ethanol. Haemoperfusion effectively removes barbiturates, carbamazepine, disopyramide, ethchlorvynol, glutethimide, meprobamate, methaqualone, theophylline and trichloroethanol derivatives. However, MDAC is as effective as haemoperfusion in phenobarbitone, carbamazepine and theophylline poisoning and is easier to use.

D. Antidotes: Table 6 lists antidotes used to treat poisoning that may be lifesaving in patients with certain types of poisoning. Mechanism of action – (a) *Inert complex formation* – e.g. chelating agents for heavy metal poisoning, cyanide antidotes, Prussian blue. (b) *Accelerated detoxification* – e.g. thiosulphate for cyanide poisoning.

Table 6: Antidotes used to treat poisoning

Poison	Antidote
• Aluminium	Deferoxamine (desferrioxamine)
• Arsenic	Dimercaprol (BAL), DMSA
• Benzodiazepines	Flumazenil
• β -adrenoceptor blocking drugs	Atropine, glucagon
• Copper	D-penicillamine, DMPS
• Cyanide	Oxygen, dicobalt edetate, hydroxocobalamin, sodium nitrite, sodium thiosulphate
• Digoxin and digitoxin	Digoxin-specific antibody fragments
• Ethylene glycol	Ethanol, fomepizole
• Iron salts	Deferoxamine (desferrioxamine)
• Lead (inorganic)	Sodium calcium edetate, DMSA
• Methaemoglobinemia	Methylthionium chloride (methylene blue)
• Methanol	Ethanol, fomepizole
• Mercury (inorganic)	DMPS
• Opioids	Naloxone
• Organophosphorus insecticides	Atropine, pralidoxime
• Paracetamol	N-acetylcysteine
• Thallium	Prussian (Berlin) blue
• Warfarin and other anticoagulants	Vitamin K ₁

• *Reduced conversion to more toxic compound* – e.g. ethanol fomepizole. (d) *Competition for essential receptor sites* – e.g. Oxygen in CO₂ poisoning, naloxone in opiate poisoning, vitamin K for oral anticoagulants. (e) Blockade of receptor sites – Atropine and pralidoxime for anticholinesterase poisoning. (f) Bypassing the effects of the poison – e.g. oxygen in cyanide poisoning, glucagon in β -blocker poisoning.

E. Maintenance of vital function:

Respiration: (a) *Maintenance of patent airway* – by repeated suction of throat and nasopharynx. Preventing tongue from falling back by pulling the jaw forwards or use of J-shaped metallic airway. Endobronchial suction if profuse secretions, or collapse of lobe or lung segment from bronchial obstruction. Tracheostomy if prolonged coma with profuse secretions or in cases requiring assisted mechanical respiration. (b) *Mechanical respiratory support* – for medullary or peripheral neuromuscular paralysis as in barbiturate, opium and organophosphorus poisoning. Ambu's bag can be used if respirator is not available, when artificial respiration is required only for a short time, or in case of emergency. (c) *Oxygen* – by intranasal catheter or mask.

F. Medicolegal responsibilities of attending physician: (a) Samples of gastric content should be saved for chemical analysis. (b) Immediate information to the police. (c) In case of death due to poisoning, autopsy must be performed and blood samples and viscera sent to chemical analyser.

G. Psychiatric and social problems – need appropriate management.

3. POISONING WITH PESTICIDES

ORGANOPHOSPHATE AND CARBAMATE POISONING

Clinical Features

Combination of nicotinic and muscarinic effects (acetylcholine excess Table 7).

Investigations

Diagnosis can be confirmed by measurement of plasma (normal 100–250 U/mL) and, preferably, erythrocyte cholinesterase activity (Normal 150–300 U/mL). Moderate poisoning is often associated with reduction of enzyme activity to 10–20% of normal value, severe poisoning to less than 10%. Other investigations include liver and kidney function tests, ECG, X-ray chest, arterial blood gas analysis.

Table 7: Action of acetylcholine and effects of organophosphate poisoning

Site of action	Physiologic effects
<ul style="list-style-type: none"> • <i>Muscarinic effects</i> <ul style="list-style-type: none"> – Sweat glands – Pupils – Lacrimal glands – Bronchial tree – GI tract – Cardiovascular – Ciliary body – Bladder 	<ul style="list-style-type: none"> Sweating Constricted pupils Lacrimation Wheezing Cramps, vomiting, diarrhoea, tenesmus Bradycardia, fall of BP Blurred vision Urinary incontinence
<ul style="list-style-type: none"> • <i>Nicotinic effects</i> <ul style="list-style-type: none"> – Striated muscle – Sympathetic ganglia 	<ul style="list-style-type: none"> Fasciculations, cramps, weakness, paralysis, respiratory distress, cyanosis Tachycardia, elevated BP
<ul style="list-style-type: none"> • <i>CNS effects</i> 	<ul style="list-style-type: none"> Anxiety, restlessness, ataxia, convulsions, coma

Factors associated with increased mortality:

1. Increased time delay in initial atropinisation
2. Higher dosage of PAM in first 24 hours
3. Respiratory paralysis at time of admission
4. Development of intermediate syndrome

Management

1. *Removal of unabsorbed poison:* Gastric lavage with 1–3% potassium permanganate or 0.5% soda bicarb.
2. *Administration of antidotes:*
 - a. *Atropine* – 2 mg slowly i.v. (child 0.02 mg/kg) every 5 minutes till the pupils start to dilate. As much as 50–100 mg may be needed in severe cases. Once the pupils dilate atropine is stopped. If over a period of few hours the pupils again constrict, further atropine is required. Patient should be well oxygenated while on atropine as it may precipitate ventricular fibrillation in presence of hypoxia. Atropine can also be administered as continuous drip 150 mg in 250 mL 5% dextrose 6 hrly for 24 hrs. Atropine has no effect on respiratory paralysis. Ventilatory support is necessary. PEEP may be used in presence of pulmonary oedema, once circulation and BP have been stabilized.
 - b. *Oximes* – are choline esterase inhibitors and can be given simultaneously with atropine or as soon as possible after atropine. Effects of the drugs are most prominent at skeletal neuromuscular junctions and muscle weakness and fasciculation should improve within 30 minutes.
 - i. Pralidoxime (PAM) Dose – 30 mg/kg IV at rate not exceeding 500 mg/minute, or IM every 4 hours for 24 hours.
 - ii. Obidoxime 3–6 mg/kg IV 4-hourly for 24 hours.

3. *Diazepam:* Early addition of diazepam 5–10 mg IM or IV not only affords further protection against occurrence of seizures, but also diminishes the severity of muscle twitching.

4. Management of complications:

Acute complications – (a) Pulmonary oedema – (i) Suction of throat and nasopharynx to remove froth and maintain patent airway. (ii) Oxygen. (iii) IV atropine till appearance of signs of adequate atropinisation in order to reduce bronchial secretions. (iv) IV Frusemide 60–80 mg. (b) Respiratory paralysis – May occur in acute stage due to severe poisoning or as a delayed complication after initial period of improvement often associated or preceded by palatal paralysis and facial palsy. It can be detected early by measuring chest expansion at frequent intervals. Intermittent positive pressure respiration is used. Antibiotic cover to prevent bronchopneumonia. (c) Medullary paralysis – Fluctuations in pulse rate and blood pressure. Cardiac arrhythmias and profound hypotension may occur in terminal stages.

Delayed Complications

Intermediate syndrome (Type II paralysis) – occurs in 5–10% of patients 1–4 days after acute poisoning. Features include proximal and neck muscle weakness and dysphagia in absence of muscarinic signs. It reverses in 4–18 days. Atropine, PAM have no effect on this syndrome.

Delayed neuropathy – TOCP (Triorthocresyl- phosphate) and TCP (Tricresyl phosphate) particularly produce delayed neurotoxicity. It appears 9–20 days after ingestion, with no initial signs of acute poisoning. There is a pure motor distal axonal degeneration neuropathy and no sensory loss. Recovery is slow.

ALUMINIUM PHOSPHIDE (ALP)

If is used as a grain preservative.

Clinical Features

Garlicky taste and smell, retrosternal burning, epigastric discomfort and recurrent vomiting. Tremors and drowsiness. Liberated phosgene gas causes dyspnoea, pulmonary oedema, bradycardia and circulatory collapse. ARDS develops if patient survives for 12–24 hrs. Activated charcoal 90 g to absorb PH_3 from GI tract. Further absorption is reduced by administration of antacids and H_2 receptor antagonists. Medicated liquid paraffin hastens its elimination.

Investigations

(a) Positive silver nitrate test in gastric aspirate or expired air. (b) ECG – Changes secondary to toxic myocarditis.

Management

No specific antidote. Clothing if soiled with vomitus should be removed, affected parts washed with soap and water. GL with 3–5% sodium bicarbonate solution which minimises conversion to phosphine. Supportive measures – Glucose saline, corticosteroids, dopamine.

PARAQUAT

Clinical Features

Initial features of poisoning include nausea, vomiting and diarrhoea, but very large doses may cause death from coma, metabolic acidosis, pulmonary oedema and myocardial depression within a few hours. Those who survive for 3–4 days have severe painful ulceration of lips, tongue, pharynx, and larynx with dysphagia, cough, dysphonia and inability to clear saliva and other secretions. Acute renal failure is common. Increasing breathlessness and pulmonary oedema herald almost certain death within a few days or weeks, as extensive pulmonary fibrosis develops.

Management

Empty the stomach and give AC. Pharmacological interventions are not effective and if plasma concentration indicates a fatal outcome, it is best to keep the patient comfortable.

THALLIUM

Thallium salts are used in some rodent poisons, fireworks, imitation jewellery. Most cases occur after oral ingestion or inhalation of fumes.

Cl. Fs. Painful peripheral neuropathy and alopecia are two cardinal symptoms. Other associated symptoms are GI and cardiac problems which appear early. Ataxia, tremor, athetosis, cranial nerve palsy and rarely convulsions and coma.

Tr. Prussian blue (potassium ferric ferrocyanide) or potassium as potassium chloride.

PHENOXYACETATE HERBICIDES

Clinical features include burning sensation in mouth and throat, nausea and vomiting, sweating, hyperventilation, convulsions and coma. Acute myositis with pain, fasciculation, myotonia, weakness and myoglobinuria have been reported.

Management: Supportive measures, induction of isotonic sodium bicarbonate to raise urine pH to as close to 8 as possible.

Anticoagulants – are used as rodenticides.

Clinical features: Symptoms are unlikely after accidental ingestion, because very large amounts have to be eaten to ingest a significant amount of anticoagulant to cause haemorrhagic complications.

Management: Vitamin K until clotting returns to normal. For severe acute cases whole blood, fresh frozen plasma or clotting factor concentrates may be required.

4. PETROLEUM DISTILLATES

Kerosene, white spirit

Clinical features: Nausea, vomiting and diarrhoea. If ingestion of large quantity, CNS effects – initial excitation followed by impaired consciousness. Aspiration into respiratory tract may result in haemorrhagic pneumonitis with breathlessness, wheezing and cyanosis. Convulsions and intravascular haemolysis may occur occasionally.

Investigations: (a) WBC count. (b) X-ray chest – 6 hours after ingestion, no change before that.

Management: (a) Hospitalize. Ascertain amount, vomiting (because of danger of aspiration), whether any drug ingestion, and respiratory distress. (b) Emptying of stomach and lavage if quantity taken is large. Prior protection of lungs by cuffed endotracheal tube is essential as emesis and lavage may lead to aspiration of the poison. Pinch lavage tube while withdrawing to prevent aspiration. (c) Liquid paraffin – Absorption of ingested kerosene can be slowed down by giving liquid paraffin 250 mL orally. (d) Supportive measures. (e) Corticosteroids and antibiotics only if lipid pneumonitis.

Sequelae: (a) Persistent cough. (b) Pneumatocele with danger of pneumothorax 4–6 weeks later.

5. POISONING WITH PSYCHOTROPIC DRUGS

ANXIOLYTICS

Barbiturates

Clinical features: Impairment of consciousness, varying from drowsiness to deep coma, hypotonia of limbs, depression of deep reflexes. Plantars may be extensor. Depression of vital centres produces: Respiratory paralysis and hypotension. Hypothermia, shock and anuria may occur. Bullous rash on skin especially on pressure points is characteristic but not diagnostic.

Management

Assessment of patient: According to depth of unconsciousness, presence of respiratory depression, hypotension, hypothermia and shock; presence of anuria, type of barbiturate and the amount consumed, duration of time between ingestion of poison and hospitalisation, and estimation of blood barbiturate levels.

Management of the poisoning:

1. **Removal of absorbed poison** – by induced vomiting or gastric lavage. Nasogastric intubation is required in most cases since patient is unconscious.
2. **Removal of absorbed poison:**
 - a. **Alkaline diuresis** – has already been described.
 - b. **Haemodialysis** – advantages are faster elimination of the poison and its effectiveness even in case of short and intermediate acting barbiturates. Indications – (i) Severe poisoning with deep coma and depression of vital centres. (ii) Blood barbiturate level is high to begin with (10 mg/100 mL or more) or continues to rise under observation. (iii) Patient fails to improve or deteriorates in spite of forced diuresis. (iv) Presence of renal disease. Contraindications – Presence of bleeding piles or peptic ulcer which contraindicates anticoagulation. As patient improves after dialysis or forced diuresis, a close watch must be kept for next few days as re-excretion into the circulation of the poison bound to tissue proteins may cause a relapse.

Benzodiazepines

(diazepam, alprazolam, lorazepam, etc.).

Clinical features: Most important is CNS depression. Occasionally, this may be sufficient to cause respiratory insufficiency, particularly in those with pre-existing chest disease such as chronic bronchitis. Usually, the onset of coma is progressive, but patients may experience symptoms such as confusion, dizziness, nystagmus, ataxia and dysarthria prior to coma. BP may fall with increasing coma.

Management: Nursing and supportive care. Mechanical ventilation may be necessary. Flumazenil, a specific antagonist may be given in severe cases (coma, hypotension or respiratory depression). Dose 0.5 mg i.v. over 1 minute, the same dose being repeated if there is no response or only a partial response, or i.v. infusion 0.1–0.5 mg/hr. If used when tricyclic antidepressants have been taken together with benzodiazepines, it may precipitate convulsions and cardiac arrhythmias.

Note: Full recovery may take several days. Patients habituated to benzodiazepines may develop withdrawal symptoms, including acute psychoses and fits.

Non-benzodiazepines (Buspirone, chlormezanone, meprobamate).

Clinical features: Symptoms similar to benzodiazepines. Meprobamate is most toxic of the group, causing hypotension, hypothermia, coma with respiratory depression and occasionally pulmonary oedema. Treatment is supportive, but haemoperfusion may be at times necessary.

ANTIDEPRESSANTS

Tricyclic antidepressants (imipramine, amitriptyline, doxepin, clomipramine)

Clinical features: Diagnostic triad of coma, convulsions and cardiac arrhythmias. Initially symptoms are related to anticholinergic actions – dry mouth, blurred vision, sinus tachycardia and drowsiness. **Additional features** of severe poisoning include hypotension, respiratory depression, hyperpyrexia, hypothermia, delirium (more often during recovery), hypertonia, hyperreflexia, extensor plantar responses, ileus and retention of urine. Tachyarrhythmias may occur as also skin blisters. The severity of poisoning can be assessed from QRS interval on ECG and plasma drug concentration. QRS >0.11 seconds and plasma concentration >1000 mg/litre usually indicate serious toxicity.

Management: 1. **Gastric lavage** – of activated charcoal 50–200 g into the stomach. 2. **Supportive measures** – (a) Correction of acidosis. (b) Arrhythmias treated with sodium bicarbonate even in patients who are not acidotic. Unless cardiac output is significantly compromised, antiarrhythmic drugs are not used because they aggravate adverse effects of tricyclics on the myocardium. (c) Adequate oxygenation. (d) Maintenance of normal plasma potassium level and correction of acidosis. 3. **Treatment of convulsions** – with diazepam 5–20 mg IV.

Antipsychotics: (Phenothiazines, butyrophenones, thioxanthenes)

Clinical features: (a) Extrapyrimal reactions – dystonia, dyskinesia, akathisia. (b) General features – Depression of consciousness, hypotension, respiratory depression, hypothermia. ECG changes and arrhythmias, fits. (c) Neuroleptic malignant syndrome – Hyperthermia, fluctuating consciousness, muscular rigidity, autonomic dysfunction (see Table 8).

Management: (a) Supportive measures. (b) Treatment of arrhythmias. (c) Specific measures for extrapyramidal reactions.

Table 8: Specific measures for extrapyramidal reactions in anti-psychotic poisoning

Disorder	Clinical features	Treatment
Dystonic reaction	Involuntary m. contraction (face and jaw). Oculogyric crisis	Benztropine 1–2 mg IM or IV. Diazepam 10 mg IV
Akathisia	Subjective motor restlessness and continual pacing	Reduce dose of neuroleptic Benztropine 1–6 mg/day Diazepam 10–30 mg/day Propranolol 40–120 mg/day
Parkinsonism	Rigidity, bradykinesia, tremor	Reduce dose of neuroleptic Benztropine 1–6 mg/day
Tardive dyskinesia (late onset)	Choreoathetoid movements (tongue, lips, jaw)	Withdraw neuroleptic Tetrabenazine Sulpiride Ca channel blocker
Neuroleptic malignant syndrome	Fever, muscular rigidity, coma and death	Discontinue neuroleptic ICU support Bromocriptine Dantrolene

SELECTIVE SEROTONIN-RE-UPTAKE INHIBITORS

Clinical features: Nausea, vomiting, agitation and tachycardia. Convulsions may develop over large overdoses (>1.5 g). Patients who have taken SSRIs in combination with drugs with serotonergic effect (e.g. tryptophan) or an MAOI are at risk of restlessness, hyperpyrexia, rhabdomyolysis and renal failure.

Management: Supportive and symptomatic. Use of dantrolene to reduce muscle spasm, or paralysis and ventilation may be required in severe cases.

MONOAMINE OXIDASE INHIBITORS

Clinical features: CNS and autonomic dysfunction, agitation, abnormal movements, hyper-reflexia, muscular rigidity, convulsions, sweating, hyperpyrexia, hyperventilation, tachycardia, hypertension or hypotension, urinary retention, coma.

Management: Parenteral diazepam or chlorpromazine to control agitation, ventilation if respiratory embarrassment caused by muscle spasm; dantrolene may reduce spasm.

6. POISONING BY ALCOHOLS

ETHANOL

Clinical features: Smell of alcohol.

Mild intoxication: Rowdiness, disorientation, irrelevant talk, incoordination.

Moderate intoxication: Unconsciousness, hypotonia, depressed jerks. Pupils normal or slightly dilated.

Severe intoxication: Deep coma, loss of jerks, extensor plantars, dilated pupils, irregular breathing. Death from medullary paralysis.

Management

- Removal of unabsorbed poison** – by gastric lavage.
- Correction of hypoglycemia** – with 50 mL 50% glucose IV. Blood should be collected for sugar estimation before giving glucose. In mild intoxication, further treatment is not necessary. In moderate to severe intoxication, patient may continue to remain drowsy for 4–6 hours and 5% glucose drip should be continued with high doses of vitamin B complex.
- Mannitol** – 350 mL of 20% solution IV if patient fails to improve.
- If patient continues to be comatose** – the possibilities are – (a) Mixed poisoning – such as simultaneous ingestion of alcohol and barbiturates or other narcotics. (b) Head injury – due to fall. Lumbar puncture should be done to rule out subarachnoid haemorrhage. (c) Hepatic coma – may be precipitated in a chronic alcoholic with liver cell failure by a bout of alcohol.
- Contamination of alcohol with methyl alcohol** – Metabolism of methyl alcohol in the body results in the formation of toxic products like formaldehyde and formic acid. Clinical manifestations are dimness of vision (irreversible blindness in severe cases), acidotic breathing, altered state of consciousness, convulsions, coma and death. Management – Treatment of acidosis by IV sodabcarb., IV glucose, and general supportive treatment. Haemodialysis can be lifesaving in severe cases.
- Delirium tremens** – may develop in patients addicted to alcohol on recovering from the acute intoxication due to withdrawal. It is characterised by restlessness, tremors, confusion, irrelevant talk. Treatment – IV glucose, high doses of vitamin B complex and sedatives.
- Treatment of associated complications** – Broad spectrum antibiotics for pneumonia, antacids and bland diet for gastritis.

ETHYLENE GLYCOL

Is most commonly used as an antifreeze. It may be drunk accidentally by children, or by adults as a substitute for ethanol.

Clinical features: See Table 9.

Table 9: Clinical features of ethylene glycol poisoning

Stage 1 (30 mins. to 12 hrs) – GI and nervous system involvement
• Nausea, vomiting, hematemesis
• Coma and convulsions (often local)
• Nystagmus, ophthalmoplegia, papilloedema, depressed reflexes, myoclonic jerks, tetanic contractions
• Vth, VIIth, VIIIth nerve palsies
Stage 2 (12–24 hrs) – Cardiorespiratory involvement
• Tachypnoea
• Tachycardia
• Mild hypertension
• Pulmonary oedema
• Congestive cardiac failure
Stage 3 (24–72 hrs)
• Flank pain
• Renal angle tenderness
• Acute tubular necrosis

Management

Treatment of cardiorespiratory depression and correction of metabolic acidosis and hypocalcemia. Ethanol 50 g p.o. given immediately (e.g. 125 mL gin, whisky or vodka), followed by further oral doses or i.v. infusion of 10–12 g ethanol/hr to achieve a blood ethanol concentration of 500–1000 mg/L. Dose may be increased to 17–22 g/hr if haemodialysis is undertaken, because ethanol is dialysable.

Fomepizole is another alternative antidote. Loading dose 15 mg/kg over 30 mins., followed by four 12-hrly doses of 10 mg/kg until ethylene glycol concentration is <200 mg/L. If haemodialysis is used, frequency of dosing should be increased to 4 hrly during dialysis because fomepizole is dialysable.

METHANOL

Methanol is found in antifreeze solutions, wind-screen washing fluid, paint removers, varnishes and shoe polish and is widely used as a solvent and to denature ethanol.

Clinical features: When ingested it causes mild and transient inebriation, nausea, vomiting, abdominal pain mild CNS depression. This is followed by a latent period of 12–24 hrs, after which uncompensated metabolic acidosis develops, coma supervenes and visual function becomes impaired; this ranges from blurred vision and altered visual fields to complete blindness. Mortality increases with the severity and duration of metabolic acidosis. Patients who survive may suffer permanent blindness, rigidity, hypokinesia and other parkinsonian-like signs.

Management: Ethanol delays metabolism of methyl alcohol to its toxic metabolites by competing for alcohol dehydrogenase.

Dose: Loading dose – (a) IV - 7.6–10 mL/kg of 10% solution in dextrose. (b) Oral - 1 mL/kg of 95% ethanol in orange juice.

Fomepizole is a direct alcohol dehydrogenase antagonist. Steroids: Retrobulbar injection of triamcinolone could salvage vision in patients having retinal toxicity since retinal toxicity is due to accumulation of toxic metabolites of methanol, treatment with folic acid and haemodialysis cause removal of these products.

Haemodialysis. Indications – (a) Persistent refractory high ion gap metabolic acidosis, visual and mental obtundation, > 30 mL of methyl alcohol ingestion or > 50 mg/dL blood levels, deteriorating vital signs despite intensive supportive care, kidney failure or significant electrolyte disturbances unresponsive to conventional therapy.

If appropriate, ethanol is continued until methanol is undetected in the blood.

7. ANTICONVULSANTS

CARBAMAZEPINE

Cl. Fs: Anticholinergic features (dry mouth, coma, convulsions). Also drowsiness, nystagmus, ataxia and incoordination are often observed. Pupils may be dilated and divergent squint may be present.

Hallucinations may occur, particularly in the recovery phase.

Mn: Initial single dose of 50–100 g activated charcoal reduces absorption, followed by MDAC 12.5 g/hr to increase elimination.

PHENYTOIN

ClFs: Nystagmus, dysarthria, ataxia, drowsiness and coma.

Mn: Single dose of AC 50–100 g will reduce absorption. MDAC will increase phenytoin elimination.

SODIUM VALPROATE

Cl. Fs: Fever, muscle spasms, hypocalcemia, coma, liver damage and thrombocytopenia. Drowsiness is common, and toxic encephalopathy and optic atrophy have been described. Cerebral oedema is uncommon and is not dose-related.

Mn: Supportive measures including correction of electrolyte and metabolic abnormalities. Neither MDAC nor dialysis increases elimination.

8. ANALGESIC POISONING

NON-NARCOTIC ANALGESICS

Salicylates and Aspirin

Cl. Fs. of salicylism in adults.

Mild to moderate intoxication (plasma concentration <700 mg/L) – Deafness, tinnitus, nausea, vomiting, hyperventilation, sweating, vasodilatation, tachycardia, respiratory alkalosis, metabolic acidosis.

Severe intoxication (plasma concentration >700 mg/L) – All symptoms of less severe poisoning plus confusion, delirium, hypotension, cardiac arrest, acidemia.

Less common complications: Pulmonary oedema, cerebral oedema, convulsions, coma, encephalopathy, renal failure, tetany, hyperpyrexia, hypoglycemia.

Biochemical alterations: (a) Respiratory alkalosis due to stimulation of respiratory centre, hyperpnoea and washing out of CO₂. (b) Hypokalaemia. (c) Hyperglycemia. (d) Metabolic acidosis. (e) Hypoprothrombinaemia.

Mn. (a) MDAC 50–100 g followed by 50 g q4h, (or 12.5 g/hr) until recovery. (b) Antacids e.g. aluminium hydroxide and milk q2h p.o. or by slow intragastric drip. (c) Correction of dehydration, electrolyte imbalance and metabolic acidosis. (d) Urine alkalization (pH 7.5–8.5) by giving 225 mL of 8.4% sodium bicarbonate. Hypokalaemia should be corrected before giving sodium bicarbonate, because it lowers serum potassium concentration further.

Paracetamol

Cl. Fs. – of severe paracetamol poisoning – (a) Nausea and vomiting. (b) Upper abdominal pain and hepatic tenderness. (c) Fulminant hepatic failure on third to sixth day, encephalopathy, cerebral oedema, hyperventilation, hypoglycemia, acidosis, hemorrhage, renal failure.

Hypophosphatemia may contribute to morbidity and mortality by inducing mental confusion, irritability, coma and abnormalities of platelet, RBC and WBC function. Phosphaturia appears to be the principal cause of hyperphosphatemia. It may occur in absence of fulminant hepatic failure and indicates paracetamol-induced renal tubular damage.

Biochemical abnormalities: (a) Metabolic acidosis and lactic acidemia initially. (b) Abnormal liver function tests with marked rise in aminotransferase. (c) Prolongation of prothrombin time. (d) Hyperbilirubinemia.

Management

See Table 10 for the management of paracetamol poisoning.

Table 10: Management of paracetamol poisoning.

Antidote	Dosage schedule	Total dose
N-acetylcysteine (i.v.)	150 mg/kg in 5% dextrose, 200 mL over 15 minutes, 50 mg/kg in 5% dextrose 500 mL over next 4 hrs and 100 mg/kg in 5% dextrose 1000 mL over next 16 hrs.	Total dose 300 mg/kg over 20¼ hrs.
N-acetylcysteine (oral)	140 mg/kg initially, then 4-hrly doses of 60 mg/kg.	Total dose 1330 mg/kg over 72 hrs.
Methionine (oral)	2.5 g initially, then three 4-hrly doses of 2.5 g.	Total dose 10 g over 12 hrs.

NARCOTIC ANALGESICS

Opioids (morphine, diamorphine, codeine, methadone, tramadol, dextropropoxyphene, buprenorphine).

Clinical Features

Pin point pupils, respiratory depression, cyanosis, hypothermia, hypotension, coma. Other complications include convulsions, cardiac arrhythmias and conduction defects, pulmonary oedema, renal failure and rhabdomyolysis.

Management

1. *Clearing the airway* and positioning the patient correctly to minimize risk of aspiration.
2. *Gastric lavage:* Dilute potassium permanganate solution is used and lavage continued till the returning fluid is of the same colour.
3. *Antidotes:* Naloxone – Dose required for full reversal of narcotic effects depends on the drug taken and severity of intoxication, e.g. very large doses may be required for pentazocine. IV naloxone acts immediately and often there is overreaction with hyperventilation, maximal pupillary dilatation, muscle tremor, rise of BP Usual dose 0.4–1.2 mg IV (or less satisfactorily IM) to total dose of 2 mg. The dose may be repeated if pupillary constriction and respiratory depression are not reversed within 1–2 minutes. Graded administration of naloxone is safer than sudden complete reversal.
4. *Supportive treatment:* IV fluids, maintenance of BP and of temperature.
5. *Assisted respiration* – in case of severe respiratory depression not responsive to above measures.

9. POISONING WITH CARDIORESPIRATORY DRUGS

CARDIAC DRUGS

β-blockers

Clinical features: With a large overdose, coma, convulsions (particularly with propranolol), profound bradycardia and hypotension. Respiratory depression and cardiac arrest can also occur. ECG changes include first degree heart block, widening of QRS complex and disappearance of P waves, and prolonged QT interval.

Management: (a) Gastric lavage if ingestion less than 4 hours. Atropine 0.6–1.2 mg will prevent vagal induced cardiovascular collapse during the procedure. (b) Activated charcoal. (c) Glucagon for severe hypotension. Bolus dose of 50–150 mg/kg, followed by infusion of 1–5 mg/hour. A temporary transvenous pacemaker may be necessary.

Digoxin

Cl. Fs.

- GI tract* – Anorexia, nausea, vomiting, abdominal pain, diarrhoea, dysphagia.
- Cardiac* – Atrial tachycardia, flutter or fibrillation; ventricular ectopics, tachycardia or fibrillation; A-V block; A-V dissociation.
- CNS* – Malaise, fatigue, stupor, coma, delirium, hallucinations, headache, seizures, photophobia, transient blindness or scotomata, disturbances of colour vision (green-yellow).

Investigations: (a) ECG – Arrhythmias, changes of hyperkalaemia (in acute overdose): ST-T wave changes; decreased QT interval. (b) Serum K – Increased in acute overdose, decreased or normal in chronic overdose. (c) Serum digoxin – High in acute overdose (>10 µg/litre if severe toxicity).

Assessment of severity: Urgent ECG and electrolytes (particularly magnesium and potassium) and digoxin concentrations. In acute digoxin toxicity, potassium levels > 5 mmol/L are predictive of major toxicity.

Treatment: (a) AC if more than 0.1 mg/kg has been ingested less than 2 hrs previously. (b) Endotracheal intubation and gastric lavage can lead to increased tone and worsen bradyarrhythmia, and premedication with atropine is necessary if these are undertaken. (c) Cardiac monitoring and IV access if ingestion of significant amounts. Normal saline is i.v. fluid of choice, glucose may worsen hypokalaemia. (d) Correction of hypokalaemia and hypomagnesaemia.

Table 11: Indications for digoxin antibody fragments

Any of the following:

- Life-threatening dysrhythmias
Ventricular tachycardia/ventricular fibrillation
Third-degree heart block
- Cardiac compromise in those with underlying cardiac disease
- Serum potassium > 6 mmol/L
Digoxin >7.8 µg/6 hrs after acute overdose or in chronic toxicity

Digoxin Fab: These digoxin specific antibodies bind rapidly to digoxin, removing it from the Na⁺/K⁺ -ATPase pump. Digoxin Fab binds to digoxin in 1:1 ratio; thus the dose required depends on the amount of digoxin to be neutralized (Table 11).

Calculation of Digoxin Fab Dose

From dose ingested: One 40 mg vial of digoxin Fab binds 0.6 mg of digoxin; thus if ingestion of 3 mg requires 6 vials.

From serum digoxin concentration: This method uses the estimated volume of distribution (adults 8 litres/kg, children 13 L/kg) and measured digoxin concentration. Total body burden of digoxin concentration in µg/L (nmol/l × 1.28) × weight (kg) × volume of distribution. Number of 40 mg vials of digoxin Fab required = total body burden/0.6.

By titration: Digoxin Fab dose may be titrated against clinical response; 4–6 vials of digoxin Fab are given and further vials administered depending on their clinical effect. This method may be more useful in patients with hyperkalaemia or heart block than in those with ventricular tachyarrhythmias, in whom treatment is more urgent.

Magnesium enhances Na⁺/K⁺ -ATPase activity without altering digoxin concentration or digoxin binding. It may be useful when digoxin Fab are indicated but not immediately available. The calcium channel blocking properties of magnesium make it useful in tachyarrhythmias.

Other drugs: Atropine 1 mg i.v. repeated as necessary to all patients with bradyarrhythmia. If other antiarrhythmic drugs are required, class 1B drugs should be used because they do not impair AV nodal conduction. Class 1A drugs are contraindicated.

Temporary pacing may be required in some patients.

Mn: (a) Supportive care. (b) Calcium gluconate 10–20 mL 10% solution IV may reverse prolonged intracardiac conduction defects. (c) Dobutamine 5–40 µg/kg/minute or isoprenaline 5–50 µg/minute IV may be needed to maintain cardiac output.

Calcium-channel blockers (Verapamil, diltiazem, amlodipine, nifedipine).

Cl. Fs: (a) *Cardiac:* Hypotension results from combination of vasodilatation, heart block and myocardial depression. It follows few hours after ingestion of a standard preparation, but may be delayed for up to 18–24 hours with controlled release preparations. Both cardiac and non-cardiac pulmonary oedema can occur. Higher degrees of heart block are common with verapamil and diltiazem. (b) *GI:* Nausea and vomiting. The effect of CCBs on the gut can lead to ileus formation. (c) *Other effects* are seldom life-threatening and include hyperglycemia, lactic acidosis and do not occur in absence of significant cardiac effects.

ACE INHIBITORS

Cl. Fs: GI symptoms (anorexia, nausea, abdominal discomfort) predominate initially, and are followed by headache and paraesthesias. Hypotension, sinus tachycardia, bronchospasm and hyperkalaemia may then develop.

Mn: (a) GL if seen within 1 hr of substantial overdose. (b) AC 50–100 g. (c) Correction of hypotension with supportive measures. Naloxone 0.8–1.2 mg can reverse hypotension. (d) Hyperkalaemia – Glucose 50 g and soluble insulin 15 units.

AMIODARONE

Cl. Fs: Acute overdose causes nausea and vomiting, headache, flushing, paraesthesias, ataxia, tremor, vertigo, marked bradycardia, hypotension.

Mn.: (a) Gastric lavage. (b) Oral activated charcoal. (c) For severe hypotension dobutamine 5–40 µg/kg/minute. Dopamine 2–5 µg/kg/minute IV should also be given for its effect on renal vasculature.

RESPIRATORY DRUGS

β₂-agonists (Salbutamol, terbutaline, etc.)

Cl. Fs: Palpitations, feeling of excitement, tremor and peripheral vasodilatation. More serious complications include hypokalaemia, ventricular tachyarrhythmias, myocardial ischemia, pulmonary oedema, convulsions, hyperglycemia and lactic acidosis.

Mn: (a) Gastric lavage and activated charcoal. (b) Correction of hypokalaemia. (c) Propranolol 1–5 mg slowly IV will control tachyarrhythmia and also reverse hypokalaemia, but may exacerbate pre-existing obstructive airways disease.

Mn: (a) Supportive care. (b) GI decontamination: GL in patients who presents within 1 hr of sustained-release verapamil or diltiazem. Atropine before lavage. (c) AC

followed by repeated doses. Whole-bowel irrigation with polyethylene glycol if sustained release preparation. Generous fluid replacement. (d) Specific treatment: Acidosis should be corrected. Atropine, inotropics, insulin-dextrose and glucagon are probably the best adjunctive treatments.

- Normal saline bolus (10–20 mL/kg)
- 10% calcium chloride 5–10 mL, or 10% calcium gluconate, 10–20 mL every 5 minutes
 - Repeat every 3–5 minutes upto 3 to 5 doses
 - If response, start calcium infusion (10% calcium chloride 1–10 mL/hr)
- Monitor serum calcium after 30 mL of calcium chloride or equivalent
- Glucagon 0.075–0.15 mg/kg i.v. (use water for injection as diluent)
 - Repeat every 5–10 minutes as needed
 - If response, consider infusion of 0.075–1.015 mg/kg/hr
- Atropine, isoprenaline and/or pacing may be tried if symptomatic bradycardia
- Dopamine infusion if persistent hypotension
- If no response to above, start insulin euglycemia therapy
 - Insulin bolus 1 U/kg with glucose, 50% dextrose infusion 0.5 g/hr, adjusted according to hourly glucose checks
- As a last resort, extracorporeal BP support (e.g. cardiopulmonary bypass) may be considered.

THEOPHYLLINE

Cl. Fs.

- Nausea, vomiting, abdominal pain, GI hemorrhage

Mn: (a) AC 50–100 g if given within 1 hr of overdose reduces absorption. MDAC 12.5 g/hr increases elimination. (b) Hypokalaemia – Potassium 40–60 mmol in 1 hr diluted in infusion fluid if severe hypokalaemia. (c) Tachyarrhythmias – Propranolol 1–5 mg by slow i.v. injection (avoided if preexisting obstructive pulmonary disease). (d) Convulsions – 10 mg i.v. diazepam.

10. STIMULANTS AND HALLUCINOGENS

STIMULANTS

Amphetamine

Cl. Fs.: Increased alertness and self-confidence, euphoria, extrovert behaviour, talkativeness, rapid speech, loss of

desire to eat or sleep, tremor, dilated pupils, tachycardia and hypertension. In severe cases excitability, agitation, paranoid delusion, hallucinations with violent behaviour, hypertonia and hyper-reflexia may occur. Convulsions, rhabdomyolysis, hyperthermia and cardiac arrhythmias are uncommon.

Mn.: GL if seen within 1 hr. AC 50–100 g. Diazepam 5–10 mg i.v. or chlorpromazine 50–100 mg i.m. To antagonize peripheral sympathomimetic action of amphetamine propranolol 40–80 mg p.o.

Cannabis

Cl. Fs.: of acute intoxication – Euphoria, distorted and heightened images, colours and sounds, altered tactile sensations, sinus tachycardia, hypotension and ataxia. Visual and auditory hallucinations, depersonalization and acute psychosis. Cannabis infusion injected i.v. may cause nausea, vomiting and chills within minutes; after about 1 hr profuse watery diarrhoea, tachycardia, hypotension and arthralgia may develop.

Mn.: Supportive care. Sedation with i.v. diazepam if patient disruptive or distressed. Chlorpromazine 50–100 mg i.m. or haloperidol 2.5–5 mg i.m. may be required.

Cocaine

Cl. Fs.: Acute intoxication produces euphoria, agitation, sinus tachycardia, hypertension, sweating, hallucinations, prolonged convulsions, hyperthermia and rhabdomyolysis. Ventricular arrhythmias, acute myocardial infarction, acute myocarditis, stroke, acute dissection of aorta, renal or intestinal infarction, retinal vascular occlusion and cardiac arrest may complicate severe poisoning.

Mn.: Sedation with i.v. diazepam repeated as necessary to control agitation and convulsions. Active external cooling if temperature exceeds 41°C. Hypertension and sedation usually respond to sedation and cooling. β -blockers are contraindicated because of the risk of precipitating paradoxical hypertension via unopposed α -receptor stimulation. Phentolamine 2–5 mg i.v. or another vasodilator if necessary. Early use of lorazepam with nitrates is more efficacious than nitrates alone in relieving cocaine-associated chest pain.

Hallucinogens (LSD, marijuana, phencyclidine).

LSD

Cl. Fs.: Distorted images, visual hallucinations, agitation and excitement, dilated pupils, sinus tachycardia, hypertension, hyper-reflexia, tremor and hyperthermia

are common. Coma, respiratory arrest and coagulation disturbances can occur in those who have snorted large amounts of pure LSD.

Mn.: Reassurance and sedation. If paranoid, chlorpromazine 50–100 mg i.m. or haloperidol 2.5–5 mg i.m., repeated as necessary. Supportive measures. Fluid replacement and maintenance of urine output. Control of convulsions. Phencyclidine induces aggressive behaviour and i.v. diazepam may be required. Haloperidol i.m. may be used if extreme agitation or psychosis.

Ecstasy

Cl. Fs.: Most cases of acute poisoning are characterized by agitation, tachycardia, hypertension, widely dilated pupils, trismus and sweating, hyperthermia, hyponatremia, DIC, rhabdomyolysis, hepatic failure and acute renal failure in severe cases.

Mn.: Diazepam i.v. for agitation. Dantrolene 1 mg/kg i.v. for hyperthermia and dehydration. Hyponatremia responds to fluid restriction. Transplantation if fulminant hepatic failure.

11. CORROSIVES

ACIDS

(a) Inorganic – Hydrochloric, hydrofluoric, nitric, phosphoric and sulphuric acids. (b) Organic – Acetic, formic, lactic and trichloroacetic acids.

Cl. Fs.: Immediate pain in mouth, pharynx and abdomen, intense thirst, vomiting, hematemesis and diarrhoea. Pain and mucosal oedema cause difficulty in swallowing with drooling of saliva. Gastric and oesophageal perforation may occur, with resultant chemical peritonitis (Table 12). Non-GI features include hoarseness, stridor, respiratory distress, and laryngeal and epiglottic oedema. Circulatory shock, metabolic acidosis, acute renal tubular necrosis, renal failure, hypoxemia, respiratory failure, intravascular coagulation and haemolysis may also occur.

Mn.: (a) Acid burns of skin – Irrigation with water or saline for 15–20 minutes. For HCL burns topical application of

Table 12: Grading of corrosive burns of the alimentary tract

Grade	Feature
1	Erythema and oedema only
2a	Localized superficial friability, blisters or ulceration
2b	As for grade 2a, but with circumferential ulceration
3	Multiple deep ulcers, areas of necrosis

2.5% calcium gluconate gel and/or s.c. calcium gluconate 0.5 mL 10% for pain relief; it can also be given intra-arterially. (b) Eyes splashed with acid – Irrigation with saline or water. Local anaesthetic for pain. (c) Acid ingestion – clear airway. Endotracheal intubation or tracheostomy may be required for life-threatening pharyngeal or laryngeal oedema. Opioids for analgesia. Soluble calcium tablets 10–20 g for hydrofluoric acid ingestion. Endoscopy should be undertaken as soon as possible. Laparoscopy with resection of necrotic tissue and surgical repair if full thickness necrosis or features of GI perforation.

ALKALIS

Substances encountered include drain, lavatory and pipe cleaners (sodium hydroxide), dishwashing detergents (sodium carbonate and silicate), urinary glucose testing tablets (sodium hydroxide) and alkaline disc batteries.

Cl. Fs.: When ingested, alkalis damage the oesophagus but spare the stomach (except in 20% cases). A burning sensation in mouth and pharynx, epigastric pain, vomiting and diarrhoea. Oesophageal ulceration with or without perforation may occur. Also hoarseness, stridor, respiratory distress, and laryngeal and epiglottic oedema.

Mn.: Endotracheal intubation or tracheotomy for severe pharyngeal or laryngeal oedema. Induced emesis and gastric aspiration and lavage are contraindicated, as also dilution or neutralization of the alkali. Endoscopy should be performed within 12–24 hrs of ingestion. If perforation of GI tract is suspected, or if severe hypopharyngeal burns are present, radiographic studies using water-soluble contrast media should be performed. Corticosteroids may decrease need for surgical repair or strictures e.g. prednisolone 2 mg/kg/day i.v. q8h. until oral intake is resumed, when an equivalent dosage is given p.o. and tapered off over 3–6 weeks.

12. METALLIC POISONING

IRON

Cl. Fs.: Acute iron poisoning can be divided into four phases:

Phase 1 (6–8 hrs): Vomiting and diarrhoea. Vomit and stools are often dark grey or black and in more severe poisoning may become blood stained if ulceration of upper GI tract. Drowsiness, coma, convulsions, shock and metabolic acidosis may develop; shock is out of proportion to amount of GI fluid and blood lost. Progressive circulatory failure and coma may cause death.

Phase 2 (6–12 hrs): Symptoms improve or disappear.

Phase 3 (12–48 hrs): Severe shock, metabolic acidosis and development of jaundice caused by hepatocellular necrosis. Liver failure with hemorrhage, hypoglycemia and renal failure may supervene. Rarely intestinal infarction and infection with *Yersinia enterocolitica*.

Phase 4 (2–4 weeks): Vomiting caused by gastric stricture or pyloric stenosis.

Mn.: (a) Hospitalization – if ingestion of 20 mg elemental iron/kg body wt. or more. (b) Preventing absorption – GL if seen within 1 hr of ingestion. (c) Whole bowel irrigation if slow-release iron preparation has been ingested and tablets remain in the bowel after GL. (d) Desferrioxamine – if severe poisoning (coma or shock). Dose: 15 mg/kg/hr as i.v. infusion; total dose should not exceed 80 mg/kg in 24 hrs. Alternatively, i.m. doses (2 g b.d. for adult, 1 g b.d. for child).

COPPER SULPHATE

Cl. Fs.: Phase 1: (1–24 hrs) GI symptoms. Phase 2 (24–72 hrs): Hepatorenal damage. Phase 3: Hepatic failure and renal failure. Cause of death is multifactorial – Hypoxemia due to massive haemolysis and methemoglobinaemia affecting brain stem function, toxic myocarditis and renal failure.

Mn.: (a) GL with potassium ferrocyanide (combines with CuSO_4 to form cupric ferrocyanide and sulphate, both of which are non-absorbable). (b) Removal of absorbed CuSO_4 by chelating agent Penicillamine 2 g p.o. or Dimer-caprol 3 mg/kg q8h for 2 days, then q12h for 5 days. (c) Vitamins C and methylene blue to prevent haemolysis. (d) Dialysis for renal failure.

Lead has widespread applications:

Cl. Fs.: Mild intoxication: Lethargy and abdominal discomfort. Severe cases: Abdominal pain (usually diffuse, but may be colicky) vomiting, lethargy, constipation and encephalopathy which is more common in children than in adults. Renal effects include reversible renal tubular dysfunction.

Mn.: Use of chelation therapy is based on symptoms and blood lead concentration. Sodium calcium edetate 75 mg/kg/day is more efficient than DMSA (30 mg/kg/day) in increasing lead excretion, but must be given i.v. Sodium calcium edetate however enhances uptake into the brain, hence oral DMSA is preferred.

MERCURY

Cl. Fs.: Metallic elemental mercury vapour is most important form toxicologically because it is absorbed rapidly

following inhalation. Acute inhalation causes headache, conjunctivitis, cough, nausea and vomiting, metallic taste in the mouth, dyspnoea and chest pain. Chemical pneumonitis and, in severe cases, renal and/or liver failure. Inorganic mercury salts are corrosive and substantial ingestion can cause haemorrhagic gastroenteritis.

Organic mercury salts have been used as fungicides and poisoning usually follows ingestion of contaminated foods.

Mn.: DMPS 30 mg/kg/day p.o. increases mercury elimination and reduces blood mercury concentrations.

ANTIDOTES USED IN HEAVY METAL POISONING

Dimercaprol (BAL) – for arsenic and mercury poisoning. Dose: 2.5–5 mg/kg i.m. q4h for 2 days, then 2.5 mg/kg for 1–2 weeks, as necessary. Side effects – Nausea, vomiting, hypotension, tachycardia, burning sensation in lips, mouth and throat; and feeling of constriction in throat and chest. Water soluble analogues of PAM – DMPS is less toxic and can be given orally in dose of 30 mg/kg. DMSA is used for lead poisoning in a dose of 30 mg/kg.

Sodium calcium edetate – 50–70 mg/kg/day for 5 days i.v. for lead poisoning.

Penicillamine – for copper poisoning. Dose: 0.25–2 g/day until recovery.

Prussian blue – for thallium (used as rodenticide). Dose: 60 mg/kg tid via NGT.

13. POISONINGS FROM INHALED GASES

AMMONIA

Is used in industrial chemicals. At concentrations of $> 50 \text{ mg/m}^3$, ammonia vapour is irritant to the eyes and upper respiratory tract, exposure to concentrations $> 100 \text{ mg/m}^3$ may lead to severe respiratory distress within minutes and $> 1500 \text{ mg/m}^3$ are life-threatening.

Ingestion induces severe caustic lesions of the mucous membranes of oropharynx, oesophagus and stomach. Oesophageal or gastric perforation may occur, causing mediastinitis or peritonitis respectively.

Management: (a) Airway: Early intubation should be avoided because an endotracheal tube may increase risk of infection, to which patients are highly susceptible. When intubation is required, the largest practicable tube should be introduced to allow adequate bronchial toilet. Eyes and skin should be irrigated with water immediately and continued for 15–30 minutes. Topical antibiotics may prevent secondary infection of the eye. (b) GI tract – Neu-

tralizing agents should not be administered after ingestion of ammonia water because the resultant exothermic reaction may worsen the injury. Following severe exposure, esophagoscopy is done as soon as possible to introduce nasogastric tube, which is necessary to prevent complete obstruction of the oesophagus. Repeated esophagoscopy about 3 weeks later is indicated in all patients in whom the results of initial esophagoscopy are abnormal.

CHLORINE

Is a greenish-yellow, corrosive gas. At concentrations of $> 15 \text{ mg/m}^3$, chlorine is irritant to the eyes and upper respiratory tract, exposure above 90–150 mg/m^3 for a protracted period may lead to severe respiratory distress, and above 1200 mg/m^3 are immediately life-threatening with swelling of the larynx and airways with bronchospasm, pulmonary oedema and severe respiratory distress.

Management: There is no specific treatment for airway injury. If intubation is required, the largest tube should be used to allow adequate bronchial toilet.

CARBON MONOXIDE

The two most common sources of gas in acute poisoning are motor vehicle exhaust fumes and smoke from fires. Others include the use of charcoal grills in confined spaces. *Clinical features:* Early—Headache, dizziness, nausea, vomiting and progressive impairment of consciousness. A syndrome suggestive of acute gastro-enteritis has been described. As severity of poisoning increases – hyperventilation, hypotension, increased muscle tone, hyperreflexia, clonus and extensor plantar responses. Skin may be cyanosed. A metabolic acidosis with normal O_2 tension but reduced O_2 saturation is characteristic. Rhabdomyolysis, myocardial infarction, pulmonary oedema, retinal haemorrhages and papilloedema secondary to cerebral oedema are potential complications.

Delayed features of CO poisoning include well-defined neurological conditions:

- Parkinsonism, chorea and choreoathetosis
- Cortical blindness
- Mutism
- Hemiplegia
- Peripheral neuropathy

Characteristics of delayed syndrome include apathy, disorientation, amnesia and hypokinesia in almost all cases. About 50% of patients who show these features start to show them 2–4 weeks after the acute incident.

Management: (a) Patient should be removed from toxic atmosphere. (b) Clear airway, adequate ventilation

and blood pressure should be ensured. O₂ in high concentration. Normobaric O₂ and hyperbaric O₂ improve oxygen delivery to cells by increasing the amount of O₂ dissolved in plasma and reducing the half-life of COHb. Assisted ventilation if necessary. (c) Reduction of increased muscle activity with dantrolene 1 mg/kg i.v. rapidly, repeated as necessary to cumulative maximum of 10 mg/kg. (d) Mannitol and dexamethasone for cerebral oedema. Administration of alkalis is contraindicated because it further impairs O₂ release to tissues through its effect on the oxyhaemoglobin dissociation curve.

SULPHUR DIOXIDE

Cl. Fs.: Exposure to the gas causes lacrimation, rhinorrhoea, cough, increased bronchial secretions, bronchial constriction and, in severe cases, pulmonary oedema and respiratory arrest. Corneal burns can follow eye exposure.

Mn.: Irrigation of eyes and skin with copious amounts of water. Hospitalization in severe cases for treatment of delayed pulmonary oedema. If necessary mechanical ventilation with positive end-expiratory pressure.

NITROGEN

Cl. Fs.: Nausea or minor irritation of upper respiratory tract may occur during first hours post-exposure. After several hours (depending on concentration and duration of exposure), ARDS may manifest.

Mn.: Hospitalization for observation. In severe cases, supportive care and maintenance of gas exchange by mechanical ventilation.

14. MISCELLANEOUS

CYANIDE

Hydrogen cyanide and derivatives (acetonitrile, acrylonitrile, cyanides, nitroprusside and thiocyanate) are widely used in industry.

Cl. Fs.: Acute poisoning—Ingestion by an adult of 50 mL of liquid hydrogen cyanide or 200–300 mg of one of its salts is likely to be fatal without treatment, though death is likely to be delayed for at least 1 hr. In contrast, when hydrogen cyanide gas is inhaled, symptoms occur within seconds, and death within minutes.

Acute poisoning is characterized by anxiety, dizziness, palpitations, headache and weakness. Loss of consciousness, convulsions, cerebral oedema, pulmonary oedema, cardiovascular collapse, cardiac conduction defects, arrhythmias and metabolic acidosis are seen in severe cases.

Tr.: In addition to O₂, dicobalt edetate 300 mg i.v. if diagnosis is certain. Alternatively, hydroxocobalamin 5 g i.v. over 30 mins. If not available sodium nitrite, 300 mg (10 mL of 3% solution) i.v. over 20 minutes and sodium thiosulphate 12.5 mg (50 mL of 25% solution) i.v. over 10 mins. 4-DMPA is an alternative to sodium nitrite. In severe cases, a second dose of each antidote is required.

QUININE AND CHLOROQUINE

Table 13 gives features of quinine and chloroquine poisoning according to the severity. Quinine is particularly toxic in children, and their management should be a matter of urgency.

	Severity	Symptoms	Dose ingested (g)	Plasma conc. (mg/L)	Serum K (mmol/L)
Chloroquine	Mild	Visual disturbances Vomiting ECG normal	< 2	< 2.5	3.5–4
	Moderate	Vomiting Visual dist. QT increased T wave decreased	2–3.5	2.5–5	2.8–3.5
	Severe	Cardiac failure Convulsions QRS increased	>3.5–4	> 5	< 2.8
Quinine	Mild	Cinchonism	< 10		
	Moderate	Blurred vision QT increased T wave decreased	10–15		
	Severe	Blindness Cardiac failure QRS increased	>15		

Management

Cardiovascular disturbances: Shocked patients—Isoprenaline or adrenaline, which is the drug of choice for severe hypotension in chloroquine poisoning. 8.4% sodium bicarbonate 250 mL for intraventricular block. Cardioversion for VT or VF. Potassium must be administered cautiously in severe hypokalaemia associated with extrasystoles or torsade de pointes.

Diazepam – may have some protective action. Dose: 2 mg/kg within 30 minutes followed by infusion of 2–4 mg/kg/24 hrs.

Gut decontamination: Once patient is stabilized, GI if substantial dose of quinine or chloroquine has been ingested less than 1 hr previously.

Elimination techniques: MDAC if ingestion of life-threatening dose of quinine.

VOLATILE SUBSTANCE ABUSE

Commonly Inhaled Substances

See Table 14.

Clinical Features

Acute intoxication: Initial features like alcoholic intoxication (i.e. initial CNS stimulation followed by depression). Features include euphoria, impaired judgement, feelings of omnipotence, blurring of vision, tinnitus, slurred speech, ataxia, headache, abdominal pain, anorexia, nausea, vomiting, chest pain and bronchospasm. Occasionally, a delirious state is seen with clouding of consciousness and hallucinations. Convulsions, respiratory depression and coma may ensue if inhalation of the volatile substance continues. Arrhythmias (e.g. asystole, severe bradycardia, ventricular fibrillation, due to sensitization of the myocardium to endogenous catecholamines), are a significant

cause of death. Inhalation of volatile nitrites may cause the additional problem of severe or even fatal methemoglobinemia.

Chronic abuse: The hair, breath and clothing of chronic abusers may smell of solvent. Bagging (substance sprayed into a plastic bag and inhaled) may cause erythematous spots around the mouth, nose (glue-sniffer's rash). Abdominal pain, nausea, vomiting and hematemesis may be presenting symptoms. Hepatic necrosis is known to occur.

Toluene abuse causes cerebellar damage. Muscular weakness can present as quadriparesis. Petrol and toluene may cause peripheral neuropathy.

Hematuria, pyuria and tubular proteinuria are common in chronic toluene abusers. Renal failure may ensue. Hypochloremic acidosis may be asymptomatic or present as with severe muscular weakness caused by hypokalaemia or with urolithiasis secondary to hypercalciuria.

Management – is mainly supportive if acute volatile poisoning. Diazepam 10 mg i.v. if necessary to prevent personal harm and injury to others. Methemoglobinemia can be corrected with methylene blue 1–2 mg/kg body wt. im. if concentrations > 30%. Management of chronic abuse is psychological.

Lithium

Cl. Fs.: Neurological, GI, cardiovascular and renal disturbances occur.

ST-T changes on ECG, and more rarely conduction disturbances may also occur.

Grades of severity:

- Grade 1 : Drowsiness, nausea, vomiting, tremor, hyperreflexia, agitation, muscle weakness, ataxia
- Grade 2 : Stupor, rigidity, hypertonia, hypertension
- Grade 3 : Coma, convulsions, myoclonus, collapse

Therapeutic serum lithium concentrations are normally 0.8–1.2 mmol/L, moderate toxicity is seen at 2.5–3.5 mmol/L, and severe symptoms are seen at more than 3.5 mmol/L. However in acute poisoning, symptoms may be absent or minor despite high serum concentrations. In acute-on-chronic poisoning, severe symptoms occur more rapidly.

Mn.: GI if ingestion of more than 40 mg of lithium carbonate/kg body wt less than 1 hr previously. Isotonic sodium chloride 2–3 liters/day in absence of renal failure or CCF. Haemodialysis is treatment of choice for rapid removal of lithium from the body. A rebound increase in lithium serum concentrations may be observed because of the

Table 14: Commonly inhaled substances

• Toluene containing glue
• Chlorinated hydrocarbons (cleaning fluids, paints, varnishes, lacquers, dyes)
• Fluorocarbons (aerosol propellants, fire extinguishers)
• Petrol
• Acetone (nail polish remover, polystyrene cements)
• Butane
• Propane
• Amyl, butyl and isobutyl nitrites (which may also be ingested)

slow diffusion of lithium from the intracellular to extra cellular compartment.

THYROXINE AND TRIIODOTHYRONINE

Only a small percentage of patients who ingest even a substantial single overdose of thyroxine (T4) or triiodothyronine (T3) develop features of toxicity.

Cl. Fs.: Symptoms may develop within a few hours of T3 ingestion but are not usually maximal for 3–6 days after T4 ingestion. Features tend to resolve in about the same time as they take to develop. Palpitations, tremor, anxiety, irritability, hyperactivity, fever, tachycardia and insomnia are most common. Atrial fibrillation, sweating and loose stools are rare.

Mn.: AC in patients who present within 1 hour of substantial overdose. Serum T4 and T3 concentrations should be measured in blood taken 6–12 hours after ingestion; a normal result excludes possibility of delayed toxicity. Patients in whom the hormone concentrations are high should be observed for evidence of toxicity; if this develops, they should be given propranolol 40 mg t.d.s. 5 for days.

WARFARIN AND OTHER ANTICOAGULANTS

Warfarin toxicity is more likely to occur in the setting of therapeutic anticoagulation than as a consequence of acute ingestion.

Cl. Fs.: Epistaxis, gingival bleeding, spontaneous bruising, hematomas, bilateral flank pain, rectal bleeding and hemorrhage into any organ may occur. Severe blood loss may result in hypovolemic shock, coma and death.

Management

Intention to continue anticoagulant

- INR <6 but >5 above target value: Reduce dose of warfarin or restart when INR <5
- INR 6–8 and patient not bleeding, stop warfarin and restart when INR <5
- INR >8, and patient not bleeding, stop warfarin and restart when INR <5

If other risk factors for bleeding, give vitamin K₁ 0.5 mg i.v. slowly. Unnecessarily large doses of vitamin K should be avoided because it can result in loss of patency of vascular graft. If major bleeding occurs, give vitamin K₁ 5 mg by slow i.v. injection, with prothrombin complex con-

centrate 50 U/kg, or, if not available, fresh frozen plasma 15 mL/kg.

Camphor is a pleasant smelling cyclic ketone with propensity to cause neurologic side effects especially seizures. Vast majority of camphor toxicity are due to accidental oral ingestion especially in the paediatric age group, few case reports suggest absorption through nasal inhalation, nasal instillation and through the skin (practice of “Cao Gion or coining”) as well as suicidal intake. With significant ingestion of camphor 50 mg/kg body wt, neurologic toxicity is common, with generalized tonic clonic activity occurring from 5 to 90 minutes after exposure.

Tr.: Since camphor is rapidly absorbed after ingestion from GI tract, neither activated charcoal nor gastric lavage is helpful. Benzodiazepines should be used to control seizures. Because of camphor's highly lipophilic nature, extracorporeal procedures to remove the toxin from the body are questionable.

Aluminium phosphide is primarily used by agriculturists, as a fumigant to destroy insects and rodents and is also used for suicide. Following ingestion, there is a metallic taste in the mouth followed by nausea, frequent vomiting with retching, diarrhoea and abdominal pain. There may be garlicky taste and smell. The liberated phosphine gas causes dyspnoea, pulmonary oedema and bradycardia followed by circulatory collapse.

Tr.: No specific antidote. If skin and clothes are soiled with vomitus they should be removed. Gastric lavage with 3–5% solution of sodabcarb which minimises conversion to phosphine. Milk and strong tea should be freely given. Penicillamine 20 mg/kg body wt is useful. Other supportive measures include glucose saline, vitamin K and corticosteroids and pentazocine for pain.

Hair dye: Most hair dyes contain paraphenylenediamine (DPD). Hair dye ingestion causes angioedema of face and neck, dysphagia, chocolate brown coloured urine, bodyache and tender muscles. *Tr.:* – No antidote. Diphenhydramine and steroids. Tracheostomy for severe angioedema. Acute renal failure requiring dialysis can be a delayed complication.

15. VENOMOUS BITES AND STINGS

SNAKE BITE

Common poisonous snakes: (a) Elapids – Indian cobra, common krait. (b) Vipers – Russell's viper and saw-scaled viper.

Venoms: Components of the venom usually reach the circulation via the lymphatics, though low molecular weight components may be absorbed directly into the capillaries. Most venoms are complex mixtures of many different toxins. (a) *Proteinases* act as cytotoxins, causing local swelling and damage in the region of bite. (b) *Neurotoxins* interfere with neuromuscular transmission; some phospholipase A2 toxins also damage myocytes directly. (c) Some venoms contain *haemorrhagins* which cause bleeding. (d) Coagulopathies may be caused by action of venom components at different sites in the coagulation pathway leading to a state resembling DIC. Venom components also act directly on platelets.

Clinical features: Depend on the species. The bite of elapid snakes (kraits, cobra) most commonly causes neurotoxicity, whereas viperine snakes (vipers, rattle snakes) cause local tissue damage, shock and coagulopathies.

Systemic Effects

- Symptoms of systemic envenoming (headache, lymph node pain and collapse) can occur within several minutes of the bite. Most signs of envenoming develop within a few hours, though neurotoxicity can occasionally take more than 12 hours.
- Fang marks are usually visible at site of the bite.
- Following bites from some species, oedema can occur at the site of the bite and progress to the whole limb. Some species cause tissue necrosis at the site of the bite.
- Painful regional lymph nodes enlargement is a common early sign.
- Venom haemorrhaging act on endothelium, causing bleeding from the gums and other sites (e.g. oral sores).
- Coagulopathies can exacerbate this effect, and occasionally lead to life-threatening bleeding.
- Shock can occur as a result of loss of fluid into a limb or haemorrhage.
- Neurological involvement classically causes progressive paralysis. Ptosis occurs initially; this progresses to involvement of bulbar muscles and ultimately, paralysis of the diaphragm.
- Destruction of skeletal muscle, following envenoming by species, such as sea snakes, leads to painful myopathy and paralysis.
- Renal failure complicates envenoming by several species.

Investigations: WBC count is commonly elevated and thrombocytopenia often occurs; particularly in patients

with coagulopathy. Renal function should be checked. Creatine kinase elevation occurs in myotoxicity.

Whole blood clotting test is an important bedside indicator of envenoming by species that cause coagulopathy. Blood left in a clean glass tube is examined after 20 minutes to see whether clotting has occurred. In some cases the test can also be used to follow the response to antivenom. Standard clotting assays (PT, APTT, fibrinogen) are sensitive indicators of a coagulopathy.

Management

1. **Local treatment:** (a) *Measures to prevent absorption of poison* – If patient is seen shortly after the bite, application of pressure bandage 2 inches proximal to site of bite. Arterial tourniquets are painful and even dangerous short-term method of delaying systemic spread of venom. Firm pressure with a pressure bandage over the site of venom injection, combined with immobilization of the limb involved results in marked retardation of venom movement. Most traditional first aid procedures (e.g. incision, suction) are more harmful than beneficial. Antivenom is indicated for systemic or severe local reactions. (b) If patient is seen late the swelling and inflammation should be treated by elevation of the limb, mag. sulph. compresses, heparinoid ointment and broad spectrum antibiotic. (c) *Surgical debridement and skin grafting* – may be necessary at a later stage in case of extensive necrosis.
2. **Antivenom:** Anti-snake venom serum available as freeze dried powder for easy storage. It is reconstituted by adding distilled water. Sensitivity should be tested by giving in intra-dermal test dose, 20 mL (though according to some test dose has no role in predicting antivenom reactions) of the serum is given IV as first dose slowly over 20 minutes. Second dose can be repeated 2 hours later if symptoms persist. Further doses can be repeated 6-hourly till symptoms disappear. Children require same dose as adults.
3. **General management:** (i) Tetanus toxoid 1 mL i.m. (ii) Antihistamines to reduce severity of allergic and inflammatory reactions. (iii) Analgesics for local pain. (iv) Sedation with diazepam. (v) Corticosteroids – IV hydrocortisone 100 mg. 6 hourly in case of severe shock, generalised allergic reactions and sensitivity reactions due to serum. (vi) An Edrophonium chloride test may be done in patients with neurotoxicity. If patient responds, he should be maintained on neostigmine.

There is no role for routine prophylaxis but adrenaline should always be available for treatment of reactions.

Effective treatment should halt local oedema and reverse coagulopathy in within 6–12 hours. The whole blood clotting test 6 hours after administration, or measurements of PT or APTT after 6 hours can help determine if further doses are necessary.

Most toxins acting postsynaptically are reversed by antivenom, but presynaptic neuropathy is less responsive, supportive therapy may be needed until spontaneous recovery occurs.

Delayed absorption of venom from a depot at the site can occur. Repeated doses of antivenom may be needed if coagulopathy redevelops, neurological deterioration occurs or limb oedema progresses.

4. **Management of complications** – (a) Care of the airway is critical in severe neurotoxicity. Bulbar involvement (demonstrated by inability to swallow secretions) is an indication for early intubation and mechanical or non-invasive ventilation if facilities are available. (b) Hypotension requires appropriate management with fluids. (c) For kidney failure peritoneal dialysis can be life-saving. (d) Fasciotomy is seldom required, even in severe oedema. The only indication is raised intracompartmental pressure. Surgery should not be performed until coagulopathy has been corrected.

BEE AND WASP STINGS

CL. FS.: People who have become sensitized to bee venom usually suffer increasingly severe reactions to successive stings. There is excessive local swelling and in severe cases, generalised urticaria, or bronchospasm with or without laryngeal oedema. Anaphylactic reaction may occur.

TR.: (a) The sting with its attached venom gland must be removed by scraping off with the blade of a knife. (b) Antihistamines for mild reaction, adrenaline for severe reaction. (c) Steroids – Single dose of 20–30 mg prednisolone may suffice.

SCORPION STING

Scorpions sting through the telson at the tip of their tails. The Indian red scorpion is small in size with segmented tail and is very poisonous. The black scorpion is less poisonous.

Clinical manifestations: Depend upon the species of scorpion and dose of venom injected at time of sting.

1. **Local:** Excruciating pain at sting site, sudden tap at or around the site of sting induces severe pain (Tap sign).
2. **Systemic:** (a) Transient projectile vomiting. (b) Profuse sweating (skin diarrhoea). (c) Thick ropy salivation. (d) Priapism. (e) Cold extremities. (f) Mydriasis. (g) CVS-hypertension, cardiac arrhythmias, tachybradycardia, pulmonary oedema, hypotension and

shock are but one process of ongoing “autonomic storm”. (h) Neurological: Hemiparesis haemorrhagic or thrombotic stroke due to DIC. (i) Acute pancreatitis.

TR.: (a) Local infiltration with 1% lignocaine, cold therapy at the site, analgesics. (b) Scorpion antivenom (SAV) – Without skin test SAV must be administered as soon as possible by IV route. Nonspecies F(ab) SAV is available. The maximum volume of venom injected in one sting by Indian red scorpion is 1.5 mg and each ml of antivenom is capable of neutralizing 1.2 to 1.5 mg. venom, hence 30 ml of antivenom should suffice, however more may be required for severe sting. (c) Prazosin – 250–500 mcg orally q3h is a physiological and pharmacological antidote to scorpion venom actions. (d) Dobutamine infusion 5–20 mcg/kg/min given in hypokinetic phase (hypotension, shock, tachycardia, delirium) with or without pulmonary oedema causes improvement in clinical condition. (e) Nitroglycerine (NTG) drip 0.5 to 5 mcg/kg/min in addition to dobutamine improves myocardial dysfunction and reduces pulmonary congestion. (f) Pulmonary oedema cases improve with dobutamine, mechanical or non-invasive ventilation or by helmet-derived non-invasive pressure support ventilation.

SPIDER BITES

Venom is injected through the fangs.

Clinical Syndromes

1. **Necrotic araneism:** Local burning, transient fever and erythematous rash, intravascular haemolysis and development of ischemic local lesion which forms a necrotic black eschar. Tr. – (a) Antivenom. (b) Dapsone may reduce extent of necrosis. (c) Skin grafting after eschar has sloughed.
2. **Neurotoxic araneism:** Bite is very painful. Systemic symptoms include headache, vomiting, muscle spasms, priapism, pulmonary oedema and coma. Tr. – (a) Arterial tourniquet or splinting with crepe bandage to prevent absorption of neurotoxins. (b) Specific antivenom. (c) Calcium gluconate for muscle spasms.

VENOMOUS JELLYFISH STINGS

Cl. Fs.: Immediate pain at site of contact is followed by acute inflammatory response, which can be sufficiently severe to cause full-thickness skin damage. Severe myalgia and panic, hypertensive crisis, acute pulmonary oedema and autonomic disturbances.

Mn.: Local use of ice, vinegar and compressive bandaging (effective on stings from box jellyfish). Stings from hydroids (e.g. Portuguese man-of-war) washed with sea

water and adherent tentacles picked off. Antivenom if available. First aid and resuscitation if large amounts of venom are absorbed.

MULTI BEE STINGS

Acute myocardial injury and rhabdomyolysis caused by multiple bee stings result of direct toxic effect in venomation and secondary to systemic anaphylactic reaction. It can also cause haemolysis with acute kidney failure.

16. CHEMICAL AND BIOLOGICAL WARFARE AND TERRORISM

The acquisition of chemical and biological weapons has increased the incidence of their use. Clinicians and other specialists must be prepared to treat civilians exposure to chemical weapons.

See Table 15 for summary of the agents.

Yellow phosphorus poisoning (smoking stool syndrome)

Diagnosis can be suspected if there is evidence of cutane-

ous burns, garlic odour in vomitus or faeces, 'smoking' and luminescence of vomitus and faeces, and characteristic course with asymptomatic middle phase. If more than 1 g is consumed, patient dies of cardiovascular collapse or acute yellow atrophy of liver. Tr. - No specific antidote. Gastric lavage with Pot. permanganate 1:5000, or 0.2% copper sulphate solution. Supportive measures.

Jatropha curcas poisoning

The plant is used as a laxative, parasitic and vermifuge. It is also used as biofuel. Symptoms -Vomiting followed by abdominal pain and loose stools. Ingestion of one or two seeds causes toxic symptoms of short duration. High concentration of phorbol esters present in the seed is the main toxic agent. Tr. is symptomatic with rehydration, salts and IV fluids. *Isopropanol poisoning.* Isopropanol is found in after-shave lotions, disinfectants, and is used as sterilizing agent.

Cl. Fs.: Cardiac and respiratory depression are common, but hematemesis, hypotension, hypothermia, renal tubular acidosis can occur.

Mn.: In severe cases, haemodialysis.

Table 15: Chemical and biological warfare agents

Agent	Mechanism of toxicity	Features of toxicity	Management
A. Chemical agent • <i>Nerve agents</i> Sarin (GB) Tabun (GB) Soman (CD) (Dermal and resp. hazards) VX (contact poisons)	Inactivate acetylcholine esterase (ACh) enzyme resulting in muscarinic, nicotinic and CNS effects	<i>Mild/Moderate</i> Miosis Blurred vision, Headache, Sweating, vomiting, <i>diarrhoea</i> , muscle fasciculation, <i>severe</i> All above Convulsions, Coma	Decontamination Sedation Oxygen Atropine 2 mg IV over 5 mins. till effective or IM if not possible, Pralidoxime 600–800 mg IM or 1–2 g IV over 20–30 min. Lorazepam or Diazepam for seizures
• Asphyxiants - Blood asphyxiant Hydrogen sulphide Hydrogen cyanide - Choking agents Chlorine Phosgene Sulphur dioxide Nitrogen dioxide	Bind with iron in cytochrome preventing cerebellar O ₂ consumption React with cytoplasmic proteins to destroy cell structure	<i>Mild/moderate</i> Palpitations, dizziness, headache, hyperventilation, drowsiness, hypotension <i>Severe</i> Convulsions, Coma, Fatal within 5 mins. Breathlessness Wheezing Laryngeal spasm Pulmonary oedema Dermal irritation ARDS	O ₂ (100%) by facial mask or intubation. Amyl nitrate inhalation 1 am q5 min Sodium nitrate 200 mg IV Sodium thiosulphate 12.5 g IV
• Vesicants Mustard gas Lewisite Phosgene oxime	Mustard forms metabolites that bind to enzymes and proteins Binds to thiol group in number of enzymes Corrosive action like strong acids	Burning and itching of skin Burning eyes, lacrimation Dyspnoea Redness of skin and blistering Nausea, vomiting Skin erythema, blistering, swollen eyes, lacrimation, pulmonary oedema	Mn. of secretions O ₂ Tr. of pulmonary oedema with PEEP to maintain PO ₂ > 60 mm Hg No specific antidote, supportive care Burn therapy For lewisite BPL IM

Dermatology

1. STRUCTURE AND FUNCTIONS OF NORMAL SKIN

Normal epidermis is a terminally differentiated, stratified squamous epithelium comprising predominantly keratinocytes. Many skin diseases affect keratinocytes. Common hallmarks of epidermal involvement are:

- Abnormal scaling of skin
- Vesicle formation
- Erosion caused by complete loss of the epithelial layer

Stratum corneum comprises anucleate, keratin-filled squames; it forms a barrier on the surface of the skin, protecting the living layer from damage by desiccation and mechanical trauma. The integrity of this barrier is dependent on the keratin cytoskeleton and the adhesion molecules that hold the keratinocytes together and maintain their attachment to the basement membrane.

Basal layer. Epidermal stem cells in the basal layer divide to form transient amplifying cells which then

migrate suprabasally, cease dividing and undergo terminal differentiation.

Melanocytes are found in the basal layer of epidermis, which forms on structures termed 'melanosomes' which are passed on to keratinocytes and form a protective 'cap' over the nuclei of these cells.

Langerhans cells in the epidermis process antigen and activate naive T cells in lymph nodes that then acquire the capacity to circulate preferentially to the skin.

Dermis is a complex tissue comprising many different cell types. Changes in the dermis such as vasodilatation and accumulation of inflammatory cells often accompany disease, such as psoriasis, eczema and lichen planus. Absence of signs of epidermal involvement and awareness of the cellular composition and pathology of the dermis assists in diagnosis.

Regional variations in skin anatomy and disease localization.

The composition of human skin varies between body sites as a result of difference in the thickness of the inter-follicular epidermis, and in the size and number of skin appendages, including hair follicles, sebaceous glands and apocrine glands. These regional differences have a key role in determining the localization and effects of different disease processes on the skin.

In addition to these morphological variations, there is evidence of marked differences in the expression of various proteins at different body sites. These are best illustrated in patients with palmoplantar keratodermas in which disease is restricted to the normal sites of expression of the mutant protein.

Hair follicles: Normal hair follicles when fully developed enter a hair cycle characterized by a growing phase (anagen), a resting phase (telogen) and a regressing phase (catagen). Illness can induce premature entry of anagenic hair follicles into telogen, and this causes increased hair shedding and temporary thinning of the hair (telogen effluvium).

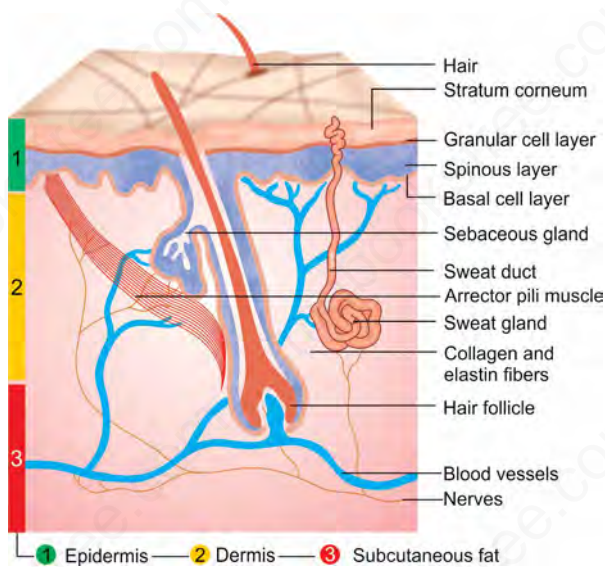

Fig. 1: Normal skin structure

Skin immune system: The skin has an important role in host defence. When the skin is exposed to a new antigen, activated antigen-expressing Langerhans' cells migrate from the skin to the lymph nodes, where they activate naive T cells, which become memory T cells, and express new surface markers that allow them to accumulate in the skin in response to cutaneous injury.

2. DERMATOLOGICAL HISTORY AND EXAMINATION

HISTORY

Symptoms: Intense itch in some eruptions (e.g. scabies, atopic dermatitis, lichen planus). In pityriasis versicolor there is often mild itching after a hot bath. Other types of symptoms include pain (e.g. chondrodermatitis of the ear, burning, chilblains and tenderness (e.g. erythema nodosum). Urticaria affecting palms often causes pain (because the edema is deeper and the firmer tissues of the palm cannot distend easily).

Duration, evolution, periodicity. In urticaria, individual lesions change from day to day, in erythema multiforme, lesions are relatively static. Overall duration is of help in localized lesions, e.g. in presumed keratoacanthoma still enlarging after a few months is probably a squamous cell carcinoma.

Some dermatoses have a characteristic evolutionary sequence (e.g. pityriasis rosea, in which a solitary larger 'herald patch' precedes the widespread eruption by a few days).

Medical history and medications: Situations in which systemic disease should be considered include unusual patterns of ulceration, e.g. pyoderma gangrenosum related to ulcerative colitis, acquired ichthyosis or generalized pruritus without rash in younger patients.

Medications may cause skin eruptions. Previous topical therapy may obscure clinical features (e.g. topical corticosteroids applied to ringworm infection, causing 'tinea incognito'). History of sun exposure and unprotected sex.

Family history may be important in genodermatoses (e.g. neurofibromatosis), and in some disorders with more complex inheritance (e.g. atopic dermatitis, psoriasis).

Occupation and hobbies: Hands are the most commonly affected site in occupational dermatitis. Hobbies can cause problems, e.g. epoxy resins adhesives, rubber chemicals (footwear, gloves) and plants are common allergens.

PHYSICAL SIGNS

See Table 1 for the shape and pattern of skin lesions.

Arrangement and symmetry. Asymmetrical eruptions often have external cause, e.g. unilateral palmar involvement in fungal infection. Also in cooks, hairdressers and others who hold a tool in the dominant hand while handling irritant materials with the other.

Distribution. Some disorders have a predilection for specific body sites.

Scalp: Hair disorders, alopecia, psoriasis, seborrhoeic dermatitis, lichen simplex (nape of neck), pilar cysts, organoid naevus (hamartoma), cutaneous metastases of internal malignancy.

Eyelids: Atopic dermatitis, contact allergy (cosmetics, nickel), seborrhoeic blepharitis, angio-oedema, dermatomyositis, basal cell carcinoma, xanthelasma.

Face: Acne, atopic dermatitis, seborrhoeic dermatitis (particularly eyebrows and nasolabial crease), butterfly rash (rosacea, erysipelas, lupus erythematosus, lupus pernio, erythema infectiosum), naevi and freckles, actinic

Table 1: Shape and pattern of skin lesion

Shape	Description	Examples
Discoid	Filled circle	Discoid eczema
Petaloid	Discoid lesions that have merged together	Seborrhoeic dermatitis on the trunk
Arcuate	Incomplete circles	Urticaria
Annular	Open circles, central skin different from that of the rim	Tinea corporis, granuloma annulare (Fig. 2)
Polycyclic	Circles that have merged together	Psoriasis
Livedo	'Chicken wire' criss-cross pattern	Erythema ab igne, vasculitis
Reticulate	Fine, lace-like pattern	Oral lichen planus
Target	Multiple concentric rings	Erythema multiforme
Stellate	Star-shaped	Lesions of meningococcal septicaemia
Digitate	Finger-shaped	Chronic superficial dermatosis
Linear	Straight line	Koebner reaction to a scratch, lichen planus
Serpiginous	Snake-like	Cutaneous larva migrans

Fig. 2: Granuloma annulare

keratoses, basal and squamous cell carcinomas, keratoacanthoma, lentigo maligna.

Lips: Dermatitis (atopic, contact), cheilitis (angular, actinic), angio-oedema, contact urticaria, impetigo, erythema multiforme, warts, vascular lesions (venous lake, pyogenic granuloma), squamous cell carcinoma.

Hands: Dermatitis (dyshidrotic, pompholyx, contact), psoriasis and palmoplantar pustulosis, keratodermas, dermatophyte infections, erythema multiforme, photosensitivity (dorsal hand), scabies (particularly finger webs), collagen vascular disorders and vasculitis (particularly nail-fold and fingertip), viral warts, actinic keratoses, squamous cell carcinoma, granuloma annulare, nail disorders.

Limbs: Psoriasis, atopic dermatitis (limb flexures), discoid eczema, venous eczema and ulceration (lower leg), asteatotic eczema (lower leg), lichen simplex (lower leg), lichen planus (flexor forearms, shins), dermatitis herpetiformis (knee, elbow), erythema nodosum (legs), vasculitis (legs), papular urticaria, flea bites (lower leg), dermatofibroma, Bowen's disease (lower leg).

Feet: Dermatitis (pompholyx, contact, juvenile plantar), psoriasis and palmoplantar pustulosis, dermatophyte fungal infection (skin and nails), pitted keratolysis, vasculitis and arterial disease, callosities, corns, verrucae.

Axillae: Psoriasis, contact dermatitis, staphylococcal boils, hidradenitis suppurativa, acanthosis nigricans, erythrasma, fibroepithelial polyps, freckles in neurofibromatosis (Crowe's sign).

Genitals: Scabies, Psoriasis, Reiter's syndrome, lichen planus (penis), lichen sclerosus (penis, vulva), lichen simplex (scrotum, vulva), fixed drug eruption (penis), sexually transmitted diseases/genital warts, Zoon's balanitis (glans

Table 2: Morphology of skin lesion

• Macules (flat patches)
• Plaques (flat-topped but palpable)
• Papules and nodules (dome-shaped, flat-topped, umbilicated or crusted)
• Blisters (vesicles, bullae)
• Pustules
• Various breaks in skin (ulcers, erosions, fissures)

penis), epidermoid cysts (scrotum), squamous cell carcinoma (penis, vulva). Fixed drug eruption.

Colour: (a) Shades of red, e.g. violaceous colour of dermatomyositis or lichen planus, brownish-red of seborrhoeic dermatitis, and pillar-box red of erysipelas. (b) Non-blanching on pressure in extravasation of blood. Scaling alters colour by introducing hair-keratin interspaces. (c) Inflammation of the skin disrupts pigmentation. Residual pigmentation is a characteristic feature of lichen planus.

Close-up morphology: Accurate description of skin lesions is based on recognition of morphology as given in Table 2.

Changes in the skin in form of thickening and thinning can be made out by both palpable and visible physical signs (e.g. increased skin markings in lichenification, more visible vessels as a result of atrophy). Scaling and crusting imply an epidermal contribution; thus annular lesions of ringworm (scaly) and granuloma annulare (no scaling). Also quality of scale (e.g. large, hard, silvery scale of psoriasis, fine 'bran-like' scales of pityriasis versicolor).

Interventional physical signs: (a) Feeling of skin in assessing thickness of lesions, texture, tethering and temperature. (b) Application of oil to the skin fills air spaces (e.g. identification of Wickham's striae in lichen planus). (c) Diascopy compresses vessels and reduces erythema allowing other colours to be seen (e.g. brownish translucency in sarcoid). (d) A scalpel can be used to exaggerate the minor scaling of pityriasis versicolor, and to obtain scale samples of fungal cultures. (e) A needle can be used to extract scabies mites from the skin. (f) Wood's light is used to distinguish epidermal from dermal pigmentary abnormalities, and for fluorescence of scales in tinea capitis (but only caused by cat or dog ringworm) and some other infections and dull green in favus.

Combination of physical signs, e.g.

- Discrete scaling plaques: Examine nails for psoriatic pit, onycholysis
- Scattered, discrete purplish lesions: Examine mouth for striae of lichen planus

- Erythema and scaling of one palm or 'asymmetrical eczema': Examine feet to confirm tinea pedis.

3. DERMATOLOGICAL PHARMACOLOGY

TOPICAL THERAPY

The effectiveness depends on their ability to penetrate the epidermis and is influenced by the choice and concentration of the drug, its vehicle or base, and the age and degree of hydration of the skin. The site to be treated is also important, e.g. absorption is greater at flexural sites and face.

Vehicles hydrate the skin, can have anti-inflammatory effect, and help the active drug penetrate the skin.

Creams are water-based products with a cooling and emollient effect. They contain preservatives to prevent bacterial and fungal growth. Creams are less greasy than ointments and are cosmetically better tolerated.

Ointments are oil-based products which provide an occlusive layer over the skin surface that helps enhance absorption, and are therefore useful in chronic dry conditions.

Lotions are watery suspensions which can be used over hairy and large body surface areas. They have a drying, cooling effect.

Gels are watery suspensions of insoluble drugs such as corticosteroids, salicylic acid and retinoids. Gelling agents are added to aid their absorption.

TOPICAL AGENTS

Indications for various topical agents is given in Table 3.

Emollients: The term 'emollient' covers a diverse range of products including soap substitutes, bath additives, creams, ointments and even an aerosol spray product. They are important in management of itchy, dry skin conditions,

giving symptomatic relief. Their effects are temporary, and frequent applications are needed. Emollient creams, ointments and sprays are best applied following a bath.

Topical corticosteroids: Cutaneous effects include vasoconstriction, reduced dermal blood vessel permeability and inhibition of phospholipases, fibrin and kinins. Table 4 gives topical corticosteroids classification according to their potency.

In addition, inhibition of phospholipases leads to blockage of the arachidonic acid pathway, which leads to a cascade of inflammatory mediators; anti-inflammatory effects thus occur.

Inflammatory skin conditions involving the delicate skin on the face or genitalia require a mild or moderately potent corticosteroid, in contrast, palms, soles and markedly thickened skin (as may occur in chronic scratching) often require a potent or very potent agents.

The *quantity* applied can be assessed using the 'finger-tip unit' concept - An amount of ointment or cream, the length of an adult fingertip is about 0.5 g and is sufficient for 300 cm² of affected skin (thus, a single application for one arm or leg requires 3FTU or 6FTU respectively).

Tropical retinoids act via nuclear retinoid receptors.

Tazarotene is a selective retinoid receptor agonist with anti-inflammatory and antiproliferative effects on keratinocytes. It is used for plaque psoriasis affecting up to 10% skin area. It should be avoided in women of child-bearing age, and on facial and sexual skin.

Adapalene is used for acne, both comedonal (Fig. 3) and inflammatory.

Tretinoin and *isotretinoin* are useful in comedonal acne but have little effect in inflammatory acne.

Tazarotene is a potent selective retinoid. It should be avoided in seborrheic dermatitis and in pregnancy.

Topical vitamin D derivatives are first-choice topical therapies in treatment of psoriasis, and can be combined with topical corticosteroids and phototherapy.

Calcipotriol is used in treatment of mild to moderate plaque psoriasis affecting up to 40% body surface area. It is contraindicated in pregnancy and should not be used on the face.

Table 3: Indications for various topical agents

Topical agents	Indications	Side effects
Corticosteroids	Inflammatory Dermatoses	Striae, telangiectasiae, bruising, contact dermatitis,
Emollients	Xerosis, eczema, psoriasis	depigmentation, worsening of infection, rebound phenomenon,
Retinoids	Psoriasis, acne, photo-damage	suppression of hypothalamic-pituitary-adrenal axis
Vitamin D analogues	Plaque psoriasis	Folliculitis
Coal tar	Plaque psoriasis	Skin irritation, erythema
Dithranol	Plaque psoriasis	Skin irritation, pruritus, erythema, hypercalcaemia
		Skin irritation, staining folliculitis, skin cancers
		Skin irritation, staining

Table 4: Topical corticosteroids classified according to their potency

Potency	Corticosteroid	Risk of skin thinning with long-term use
Mild	Hydrocortisone	Low
Moderate	Clobetasone butyrate	Some risk
Potent	Betamethasone valerate	High
potent	Hydrocortisone butyrate	Very high
Very	Clobetasol propionate	

Table 5: Systemic agents

Agents	Indications	Dose	Monitoring	Side effects
Acitretin	Psoriasis, Ichthyosis	0.2–1 mg/kg o.d.	FBC, LFTs, lipids, spinal radiography	Mucosal dryness, epistaxis, myalgia, alopecia, teratogenicity, hyperlipidemia, mood changes, diffuse interstitial skeletal hyperostosis
Isotretinoin	Acne	0.5–1 mg/kg o.d.	FBC, LFTs, lipids	As above
Cyclosporine	Eczema Psoriasis	2.5–5 mg/kg o.d.	FBC, LFTs, urea and electrolytes, BP, creatinine clearance	Renal impairment, infections, hypertension, gum hypertrophy, Hirsutism
Azathioprine	Autoimmune and bullous disorders	1–3 mg/kg o.d.	FBC, LFTs, urea and electrolytes	GI symptoms, infections, myelosuppression, hepatotoxicity
Methotrexate	Psoriasis	5–25 mg/week	FBC, liver biopsy, urea and electrolytes, LFTs	GI symptoms, stomatitis, myelosuppression, liver fibrosis, nephrotoxicity

**Fig. 3:** Comedonal acne

SYSTEMIC THERAPIES

Indications, dosage, monitoring and side effects of systemic agents are listed in Table 5.

4. HAIR AND NAILS

HAIR DISORDERS

Alopecia can be divided into cicatricial and non-cicatricial. Non-cicatricial alopecia can be divided into patchy and diffuse alopecia. Cicatricial alopecias have poor prognosis. Table 6 gives the classification of alopecia.

Patchy Alopecia

1. **Alopecia areata:** A non-scarring autoimmune disorder affecting any hair-bearing area. Typically, there is a sudden onset of well circumscribed, totally bald,

Table 6: Classification of alopecia

A. Non-scarring:

1. Patchy:

- Alopecia areata
- Tinea capitis
- Androgenic alopecia
- Traction alopecia

2. Diffuse:

- Alopecia universalis
- Ectodermal dysplasia

B. Scarring:

- Congenital-Alopecia cutis
- Infective-Favus, kerion
- Inflammatory: Lichen planopilaris, discoid lupus erythematosus
- Neoplastic: Basal cell carcinoma
- Nevi: Nevus sebaceous
- Injury: Physical, chemical
- Idiopathic

smooth patch, often with 'exclamation-mark' hairs at the border, usually affecting the scalp (Fig. 4). Spontaneous growth frequently occurs, but the areas may spread peripherally and may eventually involve the whole scalp (alopecia totalis). The reason why white hairs appear to be relatively spared compared with pigmented hair is not understood (this phenomenon may explain reports of sudden greying and hair turning white overnight). Alopecia areata in atopic individuals has a worse outcome.

Aetiology: (a) *Genetic predisposition* – Family history increases likelihood. (b) *Association with autoimmune diseases* (thyroid disease, vitiligo and Addison's disease)

Fig. 4: Alopecia areata

suggests autoimmune origin; presence of lymphocytic infiltrate in and around anagen hair follicles is further evidence. Alopecia areata differs from other autoimmune diseases in that it does not result in complete loss of function of the target organ, but in a temporary switching off of hair follicle activity, which can return to normal. This suggests that the target may be a controlling growth factor or its receptor.

Treatment. 'Wait-and-see' approach can be tried.

- i. **Corticosteroids:** (a) Systemic result in regrowth of hair in many cases, but most patients relapse. (b) Topical – may be effective. Folliculitis may be a side effect. (c) Intralesional – Injection around and within the lesions. Triamcinolone suspension 0.1 mL with each injection for maximum of 2 mL. Reinjection at 4–6 weeks interval. Skin atrophy is a side effect; it can occur both at site of injection and in a linear manner following the direction of lymph flow. It should hence be used principally for accelerating regrowth in well-circumscribed and cosmetically disfiguring areas of hair loss.
 - ii. **Topical sensitizers:** Topical immunotherapy if more than 50% of scalp is involved. Repeated application of dinitrochlorobenzene (DNCB) and squaric acid dibutylester (SADBE). Side effects—Mild rash, pruritus, adenopathy and rarely erythema multiforme.
 - iii. **Anthralin** applied (0.1% to 0.4%) for night treatment) increased if tolerated to 1.0% once or twice a week for at least 6 months.
 - iv. **Minoxidil:** Topical application of 5%, not more than 25 drops bd for 12 weeks. Side effects – Hypertrichosis, irritation. It can be used in combination with other topical agents.
 - v. **Photochemotherapy** – PUVA therapy is combination of psoralen and UV light.
 - vi. **Topical immunomodulators** – Tacrolimus and Pimecrolimus have smaller molecular size which does not allow them to reach the site of pathology (i.e. the deep dermis).
2. ***Tinea capitis:*** Irregular patch of alopecia with scaling and broken off stubs of hair within the patch. Multiple patches may develop. Occasionally the patch may be inflamed (kerion). *Tr.* – Topical antifungal therapy is ineffective. Griseofulvin 10 mg/kg/day for 6 weeks or ketoconazole, itraconazole and terbinafine.
 3. ***Lichen planopilaris:*** Lichen planus affecting hair follicles produces a patchy, scarring alopecia. Minute, purple papules may be seen around hair follicles at the edges of the patches. *Tr.* – Clobetasol topically. If not controlled 20–30 mg prednisolone p.o. for 6–8 weeks.
 4. ***Folliculitis decalvans:*** Rare cause with pustules around follicles which heal with scarring and destruction of hair follicles. *Tr.* – Anti-staphylococcal antibiotics.
 5. ***Skin diseases:*** That produce alopecia are discoid lupus erythematosus and morphea.
 6. ***Trichotillomania:*** Produced by patient with psychiatric illness plucking her hair.
 7. ***Traction alopecia:*** Produced by tying a tight pony tail. This is most prominent along hair margins because distant hair is subject to most traction.

Diffuse Alopecia

- The most common cause of diffuse hair loss is an androgenetic alopecia (common baldness, male-pattern alopecia). In men it causes typical temporal recession and thinning at the vertex ('Hamilton patterns' Fig. 5). In women a more diffuse hair loss is generally seen (Ludwig pattern).
- Other causes of diffuse hair loss include telogen effluvium, thyroid disease, severe iron-zinc, and protein deficiency. Drug-induced, e.g. cytotoxic agents such as vincristine, methotrexate, cyclophosphamide. These lead to hair thinning over the whole scalp in contrast to frontoparietal loss in androgenic alopecia.

Assessment of diffuse hair loss: It is important to examine the scalp to exclude inflammatory scalp disease or scarring alopecia.

- Detailed medical history
- Full blood count
- Serum iron and ferritin measurement
- Liver, renal and thyroid function tests

Fig. 5: Androgenetic alopecia

- Microscopy for hair (look for weathering, fractured hair caused by cytotoxic injury and any congenital abnormalities that may have made the hair shaft more susceptible to trauma).
- Trichogram, trichometry

Assessment of Women with Androgenic Alopecia

- Enquiry about amenorrhoea or oligomenorrhoea, which may suggest polycystic ovary disease
- Enquiry about galactorrhoea (elevated prolactin levels)

Examination for hirsutism and cutaneous virilism when the following investigations are necessary:

- Prolactin
- Luteinizing hormone (LH)
- Follicle-stimulating hormone (FSH)
- Testosterone

Androgenetic alopecia is a genetically determined physiological change which involves a shortening of the anagen phase of the hair cycle and consequent increase in the proportion of telogen hairs. Structurally the terminal hair follicles transform into progressively smaller follicles ('miniaturization phenomenon').

Genetic basis. An autosomal dominant inheritance has been suggested, a multifactorial inheritance is possible.

Androgens. Men with syndrome of androgen insensitivity (e.g. 5 α -reductase deficiency) fail to develop temporal recession after puberty. A number of studies have failed to show a correlation between testosterone levels and baldness. In women baldness may be associated with elevated levels of circulating androgens; changes in hair patterns occur most commonly after menopause.

It appears that the essential inherited factor responsible for androgenic alopecia is the manner in which the follicles of the frontal and vertex regions of the scalp react to androgens.

Treatment

Non-surgical

Drugs

- Minoxidil*, a piperidino-pyrimidine derivative, is a potent vasodilator. Applied topically twice daily as a 2% solution results in conversion of some miniaturized hairs in about one third of men and 55% of women. Main side effect is local irritation. Five percent minoxidil may give better results but is not recommended in women because hypertrichosis may result due to its absorption.
- Cyproterone acetate* 50–100 mg may prevent further progression of hair loss. 2 mg of the drug with ethinyloestradiol may maintain the improvement in women in early stages of hair loss. Side effects: Lassitude, weight gain, breast tenderness, loss of libido and nausea.
- Spironolactone*: Subjective improvement may occur but patients complain of mood swings, irregular menses and breast tenderness.
- Flutamide* is a pure anti-androgen and there are short term reports of its effectiveness. It is potentially hepatotoxic.
- Finasteride* is a selective inhibitor of type 2 isoenzyme of 5 α -reductase, which converts testosterone to dihydrotestosterone. Dose of 1 mg/day p.o. results in increase in DHT levels in the scalp and serum. There are no significant side effects and no impairment of fertility. Because of its potential feminizing effect on male foetuses, it is contraindicated in pregnant women or those who may become pregnant.
- PUVA prolonged therapy may induce regrowth of scalp and body hair.

Surgical

- Direct hair implant (DHI)** is a hair transplant technology, leaves behind no scar or stitches and is painless. The technique removes hair follicles one by one from the sides and back of the head and replants them with precision to restore hair line and density. It is performed under local anaesthesia. The implanted hair never falls and there is not much difference between the existing hair and the transplants.

2. **Hair additions:** It is a hair-bearing contraception that is added to the existing hair to give a 'fuller hair of head' appearance.
3. **Stem cell injection** that can cause local swelling and redness for 48 hours. They work by releasing proteins to coax hair growth. However if the hair roots are dead there is no technology that can revive it.

Telogen effluvium: As part of natural hair growth cycle, hairs in the telogen phase are shed from all areas of the scalp at a rate of up to 150 per day. Normally, these follicles then re-enter and no obvious hair thinning is apparent. If a large number of hair follicles enter catagen together, however, diffuse excessive hair loss is observed 2-3 months later. This may be seen following significant physical or emotional stress or after severe febrile illness. Once the stress passes, the hair usually returns to normal.

Other Causes of Diffuse Hair Loss

- High fever
- Hemorrhage
- Sudden starvation
- Malignancy
- Significant surgery
- Severe impairment of liver or kidney function
- Certain drugs
- Industrial or accidental exposure to certain chemicals

Slow onset of hair thinning is sometimes seen in absence of obvious hair shedding if hairs at the end of normal telogen fail to re-enter anagen. This is the pattern most often seen in iron deficiency anemia, hypothyroidism and hypopituitarism.

Secondary syphilis: The hair typically has a 'moth-eaten' appearance and tends to regrow after 4-6 months.

Chronic kidney failure: Mechanism is not understood. Hair loss is not reversed following dialysis.

• Allopurinol	• Heparin
• β -blockers	• Lithium
• Borax	• Mercury
• Bromocriptine	• Pitressin
• Carbamazepine	• Retinoids
• Colchicine	• Sodium valproate
• Coumarins	• Thallium
• Cyclophosphamide	• Triparanol
• Doxorubicin	

Drugs: Drugs causing diffuse hair loss are listed in Table 7.

Chemical agents (e.g. hair dyes, bleaches, perm solutions) due to weathering of hair shafts.

Hirsutism

Hirsutism is growth of terminal hair on the body of a woman in a pattern similar to that which develops in healthy post-pubertal men. Hirsutism occurs in response to androgens and thus effects androgen dependant hairs. Hypertrichosis refers to growth of terminal hairs including non-androgen dependant follicles that is considered excessive for the site and age of the patient. Table 8 gives the causes of hirsutism.

Diagnosis

Physical examination: Pattern and severity of the hair growth, and associated androgenetic alopecia, acne vulgaris, obesity, acanthosis nigricans, deepening of the voice, increased muscle bulk, hypertension, galactorrhoea, striae distensae and cliteromegaly. Cliteromegaly is the most important sign suggesting virilization; if it is associated with a short history of hirsutism (< 1 year), it is highly suggestive of a tumorous cause.

Investigations

- In long-standing mild hirsutism with a regular menstrual cycle and no features of systemic virilism, no further investigation is required.
- Some patients with moderate hirsutism with or without menstrual irregularities have polycystic ovary disease, which can be confirmed by ultrasonography. Plasma testosterone levels may be helpful.
- Patients with severe hirsutism and virilization with a short history or very severe hirsutism with a long history, need investigation for an androgen-secreting tumour.

• Ovarian causes
– Polycystic ovary syndrome
– Ovarian tumors
• Adrenal tumors
– Congenital adrenal hyperplasia
– Adrenal tumors
• Cushing's disease
• Androgen therapy
• 'Idiopathic' hirsutism

Management

Cosmetic approaches include bleaching, shaving, plucking (e.g. waxing, sugaring), and depilatory creams. Electrolysis is the only permanent method of hair removal, but can be painful. Laser removal of hair takes long but is successful.

Systemic Antiandrogens

Cyproterone: (a) Low-dose therapy is given in the form of contraceptive pill 35 µg ethinyloestradiol and 2 mg cyproterone acetate taken for 21 days in every 28. (b) High-dose therapy: Cyproterone 50–100 mg for first 10 days only.

Spironolactone: 50–100 mg daily or cyclically (daily for 3 out of every 4 weeks). Spironolactone may feminize male foetuses; women taking the drug should avoid pregnancy.

Other agents: Flutamide and ketoconazole reduce hirsutism, but carry the risk of hepatic toxicity.

NAIL DISORDERS

The nail grows from the matrix and is supported by the nail bed until it reaches the free edge. At the proximal and distal margins, it is embedded in the nail folds. Local and systemic disease can alter the appearance and function of all four structures.

Local diseases: Common are:

- Fungal nail infections
- Periungual eczema
- Viral warts
- Tumors: squamous cell carcinoma and malignant melanoma

Systemic diseases:

- Vascular phenomena (e.g. splinter haemorrhages, cyanosis)
- Changes in nail growth as a result of general metabolic factors influencing nail matrix function
- Psoriasis

Nails in Systemic Disease

Nail Plate

1. **Grooves:** Beau's lines. Any severe illness may lead to a transverse linear depression on each nail. Because the average rate of fingernail growth is known, the position of the line indicates the approximate date of onset of the original illness. Also psoriasis, zinc deficiency.
2. **Ridges:** Longitudinal in lichen planus, RA. Impaired peripheral circulation may lead to longitudinal ridging and thinning of the nails.

3. **Pitting** – Psoriasis, alopecia areata, eczema, idiopathic.
4. **Thickening (tenting)** in pachyonychia congenita.
5. **Tachyonychia** – Grey rough surface affecting all nail plates (20-nail dystrophy).
6. **Colour changes:**

White – (a) *Punctuate spots* of no significance. (b) *Transverse bands* – Arsenic poisoning (Mees' lines), sometimes with palmar keratosis. (c) *True leukonychia* – Congenital or acquired, e.g. after systemic illness such as myocardial infarction, shock or ulcerative colitis. Opaque nails (opacity obscuring the lunula) in cirrhosis; also diabetes mellitus, cardiac failure. (d) *Half-and-half nails* – In chronic kidney failure. Two parts separated transversely by a well-defined line. The phenomenon disappears within 2–3 weeks of successful renal transplantation. (e) *Paired, narrow, white bands* – Hypoalbuminemia. (f) *Longitudinal white lines* – In Darier's disease (keratosis follicularis).

Splinter haemorrhages – Represent blood escaping from the longitudinal capillaries in the nail bed beneath the nail. The cause may be systemic or local. Trauma, rheumatoid arthritis and other collagen disease (reflecting the vasculitis), trichinosis, psoriasis, infectious mononucleosis, blood dyscrasias, cryoglobulinaemia, mitral stenosis sometimes, chronic mountain sickness, indwelling radial arterial catheters.

Linear pigmentation (Longitudinal melanonychia) – Coloured races, Addison's disease, pituitary tumours, cytotoxic drugs, vitamin B₁₂ deficiency. In a single nail indicates underlying malignant melanoma.

Yellow nails – Yellow nail syndrome is characterised by increased transverse and longitudinal nail curvature, slow rate of growth and yellow discolouration of nails. It may be associated with lymphoedema, idiopathic pleural effusions, chronic chest infections and chronic sinusitis, tetracycline therapy, jaundice.

Green nails – Secondary pseudomonas infection in chronic paronychia.

Blue nails – Antimalarial drugs (e.g. chloroquine), Wilson's disease (restricted to lunula). Azure lunulae in argyria.

O-spots – Yellowish red discolouration in centre of nail. Typical of psoriasis.

Longitudinal brown streaks – (a) Subungual hematoma, often with red tinge. (b) Benign racial: often multiple. (c) Melanocytic naevus. (d) Malignant melanoma. (e) Drugs: minocycline, zidovudine. (f) Addison's disease.

(g) Multiple benign streaks with buccal pigmentation.
 (h) Frictional: On edge of toes, or occupational on hands.
 (i) Fungal infection. (j) Lichen planus. (k) Squamous cell carcinoma, eczematous dermatitis, pityriasis rosea, rheumatoid arthritis, Reiter's disease, SLE, dermatomyositis, sarcoidosis, diabetes mellitus (Rosenau spots), congenital pitting. (l) Peutz-Jeghers syndrome.

Red nails – Congestive heart failure (lunula).

Shiny nails – Indirect evidence of pruritus.

Changes in Shape

Koilonychia – Spooning of the nails in iron deficiency classically. Also in early infancy (temporary condition), hyperthyroidism, occupational, liver disease. High altitude (more common in upper limbs).

Clubbing – (See clubbing of fingers).

Onycholysis – Separation of the nail plate from nail bed sometimes in thyrotoxicosis. A form of clubbing termed (thyroid acropachy) occurs in Grave's disease.

Abnormalities of Nail Folds

1. *Proximal and lateral folds* – (a) Local infection or systemic disease such as collagen disease, psoriasis and Reiter's disease. (b) Pterygium – Prolongation of proximal nail fold into the nailbed, splitting and subsequent destruction of the nail in severe lichen planus.
2. *Cuticles* – Thickening and hyperkeratosis in dermatomyositis. These remit with lessening of disease activity.
3. *Vessels* – (a) Dilated and deformed capillaries in systemic sclerosis associated with Raynaud's phenomenon. (b) Loop appearance of vessels (resembling a glomerulus) in early lupus erythematosus.

Nailbeds

- Telangiectasia, erythema and thrombosed capillaries may be observed in connective tissue diseases.
- Cuticles may be frayed in nail biters, due to cosmetics and in connective tissue disease.

5. SKIN PROBLEMS IN PREGNANCY

Physiological changes in skin, nails and hair during pregnancy are listed in Table 9.

Pruritus gravidarum is probably the most distressing physiological symptom and the aetiology seems multifocal. Oestrogens impair transport of bile to bile canaliculi, leading to increase in circulating bile salts, and prostaglandins reduce the threshold for pruritus. Liver function tests should be done to exclude cholestasis of pregnancy and common skin disorders. Some skin disorders improve

Table 9: Physiological changes in skin, nails and hair during pregnancy

• Hyperpigmentation
• Melasma
• Hirsutism
• Nail changes
• Vascular changes
• Increased eccrine activity
• Decreased apocrine activity
• Increased sebaceous activity
• Striae (vertical, dark red/purple)
• Pruritus gravidarum

with pregnancy (e.g. atopic eczema, acne vulgaris, hydradenitis suppurative, psoriasis), but a greater number tend to deteriorate (e.g. SLE, infections, such as candidosis, viral warts and herpes simplex).

SPECIFIC DERMATOSES OF PREGNANCY

1. **Polymorphic eruption of pregnancy** is the most common rash in pregnancy. There is an association between excess maternal weight gain and increased newborn weight. Most patients are primigravida and the rash most commonly develops in the third trimester or postpartum, and lasts on an average for 6 weeks. Lesions begin on lower abdomen within striae. The umbilicus is spared. The upper inner thighs are also affected. Pruritic urticarial papules develop which coalesce to produce plaques, vesicles, target lesions and polycyclic wheals.

Tr. – is symptomatic. Moderately potent corticosteroids are usually more effective than antihistamines in relieving pruritus.

2. **Pemphigoid gestationis** classically presents as a bullous disorder during pregnancy and puerperium. It can also be associated with choriocarcinoma, trophoblastic tumors and hydatidiform mole. It is a serious condition and the neonate may develop severe bullous eruption at birth. The disease also produces small-for-date babies because of placental insufficiency.

Pemphigoid gestationis usually develops in the second or third trimester or in the immediate puerperium. It often recurs in subsequent pregnancies with more severe disease.

Immunofluorescence performed on frozen sections of uninvolved skin and serum is the best diagnostic test for the disease and is positive in all cases.

Tr. – Mild cases respond to moderately potent topical corticosteroids but systemic corticosteroids are

generally required (e.g. 20–40 mg for less severe cases, 40–80 mg for severe cases, in a reducing course). A postpartum flare invariably occurs, requiring a higher dose. Severe cases may require plasmapheresis or the luteinizing hormone-releasing hormone analogue goserelin, which induces a reversible chemical oophorectomy. However, the drug can only be used in the postpartum phase.

3. **Prurigo of pregnancy** usually begins in the third trimester and often persists for several months postpartum. The lesions are grouped excoriated papules on extensor surfaces of limbs, abdomen and shoulders. Fatal prognosis is poor.

Tr. – Topical application of moderately potent corticosteroids and if necessary sedating antihistamines.

4. **Pruritus folliculitis of pregnancy** is thought to be a pruritic hormonally induced acne. Clinical appearances are of a folliculitis similar to the monomorphic acnes seen in patients taking corticosteroids or progestogenic steroids.

Clinically, the disease is characterized by grouped lesions consisting of urticarial papules and polycyclic wheals. Most patients first develop a rash in the umbilicus that later spreads to the thighs, palms and soles but seldom involves the face or oral mucosa. Target lesions, vesicles and large tense bullae subsequently develop and closely resemble bullous pemphigoid.

Tr. – Topical application of 1% benzoyl peroxide and 1% hydrocortisone cream.

Chloasma (melasma, pregnancy mask) is an increase in epidermal or dermal pigmentation that occurs during pregnancy. The hypermelanosis affects the cheeks, forehead and chin and becomes more marked following sun exposure. It occurs in later half of pregnancy or postpartum. Grouped, well-defined, 2–5 mm, light to dark brown macules tend to coalesce in the centre resulting in bigger brown patches. Macules remain more or less discrete at the periphery, which become irregular in outline.

Treatment – Avoidance of sunlight and application of a sun screen. Hydroquinone cream applied over a long time may help to lighten the patches, but total clearing is rare. Chemical peeling, Laser therapy are also used.

EFFECTS OF PREGNANCY ON PRE-EXISTING SKIN CONDITIONS

Psoriasis. Effects are variable. A rare form of generalized pustular psoriasis (impetigo herpetiformis) may be seen.

Acne usually improves in pregnancy, but may deteriorate. Erythromycin topically or systemically is a safe treatment option.

Atopic eczema. Effects are variable. A few women develop prurigo of pregnancy. Breast feeding may be desirable in atopic women because it may reduce the infant's risk of developing eczema.

6. TUBERCULOSIS OF THE SKIN

Cutaneous infection with *M. tuberculosis*. Clinical appearance varies with mode of infection, which can be metastatic or from draining lymphnodes (Table 10).

LOCALIZED FORMS OF CUTANEOUS TUBERCULOSIS

1. **Primary tuberculous complex (tuberculous chancre)**, is found usually in those children and young adults who have not contacted TB. Lesion is a nodule which, through central necrosis, breaks down to form an indolent indurated ulcer. It occurs on the face, genitals and limbs. Adjacent lymphadenopathy. Microscopic examination shows typical tubercular histology.
2. **Lupus vulgaris** is the most common type of inoculation tuberculosis. These patients have a moderate to high degree of immunity against TB bacilli.

The primary lesion is a reddish-brown pin-head sized nodule. A number of these nodules may coalesce to form a dark-red inflammatory patch which slowly extends peripherally (Fig. 6).

The patches are irregular in shape and vary in size, but are always elevated above the surface and studded with minute brownish nodules. When the patch is examined by diascopy, the nodules assume the 'apple jelly' colour from which they derive their name. The disease spreads slowly over many years with resultant scarring.

Sites – Begins in childhood or adolescence upon the face, the cheeks and nose being most commonly affected. Also buttocks, thighs.

Table 10: Tuberculosis of the skin

• Primary inoculation tuberculosis (tuberculous chancre)*
• Reinoculation TB – Lupus vulgaris, tuberculosis verrucosa cutis
• Contiguous spread from underlying organs – Scrofuloderma
• Haematogenous spread – Miliary tuberculosis
• Autoinoculation TB, e.g. perioral TB in pulmonary tuberculosis or periurethral in renal tuberculosis

*Due to direct inoculation of the skin through minor cuts, abrasions, insect bites or other wounds and is analogous to the primary complex of pulmonary TB.

Fig. 6: Lupus vulgaris

Fig. 7: Tuberculous verrucosa cutis

Fig. 8: Scrofuloderma

Fig. 9: Scrofuloderma

Clinical types or variants:

- Atrophic or smooth, composed mainly of scar tissue and containing many 'apple-jelly' nodules.
- Hypertrophic type - keratotic verrucose surface of the plaque (Fig. 7)
- Ulcerative resembling scrofuloderma

3. **Tuberculous verrucosa cutis** (Anatomist's wart, post-mortem wart). The bovine bacillus is usually responsible.

A reddish papule or small nodule appears at the site of inoculation. It tends to heal at one end and progress at the other.

In time papillomatous changes occur and a dusky-red, wart-like lesion results.

Sites: Knuckles and or back of hands, i.e. those parts most exposed to abrasions or cuts.

4. **Scrofuloderma** (Figs. 8 and 9) is the result of direct extension from subcutaneous tuberculous structures, commonly lymph nodes, bones or joints. The overlying skin breaks down with resulting sinuses discharging serosanguinous fluid. The lesions heal with puckered scarring.

Skin covering the affected organ becomes purplish and stretched and finally yields, giving rise to one or more sinuses through which a seropurulent fluid and caseous matter is discharged. Later ulcers form around these sinuses with irregular, undermined bluish borders. The ulcerative process may become extensive and pockets and fistulae are common. The disease may persist for years with disfiguring scarring.

Scrofuloderma. Multiple discharging sinuses with underlying matted lymphnode swellings in the neck are typical.

5. **Tuberculosis cutis orifacialis** (acute tuberculous ulcer) affects the skin at mucocutaneous borders of body orifices and is secondary to TB of internal organs particularly the lungs. The ulcers are soft, shallow, rounded or oval, discrete, indolent with irregularly undermined edges and thin yellow crusts. Tongue is the most common site of involvement, other sites of involvement include floor of mouth, soft palate, anterior pillars and uvula. Secondary involvement of the draining lymphnodes may occur.

Sites - Oral, anal and genital regions. They are painful and healing is slow. Healing may not take place without effective AKT because of poor immunity of the patient.

6. **Tuberculides.** Group of diseases, probably a hypersensitive reaction to *M. tuberculosis*, characterized by evidence of manifest or past TB, absence of bacilli in skin biopsy specimen and culture, response to anti-TB treatment. The clinical entities are (i) Lichen scrofulosorum, (ii) Papulonecrotic tuberculide (papules with central necrosis which come out in crops and symmetrically distributed on face or extremities) (Fig. 10).
7. **Tuberculosis miliaris acutus** is a disease neither tuberculide nor a sarcoid. It is a disease of childhood, as a concomitant of exanthematous miliary TB and usually follows measles, whooping cough or scarlet fever. Due to breaking down of a tubercular lesion and the subsequent embolic spread, TB bacilli are disseminated widely through the blood stream. Lesions are generalized and papular, soon becoming ulcers. Tuberculin test may be negative since patient's resistance is low.
8. **Tuberculous gumma.** Haematogenous dissemination from a tuberculous focus can result in a gumma seen mainly in immunocompromised children. The lesion is initially a subcutaneous nodule which breaks through the skin to form an ulcer with undermined edges.
9. **Primary tuberculous infection of glans penis.**

Fig. 10: Tuberculids

Life Cycle

The fertilized female excavates a sloping tunnel (burrow) in the stratum corneum, depositing eggs and then dying in the burrow. The larvae emerge from the eggs after 3-7 days, wander to the skin surface and form shallow pockets in the horn of the original or a new host, and reach maturity 14-17 days after the eggs were laid. Copulation occurs in the pocket and the female excavates her burrow, while the male soon dies. In children, palmar involvement is common. In spite of widespread manifestations, total number of mites is 10-15 ovigerous females.

Clinical Features

Pruritus - The sole complaint is severe itching worse at night. Itching starts two to four weeks after the contagion, this time lag being required for the development of lesions other than the burrow.

Burrow - It is the diagnostic sign of scabies. It is a slightly elevated greyish tortuous or dotted line in the skin ridge. It represents a tunnel made by the female mite in the horny layer of the skin in which to lay her eggs. Burrows are best seen in the soft parts of the skin, such as the hands, feet, penis and scrotum.

Scratching destroys the roofs of the barrows and mites, keeping the population under control.

Rash - During the initial phase of infection, the host is asymptomatic but after 4-6 weeks a hypersensitivity response to mite antigen occurs and an itchy rash develops. The rash comprises tiny inflammatory papules which occur predominantly in the interdigital folds (Fig. 11) of hand, around the axillae, in the periareolar regions, on the

7. INFECTIONS

ECTOPARASITE INFECTIONS

SCABIES

A contagious disease caused by a mite, *Sarcoptes scabiei*, is spread through contact with infected individuals, or rarely through contact with infected clothes, bed linen or towels.

Fig. 11: Scabies with autosensitization

abdomen (particularly the periumbilical region) and on the buttocks and medial aspects of thighs, legs and feet. In males inflammatory papules on penis and scrotum, which are pathognomonic of scabies.

Complications

1. **Eczematization.** It is common in infants and young children. Involved areas of the extremities and trunk show erythema, oedema, vesiculation, oozing and crusting. The face is commonly involved in infants.
2. **Secondary infection.** Secondary bacterial infection (Strepto or staphylococcal) may occur in case of untreated scabies. The existing lesions turn into pustules and even bullae which when they burst are covered with yellowish crusts. Scratching results in excoriations.
3. **Id eruption.**
4. **Urticaria.**
5. **Contact dermatitis to antiscabietic drugs.**

Variants of Scabies

1. **Scabies in the clean** – These have fewer lesions, some of which are at atypical sites, but cause severe itching.
2. **Scabies incognito** – occurs in persons treated with steroids.
3. **Nodular scabies** – Urticated papules and occasional vesicles are thought to be a hypersensitivity reaction. Red pruritic nodules are often found on the genitals. Scabietic nodules often do not contain mites.
4. **Genital scabies** – In males there are inflammatory papules on the penis and scrotum which are pathognomonic of scabies.

5. **Norwegian (crusted) scabies** is an uncommon subtype in which a deficient immune response allows large numbers of mites to multiply. The crusts and psoriasis-form scales, loaded with scabies mite affect the hands, scalp, face and trunk. Itching may be minimal. Susceptible individuals are only marginally immunosuppressed and may simply be elderly, or pregnant.
6. **Scabies in AIDS** is more severe and extensive with involvement of face and scalp.
7. **Paraphimosis** may be a complication in children.
8. **Immunological sequelae** from associated streptococcal infection may manifest as glomerulonephritis or rheumatic fever.
9. **Animal transmitted scabies** can be acquired from animals, e.g. dogs. Clinical pattern is quite different from that produced by human bite. Lesions are most common on forearms, lower chest, abdomen and thighs, areas most exposed to the mite, by the person carrying the affected pet. Burrows are conspicuous by their absence. The infestation has a short incubation period.

Diagnosis. History of similar illness in other members of the family. Characteristic distribution pattern of lesions. Itching worse at night. Diagnosis is made by deroofing a burrow with an oil-coated needle and examining scrapings for mites and their ova microscopically.

Differential Diagnosis – Similar signs are found with papular rashes from fleas, including papular urticaria; also atopic skin lesions in young children with maximal lesions on extremities; generalised pruritus, delusions of parasitosis.

Management

1. All the family members should be treated at the same time.
2. The clothes, bed linen and towels should be disinfected.
3. Secondary infection should be treated first.
4. **Specific therapy** – The patient must bathe and scrub the body with a brush to lay open the burrows. After the bath, the skin is dried and the scabicide applied from neck to toes (Table 11).

Treatment of crusted scabies is as for ordinary scabies, but several applications of scabicide are necessary. Oral Ivermectin may be useful in resistant cases.

Treatment of Complications

Bacterial infections – Antibiotics like erythromycin or roxithromycin. Topical antibiotic, e.g. mupirocin or framycetin.

Table 11: Specific therapies for scabies

Drug	Regimen	Adverse effects
Permethrin 5% dermal cream	Treatment of choice Single application washed off after 12 hrs	Nil significant
BenzyI benzoate 20% emulsion	2 or 3 applications within 24 hrs, on successive days or at intervals of 1 week	Irritant
Gamma benzene hexachloride 1% lotion and cream	Applied for 8–12 hrs and then washed off	Not to be used in pregnant women. Neurotoxicity in infants or young children or those with seizure disorders if overuse
Malathion 0.5% in aqueous base	2 applications separated by interval of 7 days	Nil significant
Crotamiton 10% cream and lotion	Twice daily for 5 days	Nil
Precipitated sulphur 5% gel or cream	3 night washed off after last application	Advantage of antipruritic action
Ivermectin 20 µg/kg	Single oral dose	Not to be used in underweight children, pregnancy

Eczematization – Condy’s solution compresses in oozing stage followed by topical steroids. Later treatment of scabies.

Nodular scabies – Topical or intralesional steroids.

PEDICULOSIS (LICE)

All lice feed on blood, using piercing mouthparts. The lice that parasitize humans are:

Head lice (pediculosis capitis). Head louse infection is acquired by head-to-head contact with an affected individual. Spread of infection is predisposed to by poor hygiene and overcrowding. Also boarding schools.

Clinical manifestations – Head itching is the principal manifestation. Secondary bacterial infection may occur due to scratching, and concomitant head louse infection must always be considered in cases of scalp impetigo. Hair with empty egg cases are in the postauricular and occipital regions. Posterior cervical lymphadenopathy is a common presentation.

Adult lice and nymphs may be detected by combing wetted hair with a fine-toothed comb.

Treatment

Insecticides (See table). Lotion preparations are preferred because these expose the lice and eggs to a higher concentration of insecticide for a longer period of time than shampoos. They should remain on the scalp for 12 hours. Treatment should be repeated after 7–10 days.

Vinegar or formic acid is used to remove the glue to hold the mite firmly to the hair shaft. Other family members should be treated if there is evidence of infection.

Manual removal of eggs is an alternative to chemical means. Regular combing of wetted hair with a fine toothed

comb is time-consuming but can effectively eliminate louse infection.

Pediculosis corporis (Clothing lice). These parasites are correctly designated because they live and lay their eggs on seams of clothing and visit the body only to feed.

Itching is the main complaint and the body is covered in excoriations, and the skin is often hyperpigmented in those who harbour lice for a long period (vagabond’s disease). Since lice cause irritation, there may be small red papules with a tiny central clot. Lice and eggs should be looked for in the clothing.

Treatment – The clothing and not the patient requires treatment. High temperature laundering is effective means of killing both lice and eggs.

Pediculosis pubis (Crab lice). The louse adapted to living in hair of a particular density, apart from the pubic area, it may be found on the scalp margins, eyelashes and beard, axillary hair, hair on the trunk and limbs and the perianal regions. It is transmitted by close physical, usually sexual contact.

Itching, mainly in the evening and nights is the principal symptom. Close inspection of hairy areas reveals lice grasping hair close to the skin surface, eggs attached to hair shafts and rust-coloured louse faeces on the skin and hair.

Treatment – Malathion and carbaryl are effective. Treatment of choice is an aqueous preparation, alcohol based preparations irritate delicate areas such as the scrotum. All hairy areas should be treated, and treatment repeated after 7–10 days.

Eye lashes should be treated with white soft paraffin applied three times daily for 2–3 weeks.

Treatment of pediculosis

See Table 12 for the treatment of pediculosis.

8. CUTANEOUS FUNGAL INFECTIONS

Fungal infections are caused by non-photosynthetic vegetable parasites called fungi. Depending on whether the species resides in soil, animals or human beings, it is said to be geophilic, zoophilic or anthrophilic. Infection with zoophilic are often suppurative. Common cutaneous mycoses and sites of infection are given in Table 13.

SUPERFICIAL MYCOSES DERMATOPHYTOSIS (RINGWORM)

There are three genera of dermatophytes: *Trichophyton*, *Microsporum* and *Epidermophyton*. They are grouped according to their natural habitat as geophilic (soil), zoophilic (animals), and anthrophilic (humans).

Transmission may be indirect (via desquamated epithelium) or direct through bodily contact.

Predisposing factors - Warm, humid climate, poor nutrition and hygiene, obesity, diabetes mellitus and debilitating illness.

Common symptom is pruritus in all types of dermatophytosis. In AIDS patients, dermatophytosis leads to widespread or atypical infections and rapidly spreading white onychomycosis involving the whole nail plate.

Tinea Capitis

- Non-inflammatory type* - (a) Partial or complete round or oval shape areas. (b) Black dot patch - Scaly areas of alopecia with black dots due to broken off hair from endothrix infection. (c) Grey patch, dull grey hairs with scaly alopecia patch. (d) Seborrhoeic dermatitis type with dry scaling.
- Inflammatory type* - (a) Kerion due to zoophilic fungi. Boggy painful inflammatory swelling with exuda-

tive folliculopapules, with fallen off or easily pluckable hair. (b) Favus - Circular yellow crusts (scutula) around hair follicles. Patients have a "mousy" odour.

Tinea Barbae

Is usually found in adult males. It is acquired from a barber's instruments, or from animals. They commonly are observed on the chin, neck and maxillary areas. Hair in the affected areas can be easily pulled out. Resolution leaves behind scarring and alopecia.

- Superficial or sycosiform type* - Diffuse erythema with perifollicular papules and pustules. Anthrophilic organisms (*T. rubrum* and *T. violaceum*) invading the endothrix are the cause.
- Circinate or spreading type* - with a vesiculopustular spreading border, spreading peripherally and clearing in the centre.
- Non-inflammatory type* - starts as a small erythematous papule surrounding a hairy shaft, later on these patches of partial alopecia, circular or oval in shape, showing numerous broken off hair, dull grey or lustreless.
- Inflammatory type* - Lesions are nodular and boggy, often associated with seropurulent discharge.

Tr. - Systemic antifungal, e.g. griseofulvin 500-1000 mg/d. Topical antifungals, wet compresses and debridement of crusted lesions.

Tinea Faciei

Annular, shiny lesion due to lack of scaling.

Table 13: Common cutaneous mycoses and sites of infection

Table 13: Common cutaneous mycoses and sites of infection	
Superficial	
• Dermatophytosis - Tinea corporis, tinea pedis, tinea capitis	
• Superficial candidosis - Cutaneous, oropharyngeal, vaginal	
• <i>Malassezia</i> infections - Pityriasis versicolor, seborrhoeic dermatitis, <i>Malassezia</i> folliculitis	
• Others (e.g. black piedra, white piedra, <i>Scytalidium</i> infections)	
Subcutaneous	
• Mycetoma	
• Chromoblastomycosis	
• Sporotrichosis	
Site of involvement	
• Scalp: Tinea capitis	
• Beard area: Tinea barbae	
• Face: Tinea faciei	
• Groin and buttocks: Tinea cruris	
• Body: Tinea corporis	
• Hands: Tinea manuum	
• Feet: Tinea pedis	
• Nails: Tinea unguium	

Table 12: Treatment of pediculosis

Type	Therapy	Comments
Capitis Corporis Pubis	GBH 1% lotion or Permethrin 1% lotion or 5% cream Malathion 0.5% High temp. laundering or wash clothes in boiling water and press with hot iron Application of permethrin or GBH to all affected hairy areas	To be applied overnight Antibacterials if secondary infection Clothing can be treated with GBH Treat all sexual contacts of infected individuals if possible

Tinea Corporis

Ringworm of the glabrous skin can occur anywhere on the body. It is caused most often by *Trichophyton* species.

Description – The lesion starts as a papule which spreads ring-like peripherally with central clearing. The lesions are usually circinate (Fig. 12) with an active border consisting of vesicles and scaling.

Distribution – Waistline, axillae, buttocks, other parts of the trunk and extremities but not palms, soles and groins.

D.D. – (a) Tuberculoid leprosy where minimal infiltration in the periphery mimics the active border of *Tinea circinata*. (b) Intertrigo with scabies with lesions in flexural and moist sites which are also sites of predilection for *T. circinata*. (c) Impetigo circinata particularly in children. (d) *Tinea versicolor*. (e) Psoriasis. (f) Secondary syphilis.

Complications – (a) Eczematization: Due to scratching, skin can get inflamed with redness, oozing and crusting. (b) Secondary pyogenic infection. (c) Id reaction – An allergic eruption to the antigenic reaction, particularly on palms and soles. (d) Dissemination in immunocompromised individuals.

Tinea cruris – Ringworm of the groins and upper and inner parts of the thighs. Obesity, moisture, warmth and friction are the important factors for its existence. It spreads to the buttocks, and lower abdomen.

Tinea Pedis

It is very pruritic, may be vesicobullous in nature, and occurs on the instep and plantar surface of the foot. The fungus is acquired from the flooring, shoes and socks or communal baths. *Between the toes*, it causes maceration especially of the space between the fourth and fifth

Fig. 12: Tinea corporis

toes, and may result in fissuring and secondary infection. Sometimes the only evidence is a chronic, hyperkeratotic scaling eruption with minimal infiltration.

Four types with overlap:

- Chronic intertriginous type
- Chronic papulosquamous pattern – Inflammatory and patchy or diffuse moccasin-like scaling over soles
- Vesicular type near instep and mid-anterior plantar surface
- Acute ulcerative variant with maceration

Tinea manuum affecting the hands, is usually caused by *T. rubrum*. Inflammation is often minimal. The palm becomes dry with mild scaling which is most obvious in the palmar creases.

Tinea Unguium

Is a dermatophyte infection of the nail plate with brittleness, friability and thickening of the nail. The infection usually starts at the free margin and lateral border of the nails and progresses towards the nail fold. There may be a tinea infection on other parts of the body.

Tinea Incognita

Topical and/or systemic steroids may mask inflammatory features of tinea.

INFECTIONS

1. *Onychomycosis* includes all infections of the nail caused by any fungus including non-dermatophytes and yeasts (Fig. 13).

Fig. 13: Onychomycosis

Fig. 14: Acute paronychia

Fig. 15: Chronic paronychia

Cl. Fs. - Nail plate is yellow and thick with subungual hyperkeratosis, which is friable: Toe nails are more frequently involved.

2. *Paronychia* - is inflammation of nail folds.
 - a. Acute paronychia - Swollen, tender red nail fold with visible pus under it (Fig. 14).
 - b. Chronic paronychia - Inflammatory dermatosis of nail folds with secondary effects on nail matrix and nail growth (Fig. 15). Predisposing factors - Network as in domestic workers, house wives, DM, candidal vulvo vaginitis.

Cl. Fs. Swollen nail head. Adjacent nail plate becomes ridged and discoloured.

Laboratory Diagnosis

Dermatophytes are seen as hyphae and spores in skin scales (obtained by scraping with a scalpel) or in nail or hair samples, and mounted in 10% KOH for 20 minutes. These can also be cultured on Sabouraud's medium, or on Dermatophyte Test Medium (DTM).

Management

Prophylaxis

1. Patients who sweat a lot should change their clothes frequently, wear cotton socks and avoid synthetic material.
2. Clothes, especially the underwear, and towels should be boiled in hot water.
3. Footwear should be of the open type permitting sufficient aeration.
4. Intertriginous areas should be kept dry with powders, e.g. talcum or antifungal powder.

5. Shampoo the hair immediately after visit to the barber's shop.

Specific treatment

1. *Topical antifungal agents* -
 - Clotrimazole - Cream 1%
 - Miconazole - Cream 2%
 - Econazole - Cream 1%
 - Ketoconazole - Cream 2%
 - Oxiconazole - Cream, lotion 1%
 - Sulconazole - Cream, solution 1%
 - Terbinafine - Cream 1%
 - Butenafine - Cream 1%
 - Luficonazole - Cream 1%
2. *Wet compresses* - Blisters, and pustules should be broken down and treated with wet compresses of 1:4000 solution of potassium permanganate, or Burrow's solution (Aluminium acetate) diluted 1 in 15.
3. *Keratolytic agents* - are best used on palms and soles, lesions which require softening and exfoliation. Half strength Whitfield ointment is applied b.d.
4. *Surgical avulsion* - of infected nails together with systemic griseofulvin therapy for infection of the nails.

Systemic Therapy

See Table 14 for the systemic therapy of fungal infections.

In *Tinea imbricata*, concentric polycystic rings become confluent to form a bizarre pattern covering most body surfaces. *T. rubrum* can produce large, scaly, minimally inflammatory plaques with little marginal accentuation.

Table 14: Systemic therapy of fungal infections				
Drug	Dose	Duration	Comments	Adverse effects
Griseofulvin	Adult 500 mg o.d. Child 10 mg/kg with food	Corporis 4 wks Capitis 2 mths Pedis 3 mths Finger nails 5-6 mths Toe nails 18 mths	Not effective in versicolor or candidiasis	Not common—Headache GI irritation, skin rash, photosensitivity
Terbinafine	250 mg o.d.	Finger nail 3 mths Toe nail 6 mths	Not effective in candidiasis, contraindicated with ketoconazole	GI symptoms, rash, taste disturbances
Ketoconazole	200–400 mg o.d.	Corp. 3–6 wks Cap./man/pedis 6–8 wks Fin. nail 6 mths Toe nail 1 yr	LFT monitoring, Contra. with terfenadine because of CVS effects	Hepatotoxicity Anaphylaxis Interference with steroid synthesis and with oral anticoagulants
Itraconazole	100–200 mg/d	Pity. 5 days Corp. 5 days Fin. nails 3 mths Toe nails 4 mths Cap/man/pedis	Safer than Ketoconazole Level of drug is higher in epidermis than plasma, therapeutic conc. up to 4 wks after stopping. Hence intermittent therapy 200 mg x 7 days once a month	Nausea, vomiting, elevated liver enzymes
Fluconazole	150 mg once a week. 400 mg stat at night for tinea versicolor	3–7 days	With food to avoid gastritis. Effective in candidiasis	Nausea, vomiting, diarrhoea, abdominal pain Skin rash

Fig. 16: Pityriasis versicolor vitiligo

MALASSEZIA INFECTIONS

Malassezia are common surface commensals of greasy skin sites, such as scalp and face. They are associated with pityriasis versicolor, seborrhoeic dermatitis and a form of folliculitis.

PITYRIASIS (TINEA) VERSICOLOR

It is the most superficial fungus infection produced by Malassezia furfur, characterized by scaly white or brown patches, asymptomatic in nature (Fig. 16).

Description – Asymptomatic macules and patches of various sizes and shapes, yellow, white or brown in colour.

Distribution. Occur at any site in the body commonly on the trunk. The lesions are scaly and easily detected when the part is abraded with a pin. It is usually seen in people who sweat excessively. The patches resemble vitiligo, but presence of scaling is typical and the lesions are never totally lacking in pigment.

Scales can be made more obvious by striking the lesions with a blade or knife (*Scratch sign*). At times the lesions may assume different colours such as reddish brown, dark brown or even black (hence the term versicolor).

Diagnosis – (a) The patches fluoresce golden yellow, under Wood's light. (b) Scraping the lesions and mounting them in 10% KOH solution reveals clusters of spores and short broad hyphae, resembling 'spaghetti and meat balls'.

Management

Any of the following may be used locally:

A. Topical therapy –

1. Sodium thiosulphate – in a 20 per cent solution applied, allowed to dry and left in place before rinsing, for 5–7 days.
2. Ketoconazole 2% shampoo applied to the skin, allowed to dry and left on overnight as a single dose or daily for 3 days.
3. Selenium sulphide – 2.5% as shampoo applied to the skin for 5–10 minutes once daily for 3–4 weeks before bath.
4. Antifungal creams or solutions including imidazoles, tolnaftate.
5. Zinc pyrithione shampoo applied for 5 minutes daily for –2 weeks.

6. Keratolytic creams or lotions.
7. Retinoic acid cream.

B. **Systemic therapy** – Oral antifungals, e.g. ketoconazole 200 mg o.d. × 14 days or Fluconazole 200 mg o.d. × 10 days if persistent or recurrent.

Seborrhoeic dermatitis – is a chronic inflammatory dermatosis affecting areas rich in sebaceous glands, such as the face, nasolabial folds, the front of the chest and the scalp (dandruff). Severe seborrhoeic dermatitis is particularly common in patients with AIDS or chronic neurological conditions such as Parkinson's disease.

Distribution – Seborrhoeic regions of young adults who have active sebaceous glands – Commonly on the trunk, also axillae, groins, proximal extremities and occasionally face and inframammary folds in females.

Clinical Features

Infants: Seborrhoeic dermatitis usually begins within first few days or weeks after birth, as greasy scaling in the scalp (cradle cap). Small, round or oval, erythematous, scaly lesions are seen on the face and napkin area. Apart from the face, retroauricular areas and temples are also affected. Most cases clear within a few weeks.

Adults – Lesions may be seen on the hairy skin of the scalp, face (especially eyebrows and nasolabial folds), on and behind the ears, presternal and interscapular regions, flexures (inflammatory folds, axillae, groins, anogenital folds) and periumbilical.

Scalp – Dandruff is an exaggerated loss of keratinized cells from the surface of the scalp and itchy dandruff is considered a manifestation of seborrhoeic dermatitis. Later perifollicular erythema and scaling form well-defined patches which coalesce and cover the scalp to extend beyond the forehead hairline as the 'corona seborrhoea'. Behind the ears there is erythematous greasy scaling, and a crusted fissure may develop in the retroauricular fold.

Face – Erythema and scaling involve nasolabial folds. Blepharitis occurs in the form of a red eyelid margin covered by small scales. Eventually small ulcers covered with crusts form, leading to destruction of eyelid hair. In men the beard area is affected with lesions similar to those in the scalp, but more follicular with more pustulation.

Trunk – Interscapular and presternal areas show small brown follicular papules covered by a greasy scales, extension and coalescence of which give rise to circinate patterns (petaloid form).

Flexures – Diffuse, well-margined erythema with greasy scaling and a fissure covered with crusts. Secondary bacterial and candidial infection is common.

Seborrhoeic dermatitis can be associated with AIDS. Lesions may appear before other manifestations of AIDS.

Management

1. Agents for eliminating seborrhoeic dermatitis and dandruff. (a) Ketoconazole 2% shampoo or cream twice weekly for 2–4 weeks. (b) Shampoo containing 0.1% triamcinolone daily for 2 weeks. (c) Selenium sulphide shampoo 2.5% two or three times weekly. (d) Preparation containing 1–2% Zinc pyrithione. (e) Bifonazole 1% shampoo for scalp in infants and children. (f) Chloroxine shampoo. (g) Any non-medicinal shampoo containing surfactants and detergents will remove scales. They can be used every 2 days to control dandruff.
2. For extensive or inflammatory lesions – Application of corticosteroid (Betamethasone) lotion, or sodium sulfacetamide 10% lotion bd. Topical steroid mousse formulations (betamethasone valerate and clobetasol) are useful adjuncts for scalp seborrhoeic dermatitis because the foam melts at skin temperature leaving minimal residue.

For thick scalps – Overnight applications of a keratolytic agents, e.g. salicylic acid with or without plastic cap occlusion.

Malassezia folliculitis is an itchy follicular eruption on the back and shoulders which may resemble acne.

Oral therapy – Fluconazole 400 mg, Ketoconazole 200 mg od for 7–10 days, but the drug should be reserved for cases not responding to topical therapy because of the risk of hepatotoxicity.

CANDIDOSIS

Superficial Candidiasis

Superficial candida infections are usually caused by candida albicans. This organism is a common commensal in the mouth, vagina and GI tract in healthy individuals. Secondary bacterial infection may occur.

Predisposing factors – Excessive sweating, maceration, obesity, diabetes, leukaemia, systemic antibiotics, immuno-suppression due to drugs, HIV, systemic steroids, pregnancy, oral contraceptives, and prolonged topical steroids, etc.

Occupational, e.g. housemaids (affection of finger web and toe webs).

Description – Moist erythematous patches at opposing surfaces of body folds.

There is scaling at the periphery of relatively drier patches. The patch may be surrounded with satellite lesions. In advanced cases, the surface of these patches may be eroded or even ulcerated with discharge of serous or seropurulent fluid.

Distribution - Groin, beneath pendulous breasts, axillae and abdominal folds, neck folds and natal cleft in obese.

Tr. - Application of clotrimazole or miconazole as cream or lotion. Topical antibacterial if secondary infection. Drying of affected parts after washing and powdering the parts with clotrimazole or miconazole powder.

Cutaneous Candidiasis

1. **Onychia and paronychia** - Inflammation of the posterior nail fold, edges of the nails are eroded and the nail discoloured. Seen mostly in housewives, domestic and dish washers.
2. **Intertriginous candidiasis** - as described above
3. **Candida in nonintertriginous areas** - appear usually as satellite lesions of mucosal or intertriginous infection as erythematous, slightly raised 1-2 mm papules with superficial collarette of scales.
4. **Erosio interdigitalis** - Maceration and erosion in the webs of the fingers, and toes.

Mucosal Candidiasis

1. **Oral thrush** - (Acute pseudomembranous candidiasis) is characterized by a sharply defined patch of creamy white pseudo-membrane which when removed leaves an underlying erythematous base. One or more patches may occur. Tissues involved are the tongue, gums and palate. Rarely erosions and ulcerations may occur in the pharynx and oesophagus. Diseases such as diabetes, malignancy and immunodeficiency states, antibiotic therapy and dentures may predispose, and it may be occasionally the primary presentation in AIDS.

Tr. - Clotrimazole % as mouth paint. Fluconazole 50-100 mg/day for one week or 150 mg/day for 3 weeks in immunocompromised or debilitated patients.

2. **Perleche** - is fissuring and maceration at the angles of the mouth.
3. **Vulvo-vaginitis** - often associated with itchy and creamy white vaginal discharge.
4. **Balanoposthitis** - (balanitis). Two forms are associated with *Candida spp.* Both types may be acquired sexually.

A true superficial but invasive infection occurs particularly in diabetic and uncircumcised males. It

is characterized by intense pruritus, discomfort, erythema and swelling that is localized primarily to the glands, but may extend to involve the penile shaft and scrotum. Treatment comprises topical antimycotics and systemic azoles.

5. **Chronic mucocutaneous candidiasis** is characterized by recurrent and persistent infection of skin, nails and mucus membrane without disseminated candidiasis.

Management

The predisposing cause must be investigated and treated. Wet work must be avoided in paronychia. Intertriginous areas must be kept dry. Obese patients must reduce weight.

Imidazole derivatives - clotrimazole, miconazole or econazole topically for 2 to 3 months on nails, 1 month on skin.

Ketoconazole tablets: 200 mg daily for initial 10 days in severe cases.

Vulvo-vaginitis may require clotrimazole vaginal tablets in addition for 8 to 15 days.

Antifungal powder clotrimazole or miconazole in affected axillae, intertriginous areas, i.e. below breasts, abdominal fold, groins, between toes.

DEEP FUNGAL INFECTIONS

Mycetoma

(Madura foot) is a chronic subcutaneous infection caused by either actinomycetes or filamentous bacteria (actinomycetomas), or fungi (eumycetomas), with a tendency to form large colonies in tissues. These are discharged as granular matter (grains) through sinuses (Fig. 17).

Fig. 17: Foot mycetoma

Description – The lesions start insidiously, with a hard subcutaneous swelling which enlarges and discharges pus through small sinuses which discharge dark (eumycetoma) or pale coloured (actinomycetomas) granules. Characteristically, small fungal or actinomycete aggregates (grains) are present. Lytic bone lesions and periosteal proliferation may develop.

Sites – The foot is most frequently affected being exposed to injury. Rarely hand, shoulder or buttocks.

Diagnosis – Biopsy or removal of grains from sinuses; these can be examined by direct microscopy, histopathology and culture.

Treatment – Dapsone 20 mg daily for 6–24 months. Cotrimoxazole 2 tabs (480 mg) b.d. for 6–24 months. Inj. Streptomycin 1 gm im daily × 2 months. Inj. Amikacin 500 mg im daily for 3 weeks followed by 2 weeks of rest. To be repeated if required. Saturated solution of pot. iodide 5–30 drops t.d.s. can also be given. (a) Actinomycetoma – 9 months course of (i) Streptomycin + cotrimoxazole or dapsone (ii) Co-trimoxazole + streptomycin or (iii) Tetracycline + Strepto + Rifampicin (b) Eumycetoma – Ketoconazole or Itraconazole or Amphotericin B (in resistant cases).

Surgery – Deep debridement. Amputation as a last resort.

Sporotrichosis – Caused by *Sporothrix schenckii*. **Types** – (a) Lymphatic presents as a nodule which ulcerates. Later a chain of nodules are seen along lymph vessels draining the area. (b) Fixed – Single infiltrated plaque. **Tr.** – Itraconazole or saturated solution of potassium iodide.

Chromoblastomycosis – Painless warty papule enlarges gradually to form a cauliflower-like hypertrophic plaque, studded with black dots.

Subcutaneous phycomycesis – Slowly spreading subcutaneous swelling with smooth edge, but no ulceration. Common site are limbs, face. **Tr.** – Pot. iodide.

PYODERMA

Skin infections produced by pus forming organisms, mostly Gram positive group A beta haemolytic streptococci, and *Staph. aureus*. A variety of clinical pictures are produced depending on site of infection.

Clinical Manifestations

1. **Impetigo** – Impetigo is an acute superficial infection of the skin caused by *Staph. aureus*, or less commonly

Fig. 18: Impetigo

group A-hemolytic streptococci. It presents as golden yellow crusts, formed from exuding serum (Fig. 18), usually affecting the face. The lesions spread locally and may coalesce; multiple lesions are common. Blisters can be a feature and, as they rupture, typical crusts form at the edge of the lesions. Systemic upset is not usual.

- a. **Impetigo contagiosa** – The most superficial of all the pyodermas, it can occur as such, or secondary to scabies, pediculosis, insect bites, herpes, and eczemas. Common in children, it begins as an erythematous spot, rapidly forms a vesicle with clear fluid, which becomes purulent and dries forming a thick yellow crust. Removal of this crust, exposes underlying eroded surface with a little oozing, this fluid is contagious to the surrounding areas or infects the hair follicles giving rise to a folliculitis.
 - b. **Impetigo bullosa** – Bullous lesions may be of limited extent but in very small infants, infections may spread widely causing fatal outcome without vigorous antibiotic therapy (Table 15).
 - c. **Impetigo circinata** – Sometimes lesions of impetigo contagiosa appear grouped. With central clearing of older lesions and superficial crusting of peripheral lesions a circinate pattern appears. The lesions tend to be more localised.
2. **Ecthyma** – A deeper infection, usually seen in debilitated individuals or with poor hygiene. The lesions start as vesicles which dry up to form thick crusts, removal of which displays an underlying lake of pus in a saucer-shaped ulcer. It is found mostly on the legs, and heals with scarring.

Table 15: Differences between *Impetigo contagiosa* and *Impetigo bullosa*

	<i>Impetigo contagiosa</i>	<i>Impetigo bullosa</i>
Organism	Staph. aureus/Str. pyrogens	Staph. aureus
Age	Young children	Infants
Site	Orofacial, scalp, extremities	Face
Skin lesions	Thin walled blisters which easily rupture with formation of honey-coloured crusts. Lesions spread peripherally and coalesce	Fluid filled bulla rupture after few days to form thin varnish-like crusts Central healing of lesions with plaque formation
Complications	Glomerulonephritis Eczematization	Staphylococcal scalded skin syndrome

3. **Folliculitis** – A pyoderma of the hair follicle. These, are two types –
 - a. *Superficial folliculitis (Bockhart's impetigo)* – Folliculitis of the superficial part of the hair follicles and perifollicular region giving rise to follicular pustules covered by crusts. Infection spreads from one follicle to another. This type of impetigo which appears on the legs becomes chronic till after some years atrophy of the skin results.
 - b. *Deep folliculitis* – Sycosis barbae is a folliculitis of the beard area of the face. There is no pain but itching and burning may be the only symptoms, there is no oozing or weeping at any stage.
4. **Furuncle (common boil)** – is a deep-seated infection of the hair follicle around the hair root. The causative organism is most often *Staphylococcus aureus*. It is frequently found around the hairy areas of the body, especially those subjected to friction and maceration. Furuncles are painful. It starts as a firm nodule but softens and ruptures after a few days discharging pus. A thorough search for an underlying cause is mandatory in all cases of chronic recurrent pyodermas. Diabetes mellitus, poor general health, malnourishment, blood dyscrasias, chronic nephritis, immune deficiency should be ruled out.
5. **Periportitis** – Sweat gland abscesses, non-tender, rounded, fluctuant, erythematous nodules. Can occur in the scalp especially in children.
6. **Carbuncle** – is a conglomeration of boils. It is a deeper and more extensively infiltrated lesion. *Predisposing factor* – Uncontrolled diabetes mellitus. *Description* – It starts as a tender, erythematous, indurated deep

**Fig. 19:** Carbuncle

plaque on the back, neck or thigh, associated with fever and malaise. Multiple pustules appear on the involved area which is now violaceous, and the mass breaks down at multiple points discharging pus. Often the whole area sloughs off leaving a deep ulcer.

Site – Typically the nape of the neck (Fig. 19). Less often trunk and extremities.

7. **Hidradenitis suppurativa** is a chronic suppurative inflammatory disease of apocrine glands and surrounding tissues caused by *Staph. aureus* and *anaerobic streptococci*. It is most commonly seen in the axilla in females/and in perianal regions in males. Indolence and chronicity are the hallmarks of the disease.
8. **Cellulitis** – is an infection of the dermis and subcutaneous tissue usually caused by a group A streptococcus and *Staph. aureus*. It typically occurs near surgical wounds or a cutaneous ulcer or, like erysipelas, may develop in apparently normal skin. Recurrent episodes of cellulitis may occur with local anatomic abnormalities that compromise the venous or lymphatic circulation. In cellulitis the borders are indistinct.
9. **Erysipelas** – is an acute, inflammatory form of cellulitis that differs from other types of cellulitis in that lymphatic involvement (streaking) is prominent. Erysipelas is also more clearly demarcated from normal skin than cellulitis (Fig. 20). The lower legs, face and ears are most frequently involved. Fever, chills and regional lymphadenopathy are associated features. Recurrent erysipelas leads to chronic lymphoedema with elephantiasis.
10. **Intertrigo** – is inflammation of apposed skin surfaces. Predisposing factors are heat, moisture, friction and

Fig. 20: Erysipelas

sweat retention; these cause maceration and inflammation in these areas. Chronic bacterial or candidal infection usually follows. Common organism is *Strep. pyogenes*. Initially the skin is red and somewhat macerated. The folds when separated reveal erythema of contiguous surfaces, covered by a macerated horny layer, usually with a deep fissure. In severe cases, there may be complete denudation of the surface. Itching, burning and exudation are usual. An offensive odour is due to coryneforms (*Brevibacteria*).

11. Acute paronychia

12. **Periportitis** (Multiple sweat gland abscesses) – Staphylo. infection which starts as multiple erythematous papules and nodules over face, forehead, scalp and upper trunk. These progress to form non-tender, thin-walled, fluctuant abscesses. There is no central follicular pointing as in the case of furunculosis.

Management

1. *Treatment of underlying cause* and attention to predisposing factors.
2. *Local hygiene*. Wash the parts with an antiseptic preferably Cetavlon lotion 0.5% or povidone iodide. Bandage, and change the dressing daily. Boil the clothes, bed linen and towels of the patient.
3. *Local treatment* – Wash the part well with soap and water, and remove the crusts. Apply an antiseptic lotion around the area consisting of 0.5 per cent cetrimide solution or povidone iodine. Furuncles if pointing should be incised, so also the blisters of impetigo. Apply Bacitracin, Fucidin, Neomycin, Mupirocin or povidone iodine skin cream or for chronic or recur-

ring infections, use the povidone iodine solution 1 or 2 hours before bath on affected areas as well as over 4" to 6" of normal skin around.

4. *Systemic antibiotics* – for extensive and deep infections, especially if the pyoderma is chronic or situated on the upper lip, nose or cheek: Ampicillin 500 mg 6 to 8 hourly or erythromycin 500 mg, cephalexin 500 mg 6 to 8 hourly or co-trimoxazole.

VIRAL SKIN INFECTIONS

See Table 16 for the viruses affecting skin or adjoining mucous surfaces.

Viral Warts (Verrucae)

Verrucae or warts are epidermal growths resulting from infection of the skin with a filtered DNA virus called the Human Papilloma Virus (HPV). They are autoinoculable and contagious. They can affect any part of the body. The type of wart is dependent on the anatomical site and age of the individual (Fig. 21).

Types

1. **Verruca plana or juvenile warts** – are seen in children usually on the back of the hands or on face. They are smooth, small, flat topped papules of skin colour.
2. **Verruca vulgaris** – These affect any part of the body especially the hands and feet, varying in size from pin-head to pea size. The surface is rough and hyperkeratotic. They are firm in consistency and not tender.

Fig. 21: Warts

Fig. 22: Filiform warts

Fig. 23: Genital warts

Fig. 24: Genital warts

3. **Filiform warts** – These are finger-like growths, slender and thin found on the face and neck (Fig. 22).
4. **Plantar and palmar warts** – These occur on the palms and soles of the feet. They are flat due to pressure, but are deep in the skin. They are painful and tender, occur on sites of pressure like the balls of feet and heels. Often a number of these warts conglomerate to form a mosaic wart. Clinically, it must be differentiated from a corn which also occurs on pressure points, tender at the centre, but has no papillomatous surface when scraped. The normal lines of the skin stop at the margins of a wart. When the surface is gently scraped, small bleeding points or black dots are seen.
5. **Genital warts (*Condylomata acuminata*)** –
Predisposition – Sexually active adults of either sex.

Description – Single or multiple (Figs. 23 and 24), white, pink, moist or slightly hyperpigmented hypertrophic warts which resembles a cauliflower. Early lesions may be flat.

Distribution – Anogenital region – Penile, vaginal or rectal mucosa may be involved.

Diagnosis – The verrucous, irregular surface of the lesion is highly suggestive. Biopsy may be necessary to exclude squamous cell carcinoma.

Occupational warts are common wart-like papillomatous and/or dome-shaped, deep warts with a smooth surface located on both dorsal and palmar sides of the hands. They occur in butchers and fish handlers.

Management: It is best to destroy the wart, by chemical, electrical or surgical means, the choice depending on the type and location of the wart -

- a. **Chemical cautery** - With trichloroacetic acid (50%), phenol (95%) or salicylic acid (30-40%) can be used in any of the warts. Genital warts can be more easily treated with local application of 25% suspension of podophyllum in tincture benzoin. First vaseline is applied on the skin surrounding the lesion to protect it from an overflow of the medicine. The podophyllum should be allowed to dry and after 2 hrs the whole area washed with soap and water. If the lesion is big, podophyllum may have to be repeated at weekly intervals. Sometimes the warts may disappear without any treatment.
- b. **Cryotherapy** - With liquid nitrogen or carbon dioxide snow destroys the warts by freezing, and will leave no scar.
- c. **Electrocauterization** - Under local anaesthesia.
- d. **Laser surgery** - CO₂ laser therapy clears chronic, recalcitrant lesions, pulsed dye laser for vascular component.
- e. **Keratolytic agents.** Salicylic acid (10-20%).
- f. **Formalin** (2-3%) soaks in water for 15 minutes for plantar warts.

Molluscum Contagiosum

It is caused by a pox virus which gets implanted on the skin by contact with other infected individuals. The disease is common in children.

Description - Asymptomatic, multiple, small, skin-coloured or pink, dome-shaped papules (1 mm to 1.5 cm in diameter, with a central dimple or umbilication) (Fig. 25).

Distribution - Neck, axillae and upper chest more common.

Diagnosis - Examination of the keratotic debris reveals eosinophilic molluscum bodies.

Treatment - (a) Curettage of individual lesions. (b) Trichloroacetic application. Application of KOH 10% or Tretinoin, cidofovir and imiquimod. (c) Cryosurgery. (i) Electrodesiccation.

Herpes Simplex

The DNA virus of herpes simplex causes a grouped vesicular eruption of the skin and mucous membranes. It manifests in two forms - (a) *Primary herpes simplex* occurs, when the patient has been exposed to the virus for the first time. (b) *Recurrent herpes simplex*. Following the infection, many patients become long-term carriers. There are

Fig. 25: Molluscum contagiosum

two strains of herpes simplex virus - (i) Type 1, i.e. (HSV-1) is primarily responsible for infection around the mouth, (ii) Type 2, i.e. (HSV-2) causes genital infection and is usually sexually transmitted.

Primary infections

A. Mucous membranes:

1. **Acute gingivostomatitis** - It is usually a primary infection, characterized by soreness of mouth, salivation, fever and malaise. There are vesicles in the mouth and submandibular gland enlargement.
2. **Keratoconjunctivitis** - Presents with painful conjunctivitis, usually unilateral. Dendritic ulceration of the cornea may occur and lead to chronic scarring.
3. **Genital herpes** - Usually acquired venereally with Type 2 strain in adults. In *females* there are grouped vesicles on the vulva, cervix or vagina. In *males* grouped vesicles on the glans or prepuce, or, less commonly, urethritis. Recurrent herpes on the penis is common in males (herpes progeneralis).

B. Skin:

1. **Disseminated herpes simplex** - Mostly seen in newborn infants. The brain, liver, lungs and other organs may be involved. It is often fatal.
2. **Eczema herpeticum** - In patients of atopic dermatitis, herpes simplex sometimes develops into a severe varicelliform eruption.
3. **Herpetic whitlow** - This is probably a true viral wound infection and manifests as an indolent inflammatory lesion, arising at the site of a minor

skin trauma, usually on a finger, in the form of deep, painful, grouped vesicles on the finger tip. *Facial lesions*, which may be multiple, can spread through rugby packs ('Serum pox') and among wrestlers. Axillary adenopathy and systemic symptoms occur. It occurs either in medical or paramedical personnel in whom HSV-1 is usually responsible.

4. *Anal infection* - especially in male homosexuals. Intense pain, tenesmus, blood-stained discharge and local vesicles are present.

Recurrent infections

1. *Herpes labialis* - Fever blisters and cold sores. A few hours before the onset, there is a feeling of burning, or pain; this is followed by a crop of vesicles which break down in 48 hours. These crops recur and the attack lasts for 3 to 7 days. It commonly occurs on the face at the mucocutaneous junction (Fig. 26). There may or may not be a scar left after the attack. It is precipitated by fever, strong sunlight, emotional stress, local trauma.
2. *Eye infections* - May recur as a superficial keratitis. More seriously uveitis.
3. *Genital infections* - Usually milder and shorter than the primary disease.

Recurrence of the latent virus, usually in the trigeminal ganglia, produces grouped vesicles on the face, usually on the lips (cold sores), attacks may be precipitated by sun exposure and concurrent illness.

Complications: (See Chapter on Infectious Diseases)

Fig. 26: Herpes labialis

Diagnosis - A swab taken from the base of the lesion is wiped across a glass slide for staining with immunofluorescent antibodies. The swab can also be placed in sterile saline for detection of viral DNA by PCR.

Management of skin lesions:

1. *Acyclovir (ACV)* - 5% cream applied every 4 hours. For severe infection ACV by mouth. Dose 200 mg 5 times a day (Children under 2, half the dose). IV acyclovir 5 mg/kg every 8 hours by slow infusion. If ACV is started early in an attack, i.e. during prodrome or on the first day, it significantly reduces duration and severity.
2. *Antibacterial therapy* - May be used in mucocutaneous herpes to reduce risk of secondary infection.

Herpes Zoster (Shingles)

A unilateral, inflammatory, vesicular eruption caused by a latent herpes varicella virus from within sensory ganglia which attacks the posterior root ganglion and produces the skin eruption secondarily along a dermatomal distribution.

Predisposing factors: Herpes zoster is more common in people with diminished cell mediated immunity. This includes elderly people, patients with lymphoma, those receiving chemotherapy or steroids, and individual with HIV. In contrast to herpes simplex, precise trigger for herpes zoster are not known.

Clinical Features

Incubation period - 7-21 days.

1. **Pre-eruptive stage** - Pain with hyperaesthesia along the course of the nerve, and fever.
2. **Eruptive stage** - May be the first manifestation of the disease in some cases.

Description - There are several oedematous patches along the course of a nerve with intervening clear areas, these are very tender and painful. A few hours later, they are surmounted with small vesicles in cluster (Fig. 27). The vesicles occur in crops. The contents may become purulent. The vesicles crust over, and in absence of secondary infection, clear within a week. Immunosuppression can result in atypical widespread lesions with the risk of systemic spread. Chronic ulcerative lesions may be seen in AIDS patients. The regional glands are painful and tender. An attack lasts for 2-3 weeks. The rash is usually unilateral. The rash leaves behind pigmentation and scarring.

Sites - The thoracic and lumbar dermatomes are most commonly affected. An eruption in the mandibular or maxillary distribution of trigeminal nerve is associated

Fig. 27: Herpes zoster

with oral, palatal and pharyngeal lesions. If the ophthalmic division is affected, there may be keratitis or uveitis, with vesicles in the nose. In Ramsay-Hunt syndrome, the geniculate ganglion is affected. Pain in the ear and throat is followed by vesicles in and around the external auditory meatus associated with lower motor neuron facial paralysis.

Complications

1. *Post-herpetic neuralgia* - Risk factors - (a) Age > 50 years. (b) female sex. (c) Presence of a prodrome. (d) Severe or disseminated rash. (e) Severe pain at presentation. (f) Ophthalmic zoster. (g) PCR detectable varicella zoster viraemia.
2. *Keratitis and corneal ulceration* - when the trigeminal nerve is involved.
3. *Neurological* - including encephalitis, meningitis and myelitis.

Management

1. *Calamine lotion* applied several times a day.
2. *Analgesics*.
3. *Acyclovir* - 800 mg. 5 times a day p.o. will abort the attack if started within 48 hours.
4. *Antibiotics* - Systemically if there are signs of infection. Local application of an antibiotic ointment once the vesicles break down.
5. *Steroids* - given early reduce pain and incidence of complications including post-herpetic neuralgia in patients over 50 years of age. Prednisolone 40 mg daily for 6 days, reducing to zero over further 2 to 3 weeks.

Table 17: Aetiological factors for acne

- | |

| • Follicular keratinization |
| • Heredity |
| • Propionibacterium acnes |
| • Immunological factors |
| • Environmental factors |

6. *For post-herpetic neuralgia* - (a) Analgesics. (b) Amitriptyline. (c) Gabapentin. (d) Pregabalin. (e) Tramadol. (f) Carbamazepine.

Milker's nodule and Orf (Farmyard pox). Milker's nodule is a disease of Milker's or veterinarians caused by paravaccinia virus transmitted from udders of infected cows. The lesion is a single, erythematous nodule on a finger or not more than 4 on hands and forearm. They usually heal spontaneously.

9. ACNE AND OTHER FACIAL ERUPTIONS

Acne vulgaris is a disease in which the pilosebaceous follicle becomes oversensitive to normal levels of testosterone. Table 17 gives aetiological factors for acne.

Exacerbating factors - Acne worsens with stress and in premenstrual period. In patients with aggressive or recalcitrant acne, underlying cause may be a virilising syndrome in women, acromegaly, occupational exposure to acnegenic agents. Drugs that worsen acne are steroids, hormones (androgen and progesterone), anti-epileptic drugs, iodides; can follow facial massage.

Genetic and hormonal factors also play a role.

GRADING OF SEVERITY

- Mild disease: Open (black heads) and closed (white heads) comedones with sparse inflammatory lesions (Fig. 28). Some comedones are deep seated (submarine comedones).

Moderate: Numerous papules and pustules

Severe: Polymorphic eruption with comedones, papules, pustules, nodules and cysts.

MANAGEMENT

1. Topical therapies are the mainstay of treatment for mild acne.
 - **Benzoyl peroxide** 5% has antibacterial and keratolytic properties. It treats both inflamed and non-

Fig. 28: Acne vulgaris with acne scars

inflamed lesions effectively, but can cause irritation and bleaching. Bacterial resistance is reduced when used in combination with antibiotics.

- **Topical antibiotics** are useful in reducing inflammatory lesions. Patients with greasy skin may tolerate clindamycin 1% and erythromycin 2% because of the alcoholic base. Clindamycin lotion is less irritating to dry, scaly skin.
 - **Topical retinoids** are particularly useful in non-inflamed lesions. Tretinoin - normalizes follicular keratinization of the barrier layer and potentiates the penetration of other topical agents. Tretinoin cream or gel (0.25-1%), adapalene (0.1%) cream or gel or solution applied at night to entire face (cream for dry skin and gel for oily skin) and leave it for 20-30 minutes and then washed off with a mild soap. Isotretinoin (0.5-1 mg/kg/day) for severe nodulocystic acne resistant to therapy for 6 months (Total dose 100-120 mg). The drug is teratogenic and fertile women must use contraception while taking the drug and 4 weeks post treatment.
 - Sulphur and resorcinol, e.g. sulphur calamine lotion.
 - Salicylic acid can be used as an adjunctive therapy and is found in cleaners, toners
 - Azelaic acid (20%) cream possesses antimicrobial, anti-inflammatory and comedolytic properties.
2. **Systemic therapy** antibiotics reduce inflammatory mediators and have to be used for 3-6 months. Higher doses may be required in patients with marked seborrhoea. Tetracycline 500 mg bd or doxycycline 100 mg bd for 2 weeks to 10 months. Erythromycin 500 mg bd if patient cannot tolerate tetracycline because of

side effects or in pregnant women. Pulse therapy with azithromycin and clindamycin.

- **Corticosteroid** - Prednisolone or dexamethasone once at night useful in females with severe acne unresponsive to conventional therapy.
- **Other drugs** - Oral contraceptives, spironolactone, cyproterone acetate, flutamide and gonadotropin releasing hormone may help in young women after failure of conventional therapy.
- **Adjunctive therapy** - Intralesional steroids for neurocystic lesions. Comedone extraction, chemical peels, dermabrasion, laser and light therapy.

Hormonal therapy is useful because androgen hormones mediate sebum production. Cyproterone acetate 2 mg with ethinyloestradiol 35 µg is effective if given for 3-6 months.

Management of scarring - (a) *Punch excision, elevation*: In depressed scars, punch elevation followed by full-thickness graft of normal skin. For superficial ice-pick scars punch elevation to raise level flush with surrounding skin. (b) *Intralesional triamcinolone and/or cryotherapy* for hypertrophic and keloid scars. (c) *Dermabrasion* - The skin is planed using a deep-wire brush. (d) *Laser therapy* - CO₂ ultrapulse and Er: YAG lasers have been used successfully.

VARIANTS OF ACNE

Acne fulminans is a rare disorder that can appear suddenly in the context of normal acne. There is a profound acne flare with muscular pain and fever. Osteolytic bone lesions have been described.

Treatment - High dose corticosteroids (1 mg/kg/day), followed by cautious introduction, after 2-3 weeks, of isotretinoin, 0.1-0.2 mg/d/p.o.

Infantile acne - Inflammatory lesions occur before or at about 3 months of age. Lesions are usually mild and disappear without scarring. Infantile acne often occurs in the context of a strong family history. Prepubertal resurgence of acne is likely.

Treatment - Topical therapies with or without oral erythromycin or trimethoprim. In severe cases, low dose isotretinoin may be required.

Pyoderma faciale is more common in young women in context of emotional stress and not necessarily with coexisting acne.

Treatment - Prednisolone 1 mg/kg/day and daily application of class IV corticosteroid for one week, followed by Isotretinoin 0.5 mg/kg/day gradually increased to 1 mg/kg/day for 4-6 months.

Acne conglobata - Multiporous comedones with intercommunicating abscesses, cysts and sinuses with serosanguinous fluid or pus.

Occupational acne - From exposure to industrial chemicals. Sites of involvement forearms, legs and retroauricular region.

Cosmetic acne - Comedones on the chin.

Drug-induced acne - Comedone and papules on back of trunk and face due to androgens, steroids, oral contraceptives, anticonvulsants.

ACNE-LIKE ERUPTIONS

Acne rosacea is a chronic dermatosis that usually affects the face (Fig. 29). The hallmark is intermittent flushing of the face, which may occur spontaneously or may be triggered by hot and spicy food, alcohol, temperature changes, wind or emotional upset. It presents with papules and pustules and is often associated with telangiectasis. There may be associated conjunctivitis, keratitis and blepharitis. Rhinophyma is caused by hypertrophy of sebaceous glands leaving a red bullous nose. Fixed facial oedema may occur.

Periorbital and perioral areas are not affected.

Complications - (i) Ophthalmic - Blepharitis, conjunctivitis, keratitis. (ii) Rhinophyma. (iii) Lymphoedema - Forehead and infraorbital.

Treatment - 1. Sunscreens for patients with marked photosensitivity. 2. Topical agents - (i) Metronidazole (0.75%) for mild to moderate rosacea. Good response to papulopustular lesions. (ii) Retinoic acid (0.025%). 3. Immunomodulators - Tacrolimus 0.03% ointment, pimecrolimus 1% cream useful to wean off patients from topical steroids.

Fig. 29: Acne rosacea

Isotretinoin - Effective against all severities and all lesions. Dose - 0.5-1 mg/kg body weight daily for 6 months. 4. Antibiotics - Doxycycline - Initial 100 mg/d, then on alternate days for 3-6 months is the drug of choice.

Milia are small, subepidermal keratin cysts most commonly seen around the eyes resembling whiteheads. The eccentrically placed punctum seen in whiteheads is not visible in milia.

Sycosis barbae is caused by ingrowing curly facial hairs which penetrate the follicles.

Peri-oral dermatitis often occurs in women aged 20-35 years. It presents as red papules, which form superficial plaques around the peri-oral area, nasolabial folds and/or lower eyelids. It is minimally itchy. Cause is unknown.

Gram-negative folliculitis is a sudden eruption of pustular lesions often seen in those on long-term antibiotics and is commonly mistaken for a flare of acne.

10. DERMATITIS/ECZEMA

CLASSIFICATION

Table 18 gives the classification of eczema.

ATOPIC DERMATITIS

Atopic dermatitis (atopic eczema) is a common endogenous form of dermatitis and usually begins in childhood. It is an itchy, chronic and relapsing dermatitis.

Pathogenesis. Atopic dermatitis depends on a complex interaction between genes and environment. Genetic studies have shown linkage in three loci, but the environment in early life also has a profound influence on the immune over-activity that develops in this condition. An 'imbalance' in the immune system with preferential

Table 18: Classification of eczema

Endogenous eczema	Exogenous eczema
Atopic dermatitis	Contact dermatitis
Seborrhoeic dermatitis	Irritant
Nummular eczema	Allergic
Lichen simplex chronicus	Photodermatitis (Fig. 30)
Pityriasis alba	Infective dermatitis
Pompholyx	
Stasis dermatitis	
Asteatotic eczema	
Prurigo nodularis	

Fig. 30: Photodermatitis of hand

activation of Th2 CD4 lymphocytes seems to be a crucial step in the development of atopy.

DIAGNOSTIC CRITERIA FOR ATOPIC DERMATITIS

- An itchy skin condition (or parenteral report of scratching or rubbing in a child) plus three or more of the following:
 - Onset in infancy
 - History of skin creases involvement (including cheeks) in children under 10 years
 - History of generally dry skin in the past year.
 - Other atopic features (or history of any atopic disease in a first-degree relative in children under 4 years)
 - Visible flexural dermatitis (or dermatitis of cheeks/forehead and outer limbs in children under 4 years).

CLINICAL APPEARANCES OF ATOPIC DERMATITIS

- | | |
|-----------------------|---------------------------|
| • Acute dermatitis | Red, wet, weepy vesicles |
| • Subacute dermatitis | Red, dry, scaly |
| • Chronic dermatitis | Dry, thickened excoriated |
- In many patients, these clinical features overlap.

Distribution – In infants eczematous lesions are often present on exposed areas such as the cheeks, or outer aspects of forearms. In older child, eczema usually affects flexural sites such as the front of the elbows and popliteal fossa (Fig. 31), the front of the ankles and around the neck and face.

Fig. 31: Adult atopic dermatitis

Variants

- Follicular eczema may occur, especially in dark skin.
- Discoid eczema is a morphologically variant seen in all racial groups. It can occur in both atopic and non-atopic individuals. It presents as itchy, well-circumscribed, crusted lesions, often on the limbs. Secondary infection is common.

INFECTIVE COMPLICATIONS OF ATOPIC DERMATITIS

Bacterial infection because bacteria adhere well to scaly, inflamed skin. It is usually not associated with pyrexia and malaise.

Eczema herpeticum describes a widespread herpes simplex virus infection of atopic skin with swinging pyrexia, malaise and occasionally severe morbidity. It presents with clusters of vesicles particularly on face, but can occur anywhere. These erode rapidly, leaving the typical picture of multiple, superficial punched-out or crusted lesions.

Investigations – These may reveal peripheral eosinophilia, raised serum IgE to a variety of common environmental agents (detected by radioallergosorbent tests or skin-prick tests). However, they are not needed routinely for diagnosis.

MANAGEMENT

1. **Avoiding irritants and allergens.** Use of cotton clothes and bedding covers. Families should be advised not to keep cats or dogs. Swimming can worsen dermatitis because of irritant effect of chlorine.

2. **Dietary manipulation.** Standard dermatitis therapies usually control the dermatitis without the need for dietary change.
3. **Emollients and washing.** Regular bathing to remove skin debris and crusts. Soaps should be avoided; bath oil and soap substitutes such as aqueous cream prevent the skin drying out.
4. **Corticosteroids** on inflamed skin only. Mild corticosteroids on face and under the nappy, and moderate strength on body. However prolonged use of topical corticosteroids, particularly if potent, is associated with many side effects.
5. **Non-steroidal topical therapies** - Tacrolimus, pimecrolimus and cyclosporine are immunosuppressants derived from the naturally acting macrolactam ascomycin. Unlike cyclosporine, tacrolimus and pimecrolimus are relatively small molecules that can penetrate through the skin and are therefore suitable as topical therapies. These drugs inhibit production of the pro-inflammatory cytokine interleukin-2 (IL-2), reduce lymphocyte proliferation and activation, down-regulate high-affinity IgE receptor expression on Langerhans' cells, and reduce IgE-induced mediator release from mast cells and basophils.
Dosage - Tacrolimus ointment 0.03% for patients aged 2 years and more, and 0.1% for those aged 16 years and more. Treatment is recommended for use b.d. for 3 weeks and then o.d. until improvement. Pimecrolimus cream 1% b.d. in patients aged 2 years and more with mild-to-moderate atopic eczema.
The potency of tacrolimus is similar to that of 0.1% hydrocortisone butyrate and 0.1% betamethasone valerate. Patient's skin should be properly hydrated.
Adverse-effects - Most common is a transient, mild burning sensation at the site of application.
6. **Adjunct therapies**
 - a. **Antibiotics** - for infected dermatitis. Oral broad spectrum antibiotics. Recurrent infections may be treated with antiseptic bath oil and emollients. For eczema herpeticum oral acyclovir can be given iv. if child is unwell.
 - b. **Antihistamine** do not help because the itch of eczema is not histamine-mediated.
7. **Systemic therapies** are used because atopic dermatitis can prevent sleep, disrupt social and educational development and cause growth retardation.
 - a. **Ultraviolet phototherapy** - Broad-band UVB, narrow-band UVA can be helpful, but their use in white-skinned patients is limited by the risk of skin cancer.
 - b. **Immunosuppressants** - Cyclosporine, oral corticosteroids and azathioprine may be used in excep-

tional circumstances. Oral corticosteroids can be used for quickly controlling a severe flare of dermatitis. Initial dose 0.5–1 mg/kg/day, reduced every 3–4 days so that the course lasts 3–4 weeks. As the dose is reduced topical therapies must be intensified.

8. **Complementary therapies** - *Psychotherapy, hypnotherapy and acupuncture* can help patients relax, and may assist in breaking the itch-scratch cycle in some.

Lichen simplex chronicus results from persistent scratching and rubbing usually in adults of both sexes of a site of the skin. The causative pruritic lesions can be a transient mechanical or chemical irritation or at times an allergic contact dermatitis or atopy. Occasionally it may be habitual (circumscribed neurodermatitis). Whatever the etiological factor, the scratch-itch-cycle perpetuates the condition.

Description. Well marked hyperpigmented plaques and prominent crisscross skin markings so that the surface resembles tree-bark or leather. The skin becomes thickened and from persistent scratching tiny crusts or erosions may be observed.

Distribution. Body areas which can be easily scratched such as nape of neck, dorsa of feet, wrists, extensor surface of forearms, scalp and external ear canal.

Treatment - (a) Patient explanation of this habit. (b) Topical potent corticosteroids and occlusion of the area for 6–8 hours with a plastic film to enhance the effect. (c) Antihistamines for pruritus.

INFANTILE ECZEMA/DERMATITIS

Infantile atopic dermatitis Rash starts on the cheeks but may occur on any part of the body. Generally the nappy area is spared. Initial lesions are oedematous, erythematous papules which may become confluent. They are often markedly excoriated with exudation and crusting. When the dermatitis flares, intermittent morbilliform erythema may appear on the trunk. Secondary infection and lymphadenopathy often occur.

OTHER PATTERNS OF ECZEMA

Infantile seborrhoeic dermatitis - In young babies, it is often difficult to differentiate it from atopic dermatitis. Involvement of axillae in seborrhoeic dermatitis and the forearms and shins in atopic dermatitis are the best morphological discriminators (Table 19).

Pityriasis alba. Multiple mildly erythematous and scaly oval patches, which cause loss of pigmentation, seen on the face. Lesions can arise, infrequently, on non-facial skin. *Tr.* - Emollients, sunscreens on depigmented areas and 1% hydrocortisone ointment.

Table 19: Comparison of seborrhoeic and atopic dermatitis

	<i>Seborrhoeic dermatitis</i>	<i>Atopic dermatitis</i>
Age of onset	Less than 2 months	2–6 months
Pruritus	Uncommon	Common
Distribution of rash	Napkin area, axillae, scalp	Face, forearms, shins
Family history of atopy	30%	> 50%
IgE levels and RASTs to milk and eggs	Normal IgE, negative RASTs	Elevated IgE, positive RASTs
Prognosis	Good, clears by 6 months	Chronic and relapsing, associated with asthma and hay fever

Lip-licking dermatitis – Chapped eczema around the mouth in a child with atopic dermatitis due to habits such as lip-licking, dribbling and thumb sucking, or as a result of chapping. It can become secondarily infected. *Tr.* – Emollients and occasionally 1% hydrocortisone ointment.

Juvenile plantar dermatosis presents in children as dry, shiny cracked dermatitis on plantar surface of big toe and forefoot. Some children are atopic or are involved in bare-footed sport. *Tr.* – Emollients, topical corticosteroids if severe flares.

Napkin dermatitis (Napkin rash) due to persistent irritation from urine or faeces due to lack of frequent changes of napkins. There is erythema and erosions of the buttock contours, and inner thighs sparing the inguinal flexures (unlike candidiasis). *Tr.* – Keeping the area dry and application of 1% hydrocortisone or soothing creams. **Stasis dermatitis** is a type of eczema secondary to chronic venous insufficiency of the lower extremity.

Cl. Fs. – Onset is with oedema which after sometime is followed by irregular patches of pigmentation (due to deposition of hemosiderin), mostly above the ankle. Melanin may also be deposited in the skin as a result of scratching. Stasis can give rise to eczema and venous ulceration.

Stasis eczema may be of the chronic scaling type with itching and irritation. Other types of more diffuse dermatitis may occur. Occasionally there may be an id eruption on other parts of the body.

Nummular (Discoid) eczema presents as multiple coin shaped eczematous plaque lesions, bilateral but asymmetrically distributed on the extremities. *Tr.* – Mid to high potency steroids. Tacrolimus and pimecrolimus and tar preparations are also effective.

Pompholyx. Deep-seated vesiculation bilaterally symmetrical on palms and sides of fingers, also at times soles of the feet. *Tr.* – High potency topical steroid. For chronic and recurrent cases systemic prednisolone, cyclosporine, methotrexate.

Table 20: Causes of contact dermatitis**External agents causing contact dermatitis**

- Degreasing agents
- Detergents
- Solvents
- Metal-working fluids
- Dusts and friction
- Low humidity
- Allergenic chemicals
- Rubber and plastics

Common allergens causing contact dermatitis

- Nickel
- Fragrance
- Rubber
- Medications including topical corticosteroids, lanolin, neomycin
- Chromate
- Formaldehyde and other biocides
- Epoxy resin
- Plant allergens
- Hair-dressing chemicals
- Direct or airborne contact may occur
- Cosmetics

Asteatotic eczema. Skin of trunk and limbs becomes erythematous, dry and pruritic and shows a crazy-pavement type of fissuring. It occurs due to excessive drying during winter months and in the aged. *Tr.* – Topical steroids and ointment and application of emollients.

Prurigo nodularis. Severe itching disorder in which rubbing and scratching of a skin area leads to formation of hemispherical nodules with warty surface over lower or upper limbs. *Tr.* – Intralesional inj. triamcinolone 10 mg/ml, or high potency topical steroids under occlusion. Antihistamines.

CONTACT DERMATITIS

Contact dermatitis is an eczematous eruption caused by external agents (Table 20).

Fig. 32: Contact dermatitis due to footwear

Causes can be broadly divided into irritant substances that have a direct effect on the skin, and allergic chemicals with which dermatitis follows delayed type IV cell-mediated hypersensitivity reactions. Contact dermatitis often exacerbates pre-existing endogenous eczema.

Irritant contact dermatitis. Any physical or chemical agent that is capable of producing, if applied for sufficient time and in sufficient concentration can lead to irritant dermatitis. Dermatitis occurs when the repair capacity of the skin is exhausted or when the penetration of chemicals excites an inflammatory response. It is often occupational in origin, the most common industries are those in which workers engage in wet-work (e.g. hair dressing, cleaning, metal engineering, food processing, fishing). Pre-existing dermatitis (particularly of the hands) of an atopic nature is a strong risk factor for developing irritant contact dermatitis (Fig. 32).

Corticosteroid hypersensitivity. Hydrocortisone has the greatest sensitizing capacity, followed by budesonide.

DIAGNOSIS OF CONTACT DERMATITIS

- Sharp demarcation in the distribution of the dermatitis.
- Definite history
- Patch-testing - The allergens are applied on day 1, left on for 48 hours and then removed; readings are taken at 48 and 96 hours. Care must be taken to ensure that the allergens do not cause false-positive irritant reactions.

Table 21: Drugs that commonly cause rashes

• Antibiotics (penicillins and their derivatives like ampicillin, cephalosporins, sulphonamides and griseofulvin)
• Non-steroidal anti-inflammatory drugs
• Anticoagulants
• Allopurinol
• Gold
• AKT drugs

Management - (a) Elimination of causative factors. (b) Topical corticosteroids with emollients and soap substitutes when appropriate. (c) Immunosuppressant (cyclosporine, azathioprine) for very resistant cases.

Photodermatitis

Infectious eczematoid dermatitis is seen mainly around discharging wounds or ulcers and other moist skin lesions. Features are an area of advancing erythema, occasionally with microvesicles.

11. DRUG REACTIONS AND THE SKIN

A rash is usually the most obvious manifestation of hypersensitivity to a drug (Table 21).

Causes of cutaneous drug reactions. Immune-mediated hypersensitivity reactions are the most common cause of drug rashes.

Immunological drug reactions

Type I hypersensitivity reactions occur when a drug-protein conjugate cross-links two or more specific IgE molecules fixed to mast cells or basophils. *Clinical features* - Itch, urticarial rash, and less commonly bronchospasm, laryngeal oedema and anaphylaxis. Drugs commonly responsible are aspirin, opiates, penicillins and some vaccines.

Type II reactions involve binding of antibody to cells and with subsequent binding of complement and cell rupture. When this arises on the surface of platelets, it may produce thrombocytopenic purpura (e.g. quinidine).

Type III hypersensitivity reactions are mediated by intravascular immune complexes. These occur when drug antigen and antibodies, usually of IgG or IgM class, are both present in circulation, with the antigen present in excess. *Clinical features* - Fever, purpuric or urticarial rash, nephritis and focal inflammation of GI tract.

Type IV hypersensitivity reactions to topical medications produce an eczematous response at the site of application.

Drug responsible for delayed reactions include topical antibiotic neomycin, topical hydrocortisone, and sunscreens containing para-amino-benzoic acid.

Patterns of drug rashes

Exanthematous reactions (Toxic erythema) typically comprise symmetrical erythematous nodules and/or papules on trunk and limbs with sparing of the face. The rash fades with desquamation after stopping the drug. If the drug is continued, generalized exfoliative dermatitis may develop.

Purpuric drug eruptions due to bleeding into the skin. In severe cases, there may be urticarial lesions, hemorrhagic blisters and even cutaneous ulceration. Drugs implicated in cutaneous vasculitis include ampicillin, thiazide diuretics, frusemide, sulphonamides and hydralazine.

Simple purpura without vasculitis may be seen with any drug that affects platelet function or coagulation (e.g. aspirin, NSAIDs, heparin, warfarin).

Erythema nodosum is an erythematous nodular tender eruption 2–4 cm in diameter usually affecting external aspects of the legs, thighs and forearms. It is caused by antigen-antibody reaction and deposition of immune complexes in and around blood vessels. Erythema nodosum is associated with acute streptococcal infection, rheumatic fever, primary tuberculosis, acute sarcoidosis, sulphonamide drugs and pregnancy.

Erythroderma and exfoliative dermatitis. Extensive confluent erythema with subsequent desquamation is one of the most serious drug reactions in the skin. It may be preceded by exanthematic drug reactions or may arise *de*

novo. Complications include hypothermia, fluid and electrolyte imbalance, and occasionally cardiac failure.

Urticaria and anaphylaxis. (See urticaria).

Lichenoid eruptions. Clinical and histological features resemble those of lichen planus. In contrast to lichen planus, oral involvement is rare. The eruption may start months after the causative drug was started. Hyperpigmentation and scaling are commonly seen as a part of the rash, and resolution is slow after the drug is withdrawn. Drugs include penicillamine, gold, β -blockers, thiazide diuretics, captopril, antimalarials and chlorpropamide.

Fixed drug eruption occurs at the same site(s) each time the offending drug is taken.

Causative agents – Tetracyclines, sulphonamides, phenolphthalein, oxyphenbutazone.

Description – The lesions, which are often painful and may cause a burning sensation, appear as clearly demarcated oval or round erythematous plaques which are sometimes bullous and usually 20 mm in diameter, though lesions up to 10 cm in diameter may occur (Figs. 33 and 34). After 1–2 days the lesion(s) become violaceous. Typically, there are one to three lesions. Lesions fade over 7–10 days and leave a hyperpigmented patch.

Sites – Usually the hands, feet, glans penis or lips. Lesions always occur at the same site.

Erythema multiforme, Stevens-Johnson syndrome and toxic epidermal necrolysis.

Erythema multiforme is a condition characterized clinically by target-like (bull's eye) erythematous lesions, most pronounced on the trunk and palms and soles (Fig. 35). The mucous membrane may be affected, and severe cases

Fig. 33: Fixed drug eruption

Fig. 34: Fixed drug eruption

Fig. 35: Erythema multiforme showing target lesions

Fig. 36: Stevens-Johnson syndrome

Fig. 37: Stevens-Johnson syndrome

Fig. 38: Toxic epidermal necrolysis

patients develop fever, malaise, myalgia and arthralgia (Stevens-Johnson syndrome). Erythema multiforme is an immune complex mediated reaction to a variety of causes. In particular herpes simplex infection, drugs (especially sulphonamides) and mycoplasma. Other possible causes include AIDS, malignancy, other infections and connective tissue diseases.

Stevens Johnson syndrome (Figs. 36 and 37) is the severe form of erythema multiforme with conjunctival involvement and blistering and erosion of oral and genital mucosa. Usually there are widespread cutaneous blisters, but sometimes the mucosal features are associated with modest macular target lesions on the periphery.

Toxic epidermal necrolysis is preceded by a flu-like illness lasting 3–5 days, this is followed by fever, mucous

membrane involvement and extensive erythematous skin lesions which either develop bullae or peel off in sheets, either spontaneously or when pressure is applied (Nikolsky's sign) (Fig. 38); mouth and eyes are often affected and manifest as hemorrhagic crusts, and white pseudomembrane of the lips.

Pneumonia complicates about 30% of cases as a result of sloughing of the epithelium lining the respiratory passages. Drugs responsible can be phenytoin, carbamazepine, sulphonamides, ampicillin and allopurinol. Causative drugs have been taken 1–3 weeks period preceding the eruption. There is occasionally a history of previous rash with the suspected drug. Mortality is 20–30%, and supportive treatment in ICU is needed in most cases.

Table 22: Differences between staphylococcal scalded skin syndrome and toxic epidermal necrolysis

	<i>Staphylococcal scalded skin syndrome</i>	<i>Toxic epidermal necrolysis</i>
Aetiology	Staph. aureus	Drugs, neoplasms, infections, graft-versus-host disease
Age	Infants and children	Adults
Constitutional disturbance	Mild	Severe
Course	1–2 weeks	More than 2 weeks
Scarring	Absent	May occur
Prognosis	Good	Bad
Treatment	Anti-staph. drugs	Stopping offending drugs

Staphylococcal scalded skin syndrome (SSSS) is caused by *S. aureus* and occurs mainly in infants and children. The onset is acute with fever and diffuse tender erythema followed by development of large fluid filled bullae which soon rupture. Site of lesions is periorifacial and body folds. Later the skin appears scalded, discoloured and denuded (Table 22).

12. PHOTOSENSITIVITY DISORDERS

Photosensitivity disorders involve abnormal sensitivity to ultraviolet (UBV and UBA) and sometimes visible sunlight. The clinical manifestations are diverse and include the exaggerated sunburn response, blistering and scarring, itchy, papular, eczematous or urticated eruptions and rarely, early onset of severe photodamage with skin cancer.

PATHOGENESIS

A specific wavelength interacts with a chemical component (chromophore), which undergoes excitation, causing clinical events mediated by toxic or allergic mechanisms.

1. **Exaggerated sunburn response** – is the most common manifestation of a sensitive response. UVR rays are responsible for most sun burns.

Drug-induced photosensitivity – A phototoxic response is induced when ultraviolet light, and sometimes visible light, absorbed by the drug produces local damage to the skin and subsequent sunburn like erythema. Each drug has characteristic clinical features that are a function of the chemical properties of the drug and its anatomical location within the skin. Amiodarone causes photosensitivity in about 40% of patients, typically with burning erythema developing within 2 hours of sun exposure. Other drugs that may cause exaggerated sunburn response are thiazide diuretics, chlorpromazine, quinine, some forms of tetracycline and fluoroquinolone antibiotics.

Other disorders in which sunburn-like erythema may be the presenting feature of photosensitivity:

- Patients with xeroderma pigmentosum develop chronic cutaneous photodamage in early childhood, and subsequently skin cancers.
- Erythropoietic porphyria is also associated with intolerance of sunlight since early childhood.
- In Smith-Lemli-Opitz syndrome, sunburn-like erythema is observed on the first exposure to sunlight with redness within minutes that persists for 24 hours or more.

2. Photosensitivity induced by topical agents

- a. **Phototoxicity.** Here, injury results from interaction of the photosensitizing agent on the skin with ultraviolet or visible radiation, leading to release of reactive oxygen species and subsequently inflammatory mediators. Only brief exposure to sunlight can produce erythema, oedema and blistering.
- b. **Photoallergy** is a type IV delayed hypersensitive response. Important topically applied chemicals responsible are fragrances such as musk and 6-methylcoumarin, and sunscreens such as para-aminobenzoic acid and benzophenones. Photoallergy presents with worsening erythema associated with an eczematous rash a few days after sun exposure.

Diagnosis can be confirmed by phototesting with the suspected allergen.

3. **Sun-induced blistering.** A relatively small dose of UVR or visible light may produce blistering in phototoxic drug reactions and in bullous porphyrias.

Drugs. Some drugs produce blistering and skin fragility, features similar to those of bullous porphyrias, and the term 'pseudo-porphyrins' is used to describe this syndrome, in which porphyrin studies are normal. **Drugs responsible** – Naproxen, nalidixic acid, frusemide, tetracycline antibiotics, amiodarone and

isotretinoin. Newer fluoroquinolones produce a more acute pattern of hypersensitivity. Similar changes are seen in chronic renal failure, on sun exposure independent of medication.

Porphyria. Sun-induced blisters on the backs of the hands are seen in bullous porphyrias. Other features include skin fragility with erosions, hypertrichosis and skin pigmentation. The tense blisters heal slowly to produce atrophic scars, milia and hyperpigmentation.

4. **Eczema and eczema-like photosensitive eruptions.** Most common is seborrhoeic dermatitis. Atopic eczema may also be aggravated by exposure to sunlight. Diagnosis is confirmed by abnormal responses to formal light-testing.

ACQUIRED PHOTOSENSITIVITY SYNDROMES

1. **Polymorphic light eruption** is the most common syndrome. It is more common in females. Features are itchy, papular eruption on some sun-exposed sites which develops within a few hours of sun exposure and persists for up to 7 days. *Treatment* of acute attacks is with potent topical corticosteroid or a short course of systemic corticosteroids. In severe cases, desensitization therapy with UVB phototherapy or psoralen plus UVA therapy should be considered.
2. **Other acquired photosensitivity syndromes** are rare.
 - Hydroa vacciniforme occurs in childhood with crusted vesicles on the face following sun exposure that heal leaving depressed scars.
 - Actinic prurigo begins in childhood with an eczematous eruption that is more severe on sun-exposed sites and is associated with prurigo nodules caused by severe pruritus. It is often a chronic persistent disorder.
 - Solar urticaria is usually seen in adults, who present with sun-induced urticarial whealing.

Harmful effects of solar radiation:

- Sunburn (acute effect)
- Photoaging: Potential long term effect of repeated sun exposure
- Keratoses, both melanoma and nonmelanoma skin cancers

Sunscreens - are agents that alter the effects of UV radiation on skin by absorption or reflection of a part of the incident radiation.

Indications for sunscreens - In most dermatological conditions requiring sunscreens (e.g. hyperpigmentation, photosensitivity disorders like polymorphous light eruptions or photocontact dermatitis) physical or broad spectrum screens are required. Physical sunscreens containing titanium dioxide or zinc oxide (or calamine) are less cosmetically acceptable since they tend to give pasty look to the skin. Chemical sun screens act as filters not allowing penetration of UV light to viable cells. Most common chemical compound used is para-amino benzoic acid (PABA).

Method of application - A sunscreen is to be applied generously on dry skin and all exposed areas of skin including the rims of the ears, lips, nose, back of neck and feet, 30 minutes before exposure. It requires to be reapplied every 2 hrs if sweating or swimming.

Adverse reaction to sunscreens - Stinging, burning, itching. Contact urticaria, irritant contact dermatitis (esp. PABA and its derivatives), acnegenicity (induce or exacerbate acne), and photosensitivity.

Types of sunscreens - (a) Physical: titanium dioxide, calamine. (b) Chemical: PABA, Methyl anthranilate octyl methoxycinnamate, avobenzene, oxybenzone, ethyl p-methoxycinnamate. Systemic photoprotection-useful drugs are beta-carotene, antimalarials and psoralens.

Sun-aggravated disorders. Common conditions include psoriasis, eczema, erythema multiforme and herpes simplex infections; rare are dermatomyositis and lupus erythematosus.

Patients with congenital or acquired metabolic deficiency may also show worsening rashes with sunlight. (a) In Hartnup disease, there is a dry, scaly rash on sun-exposed sites exacerbated by sunlight. (b) Also pellagrous rash. Pellagra may be encountered in chronic alcoholics or in those with GI or severe psychiatric disorders, or as a complication of therapy with isoniazid, 6-mercaptopurine or 5-fluorouracil.

SELF-LIMITING PAPULOSQUAMOUS DERMATOSES

Pityriasis rosea. Usually located on the trunk.

Aetiology - Probably viral, associated with human herpes virus (4HV, 6 and 7).

Cl. Fs. Healed patch followed by a secondary lesion of oval, annular erythematous plaques. These plaques show a ring of scale, attached to periphery of lesion and collarette. The lesions are arranged across the lines of the ribs (fir tree or Christmas tree appearance). When scratched across the long axis, the scales tend to fold across the line of scratch ('hanging curtain sign').

Tr. - Symptomatic treatment for itching.

Pityriasis rubra pilaris is a rare erythrosquamous dermatosis of unknown aetiology characterised by small papules with a central keratin plug, perifollicular erythema. There is a tendency to become confluent with an area of sparing, pityriasis capitis and palmoplantar keratoderma. The condition begins often with seborrhoeic rash on face and scalp which then spreads to trunk and limbs.

Tr. - Topical keratolytic agents, systemic steroids.

13. PAPULOSQUAMOUS ERUPTIONS

PSORIASIS

A chronic, recurrent, inflammatory disease of the skin of unknown origin, characterized by well-circumscribed erythematous, dry plaques of various sizes, covered with mica-like scales.

Pathogenesis

Psoriasis results from a polygenic genetic disposition and an environmental trigger. Its severity is believed to be genetically determined, and several environmental factors are known to exacerbate it. Key components of the pathogenesis are potential therapeutic targets.

(a) *Activated T lymphocytes* - appear to be important in all phases of the disease process (initiation, maintenance and resolution). Patients with psoriasis who undergo bone marrow transplantation from a healthy donor sometimes experience long-term remission. (b) *T-helper lymphocytes* migrate from blood vessels into the skin, where they interact with antigen-presenting cells and then become activated into a T-helper type 1 phenotype, proliferate and release various cytokines and chemokines which attract and activate T-cytotoxic lymphocytes. (c) *Interferon- α and tumour necrosis factor (TNF α)* are released by immune cells, further promoting inflammation and development of psoriatic lesions. (d) *Epidermal cells overlying the inflammatory process* proliferate and turn over at four times the normal rate, resulting in thickening of the epidermis with overlying scales. In the upper epidermis proliferation of vessels occurs.

Aetiology

Genetic factors - Identical twins have a concordance rate of 50–70%. There is a strong association of the disease with HLA-Cw6, and weaker associations with HLA B13, B17 and DR7. Both HLA associations and a family history of psoriasis are more common in patients who develop the disease before 40 years of age.

Environmental factors - Attacks of psoriasis can be precipitated or aggravated by stress, infection (streptococcal, HIV), pregnancy, trauma, drugs (chloroquine/antimalarials, lithium), alcohol, tobacco smoking, sunlight.

Morphology

Psoriasis vulgaris (chronic plaque psoriasis) is the most common form. The primary lesion is a plaque which is sharply marginated, indurated, erythematous (modified by skin colour). The plaque variable in size may be surrounded by a hypopigmented halo. Initial lesions are discoid but may merge to form polycyclic or geographic plaques.

The plaque surface is usually scaly (Fig. 39) and gentle scratching may produce a silvery appearance from the lifting of numerous tiny scales. Lifting larger scales may result in capillary bleeding (*Auspitz sign*) because the elongated capillaries almost reach the skin surface.

Psoriatic plaque with well-defined edge

The *Koebner's phenomenon*, in which psoriatic lesions tend to develop at sites of trauma (e.g. a surgical wound or a trivial scratch, abrasion or burn) is a helpful diagnostic feature when seen. It also occurs in lichen planus, but not in eczematous dermatoses.

Variants

1. Morphological

- **Guttate psoriasis** - occurs in children and adolescents, small erythematous papules appear in several guttate which clear within a few weeks or evolve into plaque psoriasis.
- **Rupioid psoriasis** - Instead of scaling the surface of the plaques is covered by hard, thickened firmly

Fig. 39: Psoriatic plaque with well-defined edge

adherent keratin plaques. Such lesions are classically seen in Reiter's syndrome.

2. **Modification by site**

- **Flexural psoriasis** - Well-defined erythematous lesions, mostly in elderly females in groins, axillae, inflammatory folds, vulva, gluteal cleft.
- **Scalp psoriasis** - Sharply defined indurated scaly plaques. Scaling may be massive, especially in the occiput, may spread to forehead and nape of neck (Fig. 40).
- **Psoriasis of palms and soles** - Bilateral, symmetrical, well defined plaques, scales may be adherent unlike loose scales in other parts.
- **Nails** - Pitting, nail plate thickening, subungual hyperkeratosis, onycholysis oil spots (Fig. 41).
- **Joints** - Arthritis types - (a) Asymmetrical oligoarthritis involving commonly joints of hands and feet. (b) Distal interphalangeal arthritis. (c) RA - like seronegative, symmetrical arthritis. (d) Axial arthritis - Spondylitis, sacroiliitis and with or without peripheral joint involvement. (e) Arthritis mutilans - severe, deforming arthritis of fingers and toes.
- **Penile psoriasis** in uncircumcised males. No scaling on glans, lesions erythematous, well-defined. In circumcised males lesions similar to lesions at other sites.

Complications

- Erythrodermic psoriasis precipitated by irritant effect of topical therapy or withdrawal of steroids in therapy. Plaques merge and skin becomes erythematous with marked scaling.

Fig. 40: Scalp psoriasis

- Pustular psoriasis - Precipitating factors same as above. Pustulation can be localized or generalized with red erythema followed by appearance of small superficial pustules, which become confluent. New pustules appear as the older ones are crusting. Constitutional symptoms like high fever, tachypnoea.

Management

As a general rule, topical treatments are safest. Phototherapy and systemic agents should be used only when topical treatments are ineffective.

I. Topical therapies

1. **Topical corticosteroids** - Potent category (e.g. clobetasol) applied bd to localised lesions. Overnight or occlusive therapy will initiate involution in most cases. Hydrocolloid dermatological patches can be applied over steroids on localised psoriatic plaques for 2 to 7 days. As lesions subside, use of occlusion on is decreased, and bland emollient applied. After lesions have flattened, corticosteroids can be applied in bursts (e.g. several days on and several days off). Injection of intralesional corticosteroids (e.g. Triamcinolone) beneath isolated chronic plaques will cause involution within 7 to 10 days.
2. **Topical Vitamin D analogues** - Calcipotriol ointment, cream or lotion is applied bd. Dose should not exceed 100 g/week because of risk of hypocalcemia and kidney stones.
3. **Topical tazarotene gel and cream** (0.05% and 0.1%) to minimise irritation - (i) Tazarotene should be applied to the affected skin only at bedtime, with protection of normal skin with vaseline. (ii) Apply a mid to high

Fig. 41: Psoriasis of toes with onycholysis

potency steroid in morning. Tazarotene combined with UVB phototherapy is more effective than phototherapy alone.

4. **Coal tar therapy** (3–6% crude coal tar) can be combined or alternated with topical corticosteroids. The patient should apply a formulation overnight and be exposed to UVL the following morning, or apply a corticosteroid cream with or without occlusion during the day tar overnight, and UVA exposure in morning.
5. **Other topical agents** – (i) Salicylic acid 2–10% helps to remove scales and crusts and may be used along with corticosteroid or anthralin therapy. (ii) Anthralin is effective for treatment of discrete lesions consisting of thick plaque. Disadvantage is primary irritation and staining of skin and clothes. (iii) Topical tacrolimus or pimecrolimus may be effective in intertriginous and facial psoriasis because of better absorption.
6. **Exposure to sunlight or UVB** from the point of mild erythema and induce flattening or clearing of many lesions. An excimer lens with intense radiation can clear a plaque of psoriasis with even one treatment, although usually 4 to 8 treatments are required.

Treatment of Severe or Widespread Involvement

1. Aggressive UVB phototherapy 5 times a week or daily most effective single agent therapy.
2. Photochemotherapy – Psoralen plus PUVA – 10 to 20 treatments are required. Psoriasis often recurs after stopping treatment and twice monthly treatment is required to keep most patients free of the disease.
3. Combined therapy for clearing resistant and wide spread disease include PUVA-UVB, retinoid-PUVA, retinoid UVB, methotrexate PUVA – Twice weekly UVB with one weekly methotrexate for 8 week.

II. Oral systemic agents

1. Acitretin – A synthetic vitamin A is effective in pustular, guttate and erythrodermic psoriasis. Dose 10–20 g/day with maximum 50 mg/day. Side effects – Elevation of triglycerides, hair loss, thinning of nails, xerosis.
2. Antimetabolite therapy – (i) Methotrexate oral or IM. Dose – Initial 7.5 mg/week with increase of 2.5 g/week as tolerated. (ii) Cyclosporine 3.5 g/kg/day.
Treatment schedule – Rotate therapies to try and minimize adverse effects of each, e.g. UVB, PUVA, methotrexate, acitretin and cyclosporine.
Other agents – (i) Mycophenolate mofetil 500 mg qds
Side effects – herpes zoster, neutropenia, GI symptoms. (ii) Fumaric acid. (iii) Calcitriol.

3. Biological therapies – (i) Alefacept 15 mg/week IM for 12 weeks. If CD4 count falls < 250 cells/ μ L, it should be discontinued. (ii) Efalizumab 1 mg/kg/wk sc inj. Worsening of psoriasis may occur after discontinuation of therapy or in unresponsive patients during therapy. (iii) Etanercept 50 mg sc twice a week for 12 weeks, followed by maintenance of 50 mg/week. (iv) Infliximab.

Scalp care. (i) Mild case – Tar shampoo (10%) or steroid containing shampoo. (ii) Severe case – Removal of scales and application of keratolytic gel and then covered with occlusive plastic shower cap for several hours or overnight. This will loosen the scales, after which steroid lotion should be applied under a shower cap for the night or without occlusion during the day.

Nail care. (i) Removal of subungual debris and application of corticosteroids under occlusion. (ii) Injection of triamcinolone (0.1 mL of 3 mg/mL) into the nail bed at 2–3 week intervals. The procedure is painful and a ring block can be utilized to minimize pain.

Second-line Therapy for Psoriasis

Indications:

- Topical therapies fail to control the disease
- More extensive disease
- Co-existing psoriatic arthropathy
- Erythrodermic or generalized pustular psoriasis (both associated with a mortality of 5–10%)

Special Groups

Psoriasis in childhood. Topical corticosteroids should be avoided. Phototherapy is effective, but exposure to ultraviolet light is kept to a minimum. Retinoids or cyclosporine are the systemic agents of choice.

Psoriasis in pregnancy. Retinoids are best discontinued in female patients after puberty because of the risk of teratogenicity. Pregnancy should be avoided within 2 years of taking acitretin.

LICHEN PLANUS

It is an inflammatory disorder of the skin and mucous membrane, of unknown origin. The term lichenoid is applied to eruptions that clinically resemble lichen planus, or have a similar histology, in particular a heavy lymphocytic infiltrate immediately under the epidermis, the basal layer of which suffers the most damage. Lichenoid eruptions may be caused by drugs, or may occur as a part of chronic graft-versus-host disease. The term lichen planus is applied to the more common idiopathic form.

Description – Shiny, flat-topped, violaceous, polygonal papules of varying size, clustered around on the wrists

Fig. 42: Lichen planus

(Fig. 42). Irregularly linear or reticulate white striae (Wickham's) are often seen in the papules. The lesions are usually itchy sometimes intensely so, but are occasionally asymptomatic. The inflammation usually subsides within 2 years and is commonly followed by post-inflammatory pigmentation.

Mucosal lichen planus in form of whitish papular lesions, linearly disposed, may crisscross to form a lacy pattern, coalescence of papules may result in plaque formation. It accompanies cutaneous disease in about 50% of patients, and is common alone.

Distribution – Usually flexor areas are more affected. In males the genitals may also be involved in about 10% of patients.

Variants

- Persistent hypertrophic lesions, usually on the lower legs
- Scalp lesions may cause scarring alopecia
- Bullous lichen planus – Blistering tends to occur within typical lesions in lower legs
- Erosive disease may affect the gingiva, vagina and vulvar vestibule (vulvo-vaginal-gingival syndrome of Hewitt and Pelisse). Severe vaginal stenosis may occur.

Treatment – Milder cases may require no treatment. For localized itchy lesions strong topical steroid (e.g. clobetasol propionate).

Systemic therapy – If distressing itch, extensive eruption, destructive nail involvement, or erosive mucosal lesions. Prednisolone 20 mg/day reducing according to response, and cyclosporine 5 mg/kg/day usually for several weeks. The retinoid acitretin produces a slower

response, but is a safer drug when long-term control is required. Dapsone may also be given.

Patients with severe, especially erosive mucosal lichen planus, should be followed up for early detection of carcinoma.

Lichenoid drug eruption – It may be caused by thiazides, antimalarials, gold, NSAIDs, β -blockers and captopril. Clinical picture may be atypical with psoriatic features. Lichen planus of the mouth may be drug-induced, or be a reaction to dental materials.

Graft-versus-host disease. About 10% of patients with allogenic bone marrow transplants develop chronic graft-versus-host disease. The earliest skin manifestations are usually lichenoid.

14. BLISTERING DISORDERS

See Table 23 for the classifications of blistering disorders.

Blistering results from damage to cell-cell or cell-matrix adhesion resulting in accumulation of fluid in the extracellular space. Causes of blistering are given in Table 24.

DIAGNOSIS OF BLISTERING DISEASES

History

- Age of onset (genetic disease usually presents in infancy or childhood)
- Exposure to hazardous chemicals or sunlight
- Previous or current infection
- Drug ingestion
- Duration and course of blistering

Examination

- Mucosal involvement (suggests systemic, possibly immunological disease)
- Evidence of infection (e.g. herpes zoster)
- Morphology of lesions (background erythema, excoriations, scarring, intact blisters or just erosions)
- Distribution (linear – insect bites, buttocks and elbows – dermatitis herpetiformis, dermatomal – herpes zoster)

Laboratory Investigations

If infection is suspected, specimens should be taken for bacteriological and virological culture. In cases with a genetic and/or immunological basis, skin biopsies.

Skin biopsy – An ellipse biopsy taken from the edge of a fresh blister to see the level of the split, a vital feature in diagnosis.

Table 23: Classification of blistering disorders**I. Intraepidermal (Bulla within epidermis)**1. *Subcorneal*

- Bullous impetigo
- Staphylococcal scalded skin syndrome
- Pemphigus foliaceus
- Miliaria crystallina
- Subcorneal pustular dermatosis

2. *Spinous layer*

- Herpes simplex
- Herpes zoster
- Miliaria rubra
- Chicken pox
- Dermatitis

3. *Suprabasal*

- Pemphigus vulgaris
- Pemphigus vegetans

II. Subepidermal (Bulla below epidermis)

- Bullous pemphigus
- Dermatitis herpetiformis
- Toxic epidermal necrolysis
- Epidermolysis bullosa dystrophica

- *Direct immunofluorescence* - Most immunological causes can be defined and the pattern is often diagnostic.
- *Electron microscopy of the skin* may be helpful in distinguishing between junctional and dystrophic epidermolysis bullosa when immunofluorescence testing is inconclusive.
- *Indirect immunofluorescence* of circulating antibodies can be demonstrated in blister fluid or serum. Further information can be obtained about the antibody binding site which may avoid need for electron microscopy.

BULLOUS PEMPHIGOID

Autoimmune disease common in elderly. Two target antigens have been identified - a 230 kD protein (major antigen) located in the dense plaque of the hemidesmosome, and a 180 kD protein (BP 180) which is collagen XVII traversing the plasma membrane and linking to the anchoring filaments.

Description - Typical appearance is of large, tense blisters (Fig. 43) up to 3 cm diameter on an erythematous base. In early stages of the disease a pruritic urticarial rash

Table 24: Causes of blistering*Genetic*

- Epidermolysis bullosa
 - Junctional (recessive)
 - Dystrophic (dominant and recessive)
 - Simplex (dominant)

Physical

- Heat and cold
- Irradiation (e.g. ultraviolet light)
- Contact with hazardous chemicals and irritants
- Friction/rubbing
- Oedema on legs

Inflammatory

- Infections
 - Staphylococcal (e.g. bullous impetigo caused by Staph. aureus, staphylococcal scalded-skin syn.)
 - Streptococcal (including necrotizing fasciitis)
 - Herpes simplex
 - Herpes zoster
 - Hand, foot and mouth disease
 - Fungal
- Eczema
- Erythema multiforme (including Stevens-Johnson syn.)
- Insect bites

Immunological

- Bullous pemphigoid
- Linear IgA disease
- Pemphigus (vulgaris and foliaceus)
- Epidermolysis bullosa
- Dermatitis herpetiformis
- SLE
 - Lichen planus
 - Pemphigoid gestationis
 - Porphyria cutanea tarda

Drug reactions

- Fixed drug eruptions
- Pemphigus
 - Erythema multiforme including Stevens-Johnson syndrome
 - Photosensitive reactions
 - Pemphigoid
 - Toxic epidermal necrolysis

Fig. 43: Tense blisters in bullous pemphigoid

may be the only visible sign. The blisters may be broken as a result of excoriation.

Distribution - Usually starts on the limbs and often spreads to the trunk. Mucous membranes are often involved - oral cavity, anus, vagina and oesophagus.

Cicatricial pemphigoid is a variant of bullous pemphigoid in which mucous membrane involvement only occurs, often with scarring.

Diagnosis - (a) Histology - Split at level of basement membrane with mixed inflammatory infiltrate rich in eosinophils at the base. (b) Direct immunofluorescence of perilesional skin shows a linear band of immunofluorescence with IgG and/or C3 at the basement membrane zone. (c) Serology - Circulating IgG or C3 antibody to the basement membrane is found in 75% of patients.

Treatment - In mild cases, potent topical corticosteroids. Prednisolone 30-60 mg/day in early stages. Cyclosporine is added for its corticosteroid-sparing effect. The disease often remits spontaneously after 2-5 years and treatment can then be withdrawn. Although morbidity is considerable, mortality is low. Dapsone is a useful adjuvant and allows an easy tapering of steroids.

PEMPHIGUS

Autoimmune disease, characterised by acantholysis, induced by deposition of intracellular autoantibodies.

Classifications

The level of split forms the basis of subdivision into:

- Pemphigus vulgaris - Splitting just above the basal layer

- Pemphigus foliaceus - Superficial epidermal split with short-lived blisters.
- Pemphigus vegetans - Split is suprabasal
- Pemphigus erythematosus - Split in granular layer or just below stratum corneum

Clinical Features

Pemphigus vulgaris (a) *Skin lesions* - Development of flaccid, fragile blisters which rupture to form painful erosions. Application of tangential pressure on normal skin in pretibial region gives rise to new bulla (Nikolsky sign) or to existing bulla causes spread of the bulla (bulla spread sign). Site - Scalp, face, flexures and trunk. (b) *Mucosal lesions* mostly in oral mucosa - Painful erosions with shedding of mucosa which looks ragged. Skin and mucosal infections get secondarily infected.

Pemphigus foliaceus - Superficial bullae which soon rupture to form large areas of scaling and crusting. Initial distribution on face and trunk becomes generalized resulting in erythroderma.

Pemphigus vegetans - Heaped up vegetating peripherally spreading lesions. Sites - Groins, axillae, angles of mouth. Mucosa may be involved.

Pemphigus erythematosus - Variant of pemphigus foliaceus but less severe. Dry, hyperkeratotic, scaly lesions on face (malar regions).

Pemphigus variants - (a) Paraneoplastic - Polymorphic skin lesions, painful oral mucosal lesions, associated with lymphoma, thymoma. (b) Drug-induced - Rifampicin, penicillamine, captopril *Cl. Fs.* Like PF or PV.

Investigations and Diagnosis

(a) Tzanck smear from erosion or floor of bulla reveals acantholytic cells. (b) Direct immunofluorescence shows intracellular deposits of IG, giving a fish net appearance. (c) Serology - Presence of IG antibodies with titres correlating with disease activity.

Treatment

1. Specific - (a) Corticosteroids - Prednisolone 1-2 µg/kg body weight per day with gradual tapering or Betamethasone 1-2 mg/kg or IV Dexamethasone for 3 consecutive days every month. (b) Immunosuppressive therapy - as steroid sparing therapy in patients with adverse effects or resistant to steroid. Azathioprine 2-3 mg/kg till suppression, 1 mg/kg as maintenance or Methotrexate 15-25 µg/wk or Cyclophosphamide 50-200 mg/d PO. (c) Other therapies - Mycophenolate mofetil,

high dose or IG IV, plasmapheresis, biologic response modifiers, extracorporeal photochemotherapy.

- Supportive treatment - Antibiotics for cutaneous lesions and anticandidal agents for mucosal lesions. Water and electrolyte balance.

DERMATITIS HERPETIFORMIS

Is primarily a disease of young adults. There is a strong association with HLA B8, DR3 and DQ2. The role of gluten sensitivity is established. There is a close association with coeliac disease.

Description - A vesicular rash typically occurs on an erythematous base and vesicles are often excoriated (Fig. 44). Intense pruritus is a prominent feature and may precede other symptoms.

Sites - Buttocks, extensor aspects of elbows and the knees, and sometimes the scalp and shoulders.

Diagnosis - (a) Histology - Skin biopsy shows subepidermal blister formation with collections of neutrophils, forming microabscesses in the dermal papillae. (b) Direct immunofluorescence of uninvolved skin shows a granular deposit of IgA below the basement membrane zone confined to dermal papillae; this is diagnostic. (c) Serology - Antigliadin and antiendomysial antibodies are often present.

Treatment - Dapsone 50-200 mg/day produces prompt response. 2 weekly monitoring of blood, later monthly. If haemolysis is severe alternative drug (e.g. sulphamethoxypyridazine) can be tried.

Gluten-free diet should be started on all patients, and continued for life, to prevent a relapse, and the risk of lymphoma.

Fig. 44: Dermatitis herpetiformis

PEMPHIGOID GESTATIONIS

Is an uncommon disease associated with pregnancy, or occasionally with trophoblastic tumors.

Clinical features - Initially, urticated plaques appear on the abdomen and rapidly become more widespread with blister formation. Onset is typically in the second trimester. An immediate post-partum flare is common.

Direct fluorescence shows a linear band with IgG at the basement membrane.

Treatment - Oral corticosteroids, which may need to be continued post-partum, but most cases resolve within 2 months of delivery.

EPIDERMOLYSIS BULLOSA

Epidermolysis bullosa is a group of uncommon mechanobullous disorders characterized by blisters and erosions resulting from trivial trauma. There are three principal types, each with a different level of split.

Junctional EB - Subepidermal split through the epidermal site of the basement membrane. It presents at or shortly after birth and may be fatal. The anchoring filaments are abnormal as a result of mutations a6b4 integrin, BP180 or laminin 5 molecules. Nikolsky's sign is absent.

EB simplex - It represents a collection of diseases with a suprabasal split. It presents in early childhood. Blisters occur on knees and elbows initially, and later on hands and lower legs. Responsible mutations are in keratins 5 and 14.

Dystrophic EB - Subepidermal blister below the dermoepidermal junction. Scarring is common and often leads to mutilation of the extremities. It is caused by mutations in collagen VII, the anchoring fibril protein.

Treatment - None effective known. Antenatal diagnosis of the more severe forms can be done through chorionic villous sampling. Genetic counselling to affected families.

Chronic bullous disease of childhood is an immune-mediated blistering disorder. Tense bullae, with development of new blisters around healing bullae (string of pearl appearance). Sites - Around body orifices. *Tr.* - Dapsone/erythromycin, if necessary steroids.

15. URTICARIA AND ANGIO-OEDEMA

Urticaria ('nettle rash, 'hives') presents with short-lived, itchy wheals which may be pale or pink in the centre, surrounded by a red flare. Deeper swellings of the skin or submucosa are termed 'angio-oedema'. They are usually

in the mouth, on the eyelids or on the genitals, but may occur anywhere on the skin.

Pathogenesis - Urticaria is caused by transient leakage of plasma through small blood vessels, usually as a result of release of histamine through skin mast cells. There are many causes of this including type I hypersensitivity reactions. Histamine also causes itch, by stimulating nerve receptors. Other mediators causing vasopermeability include kinins in hereditary angioedema, and leukotrienes in pseudoallergic reactions caused by aspirin and NSAIDs.

PROVOKING CAUSES

Drugs: Penicillin, sulphonamides, aspirin, phenytoin, salicylates, indomethacin, foreign sera, insulin, ACEIs.

Foods: Milk, moong dal, masoor dal, eggs, peas, fish.

Physical causes - Dermographism, pressure urticaria, cold or heat or solar urticaria, cholinergic due to decrease in core body temperature, exercise-induced.

Contact urticaria - Contact with, e.g. onion, nitrogen, mustard.

Inhalants: Pollens, fungi, insecticides, house dust.

Infections and infestations: Chronic septic focus, UTI, virus infection, candida infection, protozoal and helminthic infections.

Food additives: Yeasts, citric acid, azo dyes, benzoic derivatives.

Emotional stress especially in cholinergic urticaria.

General medical disease. Lupus erythematosus, reticuloses, polycythemia, macroglobulinemia, endocrine disorders such as thyrotoxicosis. Premenstrual aggravation of urticaria as a result of progesterone sensitivity.

TYPES OF URTICARIA AND INVESTIGATIONS (SEE TABLE 25)

Ordinary urticaria. Recurrent urticaria is termed 'ordinary' if there is no predominant physical cause or underlying small vessel vasculitis. Attacks may occur daily or less frequently. Wheals (Figs. 45 and 46) generally last 2–24 hours, are often numerous, and may occur on any part of the skin including scalp, palms and soles, where they can be painful rather than itchy. They vary in size from < 1 cm to many centimetres across, and may coalesce. Nonspecific symptoms (lassitude, indigestion) may accompany severe attacks, but wheezing is not a feature. Onset is often abrupt and unexpected, but there is sometimes a history

of preceding viral infection, immunization, eating an unusual food (e.g. fish, fruit, nuts) or drug therapy (e.g. aspirin, penicillin).

Blood tests are negative. Tests for specific IgE (UniCAP immunoassay often termed RAST) may be useful for confirming the cause of allergic urticaria.

Physical urticaria. Physical urticarias are defined by the triggering stimulus:

Immediate dermographism can be elicited by stroking the skin firmly with a blunt instrument.

Cholinergic urticaria by overheating to the point of sweating (sweat glands have cholinergic sympathetic innervation).

Cold urticaria by contact with ice or generalized chilling. Cutaneous mast cells degranulate in response to these stimuli; the mechanism is unclear. Some physical challenge tests are necessary to confirm the diagnosis.

Contact urticaria - (a) *Immunological contact urticaria* involves binding of percutaneous allergen to specific IgE in previously sensitized individuals. Localized whealing occurs within 10 minutes. Atopic patients are susceptible. (b) *Non-immunological contact urticaria* from direct mast cell degranulation or eicosanoid release is probably more common. Preservatives and fragrances in cosmetics may cause stinging, itching, and burning. Food preservatives (e.g. benzoic acid, sorbic acid) and flavourings (e.g. cinnamic aldehyde) may cause contact urticaria around the mouth.

Table 25: Types of urticaria and investigations

Type	Investigations
Ordinary urticarial Acute (<6weeks) Chronic (>6weeks)	Skin-prick test/food RAST* Autologous serum skin test
Physical urticarial Cold/cholinergic/ dermographism Delayed-pressure	Ice/overheating/skin stroking Sustained local pressure
Contact urticaria Immunological Non-immunological	
Urticarial vasculitis	Skin-prick test/RAST Skin-rechallenge
Angio-oedema without wheals Idiopathic C1 inhibitor deficiency Drug-induced (angiotensin-converting enzyme inhibitors, aspirin)	Skin biopsy, serum C3, C4 C1 esterase inhibitor, C4

* Only when indicated by the history

Fig. 45: Urticaria

Fig. 46: Chronic urticaria

Urticarial vasculitis is an uncommon systemic disorder. Patients have small vessel vasculitis caused by immune complex deposition. Skin lesions may be indistinguishable from other forms of urticaria, or may resemble erythema multiforme. They often last 2–3 days and fade with a bruised appearance. They may burn rather than itch. Patients may feel unwell with malaise and arthralgia, and associated renal, pulmonary or neurological disease must be excluded. Skin biopsy shows venulitis, ESR is raised, and some patients are hypocomplementaemic.

Angio-oedema consists of transient episodes of local subcutaneous and dermal oedema. It occurs in ordinary, physical and vasculitic urticaria but may also occur without wheals.

Description – Sudden diffuse, soft, non-tender swellings, which may be like urticaria – pale or erythematous.

Distribution – Common sites are eyelids and lips (Fig. 47). Upper extremities, feet, scrotum, vulva and penis may be involved.

Associated features – Idiopathic angio-oedema is frequently associated with urticaria. Hereditary angio-oedema is a rare autosomal dominant disorder in which patients suffer from symptoms related to subcutaneous and GI angio-oedema. These patients are at risk of sudden death due to laryngeal oedema.

Investigations – are required to exclude hereditary and acquired C_1 esterase inhibitor deficiency. Measurement of C_4 is a useful screening test; it is reduced in both type I hereditary disease (reduced absolute levels of C_1 inhibitor) and the less common type II hereditary disease (normal quantitative C_1 inhibitor on immunochemical assay but reduced function).

Fig. 47: Angioedema

MANAGEMENT

Histamine-mediated urticaria

1. Remove identifiable cause
2. Non-drug therapy
 - Explanation and information
 - Cooling lotions (e.g. calamine, 0.5% menthol in aqueous cream)
 - Avoid aspirin, NSAIDs, codeine, ACEHs
 - Minimize stress, over-eating, alcohol
 - Exclusion diet when indicated by history
3. Pharmacological therapy

First line – All patients

- Non or low-sedating antihistamine (cetirizine or loratadine 10 mg/day)

- If little or no response, add sedating H₁ antihistamine at night
- If little or no response add H₂ antagonist (e.g. ranitidine)

Second line – special indications

- Prednisolone 0.5 mg/kg stat or a tapering regimen over 1–2 weeks (in severe or delayed pressure urticaria) for short-term use
- Adrenaline 0.5–1 mL of 1:1000 Im or SC in severe throat angio-oedema

Third-line – specialist use only

- Immunotherapies – plasmapheresis or IV immunoglobulin, or cyclosporine (if severe refractory autoimmune urticaria)

Immune complex mediated urticaria – Antihistamines are often ineffective in urticarial vasculitis. Corticosteroid-sparing drugs to minimize or replace long-term oral corticosteroid exposure – dapsone 75–150 mg/day, indomethacin 25–50 mg t.d.s., hydroxychloroquine 200–400 mg/day, azathioprine 2–2.5 mg/kg/day, and colchicine 0.5–2 mg/day. Management of chronic urticaria is removal of identifiable cause followed by non-drug therapy or pharmacological therapy.

Hereditary angio-oedema – Recurrent angio-oedema caused by C₁ esterase inhibitor deficiency can often be prevented by prophylactic low-dose anabolic steroids (e.g. stanozolol 2.5–10 mg/day), which increase functional inhibitor levels.

Antifibrinolytic agent tranexamic acid 1–1.5 g b.d. or t.d.s. is used for prophylaxis and treatment of acute episodes. Severe angio-oedema of the mouth or bowel should be treated as early as possible with IV infusion containing 3 vials of freshly reconstituted C₁ esterase inhibitor concentrate or, if this is unavailable, 3 units of fresh frozen plasma. Antihistamines have no effect.

Urticaria pigmentosa is a skin disease in which clinical features are due to a pathological increase in dermal mast cell numbers.

Childhood urticaria pigmentosa presents with number of brownish dermal papules and plaques widely distributed over the body, when rubbed these become urticated (Darier's sign). Pruritus is common and in severe cases wheezing, diarrhoea and syncope. Lesions may become bullous.

Adult urticaria pigmentosa presents with an insidious onset of monomorphic pigmented maculopapular lesions, sometimes with prominent telangiectasia on trunk and limbs. Systemic symptoms include weight loss, bone pain

(osteoporosis or osteosclerosis), abdominal pain (peptic ulcer). Palms and soles are usually spared. Mucous membranes rarely affected. Episodes of flushing may occur after rubbing the skin or following intake of alcohol.

Investigations – Skin biopsies may not be diagnostic unless special tests for mast cells are performed.

Tr. – Avoidance of trigger factors including drugs like morphine and codeine and alcohol. Administration of H₁, H₂ antihistamines is helpful.

16. PRURITUS

Pruritus means 'itch', but the term generalized pruritus is usually applied when no causative primary skin disease can be seen. See Table 26 for the causes of generalized pruritus.

TREATMENT

- Specific treatment depends on the cause, e.g. cholestyramine for cholestatic itch.
- Nonspecific – Sedation, antihistamines and cooling applications, e.g. lacto calamine, bland emollients for dry skin.

LOCALIZED PRURITUS

Lichen simplex – Lichenification is a form of eczema characterized by epidermal hyperplasia and exaggeration of skin markings and results from repeated scratching or rubbing. It commonly complicates other forms of eczema or other causes of itch, but in their absence it is termed lichen simplex. An itch-scratch cycle develops, which can usually be broken by explanation, a strong topical corticosteroid and sometimes occlusive bandaging.

Pruritus ani and pruritus vulvae. The following are common causes, some of which may coexist.

- Simple irritancy due to excessive dampness from obesity, prolonged sitting or poorly absorbent clothing, urinary incontinence, faecal soiling, vaginal discharge, overuse or poor rinsing of soap.
- Local disorders (e.g. piles, infections, worm infestations, warts, occasionally neoplasm). Diabetes predisposes to candidiasis.
- Primary dermatoses include microbial intertrigo, psoriasis, lichen sclerosis.
- Secondary complications like allergic contact dermatitis from medicaments or toiletries, lichenification, and secondary bacterial or candidial infection.

A few patients in whom physical causes have been excluded, may require psychiatric treatment.

Table 26: Causes generalized pruritus**Dermatological causes –**

1. Xerosis (asteatosis, dry skin) – pruritus especially in elderly
2. Physical urticarias
3. Scabies, dermatitis herpetiformis, pediculosis, fibre glass dermatitis, atopic eczema, lichen planus

Systemic causes –

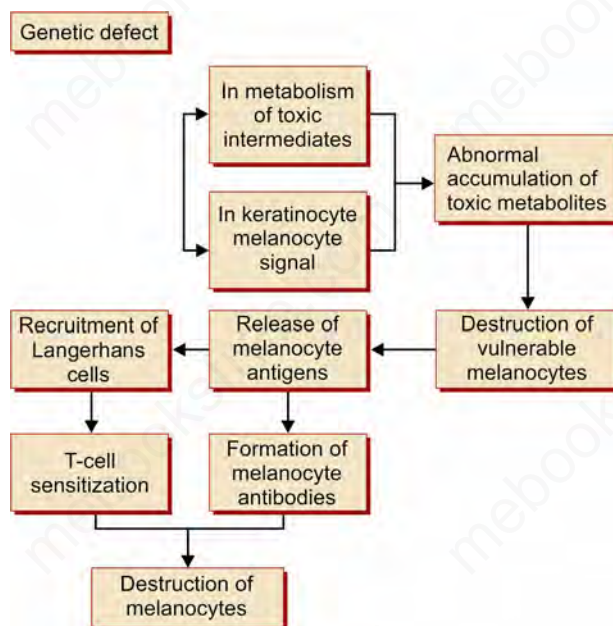

1. Liver disease – Biliary obstruction, primary biliary cirrhosis, chronic liver failure
2. Endocrine disorders – Diabetes mellitus, hyperthyroidism, hypothyroidism, hypoparathyroidism
3. Iron deficiency
4. Polycythemia vera
5. Reticuloses – Hodgkin's disease. In other neoplasms pruritus may be a feature of advanced disease
6. Drugs – Opiate and cocaine abuse, belladonna alkaloids, antidepressants, CNS stimulants, niacinamide, cimetidine, antimalarials, psoralen photochemotherapy
7. Parasitic infestations – Trichinosis, onchocerciasis and schistosomiasis
8. HIV – Severe itch alone or usually associated with identifiable lesions, e.g. itchy folliculitis
9. Autoimmune diseases – SLE, systemic sclerosis, sicca syndrome
10. Neurological disorders – Multiple sclerosis, pre-eruptive herpes zoster, brain tumours, tabes dorsalis
11. Pregnancy
12. Psychological disorders – Delusions (of parasitosis), hypochondriasis, obsessiveness, depression, hysteria
13. Chronic kidney failure
14. Senile pruritus

Other sites

- *Ear* – Fungus infection, chronic otitis media.
- *Eyelids* – Neurodermatitis or contact dermatitis.
- *Nostrils* – Intestinal parasites, brain tumour.

17. DISORDERS OF PIGMENTATION**HYPOMELANOSIS
(HYPOPIGMENTATION)****Genetic/Naevoid Factors**

Vitiligo – It is a pigmentary disorder characterised by circumscribed loss of melanin pigment secondary to melanocyte attrition. It is an acquired, sometimes familial condition, an autoimmune disease in majority. Vitiligo is associated with other autoimmune diseases such as thyroid disease, diabetes mellitus, Addison's disease and pernicious anaemia (Fig. 48).

**Fig. 48:** Mechanism of vitiligo

Pathogenesis – Vitiligo is a complex process involving the melanocytes, epidermal keratinocytes, immune system, and peripheral nervous system (composite hypothesis).

Classification1. *Localized vitiligo*

Focal vitiligo – (a) A single macule or a few macules may be localized to skin or mucosa. (b) Segmental distribution of macules.

2. *Generalized* – (a) Vitiligo vulgaris – Common form of vitiligo with symmetrical distribution over trunk and limbs. (b) Lip-tip vitiligo – Only tips of fingers or with mucosal surfaces like lips (Fig. 49), nipples or palms or penis. (c) Acrofacial vitiligo – Involvement of periorifacial and distal digits. (d) Universal vitiligo – Involvement of most of the body with only a few areas spared (Figs. 50 to 52).

Treatment*Physical Regime*

1. **Photochemotherapy** – (a) Topical application of ointment or lotion on alternate days (to avoid photosensitivity) followed by PUVA exposure to gradually increasing doses (till mild erythema is seen) of sunlight or artificial source of UVA. (b) Systemic PUVA solution 0.8 MOP, 0.6 mg/kg PO on alternate days followed by gradually increasing doses (till erythema) of

Fig. 49: Vitiligo involving lips

Fig. 50: Vitiligo involving face

Fig. 51: Vitiligo involving body

Fig. 52: Vitiligo over hands

sunlight or UVA lamps. Larger dose of UVA is needed here. (c) After exposure to UVA protection of lesions from excessive exposure to sun by using sunscreen like zinc oxide and avoiding peak sunlight.

Result: Slow repigmentation begins in perifollicular area and periphery of lesions and gradually becomes confluent especially on face, neck and hairy region.

Side effects. Phototoxicity results from excessive exposure to sun or UVA. Treatment is to stop and resort to topical or even systemic steroids.

2. **Phototherapy** - Narrow band UVA. **Indications** - Extensive disease, children and in pregnancy, and contraindications to gradually increases doses are given from specialized chambers.

Drug Therapy

1. **Steroids** - (a) Topical for single lesions or few localized lesions. (b) Systemic. (c) Patient cannot be given photo/photochemotherapy. (d) In rapidly progressive vitiligo, together with PUVA solution. (e) Vitiligo unresponsive to psoralens. Prednisolone 0.5 mg/kg body weight or to minimise cumulative effects of the drug 30-40 mg in two consecutive doses, each week (oral minipulse).
2. **Other drugs** - (a) Levamisole may arrest slowly spreading vitiligo. (b) Tacrolimus and pimecrolimus for facial lesions when topical steroid causes side effects. (c) Khellin as adjuvant to photochemotherapy. (d) Placental extract. (e) Depigmenting agents, e.g. monobenzyl ester of hydroquinone.

Surgery – can be used to treat residual vitiligo after medical treatment. Melanocyte transfer, punch grafting, blister grafting, split thickness skin grafting.

Depigmentation – In severe cases that are refractory or cannot be treated for technical or medical reasons, removal of remaining pigment through twice daily application of 20% hydroquinone. Bleached individual however, become more vulnerable to damaging effects of sunlight.

Tattooing – Vitiligo at areas such as lips and fingertips are refractory to above mentioned treatments. These can be masked by tattooing with iron oxide or pigments.

For vitiligo placental extract aqueous solution and alcoholic solution are used locally. Placental extract can also be given parenterally.

3. **Albinism** – Melanocytes are present in the skin in normal numbers but no melanin is produced. Two genetically distinct types exist: tyrosinase-negative (type I) and tyrosinase-positive (type II).
 - a. **Piebaldism** (Partial albinism) is inherited as autosomal dominant disorder. Patient has a white forelock, on central and upper part of forehead. There may be circumscribed and symmetrical areas of hypomelanosis on the trunk, arms and legs. Islands of hyperpigmented macules in the leukodermic patches and in normally coloured is another distinguishing feature. The lesions usually do not change in size or shape.
 - b. **Oculocutaneous albinism** – In the two main types of this disorder, tyrosinase positive and tyrosinase negative, there is a diffuse absence of normal pigmentation of skin, hair, iris and ocular fundi. Patients with this disease are photosensitive, and

epitheliomas may develop in areas of skin exposed to the sun.

4. **Phenylketonuria** – is an inborn error of metabolism in which phenylalanine accumulates and impairs melanin biosynthesis. The skin and hair are fair and there is mental retardation.
5. **Tuberous sclerosis** – Most children will have between 4-100 hypomelanotic macules identified with Wood's lamp.
6. **Achromic naevi** – Here areas of hypomelanosis may be unilateral on any part of the body, or may appear as symmetrical bizarre whorls and streaks in a marble-like pattern. Ectodermal and neurological abnormalities are often present.
7. **Waardenburg syndrome** – manifests as a white forelock and cochlear deafness.

Acquired hypomelanosis:

1. **Endocrine disorders** – Hypopituitarism, Addison's disease, thyroid disease.
2. **Chemical depigmentation** – either occupational or therapeutic, e.g. substituted phenols like hydroquinone or butyl phenol.
3. **Postinflammatory depigmentation and infections** – Areas of hypomelanosis may occur following the resolution of eczema and psoriasis. Also leprosy and syphilis. Scaly hypopigmented macules seen in pityriasis versicolor.
4. **Neoplasms** – A halo of depigmentation may develop around a benign pigmented naevus.
5. **Miscellaneous disorders** – Kwashiorkor and chronic protein deficiency, deficiency of vitamin B₁₂, idiopathic guttate hypomelanosis.

Diff. Diag. of hypopigmented/depigmented patch
See Table 27.

Table 27: Differential diagnosis of hypopigmented patch	
Cause	Clinical features
Vitiligo	Well-defined milky white, nonscaly, variable sized, flat lesion. Hair on lesion of vitiligo may be white. Sometimes depigmented area is separated from normal skin by a thin hyperpigmented rim (trichrome vitiligo)
Leprosy	Sharply demarcated, dry, slightly scaly, concentric anaesthetic patch or reddish hypopigmented patch which may not be anaesthetic. In contrast to vitiligo, anaesthetic patch is never milky white
Tinea versicolor	Scaly, hypopigmented macules. Typical scale is dust-like or furfuraceous. A wood lamp examination may show yellowish fluorescence of affected skin
Pityriasis alba	Most commonly occurs before puberty. Discrete, flat, hypopigmented area with poorly circumscribed or circular or oval outline
Tuberous sclerosis	Small, flat, area with oval or circular outline (Ash-leaf macule). Multiple, small, flesh-coloured papules around nasolabial fold (adenoma sebaceum) appear around puberty (Fig. 53)

Contd...

Contd...

Cause	Clinical features
Post-inflammatory	Hypopigmentation may result from healing of dermal lesions such as tinea corporis, candidiasis or polymorphous light eruption
Halo naevus	Hypopigmented or white lesion which contains a red, brown or black spot in the centre
Piebaldism	Symmetrical, flat, white areas with jagged or geographic borders. Localized areas of hypopigmented hairs (poliosis) may be present
Scleroderma	Drop-like, small, hypopigmented macules around hair follicles (especially face), producing a salt-and-pepper pattern (Fig. 54). Plaques of morphea may be hypopigmented
Incontinentia pigmenti achromicus	Asymmetrical, bizarre whorls or streaks of hypopigmentation in a marbling pattern
Naevus depigmentosus	Birth mark, usually solitary, seen as irregularly shaped, well demarcated, hypopigmented or depigmented patch
Leucoderma	The term includes all depigmented (white) lesions including vitiligo. Causes – (a) Idiopathic (vitiligo). (b) Inflammatory – Lupus vulgaris, discoid lupus erythematosus. (c) Chemicals – Hydroquinone, substituted phenols, adhesives

Fig. 53: Adenoma sebaceum in tuberous sclerosis

Fig. 54: Salt and pepper skin in scleroderma

HYPERPIGMENTATION

I. Genetic/naevoid factors

1. **Brown colour** – Hypermelanotic macules may be seen in patients with –
 - a. *Neurofibromatosis*. – Cafe au lait macules and axillary freckling.
 - b. *Albright's syndrome* – includes polyostotic fibrous dysplasia, endocrine dysfunction and segmental hyper-pigmentation.
 - c. *Multiple lentiginos* in: (i) Peutz-Jegher syndrome – Pigmented macules on and around lips, on buccal mucosa and on hands and feet. Associated intestinal polyposis. (ii) 'Leopard' syndrome – Generalized lentiginosis, cardiac abnormalities (and abnormal ECG), ocular hypertelorism, pulmonary stenosis, abnormal genitalia, retardation of growth and deafness.
2. **Blue or slate-brown colour** –
 - a. *Mongolian blue spot* in sacral region of mongoloid and negroid babies.
 - b. *Naevus of Ota* (Fig. 55) around eye.
 - c. *Naevus of Ito* on scapular areas.
 - d. *Incontinentia pigmenti* (Bloch-Sulzberger type) affects females and presents in the neonatal period with linear group of blisters. These are followed later by characteristic slate-brown streaks and whorls of hyperpigmentation. Dental and ocular defects occur.

Fig. 55: Nevus of OTA

Fig. 56: Melasma

II. Acquired hyperpigmentation

1. **Pregnancy** - A blotchy hyperpigmentation of the face (melasma or chloasma) affects the cheeks, forehead, nose and chin (Fig. 56). There is darkening of nipples, abdomen and anogenital areas. Similar pigmentation may be seen in women on contraceptive pill. In some women, it can be idiopathic. Idiopathic melasma may also occur in men.
2. **Endocrine disorders** - Cushing's syndrome, Addison's disease. Increased pigmentation of Addisonian type may also occur in ectopic adrenocorticotropin syndrome in patients with oat cell carcinoma of bronchus.
3. **Metabolic disorders** - (a) Liver disease, e.g. hemochromatosis and primary biliary cirrhosis. (b) Porphyria. (c) Chronic kidney failure.
4. **Postinflammatory hypermelanosis** - (a) Resolution of lesions of eczema, lichen planus, lupus erythematosus. (b) Scleroderma. (c) Phytophotodermatitis - Pigmentary reaction of the skin to light, potentiated by psoralens in plants. (d) Berloque dermatitis due to perfumes that contain psoralens. (e) Erythema dyschromicum perstans.
5. **Drugs** - (a) Psoralens. (b) Fixed drug eruptions. (c) Arsenic ('raindrop' appearance). (d) Minocycline. (e) Chlorpromazine and other related phenothiazines - slate grey or purple discolouration of skin. (f) Gold and silver occasionally.
6. **Tumours** - (a) Acanthosis nigricans (Fig. 57) is characterised by thickening and hyperpigmenta-

Fig. 57: Acanthosis nigricans

tion of the skin giving it a typically velvety appearance, often associated with internal malignancy. (b) Metastatic melanoma may produce diffuse slate-blue colour. (c) Mastocytosis.

7. **Nutritional** - Pellagra, protein energy malnutrition.
8. **Familial periorbital hyperpigmentation.**
9. **Becker's naevus** affecting young adult males. Pigmented asymptomatic, irregular well demarcated hypertrichotic macule (Fig. 58).
10. **Freckles** - Small, circumscribed pale brown macules that appear in sun exposed areas.
11. **Post-infective** - in malaria, kala-azar.

Fig. 58: Becker's nevus

18. DISORDERS OF SWEAT GLANDS

Hyperhidrosis is excessive sweating.

CAUSES

Generalized hyperhidrosis

1. Environmental exposure to heat, exercise.
2. Systemic disorders.
 - Infections, e.g. malaria, tuberculosis (night sweats)
 - Cardiovascular, e.g. shock, CHF, endocarditis
 - Neurological, e.g. Parkinsonism.
3. Endocrine, e.g. hyperthyroidism, diabetes mellitus, Cushing's syndrome, menopause, pheochromocytoma.
4. Neoplasms: Lymphoma, carcinoid syndrome, insulinoma, pheochromocytoma.
5. Drugs and poisons: Antipyretics, emetics, insulin, antidepressants (e.g. fluoxetine), prostigmine. Poisoning with mercury, arsenic, insecticides and herbicides.
6. Nutritional and metabolic disorders: Diabetes mellitus, hypoglycemia, porphyria, obesity, gout, rickets, infantile scurvy, alcoholism, drug withdrawal in drug addicts, pregnancy, menopause.
7. During anxiety, pain and motion sickness or vertigo.

Localized hyperhidrosis or hyperhidrosis of a relatively small area

1. Idiopathic unilateral circumscribed hyperhidrosis
2. Gustatory hyperhidrosis
 - Physiological

- Pathological: Associated with encephalitis, diabetic neuropathies, Pancoast's syndrome, parotitis or parotid abscess, herpes zoster of preauricular area
3. Emotional: Palms, soles, axillae
 4. Associated with glomus tumour, POEMS syndrome, burning feet syndrome, pachydermoperiostosis, pretibial myxoedema, vitiligo, nail-patella syndrome, palmo-plantar keratoderma, RA, Raynaud's disease.
 5. Brain tumour
 6. Injury to spinal cord or nerve

TREATMENT

Systemic - Propantheline bromide 15 mg t.d.s. may be used to treat volar hyperhidrosis. Sedatives and tranquilizers in emotionally labile individuals. In tense and anxious individual psychotherapy and biofeedback.

Topical - is useful for volar axillary forms. For the feet 1% formaldehyde or 10% glutaraldehyde act by blocking sweat pores temporarily. (a) *Aluminium chloride hexahydrate* in anhydrous ethyl alcohol applied at bed time. (b) *Iontophoresis* - Introduction by means of an electric current of ions of soluble salts into tissues of the body for therapeutic purpose. Agents used are tap water, or with anticholinergic drugs, mainly for palmo-plantar hyperhidrosis. (c) *Intradermal botulinum toxin* - Type A (BTX-A) is safe and effective for repeated treatment of axillary hyperhidrosis.

Surgical treatment for axillary hyperhidrosis consists of excision of a small area in the axilla where sweat glands are, maximally located. Cervical sympathectomy is tried as a last resort.

HYPHIDROSIS AND ANHIDROSIS

Causes

Generalized hypohidrosis

- I. *Interference with nervous control of sweating*
 1. Brain: Hyperthermia, organic lesions in cortex, hypothalamus, pons and medulla
 2. Spinal cord: Syringomyelia, pansection of cord, tabes
 3. Sympathetic ganglia: Sympathectomy, ganglion blocking drugs
 4. Postganglionic fibers: Congenital insensitivity to pain with anhidrosis, diabetic neuropathy, G-B syndrome, leprosy, alcoholic neuropathy, amyloidosis, gout, Fabry's disease
 5. Anticholinergic drugs

- II. *Congenital absence or paucity of sweat glands*: Anhidrotic ectodermal dysplasia, congenital ichthyosiform erythroderma
- III. *Atrophy or damage of sweat glands*: Alopecia areata, systemic sclerosis, systemic poisoning (e.g. barbiturates, diazepam)
- IV. *Occlusion of pores*: Exfoliative dermatitis, necrosis, and ichthyosis, seborrhoeic dermatitis, tropical anhidrotic asthenia.
- V. *Miscellaneous*: Addison's disease, hypothyroidism, uraemia, liver cirrhosis, Sjogren's syndrome, dehydration

Localized Hypohidrosis

- I. *Obstruction of duct or pores*: Miliaria, pompholyx, eczemas, papulosquamous eruptions.
- II. *Damage to sweat glands*: Inflammation, trauma, tumors, irradiation scars and scleroderma
- III. *Congenital absence of sweat glands*: Anhidrotic ectodermal dysplasia
- IV. *Local denervation*: Leprosy
- V. *Miscellaneous*: Sjogren's syndrome, local radiant heat or pressure
Tr. - Cool surrounding. Avoidance of clothes made of synthetic fibres. For poral occlusion, skin moisturizers.

SWEAT RETENTION SYNDROMES

Miliaria refers to a group of disorders in which there is obstruction to the outflow of sweat through the sweat duct. Types of miliaria:

1. *Miliaria crystallina* (Sudamina) - Discrete or confluent, transparent, thin walled vesicles resembling dew drops, occur on normal skin, often in crops. Lesions are asymptomatic and commonly found in intertriginous areas such as axilla. They soon rupture followed by brawny, superficial desquamation.
2. *Miliaria rubra* (prickly heat) - Small, discrete, erythematous papules or papulovesicles often formed in sheets. Common sites are the neck, flexures and the trunk, particularly under clothing. At times forehead and scalp margins are affected. A pricking or stinging sensation is common and sometimes pruritus.
3. *Miliaria profunda* - Pale, firm papules on trunk and limbs, with insignificant erythema or pruritus.

Treatment - Cool environment, Avoidance of exercise, and tight clothing. Emollients like lanolin and prickly heat powders. Systemic antibiotics if secondary bacterial infection.

19. SKIN MANIFESTATIONS OF SYSTEMIC DISEASE

LUPUS ERYTHEMATOSUS

Lupus erythematosus is an autoimmune connective tissue disorder with clinical manifestations ranging from primary cutaneous disorder (discoid LE) to a multisystem involvement with constitutional symptoms (systemic LE). The scales are adherent and the under surface of the scale, if removed shows sharp projections which are keratin plugs that have extended into dilated pilosebaceous openings (carpet track sign, cat's tongue). The plaques expand peripherally with a reversed margin and central depigmentation and atrophy (Fig. 59).

Chronic discoid lupus erythematosus. Lesions comprise well-defined, scaly plaques in which follicular plugging occurs. Chronic lesions show atrophy or scarring, associated with hypo or hyperpigmentation.

Common sites are the face, scalp, forearms and hands. Diagnosis is confirmed histologically, serology is usually negative. *Tr.* - Potent or very potent topical corticosteroid, sun avoidance and the antimalarials hydroxychloroquine and mepacrine. Occasionally systemic corticosteroids, oral gold, dapsone, cyclosporine or methotrexate is used.

Subacute cutaneous lupus erythematosus. Erythematous scaly eruption (which is sometimes annular) on sun-exposed sites (Figs. 60 and 61). Arthritis is a common feature. *Diagnosis*: Skin biopsy and serology. Most patients have antibodies to the extractable nuclear antigen Ro or La. *Tr.* - Topical corticosteroids, sun screen and hydroxyquinolone.

Fig. 59: Discoid lupus erythematosus

Fig. 60: Subacute cutaneous lupus erythematosus

Fig. 61: Subacute cutaneous lupus erythematosus

Fig. 62: Malar rash in SLE

Generalized lupus erythematosus (SLE). Typical butterfly rash is seen in about 50% of patients (Fig. 62). They often have nail fold telangiectasia/infarcts, and the rash on the fingers usually affects the interphalangeal skin.

Dermatomyositis usually presents with an eruption affecting the face, neck, shoulders ('shawl sign'), elbows, forearms and hands. The rash tends to be aggravated by sunlight. Pathognomonic features are a violaceous periorbital eruption and scaly eruption over the knuckles (Gottron's papules). *Diagnosis:* Skin biopsy, muscle enzymes, muscle biopsy. Patients with myositis may exhibit the Jo-1 antibody. *Tr.* - Systemic corticosteroids with second-line agents such as methotrexate, cyclophosphamide, etc.

Scleroderma can be subdivided into morphea (localized to the skin) and systemic sclerosis.

MORPHEA

Localized morphea can affect at any age, and female:male ratio is 3:1. Typical lesion is a purple/mauve area of skin. Older lesions become waxy centrally with a lilac coloured edge. Lesions may become hyperpigmented as they resolve, and this can sometimes be the presenting feature. Linear morphea is uncommon. Lesions usually unilateral on the limbs are often cutaneous, but underlying muscle and bone may be involved.

Frontoparietal morphea usually presents as an indurated area on forehead that may spread into the scalp (with associated hair loss) or on to the face.

Generalized morphea is a rare condition in which patients exhibit induration of trunk and proximal limbs. It is sometimes associated with systemic involvement. Serology (antinuclear antibodies and Scl-70) is usually negative. *Tr.* - Topical corticosteroids may help localized lesions. Systemic corticosteroid, penicillamine, interferon, calcitriol and methotrexate should be used with caution.

Systemic sclerosis usually presents with swelling of the fingers, progressing to typical sclerotic bound-down appearance (Fig. 63), with nail fold infarcts/telangiectasia. Furrowing of the perioral skin with restriction of mouth opening is a characteristic sign.

SARCOIDOSIS

Of patients with systemic disease, 20-30% have skin lesions, but cutaneous sarcoid may present without evidence of systemic involvement. Classically lesions of sarcoid have a violaceous brawny hue and may show 'apple jelly nodules' (granulomata) on compression with a glass

Fig. 63: Hide-bound skin of hands in systemic sclerosis

slide (diascopy). Lesions of sarcoid do not undergo necrosis, or it is minimal. Most typical lesions are:

Erythema nodosum is most commonly associated with 'benign sarcoid' (bilateral hilar lymphadenopathy and a tendency to spontaneous resolution). Lesions present as painful, red, round nodules of 1–5 cm in diameter on the shins which settle over 2–3 weeks with bed rest and NSAIDs.

Lupus pernio is a pathognomonic change of sarcoid. It presents as violaceous, infiltrated plaques, usually over the nose, ears and nail beds may also be affected. There is usually coexistent chronic fibrotic sarcoid of upper respiratory tract that responds poorly to treatment. Papules, nodules and plaques are seen with general skin involvement. Lesions can be itchy. As the lesions involute, hyperpigmentation remains.

Scar sarcoid. Sarcoid is one of the few conditions that appear in scars (Koebner phenomenon). Its development may signify an exacerbation of systemic disease.

DIABETES

Diabetic dermopathy is the most common dermatosis. It presents as oval, dull-red papules of 0.5–1 cm in diameter that gradually develop to leave a brown atrophic scar. Usual site is the shins. Lesions are thought to be caused by vascular disease.

Necrobiosis lipoidica presents as erythematous plaques on the shins that become yellow and waxy centrally with surface telangiectasia. Only a small proportion of diabetics develop necrobiosis lipoidica but its presents is a strong marker for the disease.

Fig. 64: Xanthomas

Other skin conditions

- Disseminated granuloma annulare
- Cutaneous infection
- Diabetic bullae
- Acanthosis nigricans (occurs with insulin resistance)
- Cobbled skin over knuckles and finger pulps (finger pebbles)
- Eruptive xanthomata (high serum triglycerides) (Fig. 64)
- Necrolytic migratory erythema with rash (rare)
- Cutaneous skin allergy to hypoglycaemic agents and insulin reactions
- Diabetic foot and diabetic wet gangrene.

MISCELLANEOUS CUTANEOUS SIGNS OF SYSTEMIC DISEASE

Pretibial myxoedema. Waxy plaques on shins with prominent hair follicles ('peau d'orange' appearance). Localized hypertrichosis may occur. It is most commonly associated with Grave's disease. *Tr.* – Topical corticosteroids and octreotide.

Pyoderma gangrenosum. Violaceous nodules, which later ulcerate to produce an ulcer with an overhanging, violaceous edge (Fig. 65). The lesions heal leaving an atrophic/cribriform scar. Underlying causes include inflammatory bowel disease, liver disease and various haematological disorders. *Tr.* – Systemic corticosteroids, cyclosporine and minocycline. Dapsone can also be used.

Acanthosis nigricans has been mentioned earlier.

Fig. 65: Pyoderma gangrenosum

Principal types:

- Hereditary benign (autosomal dominant and not associated with endocrine abnormalities).
- Benign (associated with various syndromes in which relative insulin resistance occurs).
- Pseudo (a reversible complication of obesity)
- Malignant (usually secondary to adenocarcinoma)
- Naevoid (usually isolated and localized, and not associated with endocrine abnormalities)
- Severe involvement of palms, mucous membranes or mucocutaneous junctions suggests possibility of underlying malignancy.
- Drug-induced. Drugs that cause acanthosis nigricans such as nicotinic acid, corticosteroids and oral contraceptives.

Tr. - of cause. Locally mild keratolytics like salicylic acid or retinoic acid cream.

Autoimmune disorders (see Chapter 16).

20. GENETIC SKIN DISORDERS

Disorders of keratinization - Keratins are the major structural proteins of the epidermis, and are divided into type I (acidic) and type II (basic). Each is the product of a single gene. Keratin gene expression varies from region to region of the skin, and also between various layers of the epidermis. These explain the variety of clinical manifestations that can follow mutations of keratin genes.

Epidermolysis bullosa simplex and epidermolytic hyperkeratosis. In the former minor friction damages a weakened epidermis and superficial blisters form easily.

In epidermolytic hyperkeratosis blistering is a feature in early childhood, but is superseded later by widespread hyperkeratosis.

Palmoplantar keratoderma. Mutations in the keratin genes expressed in palms and soles are responsible for some of the inherited patterns.

Other disorders of keratinization - (a) *White sponge naevus* of the mucosa. (b) *Pachyonychia congenita* - Grossly thickened nails associated with cutaneous hyperkeratosis. (c) *Monilethrix* - Hairs have a curious beaded appearance. (d) *Ichthyosis* - Fish-like appearance of skin. Collagen abnormalities

Dystrophic epidermolysis bullosa. There is easy blistering in response to friction due to weak anchoring fibrils.

Ehlers-Danlos syndrome - Variable degree of joint hypermobility, skin hyperelasticity, poor wound healing and vascular fragility. Mutations occur in a gene encoding lysyl hydroxylase, an enzyme important in the formation of hydroxylysine in collagens.

Disorders of pigment. Neural crest cells migrate out into the skin to become melanocytes. Some genetic pigment disorders are caused by a failure in this migration, others are caused by abnormal pigment production.

Piebaldism. Patchy depigmentation, white forelock, triangle of white skin in the forehead, and a diamond-shaped area on front of the trunk. Piebaldism is inherited as an autosomal dominant trait and is caused by mutations in the *kit* gene on the long arm of chromosome 14. The *kit* gene encodes a growth factor receptor on certain cells; cells without the receptor fail to respond to normal signals for migration.

Waardenburg syndrome manifests as a white forelock and cochlear deafness. The gene responsible plays an important role in migration of neural crest derivatives.

Albinism. Melanocytes are present in the skin in normal numbers, but little or no melanin is produced. Two genetically distinct types exist: tyrosinase-negative (type I) and tyrosinase-positive (type II). Therefore, children with two albino parents may inherit complementary genes and have normal pigmentation.

COMMON INFLAMMATORY DISORDERS

Psoriasis has a strong genetic component; it sometimes occurs in several generations of the same family and is linked to certain HLA types, notably HLA-CW6 and HLA-DR7. The disorder appears to be polygenic, but an alternative explanation is that psoriasis is not a single disease. For

example, flexural, guttate and pustular variants could have different genetic causes.

Atopic eczema has a complex genetic background.

21. CUTANEOUS ANTHRAX

The word anthrax literally means 'Coal' in Greek. There is a skin lesion of painless black eschar as dark as coal.

Cutaneous anthrax is due to direct contact with contaminated meat, carcasses, hair, hides, wool or bone.

Cl Fs. Cutaneous anthrax accounts for majority of all anthrax infections. Most of the lesions are seen on exposed areas such as face, neck, arms or hands. It usually begins as a painless, itchy papule within 3 to 4 days of inoculation and progresses rapidly into serous or serosanguinous vesicles, which ulcerate with a central black eschar surrounded by a group of vesicles, with marked perilesional oedema, symptoms of toxæmia can occur. The lesion heals within one to three weeks with scarring. Regional lymphadenopathy of submandibular, preauricular and axillary areas and even groins is common.

Diagnosis: A smear from the ulcer shows presence of large, brick-shaped Gram +ve bacilli.

Tr. To avoid bacteraemia, treatment with Penicillin G is advisable.

22. SKIN CANCER

Cancers can arise from any structure in the skin (Table 28).

Malignant melanoma arises from melanocytes in the epidermis.

Aetiology - There is a strong association with exposure to ultraviolet radiation, particularly intense, burning exposure on sunny days. Other risk factors include a first-degree relative with history of malignant melanoma, personal history of malignant melanoma and fair skin type,

Table 28: Derivation of malignant skin tumors

Cell of origin	Malignancy
Melanocyte	Malignant melanoma
Epidermal germ cells	Basal cell carcinoma
Epidermal keratinocytes	Squamous cell carcinoma
Endothelial cells	Angiosarcoma
Fibroblasts	Dermatofibrosarcoma
Sweat-duct	Microcystic adnexal
Keratinocytes	Carcinoma

large congenital melanocytic naevi, or dysplastic naevus syndrome.

Clinical features. Most common site is lower limbs in women and the back in men. Melanoma can also occur in the eye, juxta cutaneous mucous membrane such as oral cavity, anorectal and vaginal areas. Clinical appearance can vary with type and site of tumour.

Superficial spreading and nodular melanoma. Lesions are asymmetrical with irregular border, contain more than one colour and may be inflamed or crusted.

Lentigo maligna and lentigo maligna melanoma arises on sun-exposed parts of the face in elderly patients. It resembles a large irregular freckle and tends to grow slowly. Malignant transformation into an invasive lentigo maligna melanoma can occur at any time.

Acute lentiginous melanoma occurs on the non-hair-bearing skin of palms and soles, and under the nails (sub-ungual melanoma).

Amelanotic melanoma is often mistaken for squamous cell carcinoma or pyogenic granuloma.

Management. Surgical excision may be curative in thin lesions. Intermediate and thick lesions need lymph node biopsy, further surgery and adjuvant therapy.

Basal cell carcinoma (rodent ulcer) is a common malignancy and is believed to arise from the undifferentiated germ cells of the epidermis. It is locally destructive, but almost never metastasizes.

Aetiology. Sun exposure is the most important factor. Others include exposure to ionizing radiation, arsenic ingestion and rarely, genetic predisposition.

Clinical features. The lesions most commonly occur on exposed parts of face, ears, scalp, shoulders and back, with a particular predilection for the nose (Fig. 66). Clinical appearance can vary according to the site and type of tumour.

Nodulocystic basal cell carcinoma develops as a small translucent, pearly nodule, often with surface telangiectasia. As the lesion enlarges, it often ulcerates to leave an adherent crust and a rolled edge.

Superficial basal cell carcinoma - develops as a pink, scaly plaque that enlarges slowly. In contrast to other forms of basal cell carcinoma, it is commonly found on the trunk and can be confused with patches of eczema, psoriasis or Bowen's disease. If examined in good light, the typical rolled edge and telangiectasis can be seen.

Sclerosing (morphoeic) basal cell carcinoma develops as a slowly expanding, white scar-like plaque with a poorly defined edge, and is therefore difficult to diagnose.

Fig. 66: Pigmented basal cell carcinoma

Management - Aim of treatment is to excise or destroy the entire tumour. Excision is the treatment of choice, though many other techniques (including curettage and cautery, cryotherapy, radiotherapy and micrographic surgery) can be successful.

Squamous cell carcinoma. The spectrum ranges from relatively benign actinic keratosis, through low-grade intra-epidermal carcinoma to invasive squamous cell carcinoma with the potential to metastasize.

Aetiology - The carcinoma usually develops in an area of skin damaged by chronic ultraviolet irradiation. Other factors are chronic ulceration and scarring, exposure to ionizing radiation, contact with industrial carcinogens (e.g. tars, mineral oils), immunosuppression (transplant recipients) and human papillomavirus infection.

Clinical features - Common sites are dorsum of hand, forearm, scalp and lower lip. The lesion begins as a small, crusted papule or plaque which becomes more indurated and nodular and may subsequently ulcerate. Squamous cell carcinoma can also arise in chronic wounds, scars and leg ulcers (Fig. 67). Unexplained deterioration raises possibility of the disease (Marjolin's ulcer).

Management. Surgical excision, radiotherapy can be useful. Cryosurgery and curettage and cautery for early lesions.

Keratoacanthoma is a very rapidly growing tumour which typically begins as a small papule on a sun-exposed site; this grows to form a larger, symmetrical tumour. Untreated lesion resolves spontaneously, but often leaves unsightly scars.

Bowen's disease is squamous cell carcinoma *in situ* (confined to epidermis hair follicles). These low-grade,

Fig. 67: Squamous cell carcinoma

slow growing lesions seldom progress to invasive squamous cell carcinoma.

Clinical features. A disease of the elderly, it commonly occurs on lower leg (particularly in women), face and neck, as asymptomatic, slowly enlarging, well-demarcated, erythematous scaly plaques.

Management - Good response to topical therapy (5-fluorouracil) and superficial destructive modalities like cautery, curettage, cryotherapy and photodynamic therapy.

Actinic keratosis - presents as small, superficial, scaly lesions in sun-exposed sites. They are relatively benign with a low malignant potential. Treatment is usually reserved for larger, progressive or symptomatic lesions. Actinic keratoses can resolve spontaneously if the involved area is protected from ultraviolet irradiation.

23. BENIGN SKIN TUMORS

Benign skin tumors can arise from any part of the skin (Table 29).

Melanocytic naevi (moles) generally start to appear at puberty and early adult life. A melanocytic naevus often evolves through three stages, from flat, dark, evenly pigmented junctional naevus to a raised, pigmented compound naevus, to a more compound naevus which is flesh-coloured. Some naevi develop a depigmented halo followed by involution of the naevus and repigmentation of the halo (halo naevus).

Atypical melanocytic naevi are so-called because of their irregular outline and large size. Patients with large number

Table 29: Derivation of benign skin tumours

Part of skin	Benign skin tumour
Melanocytes	Junctional melanocytic naevus, compound melanocytic naevus, intradermal melanocytic naevus, halo naevus, atypical melanocytic naevus (Fig. 68)
Epidermal keratinocytes	Basal cell papilloma (seborrhoeic keratosis), solar keratosis
Hair follicles	Epidermoid cyst ('pilar cyst')
Fibroblasts in dermis	Dermatofibroma
Blood vessels	Campbell de Morgan spots, spider naevi, pyogenic granuloma

of such naevi may have atypical mole syndrome which is associated with an increased risk of malignant melanoma. *Mn* - Most benign melanocytic naevi do not require excision unless there is doubt about a possible diagnosis of malignant melanoma.

Seborrhoeic keratosis (basal cell papilloma) are common lesions, usually pigmented, and start to appear in the fifth decade in both sexes. The lesions are most common on the trunk and face. Typical lesion resembles a greasy, crusty plaque that is adherent to the skin surface. Many are itchy and get inflamed when scratched. Presence of plugged follicular orifices seen on the surface with a hand lens is a useful diagnostic clue.

Management - Curettage and cauterization or liquid nitrogen cryotherapy can be used to remove symptomatic or disfiguring lesions.

Epidermoid cysts are common on the scalp, neck, chest and back, particularly in young adults. They comprise an epidermoid wall surrounding a core containing keratin and its breakdown products. The cyst is situated in the dermis; the overlying skin is usually normal. Epidermoid cysts are usually asymptomatic, but can become inflamed.

Management - Non-inflamed cysts can be excised under local anaesthesia.

Dermatofibromas (histiocytomas) are common, particularly on the lower limbs of women. They are thought to be an abnormal response to insect bite, representing a proliferation of fibroblasts within the dermis. They present as a persistent, firm, hard nodule that is often itchy.

Management - Excision can be done for cosmetic reasons.

**Fig. 68:** Congenital melanocytic nevus

Pyogenic granulomas can occur at any age and are typically rapidly enlarging, bright red, juicy lesions that bleed easily. They are most commonly seen on the extremities, and there may be a history of minor penetrating injury earlier.

Management - These lesions are ideally suited for curettage and cauterization, but often bleed profusely during the procedure.

24. SKIN PROBLEMS IN TRANSPLANT PATIENTS

INFECTIOUS DISEASES

Viral infections - are generally more prevalent and severe in immunocompromised patients. In renal transplant recipients, this is particularly relevant for human papilloma virus (HPV) associated anogenital cancer and non-Hodgkin's lymphoma, which is associated with EBV infections (simplex and zoster) are a common complication of organ transplantation.

Human herpes virus (HHV8) is now known to be the cause of Kaposi's sarcoma. The condition is most frequent in transplant recipients with high endemic HHV8. It typically presents with violaceous or hyperkeratotic nodules.

Cytomegalovirus (CMV): Cutaneous manifestations are nonspecific. Diagnosis depends on histological findings.

EBV infection is common. Complications include oral hairy leukoplakia and lymphoproliferative disorders.

Bacterial and fungal infections include cellulitis, onychomycosis and other tinea infections.

Skin cancer is one of the most common complications of organ transplantation especially cutaneous squamous cell carcinoma and malignant melanoma.

25. FEVER WITH RASHES

I. Acute illnesses of short duration

1. Exanthema – Measles, rubella, varicella, typhoid, generalized vaccinia, Kaposi's varicelliform eruption.

Kaposi's varicelliform eruption may manifest as either eczema herpeticum (HIV-1 virus) or eczema vaccinatum (vaccinia virus). Both are complications of atopic dermatitis. Eczema herpeticum is sometimes fatal complication of atopic eczema. Manifested by sudden widespread papulovesicular eruption, often umbilicated, chiefly on areas already affected by atopic eczema with fever and regional lymphadenopathy.

2. Pyogenic – Erysipelas
3. Allergic rashes – Acute allergy – Drug rash, serum sickness, Hensch-Schonlein purpura.
4. Herpes zoster.
5. Rheumatic fever (Erythema marginatum).
6. Infectious mononucleosis – Rash during first week.

II. Subacute or chronic illnesses of long duration

1. Systemic lupus erythematosus.
2. Tuberculosis of skin – Miliary TB, papulonecrotic tuberculide.
3. Erythema nodosum.
4. Lepra reaction.
5. Secondary syphilis.
6. Polyarteritis nodosa.
7. Panniculitis – Commonest form is the nodular, non-suppurative panniculitis characterized by nodules and plaques of a dusky colour with underlying hard, sclerotic, easily movable masses with relapsing fever and recurrent constitutional symptoms.

III. Rashes or cutaneous diseases complicated by fever

1. Acute dissemination or secondary infection.
2. Pemphigus – Secondary infection.
3. Exfoliative dermatitis – Secondary infection.
4. Scleroderma with secondary infection.

Fig. 69: Borderline tuberculoid leprosy with type 1 reaction

5. Leprosy – Lepra reaction (Fig. 69).
6. Papulonecrotic tuberculides.

Addendum (Table 30)

Skin reactions in systemic disease – (Reaction-wise)

1. *Urticaria* – can occur following systemic medication, with infections, e.g. viral hepatitis, with lupus erythematosus, with systemic malignancy.
2. *Erythema multiforme* – Mucocutaneous herpes simplex infection (esp. if recurrent), drug hypersensitivity, infection (esp. mycoplasma pneumoniae and Strepto.), tuberculosis.
3. *Erythema nodosum* –
 - Drugs (sulphonamides, tetracycline, oral contraceptives).
 - Inflammatory bowel disease.
 - Rheumatic disease (including Behcet's).
 - Tuberculosis.
 - Leprosy.
 - Toxoplasmosis.
4. *Generalized pruritus* (Refer).
5. *Erythroderma* – Malignancy (particularly lymphoma).
6. *Purpura* – See blood diseases.
7. *Vasculitis* – Drug hypersensitivity, bacterial sepsis or endocarditis, meningococemia, rickettsial infections, collagen vascular disease, inflammatory bowel disease, chronic active hepatitis. Hensch-Schonlein purpura in children. Lymphatic leukaemia, Hodgkin's disease (Fig. 70).

Table 30: Cutaneous drug reactions

Toxic erythema	
Penicillins/Cephalo- sporins/Ampicillin	Carbamazepine
Gentamicin	Nalidixic acid
Sulphonamides (including thiazide diuretics)	Phenylbutazone and other pyrazolones
	Phenytoin
Urticaria	
Salicylates (Aspirin)	Pollen vaccines/vaccines containing egg proteins
Penicillins	
Sulphonamides	Polypeptide hormones
Animal sera	Hydantoin
Phenylbutazone	Toxoids
Yellow dye tartrazine (present in capsule)	Cephalosporins
Morphine, codeine	Phenytoin
	Radiographic contrast media
Fixed drug eruption	
Phenolphthalein	Benzodiazepines
Barbiturates	Paracetamol
Tetracyclines	Quinine
Sulphonamides	Acetylsalicylic acid
Phenylbutazone	Dapsone
Chlordiazepoxide	
Ecematous reactions (Other than contact dermatitis)	
Tetracyclines	Isoniazid
Diphenhydramine	Neomycin
Streptomycin	Hydroxyquinolines
Aminophylline	Topical para-amino products present in dyes, sun creams, benzocaine.
Fucidin	
Paraben (preservative in medicines) sensitivity	Tolbutamide, chlorpropamide.
Erythema multiforme (including toxic epidermal necrolysis and Stevens-Johnson syndrome)	
Sulphonamides (and co-trimoxazole)	Carbamazepine
Phenylbutazone	Organic arsenicals
Barbiturates	Rifampicin
Penicillins	Hydantoin derivatives

Contd...

Photosensitivity	
Tetracyclines (esp. chlortetracycline)	5 Fluoro-uracil. Nalidixic acid
Phenothiazines (esp. chlorpromazine)	Griseofulvin Amiodarone
Sulphonamides (esp. co-trimoxazole)	
Frusemide	
NSAIDs including piroxicam	
Pigmentation	
Minocycline	Gold/silver (Blue/grey on light-exposed skin)
Heavy metals	
Carotene	Phenothiazines (bluish esp. on face)
Amiodarone	
Oral contraceptives (Melasma)	Clofazimine (red, brown) Phenformin (brown on light exposed skin)
Atropine	
Pilocarpine	Lead poisoning (grey)
Antimalarials (Diffuse grey /brown)	Long-term application of topical hydroquinone (slate grey to blue-black)
	Cytotoxic drugs – Busulphan, Bleomycin, Cyclophosphamide (brown)

**Fig. 70:** Leucocytoclastic vasculitis

Contd...

8. *Pyoderma gangrenosum* - Inflammatory bowel disease, rheumatoid arthritis.
9. *Ichthyosis* (Acquired) - Hodgkin's disease, sarcoidosis, hypothyroidism, internal malignancy, drug reactions.

Systemic disease and the skin (Diseasewise)

1. *Autoimmune diseases* -
 - a. Lupus erythematosus
 - b. Dermatomyositis
 - c. Scleroderma
2. *Haematological/oncological diseases* -
 - a. Leukaemia cutis
 - b. Lymphomas, e.g. Hodgkin's disease
 - c. Multiple myeloma [as cutaneous plasmacytosis, or amyloidosis (Fig. 71)]
 - d. Metastatic malignancy
 - e. Acanthosis nigricans
3. *Sarcoidosis*.
4. *Endocrine and metabolic diseases*.
 - a. Hyperthyroidism - Onycholysis, pretibial myxoedema, dermatographism, increased sweating, hair loss, warm, sweaty palms
 - b. Hypothyroidism - Myxoedema due to accumulation of mucopolysaccharides, chondroitin sulphate and hyaluronic acid which bind water and lead to a mucinous oedema. The skin is cold and xerotic.
 - c. Addison's disease.

- d. Cushing's syndrome.
- e. Gout - Urate crystals in skin.
- f. Hyperlipidemia - Xanthomas.
5. *Gastrointestinal diseases* -
 - a. Inflammatory bowel disease.
 - b. Dermatitis herpetiformis - in gluten-sensitive enteropathy.
 - c. Liver disease - Acute hepatitis, primary biliary cirrhosis.
 - d. Malabsorption - Kwashiorkor, acrodermatitis enteropathica (Fig. 72). Livedo reticularis-like hyperpigmentation.
6. *AIDS*
 - a. Acute viraemia - Exanthema with red papules.
 - b. Nonspecific manifestations - Seborrhoeic dermatitis, extensive skin infections, oral candidiasis, molluscum contagiosum, herpes simplex, warts.

Erythema

1. *Erythema induratum* - Tuberculosis.
2. *Erythema ab igne* - Peripheral neuropathy.
3. *Erythema marginatum* - Rheumatic fever.
4. *Erythema gyratum repens* - Internal malignancy.
5. *Necrolytic migratory erythema* - Glucagonoma.

Central facial rash

1. SLE.
2. Acne rosacea.

Fig. 71: Lichen amyloidosis

Fig. 72: Acrodermatitis enteropathica

3. Lupus pernio.
4. Dermatomyositis.
5. Porphyria cutanea tarda.
6. Secondary syphilis.

Discrete hypodepigmented areas

1. Tuberculoid and inderminate leprosy.
2. Vitiligo before there is depigmentation.
3. Tinea versicolor.
4. Tuberous sclerosis ('Ash-leaf' macules).
5. Morphea (Localised patches of scleroderma)
6. Naevus depigmentosus is a congenital non hereditary leukodermic.
7. Post-inflammatory.
8. Pityriasis alba.

Conditions predisposing to ampicillin rashes

1. Infectious mononucleosis.
2. CMV infection.
3. Chronic lymphoid leukaemia.
4. Concurrent allopurinol treatment.

Koebner phenomenon

- Psoriasis
- Lichen planus
- Verruca plana
- Vitiligo
- Lichen nitidus

Table 31: Side effects of PUVA treatment

Side effects	Comments
<i>Major (long-term)</i>	
Skin cancer	Squamous cell carcinoma
Cataract	UVA screening spectacles must be used during and 24 hrs after exposure
Photodamaging	Damage to dermis results in appearance of ageing and altered elastic properties
<i>Minor (short-term)</i>	
Nausea	
Burning	
Pruritus and Xeroderma	Probably due to psoriasis
Skin disorder caused by UVR	If dose of UVR too high
Psoriasis	Emollients are helpful
Atopic dermatitis	
Acne	Not recommended for patients < 12 yrs.
Mycosis fungoides	
Pityriasis lichenoides	

- Darier's disease
- Molluscum contagiosum

Lasers in dermatology

Treatment of cutaneous vascular lesions

Port wine stains and other ectasia (excluding leg veins) Pulse-dye laser is treatment of choice. Best results are obtained on side of face and forehead

Argon-pumped-dye laser is preferred in treatment of facial telangiectasia because of absence of bruising

Frequency-doubled neodymium: YGA laser is particularly effective in removal of spider naevi and dilated veins on face

Leg vein telangiectasias – Longer wave lengths and pulse durations are required. In many patients sclerotherapy is preferred.

Hair removal – Long-pulsed Nd: YAG laser or Diode lasers can be used

Cutaneous pigmented lesions and tattoos – Epidermal pigmented lesions such as lentigos, freckles and *cafe-au-lait* macules respond well to most of the lasers listed below. More deeply located pigmented lesions require infrared Nd: YAG laser

Q-switched ruby laser

Q-switched Nd: YAG laser

Q-switched alexandrite laser

Resurfacing and ablative lasers can be used for improvement of photodamaged and aged skin. However postoperative pain, swelling and redness can be distressing.

Ichthyosis – The term is derived from 'ichthys' meaning fish and refers to the fish-scale like appearance of the skin.

Classification of hereditary ichthyosis

1. **Ichthyosis vulgaris** – Least severe and most common type. Manifests usually after first 3 months of life. Extensor surfaces of extremities more commonly affected. Condition improves as age advances. Keratosis pilaris may be associated.
2. **X-linked** – Primarily affects males. Scales larger and darker than ichthyosis vulgaris. Periodic spontaneous shedding of scales may occur.
3. **Lamellar** – More severe form of ichthyosis present usually at birth. Death in-utero or shortly after birth. At birth, affected neonates often have a collodion-like membrane over body (collodion babies), membrane is shed soon after birth. Ichthyosis is generalized, palms and soles always affected.

4. **Epidermolytic hyperkeratosis (EHK)** usually manifests at birth with tender, raw areas upon which hyperkeratosis develops later. Ridged hyperkeratosis on flexures is characteristic and presence of flaccid bullae is the most characteristic manifestation.

Psoriasis Area and Severity Index (PASI) - The severity of psoriasis is determined by using PASI. The area affected, redness, thickness of plaques and scaling scored for each body zones (head, trunk, arms and legs) and a composite score is derived, ranging from zero (no disease) to 72 (maximum disease).

Tazarotene topical retinoid for psoriasis and acne

Acne - Tazarotene 0.1% gel is applied at night (the surrounding skin being protected by Vaseline) as short contact therapy for 1 to 5 minutes every other night. The drug can be irritating and should be avoided in patients with sensitive skin or seborrheic dermatitis. For reducing

inflammatory lesions, tazarotene plus erythromycin/benzoyl peroxide are significantly more efficacious than all other regimens.

Psoriasis - Tazarotene gel (0.05 or 1%) is an approved topical therapy. However when used as monotherapy, irritation at site of application develops in a significant proportion of patients. When used with mometasone furoate 0.1% cream or fluocinonide 0.05% cream, improvement is enhanced and irritation diminished.

Medical treatment for androgenic alopecia - Androgenic alopecia if not in advanced stage could be treated with Finasteride 1 mg daily for 1-2 years along with Minoxidil 2 to 5% in male subjects.

However Finasteride is contraindicated in liver dysfunction and in patients having low levels of serum testosterone. Also females of child bearing age. Since finasteride is not helpful in postmenopausal androgenic alopecia, the drug of choice is 2-5% minoxidil preparation.

Sexually Transmitted Infections, HIV and AIDS

1. BACTERIAL INFECTIONS

GONORRHOEA

Causative Organism

Neisseria gonorrhoea, is a Gram-negative diplococcus. It infects the mucosal surface of the genital tract, including the urethra in both men and women, the genital glands (Skene's and Bartholin's in women, Cowper's and Tyson's glands in men), the uterine cervix and fallopian tubes, and the epididymides. It can also infect the anal canal and distal rectum, the oropharynx and the eye.

Transmission

Transmission is always sexual in adults, more from males to females. Vertical transmission also occurs. Neonatal sepsis may occur, particularly when there has been prolonged rupture of membranes or preterm delivery.

Clinical Features

Male urethritis – Men with urethral infection develop discharge or discharge with dysuria 3–10 days after exposure, which may vary from scant mucoid to copious and purulent (Fig. 1).

Epididymitis causes unilateral scrotal pain, swelling and tenderness. Rarely there is development of abscesses of Tyson's and Littre's glands or infection of prostate and seminal vesicles.

Cervicitis and urethritis may occur concomitantly. Symptoms include dysuria, frequency and vaginal discharge. The cervix is reddened with mucopurulent or purulent discharge. Pus may be expressed from urethra on pressure against symphysis pubis.

Pelvic inflammatory disease (PID) may occur in some women in the form of salpingitis, pelvic peritonitis and pelvic abscesses, which can give rise to lower abdominal discomfort, marked tenderness on abdominal palpation of adnexa and cervix.

Rectal gonorrhoea usually occurs in homosexual men but can also occur in females who have anal sex. Symptoms

are itching, bleeding, purulent discharge, tenesmus and constipation of varying severity. Proctoscopy may show erythema or mucopurulent exudate.

Gonococcal pharyngitis may be asymptomatic or cause sore throat.

Fitz-Hugh Curtis syndrome is gonococcal (or chlamydial) perihepatitis that occurs predominantly in women and gives rise to right upper quadrant abdominal pain, fever, nausea and vomiting.

Diagnosis

Findings of Gram-negative intracellular diplococci on a Gram-stained smear from urethra. In homosexual men, rectal cultures should be obtained if there is history of oro-anal or anogenital contact. The oropharynx should be sampled in all gonorrhoea contacts and in homosexual men. In women, diagnosis is by culture in a selective medium, of a sample from the endocervix. They may have a role in investigation of patients in whom Gram-negative intracellular diplococci are found on microscopy but who are subsequently found to be culture-negative for gonorrhoea.

Fig. 1: Frankly purulent urethral discharge in gonococcal urethritis

DISSEMINATED GONOCOCCAL INFECTION

Skin lesions – Commonly on distal extremities, begin as papules or petechiae before evolving into microscopic pustular infarcts. There are seldom more than five or six lesions.

Arthritis is polyarticular arthritis or tenosynovitis, involving knees, small joints of hands, ankles and elbows.

Endocarditis and meningitis are very rare and are most often seen in individuals with a deficiency in one of the components of the complement pathway.

Treatment of uncomplicated genital gonorrhoea

– Single dose of Ceftriaxone 125 mg IM or Ciprofloxacin 500 mg. In resistant cases, Spectinomycin 2 g IM. A single oral dose of 2 g Azithromycin is effective against both gonococci and chlamydia.

In men and women with ascending local infection (e.g. epididymo-orchitis, salpingitis), standard therapy should be supplemented with a 2-week course of an antichlamydial antibiotic. In pelvic infection metronidazole is added.

CHLAMYDIA AND NONSPECIFIC URETHRITIS

Chlamydia trachomatis is the most common bacterial sexually transmitted micro-organism causing genital and ocular disease. Serovars A-C cause trachoma, serovars D-K affect primarily the genital tract.

Men usually develop urethritis within one month of acquiring infection, but up to 50% are asymptomatic. Occasionally epididymo-orchitis develops.

Both men and women develop reactive arthritis (more common in men).

Investigations – Presence of 5 or more polymorphs in urethral smear.

Treatment – Doxycycline 100 mg b.d. for 7 days, or azithromycin 1 g p.o. single dose. In pregnancy and in women who are breast feeding, erythromycin 500 mg b.d. for 14 days or ampicillin 500 mg t.d.s.

NON-GONOCOCCAL URETHRITIS

NGU is inflammation of the urethra with discharge and/or dysuria, but may be asymptomatic.

Aetiology – *C. trachomatis* is the most common cause. Others are *Ureaplasma urealyticum*, *Mycoplasma genitalium* and *Trichomonas vaginalis*.

Cl. Fs. – Men complain of urethral discharge with or without dysuria or only penile tip irritation. Up to 30% are

asymptomatic, but about one-half of these have observable urethral discharge (genitally unaware group). Examination reveals urethral discharge which may be present only on urethral massage. Inflammation of glans and prepuce may be seen.

Circinate balanitis is associated with acquired reactive arthritis, but may occur independent of this.

Investigations – Diagnosis can be confirmed by demonstrating neutrophils in the anterior urethra with a Gram-stained urethral smear or Gram-stained preparation from a first-void urine specimen. A urethral swab should be taken for gonococcal culture and a first-void urine specimen for chlamydial diagnosis. Urinalysis of MSU specimen for using a dipstick can detect leucocyte esterase and nitrites.

Tr. – Same as antibiotics regimen for *C. trachomatis*.

Bacterial vaginosis (BV) is the most common cause of abnormal vaginal discharge in women of childbearing age. It is a syndrome of unknown cause characterized by depletion of the normal lactobacillus population and overgrowth of vaginal anaerobe, accompanied by loss of usual vaginal acidity.

Cl. Fs. – Offensive, fishy-smelling discharge most noticeable after unprotected intercourse or at the time of menstruation.

Diagnosis – Gram-stain – Examination of a Gram-stained vaginal smear is a quick and relatively simple means of confirming the diagnosis of BV. Its advantages are that it allows recognition of the flora.

Treatment – Metronidazole 400 mg p.o. b.d. for 5 days or 2 g single dose. Topical treatment with intravaginal 2% clindamycin cream or 0.75% metronidazole gel can be used when systemic treatment is not desirable. For relapse – Screening of sex partner for infections. Metronidazole 40 mg b.d. for 3 days starting 2 days before menstruation and again on 5th day of menstruation for 3 months.

SYPHILIS

Syphilis is a chronic STI that is systemic from the beginning and is characterized by florid manifestations and long periods of quiescence. The causative organism is *Treponema pallidum* related to the causative organisms of non-venereal treponematoses. It is also more distantly related to certain saprophytic bacteria found in the mouth and genitalia of healthy individuals.

Both congenital and acquired syphilis are divided into early and late manifestations, usually at 1–2 years after acquisition of infection. The superficial lesions of early syphilis are infectious, those of late syphilis tend to be non-infectious.

Primary Syphilis

Incubation period 9–90 days.

Description – Initial manifestation is a small macule that becomes a papule, which breaks down to form an ulcer (primary chancre). It is solitary, painless with a well-defined margin and an indurated base, and fails to bleed on trauma (Fig. 2). However primary lesions may not have this classic appearance due to secondary bacterial infection, mixed causes or associated HIV infection.

Site – In men the ulcer is found in the coronal sulcus, or on glans penis or penile shaft. In women, on vulva, vaginal walls or the cervix. Usually there is associated bilateral inguinal lymphnode enlargement, discrete and non-tender. In those with cervical chancres inguinal lymphadenopathy is usually absent because lymphatic drainage is to the deep pelvic nodes. Perianal and rectal lesions may occur in homosexual men.

Untreated ulcers resolve spontaneously in 3–8 weeks, usually without leaving a scar.

Secondary Syphilis

Interval between appearance of primary chancre and onset of secondary manifestations is about 6–8 weeks. In about one-third of patients, primary lesions are still evident when secondary manifestations occur.

Clinical features – Onset is characterized by a rash, often accompanied by constitutional symptoms such as fever, headache and malaise.

Rash may be sparse or extensive. Usually nonpruritic.

1. *Macular or roseolar syphilide* – Usually first eruption to appear, lasting only few days. Lesions rose pink in col-

our, rounded, discrete and chiefly on trunk and flexor aspect of upper limb.

2. *Papular syphilide* – Commonest and most characteristic lesion. Papules dull red in colour, variable in size, rounded, symmetrically distributed; may be covered with scales (Figs 3 to 5). Types of papular rash:
 - *Follicular*: Pointed papular lesions in relation to hair follicles, common on scalp (syphilitic alopecia)
 - *Annular*: Papules arranged in ring form with central clearing, commonly on face
 - *Corymbose lesions* – Large central papules surrounded by small satellite papules
 - Papules in intertriginous areas may become eroded and fissured (split papules). Such lesions occur at angles of mouth, nasolabial folds and behind the ears.
 - *Condylomata lata*: In warm moist areas, papules may become confluent, hypertrophic, pale coloured, broad and flattened. Rarely condylomata lata may involve the face, axillae and neck, or umbilicus, toe webs or eyelids, and can occur alone without any clinical manifestations (Fig. 6).
 - *Rupoid syphilides*: There is extensive tissue necrosis resulting in deeply ulcerated lesions covered with limpet-like crusts.
 - Pustular secondary syphilis may appear as small acuminate pustular syphilide (miliary pustular syphilide), large acuminate pustular syphilide (acne form or varioliform), flat pustular syphilide (impetiginoid or ecthymiform syphilide)

Fig. 2: Primary syphilis: solitary indurated ulcer

Fig. 3: Secondary syphilis

Fig. 4: Secondary syphilis

Fig. 5: Secondary syphilis

Fig. 6: Condylomata lata: flat papules and plaques, vulva

Regional lymphadenopathy is common. Glands tend to be discrete, rubbery and non-painful. Inguinal, suboccipital and axillary glands may all become involved.

Mucous membrane lesions - Mucous patches may affect oral mucosa, pharynx, larynx and genital mucosa are commonly affected. The patches have a dull red base and greyish slough. Lesions may become confluent with loss of slough, presenting with an erosion with serpiginous outline (snail-track ulcers). Laryngeal lesions involving the vocal cords may give rise to hoarseness of voice. Mucous membrane lesions are painless unless there is secondary infection superadded.

Diagnosis of early syphilis. *T. pallidum* may be detected in primary or secondary lesions using polymerase chain reaction (PCR) analysis.

Early latent syphilis. If secondary syphilis remains undiagnosed and therefore untreated, all visible manifestations of the disease gradually resolve and the patient passes into a stage of no symptoms or signs.

Diagnosis of latent syphilis is based on the results of serological tests and absence of CNS signs and symptoms.

Late Syphilis

Late latent syphilis. By definition, late latent syphilis is also associated with no clinical manifestations, but the time elapsed since acquisition of disease is more than 2 years.

Tertiary syphilis is the destructive stage of the disease. In untreated or inadequately treated patients, signs and symptoms of these late manifestations usually occur after many years after initial infection, and any organ of the body may be involved.

Clinical Features

Cutaneous, mucosal and bony gummas. Gummas are the characteristic granulomatous lesions of tertiary syphilis and usually occur on the skin and mucosal surfaces, and in bone. On healing, nodular skin gummas may leave rounded 'tissue-paper' scars. Mucosal gummas affect the submucous tissues of mouth, throat, palate, larynx, pharynx and nasal septum. They may ulcerate with a 'punched-out' appearance, and the lesions may have a sloughy base. Underlying bony structures may also be destroyed.

Bony gummas are diffuse subperiosteal reactions that often occur in the long bones, particularly anterior margin of tibia. Spontaneous healing results in formation of new bone, and irregular, tender lumps may become palpable.

Formation of lytic lesions may lead to perforation of hard palate or nasal septum, resulting in collapse of the nasal bridge. The skull may also be affected, with a 'worm eaten' appearance on radiography.

Cardiovascular syphilis. Main feature is aortitis, which may be complicated by coronary ostial stenosis, aneurysm and aortic incompetence.

Neurosyphilis may be asymptomatic or manifest as meningovascular syphilis, tabes dorsalis or GPI.

Diagnosis of tertiary syphilis is on clinical grounds and CSF. Findings of 5 or more lymphocytes/ μL , excess globulin and serological tests for syphilis are required.

Investigations

1. Demonstration of *T. pallidum* from lesions. (a) Dark ground microscopy. (b) Direct fluorescent staining method.

2. Serological tests

Reagin tests. VDRL and the rapid plasma reagin (RPR) are sensitive simple and inexpensive and are used for screening but are not specific for syphilis. Results may be presented qualitatively (e.g. reactive, borderline, non-reactive).

Treponemal tests detect antitreponemal antibodies. The tests include fluorescent treponemal antibody absorption test (PTA-ABS tests), microhemagglutination assay for antibodies. *T. pallidum* (MHA-TP) and *T. pallidum* haemagglutination assay (TPHA). Treponemal tests are very sensitive for syphilis, neither of the above tests become positive until 3 to 6 weeks after the initial infection.

Quantitative reagin tests may also be used to assess efficacy of therapy. After successful treatment of early syphilis, the titre should decrease and eventually become negative. However, positive antibody titres may persist following treatment of late stages of the disease.

Monitoring Response to Treatment

- All patients should undergo RPR or VDRL testing each time they present with a new episode of an STI.
- On receipt of all tests, results (including titres) should be noted.
- Depending on the initial clinical presentation, patients with a positive RPR test should be treated for early or late syphilis (single or three weekly injections of benzathine penicillin). Patients with no clinical signs of disease should be presumed to have latent syphilis and should be treated with three weekly injections.

- Follow-up after 3 months when RPR/VDRL serology is done. If titre remains the same or decreases further no treatment should be given. If it increases, patient should be treated, but for early syphilis only (i.e. single injection of benzathine penicillin 2.4 MU).

Note: There are no serology tests or combination of tests that can be performed on a single serum specimen to indicate whether patient has active disease or is free of disease.

Treatment of Syphilis

Primary, secondary and early latent syphilis

- Benzathine penicillin G. 2.4 MU i.m. usually into two sites (4 mL into each buttock) at a single visit. Additional doses 2.4 MU should be given 7–14 days later for latent syphilis of unknown duration because of occasional treponemal persistence in CSF after single dose regime.

In patients allergic to penicillin – Ceftriaxone 125mg IM od \times 10 days, azithromycin 1g po, od or doxycycline 100 mg bd \times 14 days.

Late or Tertiary syphilis

Post treatment follow up – Examinations and reaginic tests should be performed at 3, 6 and 12 months after treatment and annually thereafter until non-reactive. Failure to decline by 4 fold at 6 months suggests treatment failure and indicates need for retreatment.

Neurosyphilis or ocular syphilis

Aqueous penicillin 12–24 MU/day (2–4 MU every 4 hours) i.v. for 10 days, followed by benzathine penicillin G, 2.4 MU i.m. weekly for 3 weeks or

Aqueous procaine penicillin G, 2.4 MU daily i.m., plus probenecid. 500 mg q.d.s., both for 10 days, followed by benzathine penicillin G, 2.4 MU I.M. weekly for 3 weeks.

Syphilis and Concurrent HIV Infection

Unusual manifestations

- Increased severity of clinical manifestations
- Rapid progress of syphilis to tertiary stage after initial infection
- Relapse in spite of therapy
- Infection not controlled by Benzathine penicillin therapy
- Unusual features like unusual gummatous lesions

Congenital syphilis – See Diseases of Children.

VIRAL INFECTIONS

Genital Warts and Genital Papillomavirus Disease

Genital warts (Fig. 7) are usually caused by human papilloma virus (HPV) types 6 and 11. However, a wider spectrum of HPV types can infect the genital mucosa. HPV virions are small, non-enveloped capsids enclosing on 8 kb circular dsDNA genome. HPV is exclusively epitheliotropic and infects either cutaneous or mucosal epithelium.

Clinical Features

Anogenital warts refer to macular, papular or pedunculated lesions of anal/and or genital mucosa and its adjoining areas. Occur in males on the frenulum, corona, glans, urinary meatus, shaft of penis, scrotum, groin, perineum and perianal areas. In females they occur in the vaginal introitus, fourchette, labia minora, vagina, cervix, perineum and perianal area (Fig. 8). In both sexes, proctoscopy may reveal lesions in the anal canal as far as the dentate line.

Bowenoid papulosis is an HIV-16-induced disease of male and female external genitalia, with itchy, pigmented papules with high degree of intraepithelial neoplasia. In women, these may be associated with multifocal genital tract precancer involving cervix, vagina, vulva or anus.

Buschke-Lowenstein tumors (Giant condylomata) are uncommon, locally aggressive, non-metastasizing verrucous carcinomas. They contain HPV-6 or HPV-11.

Cervix - Colonoscopy shows a spectrum of change from condylomata to cervical intra-epithelial neoplasia (CIN).

Warts in oral cavity are seen occasionally and are associated with orogenital contact.

Fig. 7: Condyloma acuminata

Diagnosis (a) *Aceto-whitening* - Application of 5% acetic acid to the external genitalia in men or women, or to the cervix can disclose previously unidentified sub-clinical HPV lesions. (b) *Colposcopy* shows changes of condylomata to cervical endothelium neoplasia. It is useful for taking biopsy. (c) *Cervical cytology* when warts or a macroscopic abnormality is seen on cervix during speculum examination. (d) *Biopsy* - Excision or punch biopsy on external genital lesions in whom there is suspicion of intra-epithelial neoplasia. (e) *STI screening* - Up to 20% of patients with genital warts have another STI.

Management

1. **Podophyllin** 20–25% solution is painted on individual lesions in the clinic, allowed to dry and washed carefully off after 4 hours. One or two applications per week until warts have disappeared. There are reservations about podophyllin treatment - it is non-standardized, contains mutagens, and serious side effects (including neurotoxicity and foetal death, usually associated with use of large volumes) have been reported.
2. **Trichloroacetic acid** (TCA) 90–99% solution, is useful for small discrete lesions. It is applied directly and sparingly with an orange stick or fine swab. The treated areas are bathed twice daily and assessed after 7 days. Repeated use can cause scarring.
3. **Cryotherapy** is useful for keratinized, recurrent, large or meatal lesions. It can be administered by closed cryotherapy systems using nitrous oxide or liquid nitrogen, by direct application of liquid nitrogen. Treatment can be given weekly.
4. **CO₂ laser.**

Fig. 8: Genital warts

5. **Intralesional bleomycin**, a cytotoxic drug that inhibits DNA synthesis.
6. **Imiquimod** is an immunomodulator available as 5% cream for self-treatment of external anogenital warts. It acts by causing macrophages to release interferon- α and cytokines, which seem to induce an immune response. It must be applied for 3 nights per week for 6-12 weeks.
7. **Surgical treatments** include curettage (intrameatal or labia minora warts), electrosurgery under local anaesthesia (keratinized lesions), scissor excision under general anaesthesia (multiple, large genital warts). Laser surgery is an alternative therapy only for large or recalcitrant warts.
8. **HPV vaccine** - A quadrivalent recombinant vaccine for prevention of HPV associated genital diseases in females 9 and 26 years in 3 doses at 0, 2 and 6 months.

GENITAL HERPES

Genital herpes simplex virus is the most common cause of genital ulceration and leads to local, systemic and psychosexual complications. Following initial infection, replication of HSV at the portal of entry results in infection of sensory nerve endings. Viral nucleocapsids are then transported by retrograde axonal flow to the neuronal cell nuclei within sensory ganglia where latency is established.

Transmission

Can occur through genital-genital and oro-genital contact. Infectivity is increased during prodromes and immediately after the lesion heals.

Fig. 9: Herpes genitalis

Factors which affect transmission - (a) Infection is more easily passed from males to females. (b) Risk of infection is reduced by about two-thirds when the partner has previously been infected with a different HSV type. (c) There is little risk of reinfection when the partner has already been infected with the same viral type. (d) HSV infection in either partner facilitates transmission of HIV infection.

Neonatal herpes - During pregnancy exposure to virus occurs during passage through an infected birth canal.

Clinical Features

Incubation period is 2-14 days and the average untreated attack lasts 22-28 days.

Description - Initially erythematous papules form in which the characteristic herpetic vesicles erupt. By the time the patient presents, they have usually ruptured, with resulting ulceration. Ulcers are superficial with erythematous outline and greyish base, and are very painful. Lesions tend to be bilateral, and painful inguinal lymphadenopathy is present. Symptoms are more severe in women and in homosexual men (Figs 9 and 10).

Complications - (a) *Local* - Superinfection with fungi and bacteria. Labial and vaginal adhesions may occur, and uncircumcised men may develop phimosis. (b) *Systemic* - Involvement of pharynx, meningeal irritation. Autonomic dysfunction is rare, it results in difficulty in urinating, constipation and altered sensation in perineal, sacral and lower back areas. Transverse myelitis is another rare complication.

HSV is one of the most common causes of erythema multiforme.

Fig. 10: Herpes genitalis

Recurrent Herpes

Recurrent attacks are usually milder and of shorter duration (up to 8–12 days). Women are affected more severely. Lesions appear in localized sites and are usually unilateral, with only few vesicles. Symptoms in prodromal phase vary from mild tingling sensations in areas affected by the eruption, to severe shooting pains in thigh, buttocks or groin. Other features are malaise, fever and hyperaesthesia at the site where lesions subsequently occur.

Many patients suffer 'atypical' recurrent attacks in which vesicles and ulcers do not occur and fissuring, furuncles, excoriations and nonspecific erythema may be seen.

Genital recurrences are most common in those infected with HSV-2, particularly in the months immediately after initial infection. The fear of disease transmission and severity of recurrent illness can cause psychosexual morbidity.

Investigations

(a) Track smear is useful for rapid diagnosis and is done by scraping base of a ruptured vesicle and staining with Giemsa or Wright stain, multinuclear giant cells are diagnostic on immunofluorescence. (b) Histopathology – Ballooning of epidermal keratinocytes and formation of multinucleate intraepidermal vesicles. (c) Viral culture is a definite diagnostic test for acute HSV infection. (d) HSV direct detection tests include cytology, electron microscopy, HSV antigen detection, HSV-DNA detection. HSV-PCR a highly sensitive detection method is likely to replace viral culture for diagnosis of genital herpes in patients with active mucocutaneous lesions. (e) Enzyme immunoassay (ESA) is used for direct detection of HSV antigen.

Serology – for detecting antibodies to HSV in blood include ELISA, complement fixation test (CFT) and western block.

Management

Antiviral agents for treatment of genital herpes

See Table 1.

Drug	Dosage	Side effects
Acyclovir	400 mg po tds × 7–10 days	Nausea, vomiting, headache, diarrhoea, dizziness, rash
Famciclovir	250 mg 5 times/d × 7–10 days	Fatigue, headache, nausea, pruritus
Valacyclovir	1 g po × 7–10 days	Headache, nausea, dizziness, vomiting

Treatment

Severe disease complications – e.g. pneumonitis, disseminated infection, hepatitis, meningitis or encephalitis. *Tr.* (a) Hospitalization. (b) Acyclovir – 5–10 mg/kg body wt. IV q8h for 2–7 days or until clinical improvement followed by oral therapy for 10 days.

Recurrent genital herpes – (a) Episodic treatment – Antiviral drug for 5 days given early reduces duration and severity of recurrence (b) Suppressive treatment – Daily acyclovir is effective in controlling recurrence, however many patients experience breakthrough attacks while taking treatment.

TRICHOMONIASIS

Trichomoniasis is a common STI caused by *Trichomonas vaginalis*, a flagellated protozoan.

Transmission is by sexual contact. Also from infected mothers to female babies. Predisposing factors include non-use of condoms, or oral contraceptives, smoking and low socioeconomic status.

Trichomoniasis, like many other STIs, can act as a co-factor for HIV transmission. This is thought to occur through increased local accumulation of HIV-infected or HIV-susceptible immune cells.

Table 2: Differentiation of common sexually transmitted genital ulcers or nodules

Disease	Features
Syphilitic chancre	Solitary ulcer, indurated, rubbery and slightly tender. Non-tender adenopathy
Herpes simplex	Clusters of small, superficial ulcers on an erythematous base, painful sometimes with vesicles. Inguinal adenopathy.
Chancroid	Shallow ulcer, non-indurated, painful, ragged undermined edges. Ulcers vary in size and often coalesce. Buboec.
Lymphogranuloma venereum	Small papule or ulcer often asymptomatic is very tender and painful buboes with distal lymphedema or drainage to the skin
Granuloma inguinale	Elevated, velvety, granulomatous lesions. No inguinal adenopathy
Primary HIV infection	Multiple, shallow lesions. Systemic symptoms like fever, rash, adenopathy
Scabies (excoriated)	Multiple shallow lesions. In scabies characteristic extragenital lesions and mite burrows.
Pediculosis pubis	Presence of lice

Clinical Features

In women – Vaginitis and vulvitis. Vaginal discharge is green, frothy, itchy and malodorous. Vaginal walls may be erythematous and a ‘strawberry cervix’ may be seen. Symptoms may worsen during or shortly after menstruation.

In men – *T. vaginalis* may infect the urethra, epididymis and prostate gland. Most men remain asymptomatic. Others present with nonspecific urethritis, rarely balanoposthitis, epididymitis or prostatitis.

Diagnosis – (a) Microscopic examination of saline wet mounts taken from posterior vaginal fornix or urethra to demonstrate motile *T. vaginalis*. (b) Broth culture methods. Disadvantage is the need to incubate samples for several days.

Management – Metronidazole 2 g p.o. single dose or 400 mg b.d. for 5–7 days. For resistant cases – Metronidazole i.v. or higher dose p.o. combined with metronidazole vaginal pessaries. Alternative therapies are vaginal tinidazole, clotrimazole or acetarsol pessaries, vaginal paromomycin preparations and combinations of broad spectrum antibiotics and metronidazole.

GENITAL CANDIDOSIS

Strains of *Candida albicans* constitute 90% of yeasts isolated from the vagina. Candida is the second most common vaginal infection.

Asymptomatic candidosis is common and factors associated are:

- Pregnancy
- Uncontrolled diabetes mellitus
- High oestrogen oral contraceptives
- Corticosteroid therapy
- Antimicrobial therapy (oral, parenteral or topical)
- Use of IUD
- Immunosuppression
- High frequency of coitus (vaginitis only)

Clinical Features

- Vulval pruritus is the most common symptom.
- Vaginal discharge is often minimal. Described as being typically cottage cheese like, it may vary from watery to homogenous thick.
- Vaginal soreness, irritation, vulval burning, dyspareunia and external dysuria are common.
- Odour is minimal and inoffensive.
- Examination reveals erythema and swelling of labia and vulva, often with distinct peripheral lesions.

Diagnosis

(a) Microscopic examination of vaginal secretions. (b) pH – is normal (4–4.5). If > 4.5 possibility of bacterial vaginosis, trichomoniasis or mixed infection. (c) Vaginal cultures in suspicious cases with negative microscopy.

Management

Topical antimycotic agents – are available as creams, lotions, vaginal tablets, suppositories and aerosol sprays. Nystatin cream and vaginal suppositories achieve cure rate of about 75%. Azole derivatives (clotrimazole, miconazole, econazole, luliconazole) are successful in up to 90% cases.

Oral antimycotic agents – Ketoconazole 400 mg/day for 5 days, itraconazole 200 mg/day for 3 days or 400 mg for 1 day, and fluconazole 150mg single daily dose, achieve cure in acute candidal vaginitis. For recurrent cases suppressive prophylaxis with ketoconazole 100 mg/day for 6 months, or weekly fluconazole 100 mg, or topical clotrimazole 500 mg.

Balanitis/Balanoposthitis

Two forms are associated with *Candida* spp. and are acquired sexually.

Superficial but invasive infection occurs particularly in diabetic and uncircumcised males. It is characterized by intense pruritus, discomfort, erythema and swelling localized primarily to the glans, but may extend to involve the penile shaft and scrotum.

Tr. – Topical antimycotics or systemic azoles.

A milder but more common and particularly recurrent form in which penile cultures may be negative for *Candida*. Symptoms of local erythema or rash and pruritus appear soon after unprotected intercourse, are transient and relieved by washing or topical corticosteroids.

Scabies and Crab lice have already been described.

TROPICAL STI

Genital ulceration is recognized as a significant risk factor for acquisition and transmission of HIV among heterosexuals in developing countries.

CHANCROID (SOFT SORE)

Chancroid is an STI causing painful genital sores and inguinal lymphadenopathy that may progress to abscess (bubo) formation. Causative organism is a Gram-negative bacterium *Haemophilus ducreyi*.

Pathogenesis – Abrasions are necessary for *H. ducreyi* to penetrate the epidermis and cause infection. The organisms are found in macrophages and neutrophils, and free in the interstitium.

Incubation period 4–7 days.

Description – Lesions start as a tender papule that develops into pustule, then an ulcer. The classical ulcer has a ragged, undermined edge with a grey or yellow base that bleeds when touched. Lesions may be single or multiple (Fig. 11).

Sites – Prepuce, coronal sulcus, frenum and glans in men, and the labia minora and fourchette in women. Ulcers of vaginal wall and cervix may occur. Extragenital lesions are rare.

Lymphadenopathy – Unilateral or bilateral enlargement of inguinal lymph glands is common. Bubo formation may require aspiration. HIV-infected individuals may develop extensive genital ulceration.

Sequelae

- Phimosis or paraphimosis
- Phagedenic ulceration
- Urethral fistulas

Bubos that rupture may take long to heal.

Clinical Variants

- **Giant chancroid** – Large ulcer due to extension of single ulcer or autoinoculation.
- **Phagedenic ulcer** – Large, destructive ulcer with necrosis of tissue from secondary infection.
- **Papular chancroid** begins as an ulcer but later becomes raised around its edges.
- **Transient chancroid** – Small ulcer that resolves spontaneously in a few days. It may be followed by acute regional lymphadenitis.
- **Follicular chancroid** – Originates in the follicles and may be seen on vulva and on hairy areas of genitals.

Fig. 11: Chancroid

- **Granulomatous ulcer** resembles granuloma inguinale

Diagnosis – (1) **Smear** – Gram stain material from ulcers may show Gram-negative coccobacilli in a ‘school of fish’ or ‘railroad track’ appearance. (2) **Culture** – Sensitivity is only about 75% and requires more than one culture media.

Non-culture diagnostic tests – (a) DNA amplification technique. **Polymerase chain reaction (PCR)** tests are the most sensitive method. Serological tests are unable to differentiate between old and new infections. (b) Antigen detection using immunofluorescence techniques on smears from genital ulcers and bubo aspirates. (c) Mass spectrometric methods can rapidly identify *H. ducreyi*. (d) **Histology** – Superficial necrosis with large number of neutrophils, endothelial proliferation and infiltration with plasma cells, lymphocytes and fibroblasts.

Treatment – Azithromycin 1g orally as single dose or Ciprofloxacin 500 mg b.d. for 3 days, erythromycin 500 mg q.d.s. for 7 days (in pregnant women), or ceftriaxone 250 mg i.m. stat. Healing of ulcers is usually after 7–14 days.

DONOVANOSIS (GRANULOMA INGUINALE)

Donovanosis is a chronic progressive bacterial infection that usually involves the genital region. Causative organism is *Calymmatobacterium granulomatis* (Klebsiella granulomatis).

Incubation period is about 50 days.

Transmission – Sexually transmitted.

Description – The classical lesion (granulomatous) is a beefy red ulcer that bleeds readily on touch (Fig. 12). The lesion enlarges by contiguous spread and gradual peripheral extension. Contact infection occurs between the skin of scrotum and thigh.

Fig. 12: Donovanosis: clean shiny beefy red lesions with a pearly border

Site – Common sites are prepuce, coronal sulcus, frenum and glans in men and labia majora and fourchette in women.

Extragenital lesions may rarely involve lips, gums, cheek, palate, pharynx, larynx and chest.

Haematogenous spread to liver and bone can occur.

Inguinal lymphadenopathy is uncommon unless there is secondary infection.

A subcutaneous granuloma in inguinal region (pseudobubo) may be mistaken for inguinal lymphadenopathy.

Sequelae – Stenosis of urethra, vagina or anus, elephantoid enlargement of external genitalia and possibly carcinoma.

Diagnosis – (a) *Microscopic identification* of Donovan bodies, in tissue smears using Giemsa or Wright's stain. Donovan bodies can be seen in large mononuclear cells as Gram-negative intracytoplasmic cysts filled with deeply-staining bodies which may have a safety-pin appearance. (b) *Histological changes* include chronic inflammation with infiltration of plasma cells and neutrophils. Epithelial changes include ulceration, microabscesses and elongation of the rete ridges. (c) *Culture* of the organism has been reported in peripheral blood monocytes and in Hep-2 cells. (d) *PCR analysis* using a colorimetric detection system can be used. (e) *Tests for concomitant STDs*.

Tr. – Doxycycline 100 mg po bd or Ciprofloxacin 750 mg bd or Trimethoprim sulphamethoxazole (80/160 mg) tablet bd for 14 days. All for 3 weeks till all lesions have completely healed.

LYMPHOGRANULOMA VENEREUM (INGUINAL BUBO)

LGV is an STI caused by *Chlamydia trachomatis* serovars L1, L2, L3.

Transmission is primarily sexual but close contact with infectious secretions can result in transmission.

Clinical Features

Incubation period is 3–12 days, sometimes longer.

Primary lesion – Lesion is a papule, pustule or small erosion that is often unnoticed and heals after a few days. Lesions are found on glans penis in men and on labia or vaginal walls in women. Extragenital lesions are very uncommon.

Secondary stage (inguinal) – Inguinal and less often femoral lymphadenopathy. The characteristic groove sign is seen when both inguinal and femoral lymph glands are enlarged (Fig. 13). Buboec may develop, if untreated, these

often rupture and healing is protracted. Lymphnodes may form small areas of necrosis, which attract neutrophils or form stellate abscesses. Further inflammation may cause loculated abscesses, fistulas and sinus tracts.

Tertiary stage (anogenital-rectal syndrome) – Healing of the secondary stage by fibrosis results in lymphatic vessel obstruction. This takes a few months or years resulting in a 'saxophone penis' in males and 'esthiomene' in females.

Rectal stricture – With progressive stricture formation there is rectal discharge and bleeding, colicky pain and passage of ribbon stools. Rectal strictures are usually 2–3 cm above anocutaneous margin. Complete bowel obstruction is rare.

Clinical and histological picture of LGV proctocolitis may mimic inflammatory bowel disease.

Neoplastic change – as a sequel of genital elephantiasis and anogenital-rectal syndrome.

Diagnosis – (a) Demonstration of *C. trachomatis* from lesion swab (genital bubo aspirate or rectum). Alternatively *C. trachomatis* can be identified by direct fluorescent microscopy. (b) The complement fixation (CF) test, in a titre of > 1:250 strongly suggests the diagnosis. (c) Immunoperoxidase test is a rapid test for detecting *C. trachomatis* specific IgG and IgA antibodies. (d) PCR provides accurate diagnosis in low prevalent areas. (e) Enzyme immunoassay is suitable for antigen detection in ulcer scrapings and bubo aspirates.

Differential diagnosis of LGV – (a) Other causes of genital ulceration or acute lymphadenitis such as plague, tularemia, tuberculosis, Hodgkin's disease and cat-scratch disease. (b) Of rectal stricture – trauma, malignancy, TB, schistosomiasis and actinomycosis.

Fig. 13: Lymphogranuloma venereum: typical groove sign due to enlargement of femoral and inguinal lymph nodes

Treatment – (a) Drugs – Doxycycline 100 mg b.d. for 14 days, erythromycin 500 mg q.d.s. for 14 days (in pregnant women), or tetracycline 500 mg q.d.s. for 14 days. (b) Surgical tr. – Hot fomentation for bubo and aseptic aspiration of fluctuant bubo. Rectal strictures require periodical dilatation. Internal proctotomy may be required in some cases. Other indications for surgery are bowel obstruction, and persistent rectovaginal and other fistulae.

2. HIV AND AIDS

HIV: The virus – HIV-1 and HIV-2 are members of the lentivirus family of retroviruses. HIV-1 is probably a cross-species transmission to humans from chimpanzee virus (SIVcpz), whereas HIV-2 probably arose separately from sooty mangabey virus (SIVsm). As a result, HIV-1 and HIV-2 are relatively dissimilar; their nucleic acid sequences are only about 40% homologous. Both viruses are tropic for CD4⁺ lymphocytes and monocytes and have a similar genetic structure. Both cause AIDS, but HIV-2 appears to be less virulent progressed slowly and is less commonly transmitted vertically.

A CD4 count < 200/μL in and HIV infected individual is defined as AIDS.

Structure of the HIV virion – HIV is an enveloped RNA retrovirus and consists of:

- Outer envelope - Bilipid membrane in which the viral antigens are embedded.
- Inner core bounded by a protein coat containing 3 viral enzymes - Reverse transcriptase, Integrase, Protease.

TRANSMISSION

1. Sexual

Homosexual – Most HIV infections occur in homosexual and bisexual men who have a large number of sexual partners. The sexual practices often involve anal intercourse and fellatio with ejection of semen into mouth.

Heterosexual: Multiple heterosexual contacts, often prostitutes.

gp 120 surface envelope glycoprotein	p24 capsid protein
gp41 transmembrane Envelope glycoprotein	Accessory proteins (Vpr, Vif, cyclophilins)
Virus enzymes (e.g. reverse Transcriptase, integrase)	Diploid RNA genome coated With p9 nucleocapsid protein
p17 matrix protein	Virus envelope derived from Cell membrane

2. Blood and tissue fluids

- Contaminated blood and blood products:
 - Blood transfusion.
 - Blood products, e.g. factor VIII.

3. Contaminated needles and syringes

- Injecting drug use.
- Needle stick injuries.
- Inadequately sterilized medical equipment.

4. Organ and tissue donations

- Semen
- Kidney, skin, cornea
- Bone marrow

5. Mother to child

- In utero
- At birth
- Breast milk

Pathogenesis of HIV infection

- HIV virus infects target cells (CD4⁺ T cells, monocytes, macrophages and dendrite cells) through CD4 receptors.
- On entering T cells, the virus integrates its RNA genome into the host cell genome by first transcribing this genome into DNA (HIV provirus) with the help of enzyme reverse transcriptase.
 - Provirus is then transcribed and translated along with the host cell DNA to synthesize specific viral components, which eventually assemble to produce complete virus particles.
 - At this time patient is seronegative, i.e. antibodies against the virus are not present. But patient is highly infectious. This period is labelled “window period”.
 - Although some virions are killed, HIV continues to multiply infecting increasing number of CD4 cells.
 - Clinical manifestations depend on the effect on the immune systems:
- In early stages of immune destruction, the patient is asymptomatic
- As the immunosuppression progresses over a period of time patient becomes symptomatic.

HIV TESTING AND MONITORING

Viral replication occurs during the incubation period, during which the viral genome and briefly, viral p24 antigen may be detected. There is an early ‘window’ period during which HIV infection cannot be detected, but this can be shortened if samples are tested for presence of HIV genome.

HIV diagnostic tests can be divided into antibody detection, combined antibody and antigen and genome detection.

HIV antibody and/or antigen tests – In general, an HIV-infected individual should have mounted an antibody response within 6 weeks to 3 months post-exposure. The wide range of diagnostic HIV assays include several combined HIV-1 and HIV-2 antibody tests, with or without a core antigen (p24) component based on enzyme immunoassay technology (e.g. ELISA). Sensitivity is usually tested by testing conventional panels of sera from patients who have established infection or by testing sequential samples from patients who are seroconverting.

Other assay formats use HIV-1 viral lysate, HIV-2 synthetic peptides and HIV antibody-p24 antigen combination assays.

HIV type discrimination can be undertaken using an immunoblot format. Specific HIV-1 and HIV-2 proteins are electrophoretically blotted onto a nitrocellulose membrane that binds HIV antibodies in the blood sample.

Diagnosis of HIV infection in blood samples from babies is more difficult because of the presence of passively-acquired maternal antibody. This wanes over 12–16 months, but infection can be demonstrated earlier by examining blood samples for HIV proviral DNA or HIV RNA.

Confirmatory testing – After HIV antibody has been detected in a separated serum sample using one assay, a second test on the original unseparated sample must be performed using a different assay format.

HIV genome detection – Plasma HIV load testing is performed to assess disease progression and response to antiretroviral therapy. Viral replication is a dynamic process, and HIV RNA levels may be low in the early stages of infection. Higher levels are correlated with increased risk of disease progression.

HIV RNA can be quantified using several assays using different methodologies:

1. **Reverse transcription polymerase chain reaction (RT-PCR)** involves reverse transcription of target RNA to generate complementary DNA (cDNA). PCR amplification of cDNA is followed by hybridization of oligonucleotide probes and detection of cDNA-bound probes by colorimetric analysis.
2. **RNA transcription** – The signal amplification probe method involves a set of oligonucleotide capture probes that bind the viral RNA to microwell. A set of target probes hybridize to both the viral RNA and pre-amplifier probes. The latter bind to the amplifier probe, forming the branched DNA complex.

3. **An enzyme-labelled probe** binds to the immobilized complex and is detected by a chemiluminescent substrate that is broken down by the enzyme. Light emission is directly proportional to the amount of HIV-1 RNA in the sample.

HIV drug resistance – is said to occur when the susceptibility of the virus to one or more specific antiviral drugs is reduced. This is measured in phenotype assays, and resistance expressed as fold reduction in drug susceptibility compared with a wild-type (drug-sensitive) strain.

Genotypic assays – Specific mutations can be identified by nucleic acid sequencing of plasma virus. This technique is called ‘genotypic resistance assay’. A number of key mutations have been identified which are associated with reduced drug susceptibility to one or more antiretroviral drugs.

Recombinant virus assays in which reverse transcriptase and the protease gene from the patient’s plasma, amplified by PCR, are recombined with a laboratory strain of virus thus generating a recombinant virus containing the reverse transcriptase and protease generated from the clinical sample. This virus can be rapidly screened for drug susceptibility.

Natural history of HIV infection

The clinical spectrum of HIV infection ranges from asymptomatic state to severe illness due to a variety of opportunistic infections. HIV infected individuals are permanently infectious, and hence transmit the virus to others in the asymptomatic stages.

STAGES OF HIV INFECTION

(WHO staging) See Table 3.

Acute retroviral syndrome (ARS) – A manifestation of primary HIV infection occurs 2–3 weeks after infection.

Clinical features

- Symptoms - Fever, headache, vomiting, sore throat, arthralgia, myalgia
- Cutaneous - Maculopapular rash, mucosal ulceration (mouth, oesophagus, genitals)
- Lymphoreticular - Lymphadenopathy, hepatosplenomegaly

Investigations – (a) Haematological - (i) Initial lymphopenia followed by lymphocytosis. (ii) Depletion of CD4 cell with CD8 lymphocytosis. Atypical lymphocytes. (b) Viral markers - (i) HIV RNA detection. (ii) P24 antigen in 1/3 patients. (iii) Serology - Antibody tests negative in early stages. Anti-HIV IgM may be detected.

Tr. Anti-retroviral therapy protects susceptible CD4 cells from HIV infection.

Table 3: Stages of HIV infection

Primary HIV infection
<ul style="list-style-type: none"> • Asymptomatic • Acute retroviral syndrome: Fever with maculopapular rash primarily on trunk with small aphthous lesions on oral and genital mucosa
Clinical stage 1
<ul style="list-style-type: none"> • Asymptomatic • Persistent generalized lymphadenopathy
Clinical stage 2
<ul style="list-style-type: none"> • Unexplained moderate wt. loss (< 10% of presumed body wt.) • Infections <ul style="list-style-type: none"> • Recurrent resp. tract infections • Herpes zoster • Fungal infections of finger nails • Oral lesions <ul style="list-style-type: none"> – Recurrent oral ulcerations – Angular cheilitis • Itchy dermatosis <ul style="list-style-type: none"> – Papular pruritic eruptions – Seborrhoeic dermatitis
Clinical stage 3
Conditions where a presumptive diagnosis can be made on the basis of clinical signs or simple investigations.
<ul style="list-style-type: none"> • Unexplained symptoms <ul style="list-style-type: none"> – Chronic diarrhoea for > 1 month – Persistent fever, intermittent or constant for > 1 month • Severe wt. loss (> 10% of presumed or measured body weight) • Infections <ul style="list-style-type: none"> – Severe presumed bacterial infections – Pulmonary tuberculosis diagnosed in last 2 years • Oral lesions <ul style="list-style-type: none"> – Oral candidiasis – Oral hairy leukoplakia – Acute necrotizing ulcerative stomatitis, gingivitis or periodontitis • Conditions where confirmatory diagnostic testing is necessary <ul style="list-style-type: none"> – Unexplained anemia (< 8 g/l or neutropenia (< 500 μl) or thrombocytopenia (< 50,000 μl) for > 1 month
Clinical stage 4
Conditions where a presumptive diagnosis can be made on the basis of clinical signs and simple investigations
<ul style="list-style-type: none"> • HIV wasting syndrome • Infections <ul style="list-style-type: none"> – Pneumocystis pneumonia – Recurrent severe or radiological bacterial pneumonia

Contd...

Contd...

- Chronic herpetic simplex infection (oral, labial, genital or anorectal of > 1 month duration).
- Oesophageal candidiasis
- Extrapulmonary tuberculosis
- Neoplasms
 - Kaposi's sarcoma
- Neurological disease
 - CNS toxoplasmosis
 - HIV encephalopathy

LABORATORY DIAGNOSIS OF HIV

Tests for HIV specific antibodies in serum/plasma

Screening tests – for screening antibodies against HIV in patient suspected of being HIV infected. They are also used for screening blood and blood products and have a high sensitivity and positivity.

1. ELISA or EIA useful test can be modified frequently, to quantify the result (number of viral copies/mL). Time required 60–90 min.
2. Rapid tests - Useful in emergency clinics, casualties and trauma. Time required < 30 min.

Supplemental tests are used to confirm positive results of screening tests. These tests are false negative in early stage of infection as they are not so sensitive.

Western block (WB) is a specific test for detecting antibodies to different HIV antigens. A modified Western block can differentiate HIV-1 and HIV-2.

Combination of two or more EIAs, using different antigens can provide a more reliable information than ELISA/WB combination, at a lower cost.

Immunoblot (IB) test also allows differentiation between HIV-1 and HIV-2 infections.

Indirect immunofluorescent antibody assay is an expensive test and results are same as Western block.

Confirmatory tests – to confirm presence of virus in the person who is either positive or has equivocal results to HIV-specific antibodies.

Detection of viral RNA by PCR, the first test to become positive.

Detection of HIV-specific core antigen (p24) in the serum during the window period, during late stage of the disease, in HIV-infected new-borns, for monitoring antiretroviral therapy and in cases of HIV associated encephalopathy in CSF.

Virus isolation: HIV can be cultured from blood or any other body fluid of the infected individual.

Table 4: Conditions where confirmatory diagnosis testing is necessary

• Bacterial infections
– Disseminated non-tuberculous mycobacterial infection
– Recurrent nontyphoidal salmonella septicaemia
• Fungal infections
– Extrapulmonary cryptococcosis including meningitis
– Candidiasis of trachea, bronchi or lungs
• Viral infections
– Visceral herpes simplex infection
– Cytomegalovirus infection (retinitis or infection of an organ other than liver, spleen or lymphnodes)
– Progressive multifocal leucoencephalopathy
• Protozoal infections
– Cryptosporidiosis
– Atypical disseminated leishmaniasis
• Neoplasia
– Lymphoma (cerebral or B-cell non-Hodgkin)
– Invasive cervical carcinoma

Tests for diagnosis of disease progression and complications

Viral load estimation – Quantitative HIV RNA estimation is useful for diagnosing acute HIV infection and for predicting probability of transmission, rate of progression in chronically infected patients and for therapeutic monitoring. Treatment failure is defined as failure to decrease viral load by 1.5 log₁₀ c/mL within 4 weeks or to achieve undetectable virus status by 4 months.

CD4 cell count is a standard test to assess progression to AIDS and make decisions about antiviral therapy, and prophylaxis for opportunistic infections. The normal values range from 800 to 1050 cells/mm³. The count should be repeated very 2–4 months in patient on ART.

Diagnosis of HIV in newborn is done by one or more combinations of detection of IgA and/or IgM anti-HIV antibodies, estimation of p24 antigen, PCR, or in vitro antibody production assay, in vitro isolation of virus from blood or tissues and indirect indicators of HIV infection.

CLINICAL MANIFESTATIONS OF HIV

Primary HIV infection – may be asymptomatic, subclinical or clinical. Clinical illness is usually self-limiting, and several manifestations can occur, including a ‘glandular fever-like’ illness, meningoencephalitis and peripheral neuropathy. Seroconversion time (defined as the

time from infection to detection of specific antibodies) is 8 days to 10 weeks after onset of acute illness. Rarely, severe immuno-suppression occurs during acute HIV infection, and AIDS illnesses such as oesophageal candidosis and *pneumocystis jiroveci* pneumonia have been reported.

Early manifestations of HIV infection – Individuals may be asymptomatic or have enlarged lymphnodes with or without minor symptoms, e.g. tiredness, lethargy, excessive sweating, and pains in muscles or joints.

Bacterial sepsis manifests as pneumonia, bacteraemia or both.

Later manifestations – In addition to AIDS, other manifestations that indicate a serious prognosis:

- Constitutional symptoms and/or unexplained diarrhoea, fever (> 38°C) for > 1 month or unexplained weight loss of > 10% body weight.
- Neurological problems (e.g. neuropathy, myelopathy).
- Recurrent *Salmonella* bacteraemia, extensive herpes zoster, recurrent oral candidosis and oral hairy leukoplakia.

Opportunistic infections in HIV disease

Opportunistic infections (OIs) occur in HIV disease due to progressive deterioration in immune status as a result of steady decline of CD4 helper lymphocyte number. CD4 cell count remains the best marker of immune status in HIV disease.

Tuberculosis, herpes zoster and *Candida albicans* tend to develop when CD4 count is < 500/mm³. *Pneumocystis jiroveci* pneumonia, occurs when CD4 count is < 200/mm³. Toxoplasmosis, cryptococcosis, cytomegalovirus infections occur when CD4 count is < 100/mm³. Mycobacterium avian complex and systemic fungal infections occur when CD4 count is < 50/mm³.

***Pneumocystis jiroveci* pneumonia (PJP).** *Cl. Fs.* – Dyspnoea, fever, cough. Physical examination is usually normal. Chest X-ray is variable, interstitial pattern is most common. Elevated lactate dehydrogenase and exercise desaturation are highly suggestive. *Tr.* – Trimethoprim-sulphamethoxazole DS 2 tds for 21 days. In severe disease Prednisolone 40 mg bd for 5 days, then 20 mg od for 12 days. Patients who have not had HAART should finish therapy for PCP prior to starting HAART, those on HAART should continue anti-retroviral drugs.

Tuberculosis is the earliest HIV-related OI. It is the commonest of all OIs, is also the commonest cause of death in patients with AIDS. It is also the only transmissible OI. TB accelerates and negatively impacts the course of HIV disease.

Cl. Fs. - With preserved CD4 counts (< 200/mm³), typical radiological features are upper lobe infiltrates and cavitation are common. As the CD4 count falls, atypical features like focal, nodular and often lower lobe infiltrates occur. Extra-pulmonary TB is more common at low CD4 counts.

Tr. - Standard first line drugs should be used for 6 months, or 9 months if response is slow. DOTS should be used whenever possible with drug level monitoring in non-responders as malabsorption is not uncommon.

Whilst symptoms improve, chest radiographs resolve and sputum converts at the same time period in HIV +ve and -ve patients, these patients still have a high mortality. Much of the excess mortality is from non-tuberculous AIDS-related conditions. This has been referred to as 'treatment paradox'.

Paradoxical reactions are fairly frequent when HAART is started in patients with TB. These are transient worsening or appearance of new symptoms, signs or radiographic manifestations. Clinical manifestations are diverse and treatment involves discontinuation, NSAIDs, or steroids.

Toxoplasma encephalitis presents with neurological symptoms including sensorimotor deficits, seizures, confusion, ataxia and headaches. Toxoplasma IgG antibody is positive. *Tr.* - Pyrimethamine 100 mg loading dose followed by 50-75 mg/day, sulphadiazine 4-8 g/day, followed by lifelong suppressive treatment as relapses are common.

Cryptococcal meningitis. Onset is often indolent with fever, headache, and occasional meningeal signs. *Tr.* - Amphotericin B with or without Flucytosine for 2 weeks followed by lifelong therapy with fluconazole.

Candidiasis - often presents with odynophagia and wt. loss. Oropharyngeal thrush and oesophageal candidiasis respond well to Fluconazole 100-200 mg/day for 2-3 weeks.

Atypical mycobacterial infections (MAC) are rare. It has been suggested that prior infection with *M. tuberculosis* reduces risk of MAC disease. It usually presents with fever, wt. loss, diarrhoea and bone marrow, liver and spleen involvement. *Tr.* - Clarithromycin with ethambutol.

Cardiac complications include pericardial effusion, disturbances of rhythm, malignant infiltration. Heart muscle disease can be of three forms - global left ventricular dysfunction (more common in late HIV disease), isolated right ventricular dilatation and borderline LV dysfunction. Cause of heart muscle disease related to HIV is unknown, but it may be related to the idiopathic lymphocytic myocarditis often found in patients with ventricular dysfunction.

Incidence of pulmonary hypertension is about 0.5%.

Neurological Complications

The central and peripheral nervous systems are involved at every stage of HIV infection.

Meningeal involvement - (a) *TB meningitis* tends to occur in late latent stage with CD4 count < 300 mm³. (b) Commonest chronic meningitis is due to *Cryptococcus neoformans*. About half present with typical features of meningitis. The other presentations range from isolated headaches to cognitive impairment.

Non-focal brain involvement

AIDS-dementia complex (ADC) or HIV associated dementia is a syndrome of insidious onset cognitive decline and behavioural changes with motor dysfunction. In later stages affected individuals are demented with incontinence, paraparesis, and ataxia.

Encephalopathies in later stage of HIV infection usually due to metabolic complications are unusual and difficult to diagnose.

Focal CNS disease

Cerebral toxoplasmosis due to reactivation of *T. gondii* infection has already been discussed. CT or MRI show single or multiple inflammatory mass lesions with oedema and ring enhancement, typically located in basal ganglia.

Progressive multifocal leucoencephalopathy caused by JC virus produces multiple focal, demyelinating lesions in subcortical white matter with corresponding deficits which evolve clinically over weeks or months.

Primary CNS cell lymphomas are of B cell origin and produce focal deficits. Diagnosis requires stereotactic brain biopsy.

Mass Lesions in CNS in HIV

Four common differential diagnosis are toxoplasmosis, tuberculoma, PML primary CNS lymphoma.

Spinal cord diseases

Tubercular and pyogenic infections and lymphoma can produce arachnoiditis and spinal cord compression due to vertebral disease. The typical cord pathology of HIV is vacuolar myelopathy. It is usually associated with ADC and the typical sensory neuropathy of HIV.

Cytomegalo virus can produce an unusual rapidly developing cauda equina syndrome in patients with advanced HIV disease. *Tr.* Ganciclovir, cidofovir and foscarnet to prevent ventriculoencephalitis which can be fatal.

Peripheral neuropathies occur at all stages of the infection. (a) Distal sensory polyneuropathy presents with paraesthesiae to severe neuropathic pain. (b) Inflammatory demyelinating neuropathies resembling G-B syndrome and chronic IDP occur in early to mid-stage HIV infection.

Table 5: Oral manifestations of HIV/AIDS

• Candidiasis: Pseudomembranous, erythematous, angular cheilitis
• Gingivitis/periodontitis
• Necrotizing stomatitis
• Herpes simplex: Intraoral, perioral
• CMV infection
• Herpes zoster
• Aphthous ulcer: Minor, major or herpetiform
• Hairy leukoplakia
• Salivary gland enlargement with xerostomia
• Oral Kaposi's sarcoma: Brown, red or blue or purple macule or nodule particularly on hard palate and attached gingiva
• Oral warts/papilloma
• Focal epithelial hyperplasia

Myopathies – Patients present with weakness and myalgia. Inflammatory myopathies can develop both in early infection as well as with immune reconstitution.

AIDS and the GI Tract

Oral manifestations

See Table 5.

Oesophageal symptoms

Candidosis. Diagnostic criterion for AIDS in HIV positive patients. Pain on swallowing and dysphagia. Good response to fluconazole 400 mg single dose. If resistance itraconazole solution 200 mg/day for 2 weeks.

Ulceration

- **CMV infection** may produce ulcers of lower oesophagus or hemorrhagica oesophagitis. Both respond to i.v. ganciclovir 5 mg/kg b.d., or foscarnet 90 mg/kg b.d. for 2 weeks (in those with normal renal function).
- **HSV infection** less commonly produces discrete oesophagitis with associated fluid-filled vesicles. *Tr.* – Acyclovir 400-800 mg 5 times daily. Can be given i.v. 5 mg/kg t.d.s.
- **Ulcers of unknown aetiology** – Large shallow ulcers resembling aphthous ulcers. Prednisolone 40 mg/day or intralesional methylprednisolone acetate may be effective.

Wasting. Loss of more than 10% of ideal body wt. without obvious cause. Continuing wt. loss is usually associated with a specific pathogen most commonly a protozoal

gut infection. *Tr.* – Testosterone 40 mg t.d.s., anabolic steroids or appetite stimulants. Recombinant growth hormone 0.1 mg/kg/day increases lean body mass in wasted individuals.

Diarrhoea is the presenting feature in up to 30%. Homosexuals acquire a variety of sexually transmitted enteric infections (collectively termed 'gay bowel syndrome').

Bacterial Infections

Salmonella and Campylobacter infections. Septicaemia (20-40%) and a relapsing course (10-20%) are seen particularly in those with low CD4 + lymphocyte counts. *Tr.* – Ciprofloxacin 250-500 mg b.d.

Mycobacterium avium-intracellulare (MAI) causing diarrhoea. Jejunal biopsies (showing MAI-laden macrophages in lamina propria) may be necessary in establishing the cause. *Tr.* – Azithromycin 1 g/day and clarithromycin 1 g/day produce marked improvement in systemic manifestations with variable effects on diarrhoea.

Protozoal Infection

Cryptosporidiosis causes diarrhoea. *Cryptosporidium* can be identified in stool samples and is occasionally seen on gut biopsy when direct faecal analysis is negative. The infection responds to HAART. No medication has been shown to eradicate cryptosporidia from stool, though paromomycin 500 mg q.d.s. may reduce stool volume by up to 50%.

Microsporidia – *Encephalitozoon* and the closely related *Septata* have also been associated with diarrhoea. Most patients have marked immuno-suppression, wasting and diarrhoea of up to 1 litre/day. Diagnosis is by staining faecal samples with strong trichrome or a fluorescent stain, which demonstrates the spores. *Tr.* – Albendazole 400 mg b.d. HAART eradicates all types of microsporidia within 6 months of initiation.

CMV infection of the colon causes abdominal pain, rebound tenderness and diarrhoea which may be bloody. Toxic dilatation and perforation are complications. Multiple CMV inclusions with intense inflammation on rectal biopsy confirm the diagnosis. *Tr.* – Ganciclovir or Foscarnet.

Abdominal pain. Infection is the cause in most patients.

(a) **Right upper quadrant** pain is often associated with changes of sclerosing cholangitis or bile duct dilatation. (b) **Right iliac fossa** pain is often caused by appendicitis which may be more common because of CMV infection. (c) **Diffuse abdominal** pain, often associated with rebound tenderness, is usually caused by CMV infection.

Hepatitis

Hepatitis D virus infection occurs in two ways (a) To serum containing both HBV and HDV. It results in mild to fulminant hepatitis.

(b) Superinfection of chronic HBV carrier with a new inoculum of HDV results in – (i) Mild HBV may become fulminant hepatitis. (ii) Acute severe hepatitis. (iii) Chronic progressive disease resulting in cirrhosis.

Hepatitis C virus infection – Co-infection with HIV may accelerate the natural course of the disease resulting in progressive liver disease.

Pancreatic disease. Prevalence of acute pancreatitis can be as high as 45% probably because it is associated with various drugs used in AIDS.

Dermatological

- Superficial fungal infection: Candidiasis, dermatophytosis, pityrosporum infection
- Disseminated fungal and protozoal infection: Cryptococcus neoformans infections, histoplasmosis, sporotrichosis, dermal leishmaniasis, coccidioidomycosis
- Bacterial and mycobacterial infections: Staph. aureus, M. avium intracellulare, M. tuberculosis, actinomycosis.
- Viral: HPV infection, molluscum contagiosum, herpes simplex virus, varicella and herpes zoster, cytomegalovirus, E-B virus.
- HIV-related rash: Acute HIV exanthem, papular rash of HIV
- Pruritic papular and follicular eruptions: Folliculitis – Eosinophilic pustular, pityrosporum, demodectic. Insect bite reaction. Prurigo nodularis.
- Papulosquamous disorders: Seborrhoeic dermatitis, psoriasis, Reiter's syndrome, atopic dermatitis, lichen planus
- Malignancies: Kaposi's sarcoma, squamous cell and basal cell carcinoma, malignant melanoma
- Miscellaneous dermatoses: Acquired ichthyosis, chronic photosensitivity, granuloma annulare, vitiligo, immunobullous disorders, Sjogren's syndrome, porphyria, telangiectases, leukocytoclastic vasculitis, scabies (Norwegian), hidradenitis suppurativa, palmoplantar keratoderma.

HSV infection – Chronic HSV infection of skin or mucous membrane for longer than one month is an indicator for diagnosis of AIDS. In patients with a history of sexually acquired HSV, the infection usually presents as genital or oral ulceration.

Herpes zoster occurs both early and late in HIV disease. In fact HIV disease is multidermatomal (i.e. affected dermatomes are not adjacent or connected).

Bacillary angiomatosis is a chronic bacterial infection most commonly involving the skin. The causative agent is related to either *Rochalimaea quin-tana* or *Bartonella bacilliformis*. Skin lesions appear similar to granulation tissue or slowly healing sores. Visceral disease without skin disease may occur, involving the liver, spleen or bones. The condition must be considered in patients presenting with hepatosplenomegaly. Tr. Erythromycin or doxycycline for 6–8 weeks.

Haematological abnormalities. Severe neutropenia occurs in as many as 70% of patients and is often related to concomitant drug therapy. In addition there is evidence of defective neutrophil function in HIV/AIDS (chemotaxis, bacterial killing, phagocytosis and superoxide production).

HIV-related thrombocytopenia. An ITP-like syndrome occurs before the onset of AIDS, but is a relatively benign condition. Major life-threatening hemorrhage is rare.

Renal abnormalities. A specific HIV-associated nephropathy (HIVAN) presents as severe nephrotic syndrome as a consequence of glomerulosclerosis which may progress to end-stage kidney failure.

Rheumatological Syndromes

See Table 6.

Problems in HIV infected women. Risk of lower genital tract infection is more common. These include vaginal yeast infections, genital herpes, *Trichomonas*, and pelvic inflammatory disease. Cervical intraepithelial neoplasia can occur, but cervical cancer is seldom listed as a cause of HIV-related death.

Table 6: Rheumatological manifestations in HIV infection

Due to impaired immunosurveillance
• Infectious arthritis
• Osteomyelitis
Due to host response to HIV
• Polymyositis
• Vasculitides
• Diffuse infiltrative lymphadenopathy syndrome (DILS)
CD4 defects and persistence of antigens
• Reiter's syndrome
• Psoriatic arthropathy
• Undifferentiated spondyloarthropathy
Due to chronic immune stimulation
• Arthralgias
• Painful articular syndromes

HIV-related cancer

Kaposi's sarcoma

Epidemiology – Kaposi's sarcoma is the most common malignancy associated with HIV-1 infection. It seldom occurs in absence of HIV infection, but there are three other epidemiological forms in which the disease is less aggressive – 'classic' (found in elderly Jews and Eastern European men), endemic (initially found in sub-Saharan Africa) and transplant-associated.

Aetiology and pathology – Kaposi's sarcoma-associated herpes virus (human herpes virus 8) is a DNA virus thought to be an essential, though not necessarily sufficient factor in the causation. It has been found in affected tissue. Microscopically it comprises groups of spindle-shaped cells separated by slit-like vascular spaces containing RBCs and mingled with endothelial-lined vessels.

Clinical features and diagnosis – Kaposi's sarcoma can affect any site other than the CNS. Its course is increasingly aggressive and is potentially fatal.

Description – Lesions occur in a multifocal manner. Most patients present with mucocutaneous disease, commonly affecting the limbs, face, trunk and hard palate. Lesions start as areas of red or purple discolouration, then progress to firm, raised, non-tender nodules or plaques, which turn brown over time. In dark-skinned individuals, the lesions are brown or black.

Lymphoedema occurs as a result of small lymphatic obstruction, and affects mainly the lower limbs, can be severe in nature and lead to cellulitis. Associated lymphadenopathy should be biopsied to exclude concurrent lymphomatous disease.

Most common visceral sites are: (a) GI tract – Kaposi's sarcoma can occur throughout the GI tract and is diagnosed on endoscopy. (b) Pulmonary Kaposi's sarcoma may present with cough, wheeze, shortness of breath on exertion and haemoptysis. Reticular nodular shadowing, pleural effusions and lymphadenopathy are seen on chest radiography, but the appearances are nonspecific and may resemble *Pneumocystis jiroveci* pneumonia. Visualization of characteristic lesions on bronchoscopy is required to make a diagnosis.

Management – There is no cure for AIDS-related Kaposi's sarcoma. HAART may lead to regression. Radiotherapy is used for symptom control and for patients who are too ill to receive systemic treatment. Alternatives include cosmetics, cryotherapy, intralesional injections of vinblastine or interferon and topical retinoids.

Low CD4 count, prior opportunistic infection, visceral disease, and B symptoms (sustained fever > 38°C, night sweats, weight loss > 10% body wt.) are poor prognostic factors.

Systemic non-Hodgkin's lymphoma (NHL) develops in 10–20% of HIV-positive individuals, and may occur late in HIV disease. AIDS-related lymphomas are usually high-grade. Most patients present with advanced-stage and extranodal disease (meninges and bone marrow).

Primary cerebral lymphoma represents 15% of AIDS-related lymphomas. Presentation is with neurological deficit with multiple enhancing lesions on CT or MRI. Diagnosis can be confirmed by open or stereotactic biopsy.

Cervical carcinoma. Both HPV infection and cervical intraepithelial neoplasms (CIN) are more common in women with HIV infection.

Paediatric HIV Infection

Mode of acquisition. 90% of HIV infection in children is MTCT.

Incubation period and disease progression. HIV infection if acquired in early life has a much shorter incubation period due to immunological immaturity. 10–30% are rapid progressors and can die within 5 years.

Cl. Fs. Infected children present with non-specific common childhood disease. Diarrhoea and respiratory infections are common, recurrent, persistent, and more severe. Others include recurrent fever, failure to thrive, hepatosplenomegaly, oral thrush, lymphadenopathy, anemia, TB and bronchiectasis. Pneumocystis pneumonia can occur in first year of life even with normal CD4 counts. Developmental delay and interstitial pneumonia are unique features.

Classification of disease severity

Category N: Asymptomatic children, without signs or symptoms, or who have only one of the conditions listed in category A.

Category A: Two or more symptomatic HIV-related conditions such as lymphadenopathy, hepatomegaly, splenomegaly, dermatitis, parotitis, recurrent upper respiratory infections, otitis media and no documented B or C clinical conditions.

Category B: Defines children with moderately symptomatic, HIV-related conditions – single episode of bacterial meningitis, pneumonia or sepsis, fever lasting for more than one month, recurrent or chronic diarrhoea, anemia, neutropenia or thrombocytopenia persisting more than 30 days, cardiomyopathy, nephropathy, hepatitis, lymphoid interstitial pneumonia (LIPO), CMV infection before 1 month of age, persistent oral, disseminated varicella-zoster viral infections, herpes zoster (2 dermatomes/2 epi-

sodes), and recurrent Herpes simplex stomatitis without any category C conditions.

Category C: These are AIDs defining conditions and include recurrent, severe infections (meningitis, pneumonia, septicaemia, etc.), oesophageal/pulmonary candidiasis, cryptosporidiosis, CMV/toxoplasmosis disease of more than 1 month of age, recurrent nontyphoidal salmonella septicaemia, disseminated/extrapulmonary mycobacterial tuberculosis, atypical mycobacterial infections, wasting syndrome, pneumocystis jiroveci pneumonia, and HIV encephalopathy.

The severity of illness can also be assessed by the CD4 cell count. The CDC classification and immunological classification can be combined together.

Antiretroviral therapy

Definite indications

- Age < 12 months - Any clinical symptom of HIV (category A, B and C) or immune suppression (immune category 2 or 3)
- Age > 12 months - Category C disease or immune category 3 in children above 10 months, a positive ELISA, and a confirmatory test in form of DNA/RNA PCR or western blot in children below 18 months, presence of transplacentally transmitted material antibodies makes standard HIV IgG antibody tests unreliable. Alternative tests include HIV 'c' culture, HIV PCR or p24 antigen testing.

Prevention of mother to child transmission of HIV

MTCT of HIV-1 can occur during pregnancy, labour or breast feeding.

- | | |
|---|--|
| gp 120 surface envelope glycoprotein | p24 capsid protein |
| gp41 transmembrane envelope glycoprotein | Accessory proteins (Vpr, Vif, cyclophilins) |
| Virus enzymes (e.g. reverse transcriptase, integrase) | Diploid RNA genome coated with p9 nucleocapsid protein |
| p17 matrix protein | Virus envelope derived from cell membrane |

Therapy - Short course regimens (usually comprising ZDV, 3TC, NVP) are well tolerated with no reported teratogenicity. However with short course partly suppressive drug regimes is the risk of drug resistance and limitation of future treatment options.

If HAART is not indicated, the PHPT-2 regime is preferred. Other options are - (a) AZT-3TC (from 36 weeks intrapartum and 1 week postpartum and 1 week to neonate). (b) Antenatal (28 weeks onwards) intrapartum and neonatal 1 week AZT.

If mother has not received any therapy the infant may be given single dose NVP with 1 week AZT, starting as soon as possible after and definitely within 48 hours.

Elective Caesarean section reduces MRCT by 55-85% as compared to vaginal delivery irrespective of AZT therapy. Risk of postoperative complications is slightly higher than with vaginal delivery. The risk further increases with emergency CS and with advanced HIV disease.

Fig. 14: Sites of Action for Several important Classes of Inhibitors
*NRTIs, NNRTIs act here; ** Integrase inhibitors act here; ***PIs act here

Infant feeding. Breast feeding increases transmission rate and greatly reduces efficiency of prophylactic ARV regimes.

The risk is greatest in first 6 months but persists as long as breast feeding continues. Mixed feeding may be more risky than exclusive breast-feeding as allergic reactions to replacement feeds may damage intestinal mucosa and facilitate entry of the virus. If it is decided to have exclusive breast feeding it should be with early and rapid weaning at 4–6 months. Other options such as wet nursing by HIV-negative relative or heat treatment of expressed breast milk are not very practical but may be considered.

Antiretroviral therapy

Drugs

Major classes of antiretroviral drugs

1. Nucleoside analogue transcriptase inhibitors (NRTIs)
2. Non-nucleotide reverse transcriptase inhibitors (NNRTIs)
3. Protease inhibitors (PIs)

Initial evaluation – Before starting ART the following investigations are necessary:

- History of or presence of any STDs, VDRL/TPHA, if necessary.
- Chest radiograph or CT scan to exclude TB or any other infection.
- LFTs and tests to rule out coinfection with hepatitis B or C.
- History of alcohol intake or drug abuse.
- History of previous ART therapy by patient or partner.
- CBC – Zidovudine is contraindicated, if anemia.
- Testing for HIV-1 and HIV-2. Use of NNRTIs is not effective against HIV-2 virus.
- CD4 counts should be done at the same time each day because of diurnal variations. CD4 counts may be low with opportunistic infections like tuberculosis.
- CD4 counts should be done as soon as blood is taken or at least within 24 hours.
- A high plasma viral load (PVL) leads to a sharper fall in due course. The main value of PVL assays is in estimating the effectiveness of the antiviral therapy being used resulting in complete viral suppression (≤ 50 copies/mL or < 500 copies/mL) depending on the assay used.

TIME OF INITIATION OF ART

- All patients with CD4 count < 200 require ART.
- All patients with CD4 count < 350 , ART can be deferred.
- Patients with high viral loads CD4 count between 200 to 350, starting ART depends on patient's plasma viral load. If $> 50,000$ copies/mL there is faster progression to AIDS and a sharper rate or decline in CD4 counts.

- In patients with opportunistic infections, ART must be combined with therapy for various OIs. However it is preferable to defer ART until treatment of OI medication has been completed or at least until the patient has been stabilised on the OI medication used, because of poor patient tolerance and toxicity and subject to interactions. Also delaying ART with patient on OI reduces the incidence of immune reconstitution inflammatory syndrome (IRIS), avoiding large tablet burdens and allowing to identify the responsible drug when multiple toxicities could occur.

Plasma HIV RNA level is the stronger predictor of progression rate, except in patients having low CD4+T cell counts. Therapy is generally recommended in patients with plasma HIV RNA levels $> 30,000$ copies/mL, irrespective of CD4+T cell count, and for patients with CD4+T cell counts < 350 /cmm (350/mL) irrespective of RNA level.

Resistance. Development of resistance is a problem, common to all drugs used to treat HIV disease and is characterized by mutations at specific codons on either the reverse transcriptase gene or the protease gene in HIV. Use of drugs with different sites of action delays onset of resistance.

An important technique is the assessment of lymphocyte function and response to antigens as a means of evaluating the function of the immune system, benefits of therapy and need for prophylactic medication.

ANTIRETROVIRAL DRUGS

NRTI-based regimens

Preferred regimens

- Efavirenz + Lamivudine + Zidovudine or Stavudine (not in women with chance of pregnancy)

Alternate regimen

- Efavirenz + Lamivudine + Didanosine
- Nevirapine + Lamivudine + Zidovudine, Stavudine or Didanosine

PI-base regimen

Preferred regimens

- Lopinavir + Ritonavir + Lamivudine or Stavudine

Alternate regimen

- Indinavir + Lamivudine + Zidovudine or Stavudine
- Indinavir + Ritonavir + Lamivudine or Zidovudine or Stavudine

Note: Use of highly active anti-retroviral therapy (HAART) involves use of two NRTIS together with one NNRTI or PI.

Immune reconstitution inflammatory response (IRIS) is basically a pathological inflammatory response where paradoxical worsening occurs after HARRT, in either previously treated infections or subclinical infection with recovery of immune response. It has been described

with mycobacteria, *Cryptococcus neoformans*, herpes virus pneumocystis, jiroveci pneumonia. IRIS may occur shortly after the treatment of an opportunistic infection, or a “new” clinical syndrome resulting from a previously unrecognised occult infection.

In pregnancy – ART should be started in an untreated patient on AZT, lamivudine and Saquinavir at the beginning of the third trimester. Nevirapine has also been found to be effective as it passes through the placenta very efficiently. It is given as a single dose to the mother at the onset of labour, and one dose administered to the baby at 48-72 hours. If started early in pregnancy, it is given as an od dosage for 2 weeks and two doses daily thereafter, to be continued till birth.

Table 7: Spectrum of HIV disease

HIV associated disease	Average duration	CD4 cell count
Acute primary infection	1–2 weeks	1000–500
Asymptomatic	10 years	750–500
Early symptomatic	0–5 years	500–250
Late symptomatic	0–3 years	200–50
Advanced disease	1–2 years	50–0

Prophylaxis – HIV postexposure prophylaxis (PEP) should be started within an hour or two. Depending on the type and seriousness of the exposure, either a basic regimen (AZT + Lamivudine) or an expanded drug regimen (basic regimen + indinavir/nelfinavir) for 4 weeks is recommended.

Addendum

Table 8: Factors that increase risk of MTCT

Primary HIV infection during pregnancy
Advanced HIV disease in mother (low CD4 count, high plasma viral load)
Multiple sexual partners
IV drug abuse
Coexistent sexually transmitted STDs
Low maternal vitamin A levels
Premature delivery
Prolonged rupture of membranes
Chorioamnionitis
Vaginal delivery
Use of invasive techniques during labour
Breast feeding

Table 9: Antiretroviral drugs

Generic name	Mode of action	Dose (for adults > 60 kg)	Comments/side effects
NRTIs: Zidovudine (d4t) Lamivudine (3TC)	Complete with cellular nucleoside for incorporation into HIV DNA strands	200 mg tds 150 mg bd	Nausea, headache, neuropathy, myopathy Active against HBV; rash peripheral neuropathy, acute pancreatitis in children
Stavudine (d4T) Didanosine (ddI)		40 mg bd 125 mg bd	Peripheral neuropathy, hepatitis, pancreatitis Take on empty stomach, alcohol may exacerbate toxicity; painful peripheral neuropathy
Zalcitabine (ddC)		0.75 mg tds	Don't take simultaneously with antacids; peripheral neuropathy
Abacavir		300 mg bd	Up to 3% hypersensitivity reactions resolves within 2 days of discontinuation; don't rechallenge
NNRTIs			
Nevirapine Efavirenz Delavirdine	Bind to reverse Transcriptase	200 mg bd then 200 mg bd 600 mg od 400 mg tds	Rash Initial dizziness, avoid dirithromycin Rash
PIs			
Saquinavir (soft gel caps) Ritonavir	Inhibit protease producing immature defective virus particles	1200 mg tds 600 mg bd	Distress, headache; take with fat containing food; store in refrigerator Take with meals To be refrigerated
Indinavir		800 mg tds	Kidney stones, take on as empty stomach, drink at least 15 l of fluids daily
Nelfinavir		750 mg tds	Diarrhoea Not recommended < 3 years of age

Table 10: Post HIV exposure prophylaxis (PEP)

<i>Recommended HIV PEP. Percutaneous injuries / mucous membrane exposures and non-intact skin.</i>	
Exposure type	
HIV positive class I	
Small volume	Consider basic 2-drug PEP
Large volume	Expanded 3-drug PEP
HIV-positive class II	
Small volume	Recommend basic 2 drug PEP
Large volume	Expanded 3-drug PEP
<i>Source HIV status unknown</i>	
Less severe (secretions)	Generally no PEP warranted; however consider 2 drug PEP for source with HIV risk factors
More severe	Generally, no PEP warranted;
<i>Unknown source</i>	
Less severe (secretions)	Generally, no PEP warranted; However consider 2 drug PEP in settings where exposure to HIV-infected person is likely

Table 11: Presenting symptoms of STDs in men

<i>Symptom</i>	<i>Causes</i>
Urethral discharge and/or dysuria	Gonococcus Chlamydia Mycoplasma/Ureaplasma Nonspecific urethritis
Warts Genital ulceration	Human papilloma virus Herpes simplex virus Syphilis Nonspecific pre-malignant dermatoses
Vague genital ache Cold, numb penis Pubic crabs Intrascrotal lumps	Chronic prostatitis Psychosomatic Phthirus pubis Orchitis Epididymal cysts Hydrocele Testicular cancer Torsion of testis
Ejaculatory disorders Haemospermia Balanitis	Often psychosomatic Often no obvious cause Thrush in diabetics Often nonspecific genital dermatoses Poor subpreputial hygiene

Table 12: Genital ulcers

<i>Disease</i>	<i>Morphology</i>
Aphthae	Sharply marginated, tender ulcers with ragged base. Recurrent. May be associated with Behcet's syndrome
Chancroid	Painful, multiple nonindurated undermined ulcers with slough on floor of ulcer
Donovanosis	Nontender ulcer with raised border. Floor of ulcer shows dark red granulation tissue. Lesion not undermined
Chancre of primary syphilis	Usually single, sharp, punched out ulcer with indurated base. Pale granulation tissue on floor of ulcer
Herpes genitalis	Multiple grouped vesicles with erosions going on to ulceration
Scabies	Superficial ulcers with associated erosions, papules, vesicles and pustules.
Traumatic	Superficial or deep erosion with a clean floor. History of trauma.
Ecthyma	Multiple, rounded ulcers with thick, purulent crusts
Tuberculosis	Tender, indurated papules with ulceration
Tumour	Tumour nodule with induration and ulceration
Wart	Heaped-up cauliflower-like growth with ulceration

Miscellaneous

1. PROLONGED PYREXIA

PYREXIA OF UNKNOWN ORIGIN

The term Pyrexia of Unknown Origin (PUO) may be used to describe the condition of a patient who has

- An oral temperature of 38°C on at least two occasions
- More for longer than 3 weeks
- No known immunocompromised state
- Diagnosis that remains uncertain after a thorough history-taking, physical examination and the following obligatory investigations: determination of erythrocyte sedimentation rate (ESR) and C-reactive protein (CRP) level; platelet count; leukocyte count and differential; measurement of levels of hemoglobin, electrolytes, creatinine, total protein, alkaline phosphatase, alanine aminotransferase, aspartate aminotransferase, lactate dehydrogenase, creatine kinase, ferritin, antinuclear antibodies, and rheumatoid factor; protein electrophoresis; urinalysis; blood cultures (n = 3); urine culture; chest X-ray; abdominal ultrasonography; and tuberculin skin test (TST).

TYPES OF PUO

- *Classical PUO* - PUO in a non-compromised individual.
- *Nosocomial PUO* - refers to infection arising in hospital (e.g. nosocomial pneumonia in patient on ventilation in ICU). Three days of investigation, including at least 2 days' incubation of cultures, is the minimum requirement for this diagnosis.
- *Neutropenic PUO* - refers to infections, usually endogenous and bacterial, in patient with less than 500 WBC/mm³.
- *HIV associated PUO* - When temp. > 38°C (101°F) on several occasions over a period of more than 4 weeks in outpatients or >3 days for hospitalized patients with HIV infection. The diagnosis is considered if appropriate investigations over 3 days including 2 days of incubation of cultures reveal no source.

CAUSES

A. Infections

- Specific infections:

- a. Bacterial - Tuberculosis, typhoid, paratyphoid, meningococemia, brucellosis, septicaemias and pyemias, infective endocarditis, tularemia, listeriosis.
 - b. Spirochaetal - Secondary syphilis, leptospirosis, rat bite fever, Lyme disease.
 - c. Protozoal - Amoebiasis, malaria, kala-azar, toxoplasmosis, schistosomiasis, trypanosomiasis, trichinosis, *pneumocystis jiroveci* pneumonia.
 - d. Viral, rickettsial and chlamydial infections - Epstein-Barr virus, influenza virus, A and B hepatitis, cytomegalovirus, coxsackie virus diseases (group B), HIV infection, psittacosis, Q fever, mucocutaneous lymph node syndrome in children.
 - e. Fungal - Actinomycosis, histoplasmosis.
2. *Local septic infections or localised pus* - Sinusitis, mastoiditis, dental abscess, osteomyelitis, mammary abscess, parotid abscess. Lung abscess, bronchiectasis, upper abdominal - hepatic, pancreatic, subphrenic or splenic abscess, cholecystitis, appendicitis. Intrarenal or perinephric abscess. Pelvic abscess.
 3. *Local infections without pus formation* - Cystitis, phlebitis, inflamed piles, ulcerative colitis, Crohn's disease, diverticulitis, appendicitis.
- ### B. Non-infectious causes
1. *Neoplasms* - Hodgkin's disease and other lymphomas, hypernephroma, hepatoma, atrial myxoma, metastasis.
 2. *Blood diseases* - Leukaemia, aplastic anemia, hemolytic episodes.
 3. *Connective tissue diseases* - Rheumatic fever, rheumatoid arthritis, adult Still's disease, polymyalgia rheumatica, polymyositis, polyarteritis nodosa, erythema nodosum, systemic lupus erythematosus.

4. *Vascular disease* – Temporal or cranial arteritis, cerebrovascular accident, myocardial infarction, pulmonary thromboembolism, intravascular catheter, infections.
5. *Trauma* – Crush injury, head injury.
6. *Metabolic* – Gout, porphyria.
7. *Endocrine* – Thyrotoxicosis, Addison's disease, pheochromocytoma.
8. *Hypersensitivity reactions* – Serum sickness, drug fever, e.g. sulphonamides, atropine, morphine, salicylates, phenytoin, methyldopa, isoniazid, iodine. Post-myocardial infarction syndrome.
9. *Heat disorders* – Heat fever, heat hyperpyrexia.
10. *Skin disease* – Pemphigus, bullous dermatosis.
11. *Miscellaneous causes* – Dehydration, Recurrent pulmonary embolism, Sarcoidosis, Thyroiditis, Hemolytic states, Dissecting aneurysm, Whipple's disease, Weber-Christian disease.
12. *Metabolic and inherited disorders* – Familial Mediterranean fever, Fabry's disease (angiokeratoma corporis diffusum), Kawasaki's disease (mucocutaneous lymph node syndrome), hypertriglyceridemia and hypercholesterolemia with pancreatitis, cyclic neutropenia. Hereditary urticaria, deafness, amyloid syndrome.
13. *Thermoregulatory disorders* – Brain tumour, cerebrovascular accident, encephalitis.
14. *Factitious fever* – of the Munchausen type (malingerers).
15. *Inherited disorders* – are uncommon causes, e.g. familial Mediterranean fever. Fabry's disease, hypertriglyceridemia (with abdominal pain, recurrent fever and pancreatitis), primary amyloidosis and CNS conditions with a hypothalamic component (thermoregulatory dysfunction).
16. *Habitual hyperthermia*.
2. *Rigors* – Malaria (continuous type of fever likely in malignant infection), filaria, empyema, UTI, cholangitis, hepatic or appendicular abscess, septicaemia. Rarely typhoid at onset.
3. *Headache* – Meningitis, typhoid at onset, typhus, encephalitis.
4. *Bodyache* – Influenza, dengue fever, fever of secondary syphilis, brucellosis, rat bite fever, relapsing fever.
5. *Sweating* – Malaria, pulmonary or miliary tuberculosis, influenza, rheumatic fever, amoebic liver abscess, lymphomas, brucellosis, relapsing fever, psychogenic.
6. *Convulsions* – Cerebral malaria, encephalitis, meningitis, apical pneumonia.
7. *Delirium* – Typhoid, typhus, pneumonia, meningitis, septicaemia, plague.
8. *Loss of weight* – Tuberculosis, chronic suppurative disease like empyema or lung abscess; lymphomas, thyrotoxicosis, polyarteritis.
9. *Diarrhoea* – Malignant malaria, typhoid and paratyphoid, thyrotoxicosis, Crohn's disease, ulcerative colitis, tuberculous enterocolitis or chronic dysentery.
10. *Vomiting* – Malaria, meningitis, appendicitis, pyelonephritis.
11. *Sore throat* – Diphtheria, secondary syphilis, agranulocytosis, leukaemia, infectious mononucleosis.
12. *Frequency of micturition* – UTI, tuberculosis of kidney, chronic retrocaecal appendicitis.

Past history – Of rheumatic fever or valvular disease, tuberculous lymphadenitis, pleural effusion, rat bite or parrot bite, syphilis, filariasis.

Personal history (a) Residence in endemic area in kala-azar, amoebiasis, Mediterranean fever, and trypanosomiasis. (b) Occupational history in leptospirosis; history of infection in other members of the family. (c) Contact with domestic or wild animals or birds, such infections can be brucellosis (cattle), psittacosis (birds), leptospirosis (rats, dogs and pigs), salmonellosis (ducks, rats, tortoises, etc), Q fever (cattle and sheep), rat bite fever (rats, ferrets), cat-scratch fever (cats). (d) Contact with persons with tuberculosis. (e) Prior surgery or trauma. (f) Drugs (e.g. carbamazepine, intermittent rifampicin consumption, hydralazine ingestion, monoamine oxidase inhibitors particularly in combination with tricyclic antidepressants).

INVESTIGATION OF A CASE OF PROLONGED PYREXIA

History

- A. General – Exposure to infection, contact with animals, travel, occupational hazards. Prior abdominal surgery should suggest possibility of subphrenic, pelvic or paracolic abscess. Endocarditis and abscesses are common in intravenous drug users. History of trauma.
- B. Symptoms
 1. *Onset* – Sudden in pyelitis, pneumonia, influenza. Gradual in typhoid, infective endocarditis, pulmonary tuberculosis, brucellosis, etc.

Physical examination

General Examination

- Temperature** - Type of fever - (a) Intermittent - High peaks of fever with subsidence to normal or subnormal levels - Malaria, acute pyelonephritis, filariasis, septicaemia, local and general pyogenic infections. (b) Continuous - Temperature high throughout the day with a difference between maximum and minimum daily temperature of less than 2°F - Typhoid, miliary tuberculosis, infective endocarditis, virus pneumonia, hepatic amoebiasis. (c) Periodic or undulating - Rat bite and relapsing fevers, brucellosis, Hodgkin's disease, relapses of typhoid. (d) Double rise with morning and evening peaks - Kala-azar, malaria, liver abscess, typhoid fever, pulmonary tuberculosis, infective endocarditis, E. coli infections of urinary tract. However, many different temperature patterns may be produced by any one disease. (e) 'Hectic' fever with high peaks and relative bradycardia - adult Still's disease.
- Pulse rate** - Relative bradycardia in typhoid, meningitis, influenza, dengue, Weil's disease, adult Still's disease.
- Respiration** - Hurried in pneumonia and bronchopneumonia, pulmonary TB, pleural effusion or empyema, miliary tuberculosis, pulmonary infarction.
- Anemia** - Malaria, kala-azar, septicaemia, subacute infective endocarditis, chronic sepsis, amoebic liver abscess.
- Lymphadenopathy** - (i) *Generalized* - in tuberculous glandular enlargement, secondary syphilis, Hodgkin's disease, infectious mononucleosis, septicaemia, lymphatic leukaemia, histoplasmosis, trypanosomiasis, cytomegalovirus infection, HIV infection. (ii) *Localized in* - infectious mononucleosis, plague, rat bite fever, tick typhus, lymphogranuloma inguinale, tularemia.
- Jaundice** - with fever in viral hepatitis, Weil's disease, malaria, infectious mononucleosis, liver abscess.
- Toxaemia** - Little or no toxaemia in presence of moderately high fever points to E. coli infection of urinary tract, kala-azar, pulmonary or glandular tuberculosis, localised suppurative process, leukaemia.
- Skin** - (a) Rash - in typhoid, typhus, meningococcal meningitis, rat bite fever, trypanosomiasis. (b) Any deposits. (c) Petechial haemorrhages - Cerebrospinal meningitis, septicaemia, Weil's disease, malignant diphtheria, typhus, typhoid, SIE.
- Clubbing of fingers** - Bronchiectasis, lung abscess, chronic empyema, subacute infective endocarditis, liver abscess.

- Arthritis** - Rheumatic fever, subacute infective endocarditis, brucellosis, gout, meningococemia, leukaemia, disseminated lupus, polyarteritis nodosa, Lyme disease.
- Nails** - Transverse white bands on the nails may be seen in brucellosis.
- Herpes labialis** - occurs with pneumococcal infection, streptococcal infection, meningococemia, malaria, Rickettsial infection.
- Nodules** - in rheumatic fever, rheumatoid arthritis, leprosy, erythema nodosum, cysticercosis, polyarteritis nodosa.
- Local lesion** - Eschar in mite typhus, flare up of site of wound in rat bite, necrotic papule in tularemia, red macule or papule in Lyme disease.

Systemic Examination

- Ears, nose, mouth and sinuses** - for focal sepsis in teeth, tonsils and nasopharynx.
- Abdomen**
 - Splenomegaly - Malaria, kala-azar, Hodgkin's disease, infectious mononucleosis, typhoid, septicaemia, miliary tuberculosis, infective endocarditis, histoplasmosis, trypanosomiasis.
 - Hepatomegaly - Hepatic abscess, cholecystitis, malaria, leukaemia, kala-azar, yellow fever, Weil's disease, metastatic cancer.
 - Ascites - TB peritonitis; lymphoma.
 - Localising signs - of appendicular abscess, cholecystitis, colitis, diverticulitis, perinephric abscess.
 - Peritoneal and pelvic - Subphrenic abscess, peritonitis, salpingitis, prostatitis.
 - Testicle - Tuberculosis, teratoma.
- Heart** - Pericarditis, endocarditis. Hypertension in chronic pyelonephritis and polyarteritis.
- Lungs** - Pneumonia, pleural effusion, pulmonary tuberculosis, empyema, bronchiectasis, lung abscess, actinomycosis.
- Head and Neck** - Sinusitis, otitis and mastoiditis, diphtheria, tonsillitis, meningitis, brain abscess, and signs of encephalitis.
- Limbs** - Thrombophlebitis, osteomyelitis, cellulitis, filarial elephantiasis. Polyneuritis in polyarteritis.
- Rectum** - for missed appendicular abscess.
- External genitalia** - for sepsis or neoplasia.
- Ocular fundi** - for choroidal tubercles, retinitis, etc.
- Pacemaker implantation.

INVESTIGATIONS

Initial Investigations

- Chest radiography
- Urinalysis and urine microscopy
- C-reactive protein and ESR
- Blood culture taken at times of fever
- Urea, creatinine, electrolytes, liver function tests.

See Table 1 for further investigations.

Imaging in PUO

- CT and MRI allow identification of small abnormalities, but depend on anatomical changes that develop over time or may not develop in usual manner in immunocompromised (e.g. neutropenic patients).
- Scintigraphy (e.g. radiolabelled WBC scanning) can detect changes caused by infection or inflammation.
- Scans are chosen to help establish presence or absence of a particular diagnosis, e.g. isotope bone scan in suspected bone or joint infection, and ventilation perfusion scan in those with suspected multiple pulmonary emboli.
- Radiolabelled ciprofloxacin derivatives have been used in attempts to distinguish infection from sterile inflammation.

Invasive Investigations

When diagnosis cannot be made with non-invasive techniques, it is often necessary to obtain tissue for culture and histology. (a) Bone marrow examination and liver biopsy are commonly undertaken as part of the 'blind' investigation of PUO. (b) Other invasive techniques, e.g. bronchoscopy, lung, lymph node or renal biopsy are undertaken if clinically indicated. In addition to culture, the biopsy may be analysed using techniques such as *in situ* hybridization, to identify mycobacterial or viral nucleic acid within the tissue. (c) The role of diagnostic laparotomy has now decreased considerably, though it may be useful in patients with abdominal pain and fever in whom diagnosis remains elusive.

Management – In most patients the cause of PUO is identified within one week of intensive assessment. In the remainder it must be decided whether a therapeutic trial is merited. If the patient is clearly unwell and there is no diagnosis, a trial of antituberculous therapy or corticosteroids can be considered. A diagnosis of tuberculosis becomes likely if there is a response within one week of starting anti-TB therapy. In patients with giant cell arteritis or Still's disease the response to corticosteroids is dramatic.

Table 1: Further investigations

Indication	Investigation
Residence in or travel to endemic areas	Repeated blood films for malarial parasites
New/changing heart murmur	Echocardiography (trans-oesophageal) may be needed to reveal small aortic valve vegetations Blood films for <i>Borrelia</i> (relapsing fever) and trypanosomiasis, rickettsia, <i>Coxiella</i> , dengue, filarial and amoebic serology, <i>Schistosoma</i>
Headaches, jaw claudication	Temporal artery biopsy
Microscopic hematuria, kidney impairment	Antineutrophil cytoplasmic antibodies (vasculitis), renal ultrasonography (renal cell carcinoma)
Risk of tuberculosis (contact history, previous tuberculosis)	Culture of sputum, early morning urine, bone marrow and liver biopsies
Injecting drug misuse, 'high-risk' sexual contacts	HIV antibody, hepatitis B and C serology

2. VERTIGO

True vertigo is characterized by a sensation of turning either of the patient or his environment, and is caused by disease of the labyrinth or its central connections.

VERTIGO/DIZZINESS

Classification

Classification as central and peripheral vertigo is not particularly useful since in many cases both central and peripheral systems play a role. Classification based on the pattern with which dizziness occurs.

1. Sudden, serious short lasting.
2. Brief dizziness spells.
3. Chronic, not very severe. Persistent/protracted.
4. Sudden severe gradually diminishing.

Examination

1. General examination, BP, pulse, urine, blood tests.
2. ENT examination: For external auditory canal, ear drums, nasopharyngeal cavity, symmetrical functioning of cranial nerves.
3. Hearing test: Whispering speech. The ring of telephone is high tone stimulus.
4. Tuning fork tests: The Rinne and Weber tuning fork tests serve to distinguish between a conduction defect and a perception disorder (inner ear disorder or neurosensory hearing loss).

- Postural tests: Balance tests such as Romberg's test. The "stork" variant - standing on one leg gives more information.
- Tests for nystagmus - Gaze test: Have the patient look at point 30° away from the median line to the right and left in succession. (a) Latent nystagmus becomes stronger when looking in one direction and not dying away. Cause: Peripheral vestibular disorder. (b) Nystagmus appearing exclusively when looking to one side - Unilateral gaze nystagmus. Cause - Central disorder of the nervous system. (c) Nystagmus both when looking to the right and looking to the left (symmetrical gaze nystagmus). Cause - Disorder of CNS drug abuse.

Localizing features

- Inner ear: hearing loss, tinnitus, aural fullness, otalgia or otorrhoea
- VIII nerve: facial weakness
- Cerebellopontine angle: impaired facial sensation, clumsiness, dysarthria, dysphagia, cranial nerve palsies, hemisensory loss, hemiparesis or memory disturbances
- Cerebellum: incoordination, clumsiness, dysarthria
- Cortex: Loss of consciousness, olfactory or gustatory hallucinations

Duration of vertigo - possible causes

- A few minutes: BPPV, vestibular epilepsy
- Several minutes to <2 hours: benign recurrent vertigo, vestibular aura of migraine
- 2 hours to <24 hours: Meniere's disease, transient ischemic attack in the posterior circulation
- >24 hours: acute peripheral vestibular dysfunction, relapse of brainstem multiple sclerosis, bilateral vestibular failure.

TYPES OF VERTIGO

Table 2 gives types of vertigo.

Table 2: Types of vertigo
Paroxysmal vertigo Sudden attack which lasts for only a short time and then goes away quickly.
Single severe attack of vertigo The attack which does not disappear quickly but only diminishes slowly in the course of days or weeks and disappears spontaneously.
Chronic vertigo Often not serious but with small flare ups permanently present. Lasts months without any change.

Contd...

Contd...

Positioning vertigo

Occurs following sudden movement of the head, often in one particular plane.

Dizziness spells

More prevalent among older people.

Syndromes

- Benign positional paroxysmal vertigo** - Vertigo occurs when a person lies down in a particular way. The vertigo appears after a latent period of a few seconds, lasts not more than 30 seconds and quickly fades. The cause is assumed to come from debris in the endolymph of the posterior canal. *Tr.* Adaptation exercises (Epley's maneuver).
- Meniere's syndrome** - Attacks of vertigo lasting minutes or hours, accompanied by tinnitus in one ear and varying but gradually worsening hearing loss in that ear. The syndrome occurs with various internal disorders and also as an independent disorder, when it is called Meniere's disease. *Tr.* Pharmacotherapy, in severe cases surgery can be considered.
- Unilateral vestibular disease syndrome** (acute vestibular vertigo) caused by sudden loss of labyrinthine function. Vertigo is severe at the onset but fades away slowly over 2 or 4 weeks.
- Hyperventilation** can cause reduced CO₂ tension in the blood which can lead to cerebral ischemia. This can manifest itself in visual disturbances. Dizziness in the form of giddiness often reported. Anxiety and tachycardia. Hyperventilation can result from stress situations. *Tr.* - Counselling. Advising patient to breath into a bag in front of the head in the event of an attack, and sedative medication if necessary.
- Juvenile vertigo** occurs in children between ages of 4 and 14 and involves attacks lasting a few seconds or minutes during which the most pronounced symptom is anxiety. The syndrome disappears spontaneously within a few months to few years. *Tr.* - Low dose anti-epileptic if frequency of attack is >once a week.
- Senile vertigo** can occur in patient over age of 65. Cerebral atherosclerosis plays a major role. *Tr.* - Pharmacotherapy, avoiding drugs which cause drowsiness.
- Vestibular neuritis** mostly follows infection of upper respiratory tracts. The condition clears up within 3-6 weeks, without any persistent loss of ear function.
- Migraine:** Vertigo sometimes occurs as a side effect of migraine. Specific therapy to control the vertigo is only rarely needed.

MANAGEMENT

- Pharmacotherapy** – (a) For symptoms of acute episode antiemetic like prochlorperazine 5 mg mouth dissolving tablet. (b) Vestibular sedatives – Betahistine 60 mg/day, Cinnarizine 50-255 mg/day. (c) Piracetam may be effective in older patients 400-800 mg tds. (d) Sulpiride 50 mg tds. (e) Diazepam 10-20 mg/d in combination with a drug with more specific action to reduce severity of an attack.
- Adaptation methods.** BPPV in particular responds well to this treatment. Exercises –
 - In bed:* (i) Eye movements. Looking up and down. (ii) Looking alternately left and right. (iii) Convergence exercises. (iv) Head movements. (v) Bending alternately forward and backward.
 - Sitting:* (i) Shrugging and rotating shoulder. (ii) Bending forwards and picking objects from the floor. (iii) Turning head and trunk alternately to the left and right.
 - Standing:* (i) Changing from sitting to standing, first with eyes open, then with eyes shut. (ii) Throwing a small (ping pong) ball in an arc from hand to hand and following it with the eyes.
 - Walking:* (i) Throwing and catching a ball while walking. (ii) Walking around the room with eyes opened and closed. (iii) Walking up and down a flight of stairs.
- Surgery.** This involves severing one vestibular nerve or destroying one inner ear in the case of chronic perilymphitis or a seriously disabling form of unilateral Meniere's disease.

The application of gentamy cin into the middle ear in severe forms of Meniere's disease has shown good results.

4. Physical therapy

Peripheral vestibular dysfunction – when vertigo continues to recur after an acute peripheral vestibular episode, the patient is described as 'poorly compensated'. Central compensation is expedited by balance exercises.

BPPV – Particle repositioning manoeuvres (e.g. Epley) achieve a cure in up to 70% patients. Recurrent BPPV can be treated by Brandt-Daroff exercises.

Central vestibular disorders – Eye movement disorders that cause oscillopsia can be managed with low dose clonazepam or baclofen.

Cognitive behavioural therapy. Avoidance behaviour seen in patients with protracted vertigo or dizziness may require desensitization programmes by a therapist. Cognitive therapy may be required in more complex cases in which there is an inappropriate focus on the vestibular symptoms or when illness behaviour has developed.

3. SYNCOPE

A transient sudden loss of consciousness and postural tone due to acute decrease in cerebral blood flow. It is the most common non-epileptic cause of loss of consciousness.

CAUSES

A. Syncope due to decrease of cerebral blood flow (Neural syncope)

1. Vasomotor syncope

Vasovagal syncope (Common faint) – In susceptible individuals emotional and physical stimuli such as fright, pain and unpleasant sights, exhaustion, hot atmosphere, long period of standing in same position may produce syncope. The patient appears pale, there is usually slow pulse, low blood pressure and dilated pupils.

Carotid sinus syndrome – Attacks of unconsciousness result from hypersensitivity of carotid sinus, and occur most frequently in elderly and in association with hypertension and arteriosclerosis. Mild pressure over the carotid sinus, e.g. by tight collar combined with head turning causes bradycardia, hypotension and occasionally transient asystole lasting 10-15 seconds.

- Postural syncope** – as a result of failure of baroreceptors which normally adjust heart rate and peripheral resistance in response to change of posture. *Causes* – (a) Arising abruptly from a prolonged period in recumbent position often causes giddiness and syncope particularly in presence of cerebral vascular insufficiency. (b) Following strenuous physical exercise. (c) Chronic orthostatic hypotension may result in giddiness or syncope or both following a decline of systolic pressure usually at least 30 mm Hg. when the patient remains stationary in the upright position. (d) In association with neurologic disorders such as diabetes mellitus and other forms of polyneuritis and patients receiving drugs such as phenothiazines. Parkinson's disease especially in elderly patients treated with L-dopa.

- Cerebral syncope** – Syncope may be a consequence of direct brain damage secondary to trauma or associated with carotid or vertebrobasilar disease. Recurrent attacks of syncope more in the erect posture. In subclavian steal syndrome exercise of the involved arm is followed by syncope.

4. Situational syncope

- Cough (and sneeze) syncope* – may occur after paroxysms of cough especially in patients with bronchitis and emphysema and is caused by increase in intrathoracic pressure which occurs with coughing and impedes venous return to the heart.

- b. *Micturition syncope* - may occur in men with lower urinary tract obstruction straining excessively to pass urine usually at night. Due to postural fall in B.P., reflex vagal activity stimulated by a full bladder, and reduced venous return caused by straining.
- c. *Basilar artery migraine* - may cause transient loss of consciousness and is usually encountered in children with history of severe occipital headache.
- B. Syncope due to inadequate stroke volume (Cardiac syncope)**
- Cardiovascular**
 - Obstruction to LV outflow - AS, hypertrophic cardiomyopathy, LA myxoma, mitral stenosis.
 - Obstruction to pulmonary flow - PS, pulmonary hypertension, pulmonary embolism, tetralogy of Fallot, RA myxoma.
 - Cardiac tamponade
 - Aortic dissection
 - Arrhythmias - (a) Bradyarrhythmias: Sick sinus syndrome, 2nd and 3rd degree AV block, pacemaker malfunction. (b) Tachyarrhythmias - SVT, VT.
 - Reflex syncope** - Cardiac standstill occurring from reflex vagal activity, e.g. following distension of viscera, fainting associated with irritation of pleura or peritoneum, cardiac asystole associated with oesophagoscopy or bronchoscopy, and in glossopharyngeal neuralgia and cardiospasm, and pathological lesions in larynx and mediastinum.
- C. Syncope due to metabolic causes**
- Hypoxia** - Oxygen lack may occur at high altitudes or at lower levels of altitude in patients with aortic stenosis, congenital heart disease, pulmonary hypertension or anemia. There may be cyanosis at onset of impairment of consciousness followed by convulsions. In some subjects, breathing gas mixture with a low O₂ content can precipitate syncope. It is also one of the factors which may precipitate syncope during administration of nitrous oxide for dental procedures.
 - Hypoglycemia** - in diabetic patient, or spontaneous due to insulin secreting tumour of pancreas. Tendency to occur after prolonged period of starvation. Associated with profuse sweating, prompt relief after glucose.
 - Hyperventilation** - may induce respiratory alkalosis which can predispose to syncope.
- D. Hysterical syncope** - Loss of consciousness of psychologic origin. No alteration of pulse or blood pressure.

E. Orthostatic syncope - defined as a reduction in systolic blood pressure of at least 20 mm Hg or diastolic blood pressure of at least 10 mm Hg within 3 min of standing or head-up tilt on a tilt table, a manifestation of sympathetic vasoconstrictor (autonomic) failure (Table 3).

Management - (a) *Vasovagal attacks and syncope in general* - Immediate treatment is to place the patient at once in recumbent position in order to restore sufficient B.P. for cerebral perfusion to be resumed. (b) *Cough syncope* - Vigorous treatment of chest condition with antibiotics and antitussive drugs. (c) *Micturition syncope* - Patient on waking at night must be advised to sit on edge of the bed for a short period before going to lavatory. He should be encouraged to micturate in the sitting position. (d) *Carotid sinus syndrome* - Anticholinergic drugs or if this fails surgical denervation of carotid sinus (nerve of Herring). (e) *Postural hypotension* - Elevation of foot of bed, elasticated stockings. Mineralocorticoid fludrocortisone, indomethacin, sympathomimetic drugs or cardiac pacing may be indicated.

4. NUTRITION

DIETARY REQUIREMENTS

Energy intakes: The total energy intakes and needs of individuals of same age, sex and weight with differing levels of physical activity vary by plus or minus 30%, individuals

Table 3: Causes of orthostatic syncope

- Neurodegenerative diseases—the “Synucleinopathies”
 - Lewy body diseases
 - Parkinson’s disease
 - Lewy body dementia
 - Pure autonomic failure
 - Multiple system atrophy (the Shy-Drager syndrome)
- Secondary autonomic failure due to autonomic peripheral neuropathies
 - Diabetes
 - Hereditary amyloidosis (familial amyloid polyneuropathy)
 - Primary amyloidosis (AL amyloidosis; immunoglobulin light chain associated)
 - Hereditary sensory and autonomic neuropathies (HSAN) (especially type II-familial dysautonomia)
 - Idiopathic immune-mediated autonomic neuropathy
 - Autoimmune autonomic ganglionopathy
 - Sjogren’s syndrome
 - Paraneoplastic autonomic neuropathy
 - HIV neuropathy
 - Postprandial hypotension
 - Iatrogenic (drug-induced)
 - Volume depletion

appetites are geared to their energy needs. As adults age, they become progressively less active and lose lean tissues, including muscle, thereby reducing their BMR as well as energy expended in activity.

Foods – The consumption of appropriate mix of different foods, vitamins and minerals is necessary to avoid deficiency diseases. However, many diseases such as obesity, diabetes, heart disease, hypertension, gallstones and some cancers have a substantial nutritional component.

Proteins – for growth and repair. To maintain nitrogen balance 40–50 g of protein/day are needed. The amount of nitrogen excreted in urine represents the balance between protein breakdown and synthesis. The amount of absorbed protein retained by the body determines the biological value of protein, and this depends on the amount of essential amino acids present. Milk and eggs have high biological values, and plants such as maize and beans low values.

Carbohydrates – Carbohydrates and fats form energy foods. Carbohydrates can be consumed in the form of whole grain cereals, wholemeal bread, chapattis, pasta and rice, potatoes, peas, beans, lentils, vegetables and fruits. Intake of starchy foods provides sources of fibre, minerals and vitamins, and provides a beneficial replacement for high fat foods. Cereal fibre protects against constipation, other bowel disorders and, perhaps, bowel cancer. It may also protect against gallstones by modifying the recycling of bile salts. Soluble fibre (e.g. in fruits and vegetables) also reduces plasma cholesterol levels. Starchy foods may benefit diabetics by allowing a slower release of glucose into the blood and reduction in demand for insulin.

Fat – Guidelines for reducing total and saturated fat intake – (a) Semi-skimmed milk for older children and adults, full-cream milk for children under 5. (b) Potatoes as baked, boiled, mashed or as grilled croquettes, not fried or roast. Fresh fruits, perhaps with plain yogurt (curds), instead of ice creams, puddings, or cream cakes, biscuits and chocolates. Cheese of lower fat variety if at all. Low fat butter or margarine which is high in polyunsaturated fats and has same calories as butter. White fish is low in fat. Oily fish such as sardines, salmon, herring contain polyunsaturated oils, which may reduce cholesterol levels. Lean meat, avoiding frying. Avoid sausages, pies and pastas and most processed meats. Choose cooking oils of corn, soya, linseed, rape, sunflower, olive or safflower oils. Linoleic acid, the essential fatty acid, occurs naturally in whole grain cereal, seeds and nuts.

NUTRITIONAL DISORDERS

Obesity: has been defined as the weight-for-height above which there is increased mortality and has been discussed in the Chapter on Endocrine diseases.

Undernutrition: Optimal nutrition is necessary for optimal health, but neither variables can be measured accurately; thus it is difficult to define undernutrition. In adults weight loss is used as a simple index. In children, growth and development are sensitive markers of nutritional state, but the range of normality is considerable.

Causes of Undernutrition

1. Starvation or famine.
2. Reduced food intake for psychological reasons (e.g. anorexia nervosa).
3. Intestinal disorders leading to anorexia and/or malnutrition.
4. Severe pathology of any kind (e.g. infection, inflammatory and neoplastic disorders, and organ failure) which may lead to anorexia and enhanced catabolism.

Under all these circumstances, there is loss of body fat and wasting of skeletal muscle with variable degrees of atrophy of body viscera except the brain. The degree of wasting of individual components varies with the disease process and other factors such as age, sex, physical activity, adequacy of intake of specific nutrients and the patient's hormonal status.

Malnutrition and undernutrition in children have been described in Chapter on Diseases of Children.

Undernutrition in adults

Medical history: Indicators for risk of malnutrition include –

- Loss of weight (recent or past)
- Anorexia and loss of appetite
- Nausea and recurrent vomiting
- Recurrent diarrhoea
- Weakness, lassitude and reduced physical activity
- Recurrent fever and infection
- Recent surgery or trauma
- Drugs or medications
- Recent bereavement or social stress
- Physical disability (e.g. blindness, arthritis)

Dietary history: Daily food and nutrient intake, pattern of meals, alcohol and food fads.

General appearance – of the patient should indicate the size of subcutaneous fat stores and degree of hydration. Vitamin and mineral deficiencies indicated by pallor,

skin lesions and pigmentation. Skeletal muscle wasting is demonstrated by appearance of temporalis and periscapular muscles and by circumference of mid-upper arm. Recent unintentional weight loss of >10%, body wt. <80% of the desirable wt. for height and body mass index (BMI) <18.5 kg/m² are useful indices for undernutrition and malnutrition.

Investigations and Specific Nutritional Tests

Laboratory investigations:

- Haemoglobin or packed cell volume (anemia, hydration)
- Blood urea (hydration, protein intake)
- Dystrophy of skin and mucous membranes
- Oedema
- Reduced cardiac size
- Enlarged liver, possibly caused by fatty infiltration
- Muscle weakness disproportionate to muscle wasting
- Altered mental state

Examination may show nutrition-related disorders:

- Plasma proteins
- Acute-phase proteins - C-reactive protein and ESR (inflammatory or neoplastic pathology)
- Creatinine excretion (muscle mass)
- Short half-life nutritional proteins (e.g. transferrin, retinol-binding protein) help assess response to repletion but are also affected by inflammation.
- Total lymphocyte count (immune function)

Specific tests that can be used as bedside to assess altered nutritional status:

- Tests of muscle function (e.g. grip strength and voluntary muscle contraction using hand-grip dynamometry)
- Changes in force-frequency curve obtained by stimulating ulnar nerve at the wrist and measuring contraction and relaxation rate of adductor pollicis muscle
- Estimation of daily urinary nitrogen excretion to assess protein catabolism (use of this technique is limited by need for 24-hr urine collection).

BMI is a simple, reliable and easily obtainable measure of nutritional status in adults. It is reasonably highly correlated with body fat, (a proxy for available body energy stores) and is relatively independent of stature or height. It is obtained by dividing weight (in kilograms) by height (in meters) squared. BMI <18.5 kg/m² in adults indicates chronic undernutrition. Three grades of severity of adult undernutrition (FAO/2 WHO):

- Grade I - BMI 17-18.49 kg/m²
- Grade II - BMI 16-16.99/m²
- Grade III - BMI <16kg/m²

Nutritional Effects of Disease

Cancer cachexia - Wt. loss is a common problem in cancer patients; cancer treatments sometimes contribute to it. Patients with solid tumors are more commonly affected than those with haematological malignancies.

Endocrine disorders - (a) Diabetes: Wt. loss is a common presenting feature of type 2 diabetes and insulin therapy in both type 1 and type 2 disease results in wt. gain. (b) Hyperthyroidism. (c) Addison's disease.

Respiratory disorders

Cystic fibrosis: Potential causes of malnutrition are - malabsorption due to pancreatic insufficiency, reduced food intake due to gastro-oesophageal reflux, state of wasting associated with lung disease, occasionally a distal intestinal obstructive syndrome resulting from underlying lung disease or injudicious use of pancreatic supplements.

COPD: Factors contributing to the state of negative energy balance - Increased energy costs of breathing, metabolic costs of respiratory tract infections, breathlessness caused by act of eating, hyperinflation of the lungs causing extrinsic pressure on the stomach that results in a feeling of satiety at lower levels of food intake, and thermogenesis induced by diet and drugs (theophyllines, β -agonists).

Cardiac cachexia: The underlying mechanisms are unclear, but perturbations of neuroendocrine and immunological homeostasis driven by tissue hypoxia appear to mediate. Drug-induced side effects (e.g. anorexia with digoxin, altered taste with some ACEIs) may also contribute.

Rheumatoid arthritis and connective tissue disease: Reduced peripheral action of insulin, caused by tumour necrosis factor α (TNF- α)-driven disruption of insulin receptor signalling, may have a role in muscle wasting in RA and other connective tissue diseases. Muscle wasting is aggravated by reduced muscle activity and ensuing 'disuse atrophy'.

Chronic kidney failure: Under normal circumstances, the body responds to a low-protein diet by suppressing protein and essential amino acid degradation. Protein metabolism in uremic patients is characterized by a perturbation of this normal response, resulting in negative nitrogen balance and loss of lean body mass. Metabolic acidosis and low insulin concentration contribute to compound this state of negative nitrogen balance.

HIV and tuberculosis: Protozoal, bacterial and viral GI infections and sometimes side effects of HAART contribute to poor nutritional status. HIV enteropathy is a cause of malabsorption and wt. loss in absence of any demonstrable infection in the gut. Other nutrition derangements associated with HIV include hyperlipidemia and syndrome X (insulin resistance), and protease inhibitor therapy is associated with a lipodystrophy syndrome.

Stroke: Poor nutritional status remains a potentially remediable cause of poor outcome in stroke.

ARTIFICIAL NUTRITIONAL SUPPORT

Enteral Nutrition

Enteral nutrition is simple, cheaper, associated with improved immune function and carries a lower risk of bacterial translocation. Supplemental tube feeding is preferred in patients who are unable to take sufficient nutrition orally. In some (e.g. those with swallowing difficulty), all nutrition must be given artificially.

Access – *Nasoenteric tube-feeding* is an excellent short-term solution. Nasojejunal feeding is necessary when gastric emptying is impaired, but may also help to reduce aspiration and diarrhoea.

Pre-albumin — A marker of malnutrition

Due to very long half-life of albumin (21 days), it is not considered a very good indicator of serum loss. This means that though there is a severe loss, albumin level remains elevated, because of its transcapillary escape into interstitial fluid. This escape is markedly increased in systemic inflammatory response syndrome. Prealbumin is more sensitive to protein energy status than albumin and its levels indicate recent dietary status rather than overall nutritional value.

Interpretation of Prealbumin Test

- | | |
|----------------|----------------------|
| • Level | Risk of malnutrition |
| • <100 mg/L | Severe |
| • 100-170 mg/L | Moderate |
| • >170 mg/L | No risk |

Prealbumin measurements is very useful in patients undergoing major surgeries.

Assessing nutritional requirements

Standard equations such as Harris Benedict equation based on height, weight, age and sex can be used to estimate the Basal Energy Expenditure (BEE).

a. For male

$$\text{BEE (kcal/day)} = 66 + (13.7 \times \text{weight}) + (5.0 \times \text{weight}) - (6.7 \times \text{age})$$

b. For female

$$\text{BEE (kcal/day)} = 65.5 + (9.6 \times \text{weight}) + (1.8 \times \text{weight}) - (4.7 \times \text{age})$$

Weight in kg, height in cm and age in years.

This equation however does not take into account the stress factor which is important in critically ill patients. To simplify one can calculate daily needs from 25–30 kcal/kg/day.

Essentials of prescribing nutrition: (i) Energy – Main substrates providing energy are carbohydrates and lipids. Glucose should constitute 0.80% of non-protein calories. Proteins – In critically ill patients 1–1.5 kg/day is recommended. (ii) Micronutrients, vitamins and trace elements. Enteral nutrition intrinsically has adequate supply of micronutrients but parenteral administration requires both vitamins and micronutrients.

Types of feed – Standard feeds may be divided into two main categories: (a) *Whole-protein feeds* in which the protein source is not pre-digested and is derived from milk hydrolysed casein or soya protein. Carbohydrate is provided as maltodextrins, glucose, sucrose or corn syrup solids. Fat source is usually a vegetable oil derivative, but other fat sources incorporate a re-blending of mono-unsaturated or polyunsaturated fatty acids from rapeseed and fish oils. (b) *Elemental/peptide feeds* – Here the nitrogen source is free amino acids or peptides. Pre-digested feeds may be used in patients with absorption difficulties (e.g. pancreatitis, Crohn's disease).

Most standard feeds provide 1 kcal/mL; other feeds are energy dense, providing 1.2–2 kcal/mL. Fibre-containing feeds are used for long-term feeding, because they are thought to normalize gut bacteria and transit time. Feeds are also developed for use in particular situations:

- Low sodium, potassium and phosphate for kidney failure
- High fat for respiratory failure (the higher respiratory quotient of fat reduces carbon dioxide production, which is of theoretical benefit in patients with CO₂ retention)
- Branched-chain amino acids for chronic liver disease (said to normalize blood amino acid profile)
- Immuno-enhancing for critical illness (arginine, mega-3 fatty acids and immune glutamine can enhance function).

Parenteral Nutrition

Administration of PN has been simplified due to the availability of ready to use all-in-one (mix of carbohydrates, lipids and protein) bags which assure less handling and thereby less infection.

Indications

(a) Intestinal failure (e.g. ileus, intestinal obstruction, short bowel syndrome and severe mucositis resulting from chemotherapy), which is analogous to failure of other end organs such as the kidney, heart and endocrine glands. (b) When GI tract has to be rested, e.g. to allow a GI fistula to heal or to prevent pancreatic stimulation after severe and recurrent pancreatitis.

Access

Vascular access can be obtained peripherally or centrally. Peripheral access is used only for short-term, low osmotic load feeding, and require good peripheral veins. A small cannula should be placed into a large vein away from a joint using sterile technique. Central venous cannulation is necessary for long-term parenteral nutrition with hyperosmolar feeds. Narrow-bore silicon lines enable peripheral access to veins but more central feed delivery from the tip of the line (PICC lines).

Feed Delivery

Most feeds are delivered continuously over 24 hours in patients who are acutely unwell. A period without feeding during each 24 hours is thought to reduce liver dysfunction.

Factors which impair the administration of internal feeds in a critically ill patient - (a) Gut hypomotility. (b) Hemodynamic instability. (c) The feeds need interruption for procedures and surgeries in the ICU.

Problems with parenteral feeding

1. *Overadministration of trace elements* - IV administration of feeds has important metabolic and nutritional consequences. The GI tract normally acts as an important defence 'organ' against trace element toxicity. It is inappropriate and sometimes dangerous to administer the same quantities of micronutrients I.V. as orally.
2. *Underadministration of some amino acids* - Certain amino acids (e.g. tyrosine, cysteine, glutamine) are not present in I.V. feeds because they are poorly soluble or unstable. If amino acids are deficient, protein synthesis may be limited.
3. *Bypassing the liver* - IV administration bypasses the liver, an obligatory route by which nutrients enter the body during enteral feeding.
4. *Disuse atrophy* - may follow prolonged parenteral nutrition.

Nutrient Requirements

Protein (nitrogen N) requirements - also vary with age, degree of malnutrition and disease activity, but an intake of 11-16 g N is adequate for most adult patients. It is

seldom necessary to restrict intake to less than 9 g N/day in (equivalent to approximately 125-155 g protein/day).

Fluids - Fluid restriction may be necessary in presence of cardiac, hepatic or renal failure, and in patients with recent head injury, who may have raised intracranial pressure. In contrast excess fluid must be given to patients with large GI fluid losses, e.g. patients with high output fistulas or large nasogastric aspirates.

Vitamins - In contrast to many trace elements, the requirements of vitamins are substantial, because patients receiving i.v. nutrition often suffer from severe systemic disease. Pharmacological doses of antioxidant Vitamin A, C and E may neutralize or prevent the damaging effects of free radicals, found in excess in many disease states.

Other pharmacological agents - (a) Growth hormone (GH) and insulin-like growth factor given to catabolic patients to improve nitrogen balance and perhaps muscle strength. In some patients with respiratory disease, GH may improve respiratory m. function. (b) Recombinant human erythropoietin in end-stage kidney failure eliminates associated anemia and requirement for blood transfusions.

VITAMIN AND TRACE ELEMENT DEFICIENCY

Immunonutrition:

Glutamic acid is an amino acid which is synthesized by all tissues. It is essential for maintenance of gut metabolism structure and function and also promotes lymphocyte activation enhancing the immune system.

5. ANTIOXIDANTS

Oxidative damage from both endogenous sources and exogenous sources (e.g. smoking, ionizing radiation, ultraviolet light), is involved in the development of many diseases.

Antioxidant defence system. Antioxidants are substances that, when present at much lower concentrations than a vulnerable oxidizable substrate, significantly delay or prevent its oxidation.

- Vitamin E protects lipids in cell membranes and organelles from oxidation.
- Vitamin C scavenges reactive oxygen species and possibly regenerates vitamin E in the tissues.
- Carotenoids (e.g. β -carotene) can scavenge radicals under physiological conditions and are potent scavengers of singlet oxygen.

In addition, several enzymes with antioxidant function require trace elements such as selenium, copper, zinc, manganese and iron as co-factors.

Table 4: Sources and requirements of vitamins

Food sources, daily requirement	Symptoms and signs of deficiency and toxicity (if any)
<p>Fat soluble vitamins</p> <p>Vitamin A Animal: Milk, butter, liver and fish liver oils, egg yolk Vegetable: (carotene precursors) carrots, sweet, potatoes, apricots, spinach. • Mango, papaya • 5,000 IU (1.5 mg vitamin A) • 5,000 IU/kg body weight/day • Plasma vitamin A low • (<1 µmol/litre)</p> <p>Vitamin D Fish liver oil, milk, egg yolk, butter, yeast. Synthesis in the skin when it is irradiated. 400 IU (IU = 0.025 mg vitamin D₂) 5,000 IU/day Plasma 25-hydroxycholecalciferol is a good indicator of vitamin status. Low plasma calcium</p> <p>Vitamin E Alfalfa, wheat germ oil, lettuce, maize, molasses, peas, whole rice, meat, milk, eggs. 8 mg/day tocopherol equivalents 100–600 mg/day Plasma vitamin E concentrate 533 Resistance of RBC to haemolysis by hydrogen peroxide</p> <p>Vitamin K Green vegetables, spinach, cabbage, egg yolk, cheese, tomatoes. K1 synthesised by bacteria in intestines Adult daily requirement 2 mg Prolonged prothrombin time</p>	<p>Symptoms and signs of deficiency and toxicity (if any)</p> <p>Skin</p> <ul style="list-style-type: none"> • Asteatosis is earliest manifestation • Phrynoderma (toad skin). Brown to dark brown, dry, rough, hyperkeratotic follicular papules with central keratotic horny spurs. Bilateral and symmetrical distribution in anterolateral aspects of thighs, posterolateral aspects of arms. • In severe cases the follicular papules develop in entire upper and lower extremities, shoulders, abdomen, buttocks, face and back of neck. <p>Eyes</p> <ul style="list-style-type: none"> • Nyctalopia (earliest symptom) • Hemeralopia: inability to see bright light • Xerophthalmia: includes one or more of the following changes <ul style="list-style-type: none"> – Conjunctival xerosis – Bitot's spots (keratinizing epithelium) forming greyish-white triangular plaques on conjunctival surface lateral to the cornea. – Corneal xerosis – Corneal ulceration with xerosis – Keratomalacia • Teeth: Impaired enamel formation • Acute toxicity (massive single dose) – Abdominal pain, nausea, vomiting, headache, dizziness followed by generalized desquamation of skin. • Chronic poisoning – Bone and joint pains, loss of hair, fissuring of lips, anorexia, benign intracranial hypertension, weight loss, hepatomegaly. • Carotinaemia – is due to excessive consumption of vitamin A precursors in food, mainly carrots. Yellowing of skin maximum in palms and soles. <p>Tetany and rickets in infants and children Osteomalacia in adults</p> <p>Toxicity – Anorexia, lassitude, vomiting, diarrhoea, profuse sweating, polyuria, polydipsia and headache. Hypercalcemia causes calcium deposition in tissues and kidneys which may lead to renal failure.</p> <p>Skin: Erythematous papular eruptions, oedema and flaky dermatitis Anemia in premature infants In chronic deficiency: ataxia, posterior column dysfunction, peripheral neuropathy and visual scotoma Vitamin E deficiency usually develops in premature infants, adults with fat malabsorption syndrome or individuals with genetic anomalies in transport proteins. In severe vitamin E deficiency - Acanthocytosis of red cells, and thrombocytosis. Ophthalmoplegic and pigmentary retinopathy. Posterior column and spinocerebellar tracts may be involved.</p> <p>Hypoprothrombinaemia with defective coagulation of blood Skin: Intracutaneous haemorrhages, purpura and ecchymosis.</p>

Contd...

Food sources, daily requirement	Symptoms and signs of deficiency and toxicity (if any)
<p>Water soluble vitamins</p> <p>Vitamin B complex</p> <p>Vitamin B₁ (Thiamine) Yeast, meat, whole grain cereals, beans, liver, egg yolk, potatoes. (Synthesised by micro-organisms). 1–1.5 mg 50–100 mg Measurement of RBC transketolase activity, with addition of thiamine pyrophosphate. Elevated blood pyruvate. Blood or urine measurement of thiamine.</p> <p>Vitamin B₂ (Riboflavin) Milk, eggs, liver, germinating seeds 2 mg 5–10 mg RBC glutathione reductase activity with addition of flavin adenine dinucleotide (high degree of activation of enzyme activity indicates deficiency). Low urinary riboflavin concentration.</p> <p>Nicotinic acid (PP factor) Liver, eggs, yeast, meat, rice, fish, whole grain 20 mg 500 mg (Requirement does not increase during pregnancy)</p> <p>Vitamin B₆ (Pyridoxine) Yeast, liver, meat, cereals, milk, eggs, lettuce, spinach 2 mg 50–100 mg Estimates of deficiency – (a) Loading tests – measurement of urinary tryptophan metabolite after tryptophan loading or cystathionine assessment after methionine load. (b) Measurement of N-methylnicotinamide in urine.</p>	<p>Wet beriberi Cardio-vascular beriberi is commonly a high output biventricular failure, which is preceded by sinus tachycardia, wide pulse pressure, and severe sweating. Low-output cardiac failure (e.g. Shoshin beriberi).</p> <p>Dry beriberi Neurological features – Peripheral neuropathy, ataxia, amblyopia and burning paraesthesia (e.g. burning mouth syndrome). Wernicke's encephalopathy – Korsakoff's syndrome Lactic acidosis Angular stomatitis, perleche Cheilosis with erythema, xerosis and vertical fissuring of the lips Glossitis with smooth magenta red tongue and enlarged fungiform papillae Cutaneous: Seborrheic-dermatitis-like rash affecting naso-labial folds, alae nasi, nasal bridge, forehead, cheeks, postauricular regions, eyelids, scrotum and vulva. These areas appear red, greasy and sometimes hyperpigmented (scar skin or dyssebacia) Eyes: Neovascularization of cornea and epithelial keratitis resulting in photophobia and lacrimation Potentiation of oral anticoagulants (due to inhibition of prothrombin time) In premature children – Hepatosplenomegaly, ascites, cholestatic jaundice, and thrombocytopenia. Jaundice in the new born if given during pregnancy.</p> <p>Weakness and fatigue occur early</p> <p>Cutaneous Acute onset with appearance of well demarcated patches of erythema with pruritus, burning, resembling sunburn, symmetrically on exposed areas such as back of hands and forearms, face and neck, upper central part of chest, knees and dorsum of feet depending on pattern of clothing used. Intertrigo with redness and maceration may occur in intertriginous areas. Chronic – The patches turn reddish brown, rough and scaly, thickened and pigmented. Desquamation occurs after several weeks or months leaving areas of hypopigmentation. The sharply demarcated lesions on upper central parts of chest and neck form the Casal's necklace. On the face, there is a dull-red erythema on bridge of nose and adjacent areas on the cheeks with powdery scaling (butterfly erythema and pigmentation). Mucous membranes. Cheilosis with furrowed lips, angular stomatitis. The tip and margins of the tongue and oral mucosa, including gingival mucosa become inflamed, swollen, ulcerated and assume a bright scarlet colour. GI system – Anorexia, dyspepsia, nausea, vomiting and abdominal pain may occur. Diarrhoea, often bloody if GI hyperaemia is severe. CNS – Neuropsychiatric manifestations including impairment of memory, apathy, depression, psychosis and coma may develop. Encephalopathic syndrome may occur. Neonatal form may present as crusted or fiery red dermatitis, while the infantile form resembles acrodermatitis enteropathica.</p> <p>Paranasal erythema, seborrheic-like rashes on face, scalp, neck, shoulders, buttocks and perineum, intertrigo and pellagra-like dermatitis. Cheilosis, angular stomatitis, glossitis, flattened filiform papillae, and ulcerations may occur. Peripheral neuropathy from isoniazid therapy for TB. Somnolence, confusion, and in infants convulsions can occur. Contraindications for pyridoxine – 1. Along with L-dopa therapy. 2. Lactating mothers.</p>

Contd...

Food sources, daily requirement	Symptoms and signs of deficiency and toxicity (if any)
(c) Measurement of RBC transaminase activity with addition of pyridoxine supplements (Activation of enzyme activity of <150% is regarded as normal).	<p><i>Uses of pyridoxine –</i></p> <ol style="list-style-type: none"> 1. With INH, D-penicillamine, cycloserine, hydralazine, oral contraceptives. 2. Alcoholism. 3. Hyperemesis gravidarum. 4. Radiation sickness and motion sickness. 5. Sideroblastic anemia. 6. Infantile convulsions. 7. Homocystinuria. 8. Hyperoxaluria. 9. Hartnup disease. 10. Local application in dry seborrheic dermatitis.
<p>Pantothenic acid Liver, kidney, eggs, meat, whole grain and milk 10 mg.</p>	<p><i>Toxicity –</i> Severe peripheral neuropathy with ataxia, perioral numbness, loss of vibration sense. No sensory loss, no diminished reflexes.</p>
<p>Biotin (Anti-egg white factor) Liver, eggs, meat 4–7 mg. 10 mg.</p>	<p>Deficiency occurs with other vitamin deficiencies and protein-energy malnutrition</p> <p>Dermatological features: Xerosis, generalized pallor, intertriginous and periorificial dermatitis, fine bran-like scaling and alopecia.</p> <p>Also atrophic glossitis, brittle nails.</p> <p>Two inherited forms of deficiency (both AR)</p> <ol style="list-style-type: none"> 1. Neonatal deficiency, more severe of the two, caused by lack of enzyme monocarboxylase synthetase seen in infants in first 6 weeks of life. Infantile biotin deficiency occurring after 3 months of life is due to deficiency of enzyme biotinidase. 2. Dermatological features in adults: Xerosis, generalized pallor, intertriginous and perioral dermatitis, fine bran-like scaling alopecia. Atrophic glossitis and brittle nails are other features. <p>Neonatal form may present as a crusted fiery red dermatitis. Infantile form resembles acrodermatitis enteropathica.</p> <p>Fatty liver and cirrhosis. Haemorrhagic renal lesions, vascular congestion and tubular degeneration.</p> <p>Megaloblastic anemia, glossitis, stomatitis, diarrhoea.</p>
<p>Choline Egg yolk, liver, meat Therapeutic dose 3–6 gm.</p>	<p>Megaloblastic anemia, neuropathy, anorexia, diarrhoea, ataxia, optic neuritis, mental changes</p>
<p>Folic acid Yeast, fresh green vegetables, liver, kidney, cereals, meat 0.15 mg daily</p>	<p><i>Scurvy:</i> Hyperkeratotic hair follicles with perifollicular haemorrhages Petechiae and ecchymosis may occur on any part of body, but more commonly on areas subjected to even minor trauma or pressure. Feet and ankles are involved early (woody legs). Subconjunctival, subungual, subcutaneous, subperiosteal and intra-articular haemorrhages may occur. Follicular hyperkeratosis is seen on anterior aspects of forearm, abdomen and posterior aspects of thighs. Corkscrew hair (due to reduced disulphide bonds) are seen.</p>
<p>Vitamin B₁₂ (Cyanocobalamin) Liver, kidney, eggs, milk. 2.5 µg</p>	<p>Gingival hypertrophy with enlarged submandibular salivary glands and Sjogren-like syndrome may occur.</p>
<p>Vitamin C Green vegetables, fruits especially citrus, black currants and strawberries, potatoes 30 mg., double in pregnancy Adult 100 mg qds. Children under one year: 25 mg. qds. Plasma concentration of ascorbic acid (indicates recent intake). Measurement of leucocyte vitamin C.</p>	<p>Delayed wound healing.</p> <p>Microcytic, normochromic, or macrocytic anemia</p> <p><i>Uses of vitamin C –</i> Scurvy, wound healing, common cold, methemoglobinaemia, alkaptonuria, acidification of urine, along with iron therapy, haemorrhagic disease of newborn, correction of leucocyte abnormalities in Chediak-Higashi syndrome, atherosclerosis.</p>

Food sources, daily requirement	Symptoms and signs of deficiency and toxicity (if any)
<p>Trace elements (micronutrients)</p> <p>Zinc Oysters, shell fish, poultry, cheese, meat, nuts, whole grain, dry beans 12–15 mg 50 mg of elemental zinc/day p.o.</p>	<p><i>Side effects</i> – Precipitation of urate, oxalate or cystine stones if given in large doses. Acrodermatitis enteropathica is an AR disorder resulting from malabsorption of zinc Skin – Psoriasis-form lesions symmetrically distributed in periorifacial regions, sacral areas and bony prominences are the most common cutaneous manifestations. Vesiculobullous and pustular lesions, erosions and crusts may be the earliest presenting lesions. Non-scarring alopecia of the scalp is characteristic and may extend to the eyebrows, eyelids and even the whole body. White spots on the nails and paranasal erythema may be observed. Also angular stomatitis and glossitis. Growth retardation occurs in long-standing cases. Blepharitis, conjunctivitis, photophobia and nyctalopia are some of the ophthalmic manifestations. GI system – Anorexia, decreased taste. In some diarrhoea with steatorrhoea. Decreased wound healing Other features: Growth retardation and lack of secondary sexual and genital development (due to low testosterone levels). Delayed wound healing.</p>
<p>Magnesium Green vegetables, nuts, dried beans, whole grains, seeds, meats 700 mg/day</p>	<p>Behaviour changes: Irritability, emotional lability and schizoid behaviour.</p> <p>Muscle pain, weakness. Irritability, tremor, ataxia, carpopedal spasm. Hyperreflexia, confusion, hallucinations, epileptiform convulsions.</p>
<p>Phosphate All natural foods, meats, milk products, grains 800–1200 mg.</p>	<p>Nausea, weakness, osteoporosis Cardiac arrhythmia Haemolysis Neuroencephalopathy Glucose intolerance</p>
<p>Chromium Cereal, meat 50–200 mcg</p>	<p>Transient dermatitis, discolouration and slow growth of hair, nausea, vomiting, weight loss. Increased risk of neoplasia, especially colonic cancer.</p>
<p>Manganese Cereals, green vegetables 2.5 mg</p>	<p>Menke's kinky (steely) hair disease is a sex-linked abnormality caused by defect in intestinal absorption of Cu. Affected infants show progressive cerebral degeneration, retarded growth, abnormally sparse and brittle hair, arterial lesions and scurvy-like bone changes. Pili torti (twisted hair), trichorrhexis nodosa (bamboo hair) and monilethrix (beaded hair)</p>
<p>Copper 2–3 mg Copper sulphate 5 mg/day p.o.</p>	<p>Whitening of finger nail beds, loss of pigment of hair and skin with thinning, curling of hair (pseudo-albinism). Pancreatic and hepatic necrosis seen in children suffering from kwashiorkor may be due to selenium deficiency. Peripheral neuropathy with profound muscle weakness and muscle pain. Cardiomyopathy, arrhythmias and chronic CHF can develop.</p>
<p>Selenium Cereals, eggs, onions 70 µg/day men 55 µg/day women Sodium selenite or selenomethionine up to 500 µg/day p.o. or parental</p>	

Diseases, clinical conditions and activities associated with oxidative damage to lipids, proteins and DNA are listed in Table 5.

Deficiencies in antioxidant micronutrients

Major dietary sources of micronutrients with antioxidant function are fruits, vegetables and plant oils. In general these are recognized as essential, because deficiency causes development of a defined disease. For example, early indicators of vitamin E deficiency are related to damage to cell membranes and leakage of cell contents into external fluids. Diagnostic signs include leakage of muscle enzymes such as creatine kinase and pyruvate kinase into plasma, increased levels of lipid peroxidation products in plasma and increased haemolysis. This is evidence that vitamin E is essential to humans for its antioxidant action.

6. METABOLIC SYNDROME

Metabolic syndrome Table 6 comprises the cluster of metabolic disorders. The other terms used for metabolic syndrome are insulin resistance syndrome, syndrome X, pluri metabolic syndrome.

Pathophysiology – Insulin resistance is characterized by a high plasma insulin concentration that fails to suppress plasma glucose normally. A central feature is unresponsiveness to insulin at the cellular level because of changes in receptor binding or post-receptor mechanisms. Exposure to high free fatty acid is a common mediator. Insulin sensitivity is measured by various means. A simple clinical

method relates to fasting glucose to insulin concentration, using a mathematical formula known as HOMA-IR (homeostasis model assessment for insulin resistance). Insulin resistance is closely related to impaired glucose tolerance, diabetes and risk of heart disease.

Hypertension and insulin resistance. The relationship between insulin resistance and hypertension appears to be indirect because: (a) Controlling hypertension does not improve glucose tolerance or hyperinsulinaemia. (b) Patients with insulinoma are not hypertensive. Raised BP from increased insulin concentration may also result acutely from insulin-stimulated renal tubular re-absorption of sodium.

Other components of metabolic syndrome include polycystic syndrome and depression which may be partly explained by disturbances in insulin, cortisol and sex hormones, with reduced sex hormone-binding globulin.

Dyslipidemia. High LDL cholesterol and high triglycerides are features of metabolic syndrome. Elevated plasma small dense LDL (the most atherogenic subfraction of LDL) has been identified as a key feature in association with elevated triglyceride and LDL cholesterol. Individuals with these particles are at greater myocardial risk. Concentrations of small dense LDL are also increased in individuals with greater abdominal fat accumulation (large waist circumference).

Role of intra-abdominal fat – Increased abdominal fat mass (particularly the intra-abdominal fat depot) is easily recognized as an ‘apple-shaped’ torso and may have a direct intermediary role in the development of metabolic syndrome.

Table 5: Conditions leading to oxidative damage

<i>ARDS (some forms)</i>	<i>Ageing</i>
Alcoholism	Alzheimer's disease
AR, RA	Angina
AROS	Atherosclerosis
Cancer (some forms)	Cataract formation
Dermatitis (some forms)	Diabetes mellitus
Emphysema	Excessive exercise
Excess consumption of polyunsaturated fatty acids	Favism Hyperoxia
Hypertension	Infertility (some conditions)
Iron overload	Selenium deficiency
Ischemia/reperfusion injury	Malignant hyperthermia
Malaria	Parkinson's disease
Mechanical trauma to tissues	Retinopathy
Radiation injury	Smoking
Sunburn	Vitamin E deficiency
Muscular dystrophy	

Table 6: Features of metabolic syndrome

Endocrine and biochemical abnormalities
• Glucose intolerance
• Hyperinsulinaemia
• Insulin resistance
• Hypercortisolism
• Hypertriglyceridemia
• Low high-density lipoprotein
• Raised, small density low-density lipoprotein cholesterol
Overt pathophysiological conditions
• Type 2 DM
• Coronary heart disease
• Polycystic ovary syndrome
• Central fat distribution
• Morbid obesity
• Stress and depression
• Hypertension
• Non-alcoholic steatohepatitis

The liver accumulates triglycerides, such that non-alcoholic steatohepatitis is a common feature of increased intra-abdominal fat and metabolic syndrome. Increase in plasma free acid flux is a feature of central fat deposition; this may evoke and/or exacerbate the metabolic disorders: (a) Free fatty acids inhibit peripheral glucose metabolism and reduce insulin sensitivity. (b) Increased hepatic availability of free acids could stimulate hepatic free acid esterification and increase synthesis of LDL, thus increasing plasma triglyceride concentration, leading to increased small dense LDL. (c) Free fatty acids may inhibit cholesterol esterification, thereby reducing acquisition of cholesterol by HDL.

Skeletal muscle mass - A high waist: hip circumference ratio is found in individuals with a large waist (high abdominal fat accumulation), small hips (small amounts of gluteal fat or low muscle mass) or both. A relatively low hip circumference is known to be connected with many components of the metabolic syndrome. Type 2 diabetes is related more strongly to waist: hip ratio than to waist circumference alone, and low hip circumference and high waist circumference both, independently, predict type 2 diabetes.

Muscle is a major site of insulin action and glucose oxidation, and type 2 diabetes and metabolic syndrome are associated with a relative deficiency of type I (oxidative) muscle fibres.

An increase in proportion of white type II (glycolytic) muscle fibres and a decrease in red, oxidative muscle fibres is associated with metabolic complications.

Metabolic syndrome and fatal growth. There are striking relationships between markers of poor early growth (birth weight, length, weight at 1 year) and features of metabolic syndrome in later life. Two hypotheses have been used to describe these:

The 'thrifty phenotype' hypothesis for type 2 diabetes:

- Undernourishment during fetal or early life has an adverse effect on the structure and/or function of β -cells in the pancreas and peripheral tissues (primarily skeletal muscle)
- This limited glucose-insulin metabolism can cope in an undernourished environment
- In a good nutritional environment, the deficiencies in β -cell function are exposed, resulting in peripheral tissue sensitivity to insulin action, impaired glucose tolerance and diabetes.

Principles of 'programming' hypothesis:

- Undernutrition in early life has permanent effects
- Undernutrition has different effects at different times in early life
- Rapidly growing fetuses and neonates are more vulnerable to undernutrition

- Permanent effects of undernutrition include reduced cell numbers, altered organ structure and resetting of hormonal axes.

Metabolic syndrome and inflammation C-reactive protein is a marker of inflammation. Elevated CRP correlates significantly with features of metabolic syndrome, including adiposity, hyperinsulinaemia, and insulin sensitivity index, hypertriglyceridemia, low LDL cholesterol and type 2 diabetes.

CRP is produced by and released by the liver under stimulation of cytokines including interleukin-6 (IL-6), IL-1 and tumour necrosis factor. Adipose tissue is now recognised as a major endocrine organ, and the relationship between CRP and adiposity could be explained by the findings that adipose tissue is a source of or production and release of cytokines. Plausible biochemical mechanisms link some of these components; e.g. cytokines provoke *de novo* hepatic fatty acid synthesis and interfere with the activity of lipoprotein lipase (the essential enzyme responsible for catabolism of triglyceride rich lipoprotein). In addition, cytokines can stimulate lipolysis with consequent increase in fatty acids that may in turn lead to impaired insulin sensitivity, and may impede direct insulin-stimulated glucose uptake.

Management of metabolic syndrome - (a) Lifestyle changes to reduce risks and maintain healthy weight and body fat distribution. Maintaining BMI at 21-22 kg/m² is advantageous for those at risk for genetic or other reasons. (b) Minimize physical inactivity. (c) Daily moderate exercise at least 30 minutes/day (d) No smoking. (e) Drugs in special situations - (i) Metformin improves glucose tolerance and lipids, and increases fertility in women with polycystic ovary syndrome. (ii) Thiazolidinones increase glucose tolerance, improve lipoprotein profile and modify fat distribution towards a less central abdominal/intra-abdominal pattern. (iii) Anti-obesity drugs such as orlistat achieve wt. loss, and more importantly, reduce weight gain in the long term, which tends to reverse or delay most features of metabolic syndrome.

7. DISORDERS OF WATER AND ELECTROLYTE METABOLISM

WATER METABOLISM

Normal Water Metabolism

Under normal conditions the body gains water from oral fluid intake, from diet, and as end-product of metabolism (about 500 mL/day). Water is normally lost through the skin (about 500 mL in temperate climates), through the lungs in the breath (about 700 mL/day), in the faeces

(about 50 mL/day) and in urine. The renal loss of water is accurately regulated to maintain the osmolality of body fluids between 280-300 mosmol/kg of water. Thus, in the anuric patient intake of about 750/mL day is required to maintain total body water constant.

Disorders of Water Balance

Since cell membranes in general are freely permeable to water, the osmolality (concentration of the solute in a solution per unit of solvent) of extracellular fluid [(ECF) 290 mosmol/kg water]] is about equal to that of intracellular fluid (ICF). The term disorders of water metabolism is restricted to disturbances in osmolality, though mixed disorders or salt and water homeostasis are frequent.

Water Excess

1. Acute renal failure with oliguria or anuria. Glucocorticoid deficiency - Addison's disease, anterior pituitary failure.
2. Syndrome of inappropriate ADH secretion - Malignant tumours such as oat cell carcinoma of bronchus, head injury, acute alcoholism, encephalitis, lung disease, e.g. pneumonia or TB; myxoedema, acute porphyria.
3. Drug therapy, e.g. carbamazepine. Severe chronic renal failure and intermittent haemo- and peritoneal dialysis when intake is excessive.
4. Hypothalamic lesions.
5. Compulsive water and beer drinking.
6. Inappropriate IV fluid therapy.
7. Congestive heart failure. Liver disease.
8. Complication of transurethral resection of prostate, colorectal washes, total bowel irrigation.

Symptoms and Signs

1. Arising from CNS - Nausea, vomiting, headache, drowsiness, fits and coma.
2. Peripheral oedema - is not a feature of water excess alone.

Investigations - Diagnosis confirmed by finding a low plasma osmolality and low plasma sodium concentration in absence of manifestations of sodium depletion.

Treatment - Restriction of water intake to about 5000 mL/day. Hypertonic saline infusion if severe hyponatremia (plasma sodium <115 mmol/litre).

Water Deficiency

1. Water scarcity.
2. Inability to signify thirst - Severe illness, impaired consciousness, intubation or ventilation.
3. Severe dysphagia.

4. Cranial diabetes insipidus especially if GI losses, burns, chronic renal failure, diuretic phase of acute renal failure.
5. Nephrogenic diabetes insipidus.
6. Osmotic diuresis - diabetic ketotic coma, non-ketotic hyperosmolar diabetic coma.

Clinical features - (i) Thirst is the main symptom. (ii) In advanced cases cerebral disturbances leading to confusion, coma and even death.

Investigation - Rise in plasma osmolality and plasma sodium (to over 180 mEq/litre).

Management - Increased intake of water, if necessary IV 5% dextrose for acute hyponatremia or half normal saline (0.45/sodium chloride for chronic) hyponatremia, if unable to tolerate oral water. Over-rapid replacement should be avoided as intracerebral bleeding may occur as shrunken brain tissue is rehydrated.

DISORDERS OF SODIUM METABOLISM

Control of Sodium Balance

Under normal conditions, plasma sodium concentrations are finely maintained within narrow range of 135-145 mmol/L despite great variations in water and sodium intake. Main determination of plasma sodium concentration is the plasma water intake (thirst or habit), insensible losses such as sweat and urinary dilution. The last of these under most circumstances, the most important and is predominantly determined by arginine vasopressin, which is synthesised in the hypothalamus and then stored in and released from the posterior pituitary. In response to arginine vasopressin, concentrated urine is produced by water reabsorption across the renal collecting ducts. This is mediated by specialised cellular membrane transport proteins called aquaporins.

Sodium Excess (Hyponatremia)

Classification

See Table 7.

Clinical features - (a) Altered mental status is the most frequent manifestation, ranging from mild confusion and lethargy to deep coma. (b) Peripheral and pulmonary oedema, pleural effusions and ascites. (c) Systemic hypertension - When cardiac function is satisfactory and plasma protein concentration normal, increase in extracellular fluid volume also causes hypervolemia, which increases cardiac filling pressure and cardiac output with resultant hypertension. This occurs in primary aldosteronism and acute glomerulonephritis. (d) Oedema with signs of hypovolemia - postural hypotension, poor peripheral circula-

Table 7: Classification of hypernatremia

Hypovolaemia
Dermal losses – for example burns, sweating
Gastrointestinal losses – for example, vomiting, diarrhoea, fistulas
Postobstruction
Acute and chronic renal disease
Hyperosmolar non-ketotic coma*
Hypervolaemia
Iatrogenic (hypertonic saline, tube feedings, antibiotics containing sodium, or hypertonic dialysis)
Hyperaldosteronism †
Euvolaemia
Diabetes insipidus (central, nephrogenic, or gestational)
Hypodipsia
Fever
Hyperventilation
Mechanical ventilation
*Sodium often raised, even after correction for glucose. Typically mildly elevated sodium ~ 147 mmol/l, so rarely a clinical problem.

tion and oliguria (which is also seen in sodium depletion) occurs in hypoalbuminaemic states. (e) Hypernatremia leads to cellular shrinkage because of efflux of water leading to osmotic damage to muscles causing rhabdomyolysis, parenchymal bleed or subarachnoid/subdural bleed in brain.

Investigations – Plasma sodium is usually normal, but may be low if water is retained in excess of sodium, or raised, as in primary aldosteronism.

Treatment – The plasma Na^+ concentration should be corrected by no more than 10 mM/d, which may take longer than 48 h in patients with severe hypernatremia (>160 mM). A rare exception is patients with acute hypernatremia (<48 h) due to sodium loading, who can safely be corrected rapidly at a rate of 1 mM/h. (a) Diuretics. (b) Plasma protein infusion if hypovolemia is life-threatening. (c) Aldosterone antagonist spironolactone if hyperaldosteronism as in Conn's syndrome, cirrhosis and nephrotic syndrome. (d) Haemo- or peritoneal dialysis if inadequate response to diuretic therapy particularly if the disorder of fluid and electrolyte metabolism is complex and acidosis is also present.

Free water should be administered either orally or by nasogastric tube or through intravenous fluid, e.g. dextrose containing IV solution (D5%) with blood glucose monitoring.

Free water deficit is calculated as follows:

A. First step: Estimate Water Deficit

1. Estimate total-body water (TBW): 50% of body weight in women and 60% in men

2. Calculate free-water deficit $[(\text{Na}^+ - 140)/140] \times \text{TBW}$

3. Administer deficit over 48-72 hr, without decreasing plasma Na^+ concentration by >10 mM/24 h

B. Ongoing Water Losses

4. Calculate free-water clearance = $V \times [1 - (U_{\text{Na}} + U_{\text{K}} / P_{\text{Na}})]$ where V is urinary volume, U_{Na} is urinary $[\text{Na}^+]$, U_{K} is urinary $[\text{K}^+]$ and P_{Na} is plasma $[\text{Na}^+]$

C. Insensible Losses

5. 10 mL/kg per day: less if ventilated, more if febrile

D. Total

6. Add components to determine water deficit and ongoing water loss; correct the water deficit over 48-72 h and replace daily water loss. Avoid correction of plasma $[\text{Na}^+]$ by >10 mM/d.

Patients with central DI should respond to the administration of intravenous, intranasal or oral DDAVP. Patients with NDI due to lithium may reduce their polyuria with amiloride.

Thiazides may reduce polyuria due to NDI, ostensibly by inducing hypovolemia and increasing proximal tubular water reabsorption. Occasionally, nonsteroidal anti-inflammatory drugs (NSAIDs) have been used to treat polyuria associated with NDI.

Sodium Deficiency (Hyponatremia)

Classification

See Table 8.

Clinical features – Sunken eyes and cheeks. Weakness, faintness on standing, muscular cramps in legs and thirst. Cold hands and feet and sometimes peripheral cyanosis. Skin inelastic and low intraocular pressure. Tachycardia and weak pulse. Postural hypotension early sign, ultimately circulatory collapse and death may occur.

Hyponatremia leads to cellular swelling, a consequence of water movement down the osmotic gradient from the hypotonic ECF to the ICF. The symptoms of hyponatremia are primarily neurologic, reflecting the development of cerebral edema within a rigid skull. Acute hyponatremic encephalopathy ensues when these volume regulatory mechanisms are overwhelmed by a rapid decrease in tonicity, resulting in acute cerebral edema. Early symptoms can include nausea, headache, and vomiting. However, severe complications can rapidly evolve, including seizure activity, brainstem herniation, coma, and death. A key complication of acute hyponatremia is normocapnic or hypercapnic respiratory failure; the associated hypoxia may amplitude the neurologic injury.

Investigations – Plasma sodium concentration may be low or normal. Raised plasma urea or creatinine indicates

Table 8: Classification of hyponatremia

A. Hypovolemic hyponatremia	
1.	Excessive sweating.
2.	GI fluid loss – prolonged vomiting, diarrhoea, fistulae, paralytic ileus.
3.	Excessive renal loss – (a) Mineralocorticoid deficiency – Addison's disease, hypoaldosteronism. (b) Renal salt wasting – chronic pyelonephritis, renal calculus disease, analgesic nephropathy, after relief of urinary obstruction.
4.	Burns, pancreatitis, trauma.
5.	Excessive diuretic therapy.
6.	Excessive ultrafiltration by haemo- or peritoneal dialysis.
B. Euvolemic hyponatremia	
1.	Glucocorticoid deficiency
2.	Hypothyroidism
3.	Stress
4.	Drugs
5.	SIADH
C. Hypervolemic hyponatremia	
1.	Congestive cardiac failure
2.	Nephrotic syndrome
3.	Cirrhosis
4.	Acute or chronic renal failure

impaired renal function. Fluid input/output chart and daily weighing of patient and CVP line necessary.

Management – Acute hyponatremia developing within 24 hrs carries a risk of cerebral oedema, so prompt treatment is indicated with apparently small risk of central pontine myelinolysis. Patients with chronic hyponatremia are at risk for central pontine myelinolysis if plasma Na⁺ concentration is corrected by >8–10 mM within the first 24 h and/or by >18 mM within the first 48 h. Alcoholics with malnutrition, elderly women on thiazide diuretics, and patients with hypokalaemia or burns are at increased risk of myelinolysis. Fluid restriction (<1 litre/day) is the initial approach to treating chronic asymptomatic hyponatremia, and Demeclocycline is drug of choice for SIADH if fluid restriction alone does not restore sodium concentrations. Aquaretics (e.g. tolvaptan, lixivaptan) induce water diuresis without affecting urinary electrolyte or solute excretion and help in correction of hyponatremia in cirrhosis, heart failure, and SIADH. Moreover restriction of fluid may not be necessary with these agents.

DISORDERS OF POTASSIUM METABOLISM

Potassium Excess (Hyperkalaemia)

1. Inadequate excretion – Renal failure, acute or severe chronic tubular disorders, adrenal insufficiency, Addison's disease, hypoaldosteronism, potassium sparing diuretics.
2. Shift of potassium from tissues – Acidosis (metabolic or respiratory). Tissue injury (muscle damage, haemoly-

sis, internal bleeding). Hyperosmolality. Insulin deficiency. Hyperkalaemic periodic paralysis.

3. Excessive intake (especially with impaired renal function).

Clinical features – Sudden cardiac arrest may be the first manifestation. Occasionally generalised weakness of skeletal muscles.

Investigations

1. Serum K level >5.0 mEq/L.
2. ECG changes – Stages – (a) Shortening of QT interval and tall peaked T waves (serum K >5.5 mEq/L). (b) Widening of QRS complex, prolongation of PR interval, disappearance of P waves, nodal and ventricular arrhythmias (serum K >6.5 mEq/L) (c) Finally QRS complex merges with T wave in a sine wave pattern with ventricular asystole or fibrillation.

Treatment – Plasma potassium >6.0–6.5 mEq/litre is indication for immediate therapy. (a) Calcium gluconate – 5–10 mL of 10% solution may prevent sudden cardiac arrest. (b) IV glucose 300–500 mL 20% plus soluble insulin 1 IU /3 g glucose in 20 minutes. (c) Sodium bicarbonate 500 ml in 1.4% solution in 1–2 hours (only in absence of serious sodium excess). Intravenous bicarbonate has no role in the acute treatment of hyperkalemia, but may slowly attenuate hyperkalemia with sustained administration over several hours. (d) Ion-exchange resin – Calcium polystyrene sulphonate may be given orally (15 g qds.) or rectally (with 50 mL 70% sorbitol and 100 ml water) to remove potassium from the body. (e) Dialysis is rarely required. (f) Drugs and other preparations containing potassium must be stopped.

Potassium Deficiency (Hypokalaemia)

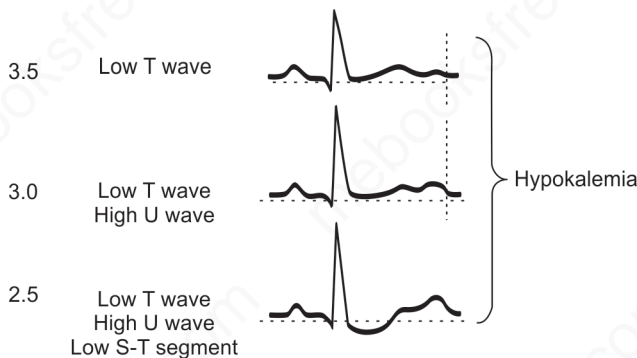

1. Gastrointestinal – Inadequate dietary intake (rarely sole cause), GI fluid loss – Prolonged vomiting, diarrhoea, fistulae, mucus secreting adenomas, ureterosigmoid anastomosis, paralytic ileus.

- Renal loss – Diuretics (thiazide, loop, osmotic) – Metabolic alkalosis. Excess cortisol – Aldosteronism primary or secondary, Cushing's syndrome, exogenous steroids. Renal tubular disorders – Renal tubular acidosis, leukaemia, antibiotics, magnesium depletion.
- Due to shift in the cells – Hypokalaemic periodic paralysis. Alkalosis. Insulin effect.

Clinical features – Muscular weakness, tetany and fatigability, thirst, polyuria, paralytic ileus and cardiac arrhythmias.

Investigations – (a) Serum K <3.8 mEq/L Metabolic alkalosis often present unless hypokalaemia is due to diarrhoea or renal tubular acidosis. Mild proteinuria usual. (b) ECG changes – ST segment depression and appearance of U waves. Severe hypokalaemia may produce premature ventricular and atrial contractions, and tachyarrhythmias.

Treatment – Treatment of cause. If necessary oral potassium (20–100 mEq/day), fruit juice, coconut water, or IV (not to exceed 40 mEq/L, rate of infusion not to exceed 10 mEq/hour). Care must be taken in patients with impaired renal function to avoid hyperkalaemia. Potassium sparing diuretics, e.g. triamterene 100 mg/day or spironolactone 25 mg. qds. Hypokalaemia and hypocalcemia may co-exist and hence correct both. Hypomagnesemia also needs to be corrected.

DISORDERS OF PHOSPHATE METABOLISM

Serum phosphate levels are controlled primarily by the rate of proximal renal tubular reabsorption.

Hyperphosphatemia

Clinical features – Most often mild and asymptomatic. In acute severe hyperphosphatemia symptoms are related mainly to those of accompanying hypocalcemia – tetany, muscle cramps, paraesthesiae and seizures can occur. Chronic hyperphosphatemia is an important factor in development of secondary hyperparathyroidism in progressive kidney failure.

Table 9: Causes of hyperphosphatemia

1. Impaired renal phosphate excretion

- Renal insufficiency
- Familial tumoural calcinosis
- Endocrinopathies
- Acromegaly
- Hypoparathyroidism
- Pseudohypoparathyroidism
- Heparin

2. Increased extracellular phosphate

- Rapid administration of phosphate
- Liposomal amphotericin B
- Phosphate salts
- Rapid cellular catabolism or lysis
- Catabolic states
- Tissue injury
- Hyperthermia
- Fulminant hepatitis
- Crush injuries
- Cellular lysis
- Hemolytic anemia
- Rhabdomyolysis
- Tumour lysis

3. Transcellular shifts of phosphate

- Metabolic acidosis
- Respiratory acidosis

Management (a) Volume expansion to improve GFR in acute syndrome. (b) Phosphate binding aluminium hydroxide antacids and sevelamer to limit phosphate absorption. (c) Haemodialysis is the most effective therapy, especially in tumourlysis syndrome and particularly if symptomatic hypocalcemia cannot be adequately treated for fear of inducing widespread soft-tissue calcification.

Hypophosphatemia

Clinical features: Hypophosphatemia is recognized most often in critically ill patient, alcoholics or other malnourished individuals, decompensated diabetics, and those with acute infections or pulmonary disorders. In severe hypophosphatemia, common are neuromuscular symptoms ranging from progressive lethargy, muscle weakness and paraesthesiae to paralysis, coma, and even death.

Haematological – haemolysis, platelet dysfunction with bleeding and impaired leucocyte function.

Treatment For severe hypophosphatemia IV phosphate at rate of 2 to 8 mm/hr of elemental phosphorus over 4 to 8 hrs often corrects hypophosphatemia. Less acute cases can be managed with oral or enteral phosphate supplements given as total of 1 to 2 gm/day of potassium phosphate in divided doses 3–4 times a day. It is necessary to avoid a serum calcium-phosphorus product >50 to reduce the risk of heterotopic calcification.

Table 10: Causes of hypophosphatemia**1. Reduced tubular phosphate reabsorption**

- Excess PTH or PTHrP
- PTHrP-dependent hypercalcaemia of malignancy
- Secondary hyperparathyroidism
- Vitamin D deficiency/resistance
- Calcium malabsorption / deficient intake
- Imatinib
- Rapid selective correction of severe hypomagnesemia

Excess phosphatonins

- Familial hypophosphataemic rickets
- Autosomal dominant hypophosphataemic rickets
- Tumour - induced osteomalacia syn. (TIO)
- Fibrous dysplasia
- Epidermal naevus syndrome.
- Idiopathic hypercalciuria

Intrinsic renal disease

- Fanconi syndrome(s), other renal tubular disorders
- Cystinosis
- Amyloidosis
- Hemolytic uremic syndrome
- Magnesium deficiency
- Wilson's disease
- Multiple myeloma
- Heavy metal toxicity

*Rewarming or hypothermia NP2a or NPT 2c mutations**Other*

- Poorly controlled diabetes, alcoholism
- Hyperaldosteronism
- Postpartial hepatectomy
- Post renal transplantation
- Drugs or toxins:

Ethanol

Acetazolamide

High dose oestrogens

High dose glucocorticoids

Calcitonin

Bisphosphonates

Paraquat

2. Shift of extracellular phosphate into cells or bone*Acute interstitial shifts*

- IV glucose, fructose
- Insulin therapy for hyperglycemia, diabetic ketoacidosis
- Catecholamines (terbutaline, dopamine)
- Thyrotoxic periodic paralysis
- Acute respiratory alkalosis, salicylate intoxication, acute gout

Contd...

Contd...

- Gram-negative sepsis, toxic shock syn.
- Recovery from acidosis, starvation, anorexia nervosa, hepatic failure

Rapid cellular proliferation

- Leukemic blast crisis
- Intensive erythropoietin, G-CSF therapy

Accelerated net bone formation

- Post-parathyroidectomy
- Osteoblastic metastases
- Tr. of vitamin D deficiency
- Antiresorptive therapy of severe Paget's disease

3. Impaired intestinal phosphate absorption

- Aluminium containing antacids

Table 11: Causes of hypermagnesaemia*Causes:*

1. Excessive magnesium intake
 - Cathartics, antacids, enemas
 - Intestinal obstruction or perforation following magnesium ingestion
 - Parenteral magnesium
2. Rapid mobilization from soft tissues
 - Burns
 - Cardiac arrest
 - Shock, sepsis
 - Trauma
3. Impaired magnesium excretion
 - Familial hypocalciuric hypercalcaemia
 - Kidney failure
4. Other
 - Adrenal insufficiency
 - Hypothermia
 - Hypothyroidism

DISORDERS OF MAGNESIUM METABOLISM

Magnesium like calcium, plays a critical physiological role in neuromuscular function, but also as a component of the mineral phase of bone.

Clinical features do not appear unless serum magnesium is >4 mEq/L. Hypotension may be one of the earliest signs. Lethargy, weakness, with reduction or absent tendon reflexes, can progress to stupor or coma with respiratory insufficiency at serum concentrations >8 to 10 Eq/L. Facial flushing and pupillary dilation can occur. Hypotension may be complicated by relative bradycardia, heart block and ultimately asystole.

Table 12: Causes of hypomagnesemia

Causes	
1. Impaired intestinal absorption	
– Malabsorption syndrome	
– Hypomagnesemia with secondary hypocalcemia	
2. Increased intestinal losses	
– Excessive GI losses: Diarrhoea, vomiting	
– Prolonged intestinal drainage	
3. Defective renal tubular magnesium reabsorption	
<i>Genetic magnesium wasting syndrome</i>	
– Autosomal dominant hypocalcemia	
– Familial hypomagnesemia with hypercalciuria	
– Hypomagnesemia with hypertension and hypercholesterolemia	
<i>Renal disease (acquired)</i>	
– Postobstruction acute tubular necrosis (diuretic phase)	
– Renal transplantation	
– Tubulointerstitial disease	
<i>Drugs and toxins</i>	
– Aminoglycosides	
– Digoxin	
– Amphotericin B	
– Diuretics	
– Cyclosporine	
– Ethanol	
4. Rapid shifts of magnesium out of extracellular fluid	
– Intracellular redistribution	
– Correction of respiratory acidosis	
– Recovery from diabetic ketoacidosis	
– Refeeding syndrome paralysis	
– Thyrotoxic periodic paralysis	
5. Accelerated bone formation	
– After parathyroidectomy	
– Calcitonin therapy	
– Osteoblastic metastases	
– Treatment of vitamin D deficiency	
6. Other losses	
– Blood transfusions	
– Extensive burns	
– Pancreatitis	
– Pregnancy (third trimester and lactation)	
– Excessive sweating	

Treatment: Identification and interruption of source of magnesium and use of cathartics or enemas to accelerate clearance from GI tract, and vigorous hydration. Haemodialysis in refractory cases with advanced kidney insufficiency. Calcium administered IV in doses of 100–200 mg over 1–2 hours, has been reported to provide temporary improvement in signs and symptoms of hypermagnesemia.

Treatment Patients with mild asymptomatic hypomagnesemia can be given oral magnesium salts 480 to 720 mg/d. Symptomatic or severe hypomagnesemia, especially if complicated by hypocalcemia (<1 mEq/L) infusions of 2 to 4 mEq/hr are needed to maintain serum magnesium in range of 2 to 3 mEq/L. In patients with active seizures or urgent indications, infusion must be preceded by slowly administered bolus of 10 to 20 mEq/hr for first hour, followed by rate of infusion 10–15 mEq/hr for first 1 to 2 hrs. only. In patients with impaired kidney function serial monitoring of serum magnesium must be done.

8. ACID-BASE DISTURBANCES

Acid-base disturbances can be easily diagnosed using a four step process. 1. Determination of serum pH. 2. Calculation of serum anion gap. 3. Estimating degree of compensation. 4. Calculation of excess anion gap.

ARTERIAL BLOOD GASES

Assessment of patient's acid-base status begins with measurement of ABG. The normal range of pH is 7.35–7.45, normal pCO₂ is 22–26 mmol/L Table 13.

Notice that the expected change occurs in the same direction in primary metabolic disorders and in the opposite direction in primary respiratory disorders. The degree of compensation for simple acid-base disorder is shown in Table 14.

Anion Gap

The negatively charged anions and the positively charged cations are equal for purposes of electrical neutrality. If so, then the unmeasured anions and unmeasured cations can be determined using the serum chloride (Cl), bicarbonate (HCO₃) and sodium (Na).

$$\text{Anion gap} = \text{Plasma Na}^+ - \text{Plasma Cl}^- + \text{Plasma HCO}_3^-$$

Normal Anion Gap

In some types of metabolic acidosis, reduced bicarbonate in plasma is associated with increase in plasma chloride resulting in normal anion gap.

Table 13: pH alterations in primary acid-base disturbances

Disorder	pH	HCO ₃ ⁻ mEq/L	pCO ₂ mm Hg
Normal	7.4	24	40
Metabolic acidosis	↓	↓	↓
Metabolic alkalosis	↑	↑	↑
Respiratory acidosis	↓	↑	↑
Respiratory alkalosis	↑	↓	↓

Table 15: Causes of abnormal serum anion gap

Increased anion gap	
Common	
• Methanol intoxication	
• Uraemia	
• Diabetic ketoacidosis	
• Ethanol	
• Drugs: Isoniazid, salicylates	
• Lactic acidosis A and B	
• Rhabdomyolysis	
Uncommon	
• Hyperalbuminaemia	
• Administered anions	
Decreased anion gap	
• Hypoalbuminaemia	
• Paraproteinemia (multiple myeloma)	
• Spurious hyperchloreaemia (Bromide intoxication)	
• Spurious hyponatremia	
• Hypermagnesaemia	

The normal anion gap is 12–15 mEq/l. An increase of over 15 mEq/l is considered to be abnormal (see Table 15).

In primary acid-base disorders and in a case of simple metabolic acidosis the anion gap will increase by one mEq/L for every 1mEq/L decrease in serum bicarbonate (one for one ratio). However, this relationship is altered in mixed acid-base disorders due to partial compensatory mechanism by the kidneys and lungs to maintain homeostasis. A comparison in the 'increment' change in anion gap relative to change in bicarbonate concentration can aid in identifying acid-base disorders. This concept is used in calculation of excess anion gap and diagnose mixed acid-base disorders. Decrease in serum bicarbonate concentration = increase in serum anion gap (see Table 16).

Table 14: Degree of compensation in acid-base disturbances

Disorder	Degree of compensation
Metabolic acidosis	PaCO ₂ = (1.5 × HCO ₃ ⁻) + 8 ± 2
Metabolic alkalosis	PaCO ₂ will increase 6 mm Hg for each 10 mEq/L increase in HCO ₃ ⁻ .
Respiratory acidosis	HCO ₃ ⁻ will increase 1 mEq/L per 10 mm Hg increase in PaCO ₂
Acute	Hg increase in PaCO ₂
Chronic	HCO ₃ ⁻ will increase 4 mEq/L per 10 mm Hg increase in PaCO ₂
Respiratory alkalosis	HCO ₃ ⁻ will decrease 2 mEq/L per 10 mm Hg decrease in PaCO ₂
Acute	Hg increase in PaCO ₂
Chronic	HCO ₃ ⁻ will decrease 4 mEq/L per 10 mm Hg decrease in PaCO ₂

Table 16: Metabolic acid-base disturbances

Metabolic acidosis:	
A. With high anion gap –	
1. Ketoacidosis – diabetic, starvation, alcoholic.	
2. Lactic acidosis – Type A – shock (including cardiac arrest, hypoxia). Type B – biguanide, fructose, sorbitol, ethanol, methanol, severe liver disease.	
3. Other conditions – Uraemia, salicylate poisoning.	
B. With normal anion gap –	
1. GI bicarbonate loss – diarrhoea, intestinal, pancreatic and biliary fistulae, ureterosigmoid-ostomy, ileostomy, colostomy.	
2. Renal tubular acidosis.	
3. Ingestion of e.g. acetazolamide, ammonium chloride, certain amino acids.	
4. Rapid IV hydration (dilutional acidosis).	

Clinical Features

Metabolic acidosis produces immediate hyperventilation. In severe acidosis cardiac output falls and state of shock results. Other effects include cardiac arrhythmias, dilatation of vessels (particularly cerebral) and increased risk of pulmonary oedema during fluid therapy. Hepatic removal of lactase by gluconeogenesis is depressed by severe acidosis, and this may exacerbate lactic acidosis.

METABOLIC ALKALOSIS

- Excessive ingestion or infusion of alkali** – Milk alkali syndrome, alkali ingestion in presence of kidney failure, forced alkaline diuresis, excessive bicarbonate therapy for metabolic acidosis.

2. **Inappropriate loss of chloride** – Vomiting or gastric drainage, diuretic therapy.
3. **Associated with hyperadrenocortisolism** – Cushing's syndrome, primary aldosteronism, Bartter's syndrome (hyperreninaemia).
4. **Severe potassium depletion**

Clinical Features

Acute alkalosis causes tetany. Apathy, confusion, drowsiness in severe long-standing alkalosis may be associated with reduced kidney function and uraemia. Compensation by hyperventilation is poor or even absent.

RESPIRATORY ACID-BASE DISTURBANCES

Respiratory Acidosis

1. *Lung disorders* – Chronic obstructive airways disease, large airway obstruction, severe asthma (uncommon).
2. *Neuromuscular and skeletal abnormalities* – Acute inflammatory demyelinating polyradiculoneuropathy, polio, myasthenia, motor neuron disease, severe obesity, kyphoscoliosis, etc.
3. *Respiratory centre disorders* – Drugs, e.g. opiates, barbiturates, benzodiazepines; organic disease affecting respiratory control.

Clinical Features

Symptom complex is labelled CO₂ narcosis. Symptoms vary from headache, blurred vision, anxiety, tremors and asterixis, to somnolence and delirium. Acidaemia induced increase in cerebral blood flow leads to increased CSF pressure and papilloedema. If systemic pH falls below 7.1, cardiac arrhythmias and hypotension can result due to peripheral vasodilatation.

Respiratory Alkalosis

1. Hyperventilation (psychogenic)
2. Excessive assisted ventilation
3. Pneumonia
4. Pulmonary embolism
5. Meningitis
6. Encephalitis
7. Hepatic failure
8. Salicylate poisoning
9. Septicaemia

Clinical features

Symptoms occur more commonly in acute resp. alkalosis and include feeling of light headedness, sacral and perioral paraesthesia, cramps, carpopedal spasm, syncope and altered sensorium. Tachypnoea accompanies hypocapnia. Supraventricular and ventricular dysrhythmias may be seen. Hypotension can result from peripheral vasodilatation.

Note: The distinction between respiratory acidosis and metabolic alkalosis can be made by knowing the cause of the disturbance and the fact that H⁺ is raised in respiratory acidosis and reduced in metabolic alkalosis.

Respiratory alkalosis occurs early in septicaemia which should be suspected when there is no obvious cause for hyperventilation.

Diagnosis – By evaluating values of pH and PaCO₂, using a suitable acid base diagram. In addition the source of metabolic acidosis can often be determined calculating the plasma 'anion gap'.

Management

1. *Treatment of primary condition.*
 2. *Treatment of respiratory acidosis* – (See management of respiratory failure).
 3. *Metabolic acidosis* – Sodium bicarbonate – Treatment of metabolic acidosis with alkali should be reserved for severe acidemia (pH <7.10). Slow infusion of isotonic bicarbonate (about 800 mL/hour) and the effect assessed by re-estimation of pH and PaCO₂ before deciding further therapy. In cases where severe acidosis and hypokalaemia coexist, if acidosis is treated without prior or simultaneous administration of potassium salts, the hypokalaemia may be exacerbated and cardiac arrhythmias or arrest may result. Chronic therapy with alkalis may be required in some conditions associated with metabolic acidosis.
 4. *Metabolic and respiratory alkalosis* – Seldom require attempts at acidification. Most metabolic alkalosis is due to potassium and chloride deficiency and adequate replacement of these is effective. However, if tetany occurs or effects on cerebral circulation suspected, breathing into a bag, oral ammonium chloride or IV arginine hydrochloride infusion is required. Indomethacin for Bartter's syndrome.
- An important dictum to distinguish between simple and mixed acid-base disorder is: In contrast to simple disorders, an abnormal value of PaCO₂ and bicarbonate in the face of near-normal values of pH should always raise the suspicion of mixed acid-base disorder.

Table 17: Four steps to solve acid-base disorders

Step 1	Determine pH status <ul style="list-style-type: none"> • Acidic pH <7.35 • Alkalaemia pH >7.45
Step 2	Calculate the anion gap If > 20 mmol/L, there is primary metabolic acidosis regardless of bicarbonate level
Step 3	What is the degree of compensation? (refer Table 15)
Step 4	What is the anion gap? <ul style="list-style-type: none"> • Calculate the excess anion gap (total anion gap – normal anion gap [12 mmol/L]) and add this value to the measured bicarbonate concentration. If the calculated $\text{HCO}_3^- > 30$ mmol/L there is associated metabolic alkalosis. • If the calculated $\text{HCO}_3^- < 23$ mmol/L there is associated anion gap acidosis. • In primary acid-base disorders, change in anion gap = change in bicarbonate level.

9. LYMPHADENOPATHY

Differential Diagnosis

I. Inflammatory or Infective group –

1. **Acute and subacute lymphadenitis** – (i) Local or generalized enlargement. (ii) Infected focus in neighbourhood of affected glands. (iii) Local heat. (iv) Tenderness. (v) Fever.
2. **Tuberculosis** – (i) Children or young adults. (ii) Adenopathy local cervical or general including mediastinal and retroperitoneal. Axillary and inguinal are usually non-specific, however when the nodes suddenly increase in size, become painful and are associated with constitutional symptoms, in absence of a known factor, tuberculosis must be suspected. (iii) Glands matted together and often caseous; may be tender. (iv) Fever always present. (v) No splenomegaly. (vi) Often tuberculosis elsewhere.
3. **Infectious mononucleosis** – (i) Children or young adults. (ii) Adenitis mostly cervical, may be generalized. (iii) Glands discrete, moderately enlarged, slightly tender. (iv) Moderate fever. (v) Splenomegaly. (vi) Acute onset, chills and sore throat. (vii) Leucocytosis with predominant small lymphocytes. (viii) Positive Paul-Bunnell test. (ix) Recovery in a few weeks.
4. **Syphilis** – (i) Usually young adults. (ii) Posterior cervical and epitrochlear glands always enlarged.

Enlargement slight. (iii) Hard, painless, discrete. (iv) Fever variable. (v) Splenomegaly sometimes. (vi) Skin rash, mucous patches, joint pains, or other evidence of secondary syphilis. (vii) Positive VDRL, TPHA tests. (viii) Spontaneous recovery common.

5. **Chancroid** – Painful genital ulceration. Painful and tender regional lymph glands on one or both sides. Diagnosis by demonstration of *H. ducreyi* by direct smear or culture.
6. **Lymphogranuloma venereum** – (a) Primary lesion – Papule, shallow ulcer/erosion which heals rapidly. (b) Inguinal syndrome – Unilateral lymphadenopathy of femoral and inguinal glands, single or multiple and firm to start with, but soon soften to become multilocular abscesses. ‘Sign of the groove’. Diagnosis confirmed by isolation of LGV agents from material aspirated from bubo. Also positive complement fixation and immunofluorescence tests.
7. **Filariasis** – Filarial lymphangitis and lymphadenitis affecting inguinal and axillary nodes. Fever with headache and malaise.
8. **Systemic lupus erythematosus** – (i) Acute onset. (ii) Generalized lymphadenopathy. (iii) Recurrent septic type of fever. (iv) Flushed or erysipelas-like appearance of face. (v) Erythematous lesions on trunk and extremities, ulcers and erosions of mouth. (vi) Splenomegaly. (vii) Arthritic pain. (viii) Cardiac manifestations. (ix) Purpura. (x) ANA and Anti-ds-DNA, ENA antibodies in serum.
9. **HIV infection** –
 - a. **Acute disease** – A glandular fever-like syndrome occurring in some before seroconversion. Sudden onset of fever, sweats, myalgia, arthralgia, headache, sore throat and diarrhoea. Generalized lymphadenopathy and sometimes transient erythematous macular rash on trunk. Spontaneous resolution of symptoms and lymphadenopathy usually in 3–14 days. Lymphopenia and thrombocytopenia and atypical lymphocytes.
 - b. **Persistent generalized lymphadenopathy** – may be symptomless and resolve in course of time, or may be associated with malaise, fatigue, weight loss, anorexia, fever, night sweats and diarrhoea and may progress to AIDS. Lymph node biopsy shows marked follicular hyperplasia.

10. **Leishmaniasis** - Rarely the disease may be localized in the lymph nodes. History of the patient having been in area of endemic leishmaniasis. Presence of L.D. bodies can be demonstrated in the gland.
11. **Acute viral hepatitis** - Lymphadenopathy in some patients, with jaundice, hepatic tenderness and hepatomegaly.
12. **Rubella** - Suboccipital, postauricular and posterior cervical lymphadenopathy and typical rash.
13. **Fungal infections** - (a) *Coccidioidomycosis* - Lymphadenopathy, and infection of skin, bones, joints, spleen, liver, kidneys, meninges and brain. (b) *Histoplasmosis* - Progressive disseminated form follows haematogenous spread from lungs and is characterised by hepatomegaly, lymphadenopathy, splenomegaly, and less frequently oral or GI ulceration.
14. **Serum sickness** - Fever, cutaneous eruptions, arthralgia, lymphadenopathy, and albuminuria.
15. **Tularemia** - Local lesion, may be an infected wound or papule. After an incubation period of 1-10 days, chills and headache are followed by fever, bodyache, and enlargement of regional lymph nodes, which may proceed to a chronic indolent abscess.
- II. **Reticuloses (malignant lymphomas and blood diseases):**
- a. **Acute lymphocytic leukaemia** - (i) Children or young adults. (ii) Glands discrete, not tender. (iii) Fever moderate or high. (iv) Moderate splenomegaly. (v) Haemorrhages, stomatitis and bone pains. (vi) Diagnostic blood picture. (vii) Short course.
- b. **Chronic lymphocytic leukaemia** - (i) Middle or old age. (ii) Glands large but discrete. (iii) Moderate splenomegaly. (iv) Irregular fever. (v) Haemorrhages. (vi) Skin eruptions.
- c. **Hodgkin's disease** - (i) Any age. (ii) Mostly cervical, may be axillary, inguinal, abdominal or mediastinal. (iii) Glands painless and discrete. Size varying from pea to a large orange. Rubbery feel. Characteristic appearance in advanced cases is a pyramidal swelling with its base at clavicle and apex at angle of jaw. (iv) Fever. (v) Pressure symptoms common. (vi) Generalized pruritus. (vii) Splenomegaly common.
- d. **Non-Hodgkin's lymphomas** -
- a. **Low grade** - (i) Age over 50. (ii) Painless adenopathy in cervical, axillary and inguinofemoral regions. In some large abdominal masses of retroperitoneal or mesenteric lymph nodes may be the presenting feature. (iii) Spleen often enlarged at onset of disease, subsequently marked enlargement producing local symptoms and hypersplenism. Favourable prognosis. (b) **High grade** - Presents with extensive, rapidly progressing, nodal disease often with bone marrow and other extranodal involvement. Rarely disease may be confined to one nodal or extranodal site. Extralymphatic involvement is not uncommon; GI tract, thyroid, testes and bone being the more common sites.
- e. **Follicular lymphomas** - Usually middle age. Occur in two phases. First phase relatively benign with enlargement of one or more of superficial lymph nodes, with or without splenomegaly. No constitutional symptoms. Lymph nodes moderately enlarged, discrete, firm and non-tender. This phase is followed after varying period by malignant phase characterised by development of histological features of lymphosarcoma or reticulum cell sarcoma or less commonly Hodgkin's disease.
- f. **Sarcoidosis** - (i) Children or young adults. (ii) Generalised lymphadenopathy. Frequent involvement of pre- and post-auricular, submaxillary, epitrochlear, and para-tracheal glands. (iii) Splenomegaly (iv) Sarcoid lesions of skin, and uveitis or parotitis. (v) X-ray of chest - Bilateral involvement of hilar nodes or miliary nodular bilateral involvement or soft infiltration or dense hilar radiation. (vi) Tuberculin test - sensitivity diminished. (vii) Liver biopsy characteristic changes of sarcoidosis in majority.
- g. **Toxoplasmosis** - Lymphadenopathy is the most common presenting feature. Painless enlargement especially of cervical lymph nodes. Nodes may be mobile, discrete and occasionally tender. Spleen seldom palpable. In some, other organs such as brain, meninges, heart, lung, liver or skeletal muscles are involved. **Diagnosis** - Dye test in which methylene blue is used to stain live *Toxoplasma*. Also ELISA test to detect significant levels of toxoplasma-specific IgM antibody.
- III. **Neoplasms** - (a) **Secondary carcinoma** - (i) Middle or old age. (ii) Glands hard, fixed and localised to a limited region; painless and not tender. (iii) Presence of a primary lesion. (b) **Sarcomas** - Synovial sarcoma, Kaposi's sarcoma.

IV. **Drugs** – Carbamazepine, allopurinol, cephaloridine, iron dextran, meprobamate, PAS, phenylbutazone, primidone, sulphadimidine and troxidone. Phenytoin may cause not only lymphadenopathy but also hepatosplenomegaly.

V. **Lipid storage diseases** – Gaucher's and Niemann-Pick disease.

VI. **Miscellaneous diseases and diseases of unknown ethology** –

- a. *Mucocutaneous lymph node (Kawasaki) syndrome*
Occurs in infants and children below 5, consisting of characteristic exanthem, enanthem, fever, lymphadenopathy, bilateral conjunctival injection, polyarteritis of variable severity.
- b. *Sinus histiocytosis* – Generalised glandular enlargement with massive cervical lymphadenopathy, fever and leucocytosis.
- c. *Amyloidosis* – Lymphadenopathy can occur with systemic amyloidosis. Evidence of other organ dysfunction.
- d. *Dermatopathic lymphadenitis* – Enlarged superficial lymph nodes in exfoliative dermatitis.
- e. *Lymphomatoid granulomatosis* – Lymphadenopathy more affecting intrathoracic nodes, less peripheral. May progress to frank lymphoma.
- f. *Angio-immunoblastic lymphadenopathy* – Spectrum of diseases characterised by lymphadenopathy, hepatosplenomegaly, fever, autoimmune hemolytic anemia and hypergammaglobulinaemia.
- g. *Multifocal Langerhans' cell (eosinophilic) granulomatosis* – Usually in childhood. Focal or generalised lymph node enlargement, and development of multiple bony lesions. Diabetes insipidus, hepatomegaly and splenomegaly may be associated.
- h. *Histiocytic necrotizing lymphadenitis* (Kikuchi's disease) is usually a self-limiting illness, characterized by pyrexia, neutropenia and cervical lymphadenopathy in young women of Asian descent.
- i. *Sinus histiocytosis with massive lymphadenopathy (SHML)* is a rare entity characterised by massive, painless cervical lymph node enlargement. Extranodal involvement occurs in a number of cases and affects the skin, paranasal sinuses, soft tissue and bone, etc.

Investigation of a case of lymph node enlargement

History

1. *Age* – Tuberculous lymphadenitis in childhood, secondary carcinoma in old age.
2. *Occupation* – Tularemia in hunters and butchers; sporotrichosis in farmers and gardeners.
3. *Duration* – (a) Acute swelling of a few days duration mostly pyogenic. (b) Subacute lymphadenitis of 3–4 weeks' duration may be due to streptococcal infection, tuberculosis, secondary syphilis, infectious mononucleosis or tularemia. (c) Chronic lymphadenopathies include tuberculosis, lymphomas, leukaemia, primary lymphatic tumours and secondary carcinoma. History of previous radiation treatment or operative removal.

Physical examination

Local

1. *Number of glands* – Single gland may appear to be affected for some time in tuberculosis, Hodgkin's and secondary carcinoma. Multiple in tuberculosis, Hodgkin's disease, leukaemia.
2. *Site* – (a) Neck usual site for tuberculous lymphadenitis, lymphosarcoma, and most other lymphadenopathies. (b) Inguinal gland enlargements may be due to syphilis, lymphogranuloma inguinale or chancroid. (c) The infraclavicular glands are seldom so enlarged as to be palpable except in secondary cancer or Hodgkin's disease. (d) Supratrochlear (epitrochlear) lymphadenopathy in non-Hodgkin's lymphoma, chronic lymphocytic leukaemia, infectious mononucleosis, secondary syphilis, sarcoidosis, i.v. drug abuse. (e) Hilar and superior mediastinal lymphadenopathy in tuberculosis, histoplasmosis, sarcoidosis, pneumococcosis, malignancy and cryptococcosis.
3. *Character* – Discrete in Hodgkin's disease and leukaemia, primary tumours of lymphatic tissue and so called "lymphadenoid" form of tuberculous lymphadenitis. Movable, discrete and painless in sarcoidosis. Matted together in tuberculosis and lymphogranuloma.
4. *Cold abscess* – in tuberculosis, lymphogranuloma, tularemia and sporotrichosis. Tuberculous glands may break through to give a typically indolent ulcer with undermined edges.

5. *Primary cause* – in the area drained by the enlarged glands; e.g. scalp if occipital or posterior auricular glands, fauces and pharynx if upper anterior cervical group, etc. Healed scar at portal of entry, scar of operative removal, or of radiation treatment.

Systemic

- Skin* – (i) Cutaneous tumours mostly on the face, usually in chronic lymphatic leukaemia. Sometimes generalised erythroderma, polymorphic rashes and purpura. (ii) Rash of secondary syphilis. (iii) Painless papules without surrounding erythema may be found on face, arms and legs in sarcoidosis. (iv) Eruption of lupus erythematosus.
- Lungs* – Pulmonary or mediastinal tuberculosis, lesions of sarcoidosis or metastatic or primary deposits in carcinoma.
- Abdomen* – Abdominal glands may be palpable in tuberculosis. Enlargement of spleen and liver in leukaemia and Hodgkin's disease.
- Genitalia* – Scar of primary sore of syphilis, or "chancre" in lymphogranuloma.
- Icterus* – Jaundice with lymphadenopathy may be met with in viral hepatitis (cervical glands), lymphoma, acute lymphocytic leukaemia, disseminated TB.
- Temperature* – raised in Hodgkin's disease, infectious mononucleosis and tularemia.

Investigations

- Blood picture* – for diagnosis of leukaemia, and infectious mononucleosis. Positive ANA and reduced complement C₄ levels in SLE.
- Special tests* – Serologic tests for syphilis. Paul-Bunnell or monospot test for infectious mononucleosis. Agglutination reaction and animal inoculation in tularemia. Autoantibodies in SLE. Liver biopsy useful in sarcoidosis and infectious mononucleosis. Serological tests for HIV infection.
- Radiography* – of lungs and gastrointestinal tract. Skeletal changes in sarcoidosis and sporotrichosis (multiple small areas of decalcification).
- Biopsy* – Needle aspiration biopsy is useful for initial evaluation of superficial lymphadenopathy. It is however not helpful in diagnosis of lymphomas and other hematologic malignancies. Lymph node biopsy tissue should be processed for culture of appropriate organisms, frozen in liquid nitrogen for lymphocyte typing

or special studies for malignant cell types, and for routine histological studies.

- CT scan* – of abdomen in lymphoma.
- Lymphangiography* – of value in diagnosing site, extent, and, in certain cases, even the nature of primary lymph node enlargement.
- Laparotomy and laparoscopy* – Lymphomas.

10. HYPERLIPOPROTEINAEMIAS

Hyperlipoproteinaemias are disturbances of lipid transport resulting from abnormalities in synthesis or degradation of plasma lipoproteins. *Hyperlipidemia* is a rise in plasma cholesterol, triglycerides or both. Elevated cholesterol primarily refers to high low-density lipoprotein cholesterol (LDL-C) since approximately 70% of cholesterol is carried in the LDL particle.

Lipid metabolism has two pathways—1. Exogenous pathway which starts from intestinal absorption of dietary fat and cholesterol. 2. Endogenous pathway that starts with VLDL production from the liver. The former is domination in the well fed state, the latter in the fasted stage. 3. Reverse cholesterol transport is the process of removal of cholesterol from tissues and returning it to the liver. HDL (synthesised and catabolised in liver and intestine) is the main lipoprotein concerned with this process.

Table 18: Causes of hypertriglyceridemia

A. Primary

- Chylomicronaemia
- Familial lipoprotein deficiency
- Familial apoprotein C-II deficiency
- Elevation of VLDL
- Familial combined hyperlipidemia
- Dysbetalipoproteinaemia
- Hepatic lipase deficiency

B. Secondary

- Hypothyroidism
- Diabetes mellitus

C. Associated diseases

- Liver disease
- Obesity
- Lipodystrophy
- Glycogen storage disease

Types of lipoproteins

1. *Chylomicrons*, which transport exogenous or dietary fat.
2. *Very low density lipoproteins* (VLDL) which transport endogenous triglyceride.
3. *Low density lipoprotein* (LDL) which transport cholesterol to peripheral cells.
4. *High density lipoprotein* (HDL) which transport cholesterol from peripheral cells.

Chylomicrons and VLDL are triglyceride-rich LDL, while HDL are cholesterol-rich. The plasma lipid values permit accurate assessment of which lipoprotein is raised. Determination of plasma cholesterol and triglyceride concentration after a 12–24 hours overnight fast is usually sufficient for clinical purposes.

Classification of lipid profiles: Plasma samples in these dyslipidemias are given in Table 19.

Risk of atherosclerosis with IIa, IIb, III. For simplification type I-V approach can be replaced with three broad patterns of excess:

1. Predominantly hypercholesterolemia
2. Predominantly triglyceridaemia
3. Mixed hyperlipidemia

Other lipids

Lipoprotein [LP (a)] is an atherogenic lipoprotein particle in human plasma related in structure to LDL. In addition to CHD, LP (a) has been shown to be an independent risk factor for cerebrovascular atherosclerosis. Elevated plasma concentrations are associated with an increased risk of premature CHD. A plasma level of more than 30 mg/dL appears to confer significantly higher risk of atherosclerotic disease. Small dense LDL particles containing

cholesterol ester considered to be more atherogenic than LDL particles.

(See Table 20 for causes of hyperlipidemia)

Clinical presentation – of hyperlipidemia

1. *Asymptomatic* and undetected until a complication occurs such as myocardial infarction due to early atherosclerosis, or during screening of suspects such as family members.
2. (i) Xanthelasmas. (ii) Lipemia retinalis. (iii) Achilles tendon xanthomata. (iv) Palmar xanthomas. (v) Tuberos or tuberuptive xanthomas. Cutaneous xanthomas are clinically subdivided into xanthelasma palpebrum, tuberos xanthomas, tendinous xanthoma, eruptive xanthoma and plain xanthomas. The presence of tendon xanthomas along with xanthelasma indicates familial hypercholesterolaemia.

Management of hyperlipidemia.

Indications – 1. Young primary hypercholesterolaemia hypertriglyceridaemic patients, especially if there is family history of early onset cardiovascular disease. 2. All hypertriglyceridaemic patients with levels in excess of 1000 mg/dL to prevent pancreatitis.

1. **Diet** – Calorie restriction and exercise in overweight patient. Reduction of saturated fats and replacement with unsaturated fats (vegetable) oils. Increase in carbohydrate content to about 55% of total calories.
2. **Weight reduction** – if overweight.
3. **Exercise** – helpful in lowering triglyceride and cholesterol levels.
4. **Discontinuation of drugs** – such as thiazide diuretics and beta-blockers can lead to reduction of cholesterol and LDL levels.

5. Drugs

See Table 21 for drugs for the treatment of dyslipidemia.

Table 19: Classification of lipid profile

Type I	Chylomicronaemia alone. Serum with creamy top, clear underneath. Very rare.
Type II	Raised cholesterol as excess LDL alone (IIa) or plus some VLDL with cloudy serum (IIa). Pattern type IIb overlaps with type IV. All three are common.
Type III	Excess of chylomicron remnants in the uncommon familial dysbetalipoproteinaemia. Usually turbid.
Type IV	Mainly triglyceridaemia with VDL, VLDL excess. Cloudy with faint creamy layer.
Type V	Everything in excess including chylomicrons. Very cloudy with creamy top on standing in fridge.
	Uncommon.

Table 20: Causes of hyperlipidemia

1. Primary (genetic).
2. Secondary
– Diet rich in saturated fat
– Sedentary lifestyle
– Alcoholism
– Diabetes mellitus
– Hypothyroidism
– Nephrotic syndrome
– Cushing's syndrome
– Liver disease (obstructive)
– Drugs (steroids, thiazide diuretics, oestrogens)

Note: Ezetimibe is combined with statins in patients who are unable to take large dosages of statins or require further reduction in LDL despite maximum statin dosage. Combination of lipid-lowering therapy and calcium channel blockers (CCBs) is effective. Serum markers of atherosclerosis and vascular integrity improve most in combination group. Synergistic effects of atorvastatin and amlodipine on acute nitric oxide release/endothelial function and additive effects of the combination in improvement of arterial compliance in hypertensive hyperlipidaemic patients has been demonstrated.

6. **Plasmapheresis, partial ileal bypass, liver transplantation** – have been used for homozygous form of familial hypercholesterolemia since these patients respond poorly to drugs. Plasmapheresis has also been used for severe heterozygous FH.

11. INBORN ERRORS OF METABOLISM

A group of inherited disorders involving genetically determined abnormalities in wide variety of metabolic pathways or structural proteins. Each defect leads to a special clinical picture which can usually be predicted by the nature of the biochemical defect.

THE PORPHYRIAS

Porphyrias are metabolic diseases caused by defects in normal haem and porphyrin biosynthesis. The porphyrias are classified into acute (inducible) and non-acute (cutaneous) presentations. They are all transmitted in an autosomal dominant manner, except for the rare congenital porphyria, which is recessive, and porphyria cutanea tarda, which may be acquired.

Table 21: Drugs for the treatment of dyslipidemia

Drug	Dose	Clinical use	Effects	Side effects
Nicotinic acid (<i>Niacin</i>) Bile acid sequestrants	1g t.d.s.	IIa, IIb, III, IV, V	HDL↑ LDL↓	Flushing, nausea, pruritus, dizziness, hypotension, liver disease, peptic ulcer.
Cholestyramine Colestipol	8 g t.d.s.	IIa, IIb	LDL↓ HDL↑ Trigl↓	Constipation, flatulence, heartburn, nausea.
HMG-CoA reductase inhibitors				
Lovastatin Pravastatin Simvastatin Fluvastatin Atorvastatin	20–40 mg b.d. 20 mg o.d. 5–40 mg o.d. 20–40 mg o.d. 10 mg b.d.	IIa, III, IV, V	LDL↓ HDL↑ Trigl↓ Apo B↓	Skin rash, myositis, elevated LFTs. Constipation, flatulence, abd. pain.
Fibrants				
Gemfibrozil Fenofibrate Benzofibrate	600 mg b.d. 200 mg o.d. 400 mg b.d.	IIb, III, IV, V	HDL↑ Trigl↓ LDL↓	Bloating, diarrhoea, headache, rash, increased risk of gallstones. Rarely myositis.
LDL oxidation inhibitor				
Probucol (Can be combined with bile resins)	500 mg b.d.	IIa, IIb	HDL↑ LDL↓	Diarrhoea, flatulence, nausea, prolonged QT interval.
Cholesterol absorption inhibitor				
Ezetimibe	10 mg o.d.	IIa, IIb	HDL↑ LDL↓	Diarrhoea. Liver enzyme elevation
Omega-3 fatty acids				
Eicosapentaenoic acid (EPA)	180 mg		Cholesterol↓	Occasional nausea and belching.
Docosahexaenoic acid (DHA) per capsule	120 mg 2 capsules t.d.s		Triglycerides↓ VDL↓ HDL↑	
MTP inhibitor				
Lomitapide	5 mg daily	IIa	↓VLDL	Nausea, diarrhoea, increased hepatic fat
ApoB inhibitor				
Mipomersen	200 mg sc weekly	IIa	↓VLDL	Injection site reaction

Molecular biology – cDNA clones have been obtained for all the enzymes of haem biosynthesis. The most striking feature in all porphyrias is the heterogeneity of the genetic lesion, except when the ‘founder effect’ is present (i.e. a genetic defect in an early generation is carried to later generations).

The porphyrias are classified as either hepatic or erythropoietic depending on the primary site of overproduction and accumulation of their respective porphyrin precursors or porphyrins (Tables 22 and 23).

Acute porphyrias – All patients have similar abdominal and neuropsychiatric or neurovisceral disturbances. Those with hereditary coproporphyria and variegate porphyria may also present with photosensitivity. During an attack, patients excrete massive excess of porphyrin precursors, 5-aminolaevulinic acid (ALA) and porphobilinogen (PBG) in their urine. However some patients remain asymptomatic, and may have normal excretion of porphyrin and precursors. Urine when first passed, is clear and darkens on exposure to light as porphyrinogens are converted to porphyrins. Attacks which may vary from several days to months, are commonly followed by complete remission.

Precipitating factors – Drug ingestion (barbiturates, sulphonamides, oral contraceptives), anticonvulsants such as carbamazepine, phenytoin, primidone, alcohol ingestion, endogenous or exogenous hormonal factors and infection.

I. **Acute intermittent porphyria (AIP)** – Most severe of acute porphyrias. Occurs usually in young adults.

Clinical features – *GI symptoms* – most common. Colicky abdominal pain, vomiting, severe constipation. *Motor neuropathy* may be the presenting feature. Weakness involves more limb and girdle muscles. Paraesthesiae and sensory loss impairment may occur. Epileptic fits may occur. *CVS* – Sinus tachycardia, hypertension which usually reverts to normal after acute attack. *Psychiatric* – Depression, hysteria, psychosis. *Precipitating factors* –

Table 22: Classification of porphyrias

A. Hepatic Porphyrias
1. 5-ALA dehydratase deficient porphyria (ADP)
2. Acute intermittent porphyria (AIP)
3. Porphyria cutanea tarda (PCT)
4. Hereditary coproporphyria (HCP)
5. Variegate porphyria (VP)
B. Erythropoietic Porphyrias
1. Congenital erythropoietic porphyria (CEP)
2. Erythropoietic protoporphyria (EPP)
3. X-linked protoporphyria (XLP)

Drugs especially barbiturates, pregnancy, infection, starvation.

1. **Porphyria variegata** – Combination of clinical features of acute intermittent and cutaneous hepatic porphyria.
2. **Hereditary coproporphyria** – Both systemic and cutaneous signs. Abdominal pain, vomiting and constipation are the usual presenting features.
3. **Plumboporphyria** – Here 5-amino-levulinic acid dehydratase activity is depressed (this also occurs in lead poisoning). Clinical picture resembles acute intermittent porphyria.

Management

1. *Reduction of porphyrin synthesis* – (a) Oral carbohydrate intake of 1500–2000 kcal/24h should be maintained throughout the attack by nasogastric tube if necessary to reduce porphyrin synthesis. If not tolerated laevulose or glucose 2 litres/day of 20% solution IV. (b) IV haematin (haem arginate) 2–4 mg/kg over 30 minutes.
 2. *For skin photosensitivity* – Barrier creams and beta-carotene 90 mg daily in VP and HC. Pregnancy should be avoided if disease is active.
- II. **Non-acute (cutaneous) porphyrias** – Here photosensitizing porphyrins are deposited in the upper dermis layer, these are responsible for the characteristic skin lesions.
1. **Cutaneous hepatic porphyria** – may be inherited or acquired. Characteristic feature is bullous dermatosis on light-exposed areas, which often causes troublesome pruritus. Hyperpigmentation is common. Biochemical evidence of liver disease. Alcohol is the most important precipitating agent.

Management – (a) Venesection of 500 ml every 2 weeks until clinical remission or fall of haemoglobin

Table 23: Manifestation of porphyria

1. Neurovisceral – seen in
– 5-ALA dehydratase deficient porphyria (ADP)
– Acute intermittent porphyria (AIP)
– Hereditary coproporphyria (HCP)
– Variegate porphyria (VP)
2. Blistering skin lesions
– Hereditary coproporphyria
– Porphyria cutanea tarda
– Variegate porphyria
– Congenital erythropoietic porphyria
3. Nonblistering photosensitivity
– Erythropoietic porphyria
– X-linked protoporphyria

below 12 g/dL (Venesection removes hepatotoxic liver iron which produces target organ damage).
(b) Chloroquine - 125 mg b.d. enhances urinary clearance of porphyrin.

2. **Erythropoietic porphyria** - Pruritic urticarial swelling and redness of skin on exposure to sunlight, and severe burning sensation in affected parts. Hepatic involvement can lead to cirrhosis and liver failure. Protoporphyrin deposition may also cause cholelithiasis.

Management - Oral β -carotene for solar sensitivity. Cholestyramine reduces plasma protoporphyrin levels and may slow activity of the liver disease.

3. **Congenital porphyria** - It is caused by a decrease in uroporphyrinogen cosynthase activity which results in overproduction of uroporphyrin I and coproporphyrin I. Symptoms usually commence during first few years of life. Skin reaction is severe and scarring on the hand may produce a claw-shaped deformity. Dystrophic nails may drop off. Lenticular scarring may lead to blindness. Teeth become brownish-pink due to their high porphyrin content.

Management - Splenectomy and chloroquine therapy and hypertransfusion have ameliorating effect, but life expectancy is short.

INBORN ERRORS OF AMINO ACID METABOLISM

Maple Syrup Urine Disease

Can lead to severe illness and death in neonatal period. Symptoms and signs may be nonspecific and mimic those produced by other common disorders, e.g. birth asphyxia or infection.

Homocystinuria

Recessively inherited disorder of methionine metabolism caused by deficiency of the enzyme cystathionine synthase. Homocysteine and methionine accumulate in the plasma. Homocysteine interferes with cross-linkage in both elastic and collagen fibres impairing their natural strength.

Cause - Enzyme cystathionine synthetase which with co-factor vitamin B₆ controls union of serine and homocysteine to form cystathionine. The block results in accumulation of homocysteine and its excretion in urine.

Clinical features - (a) Skeletal - Osteoporosis involving vertebral bodies with kyphoscoliosis, deformities of thoracic cage, genu valgum and flat feet. Reduced mobility of joints, long fingers and toes and increase in height despite spinal curvature. (b) CVS - Myocardial infarction due to narrowing of arteries. Pulmonary embolism may occur. (c) Brain - Mental retardation and epilepsy. (d) Ocular - Iridodonesis followed by downward dislocation of lens with resultant glaucoma, buphthalmia and optic atrophy. (e) RS - Asthma may occur. Majority of children are disabled by age of 10.

Diagnosis - Positive cyanide-nitroprusside test in urine. Raised level of plasma methionine with low plasma cysteine.

Treatment - For pyridoxine responsive patients - Pyridoxine hydrochloride about 600 mg/day with slight restriction of protein. Also folic acid 5 mg/day. For pyridoxine resistant patient - Methionine 130-150 mg/day given in natural protein and cysteine 100-300 mg/day. Vitamins and minerals.

Phenylketonuria (PKU)

Cause - Deficiency of enzyme phenylalanine hydroxylase which catalyses conversion of phenylalanine to tyrosine.

Clinical features - usually appear after first year of life. Mental and growth retardation; eczema and pigment dilution, seizures, tremor, muscular hypertonicity, microcephaly, enamel hypoplasia and decalcification of long bones.

Diagnosis - Serum phenylalanine raised (>1.2 mmol/litre) with raised urinary phenylacetic acid and phenylpyruvic acid.

Treatment - Dietary restriction of phenylalanine to maintain blood level at 2.5-7.5 mg/100 mL (0.15-0.45 mmol/litre).

PKU VARIANTS - result from deficiency of pterin cofactors, essential not only for metabolism of phenylalanine, but also in synthesis of neurotransmitters, dopamine and serotonin. The disorders have been labelled 'malignant' PKU, as mental deterioration is not prevented by a low phenylalanine diet alone.

LYSOSOMAL STORAGE DISEASE

Mucopolysaccharidoses (MPS)

A group of inherited connective tissue disorders caused by deficiency of lysosomal hydrolases. There is accumulation of partially degraded mucopolysaccharide which interferes with normal function of various organs and leads to urinary excretion of these compounds and glycosaminoglycans.

Clinical Presentation

1. **Prominent dysmorphic features** (MPS types I, II, VI)-
 - a. Hurler's syndrome (Type H) - Progress slows towards end of first year. Clinical manifestations may include hepatosplenomegaly, herniae, dorsolumbar kyphosis, cardiac murmurs and corneal clouding. During second and subsequent years bone dysplasia (dysostosis multiplex) becomes more prominent leading to dwarfism. Steady progression of the multisystem abnormalities leads to death by 10 years of age.
 - a. Hunter's SYNDROME (Type II) - Inherited as X-linked recessive. Features same as Hurler's but no corneal clouding, and progression at a slower rate.
2. **Behavioural disturbance and dementia** (MPS type III) - Developmental delay seen after second year of life. Gradual development of ataxia, progressive loss of mobility, and death in a vegetative state.
3. **Severe bony abnormalities** (MPS types IV and VI) - Short neck and trunk, barrel-shaped chest. Head appears to rest directly on thorax. Waddling gait and progressive genu valgum develops. Cardiac lesions, corneal clouding and deafness can occur.

Diagnosis - Abnormal urinary excretion of glycosaminoglycans in urine by electrophoresis.

CARBOHYDRATE METABOLISM

Glycogen Storage Disease (GSD)

A group of disorders in which the fine control of glycogen synthesis and catabolism is disrupted by an inherited enzyme deficiency resulting in normal or abnormal glycogen within the cell (GSD type O).

Von Gierke's disease

Cause - Due to absence of glucose-6-phosphatase activity in liver, renal cortex, GI mucosa and platelets.

Clinical features - Hypoglycemia early in life. Hepatomegaly. Bleeding due to glycogen accumulation in platelets. Gouty arthritis. Others - Hyperlipidaemia, lactic acidosis, growth retardation and delay in pubertal maturation.

Diagnosis - Liver biopsy with assay of hepatic glucose-6-phosphatase activity.

Treatment - Frequent carbohydrate feedings or portacaval shunt procedures.

McArdle's Syndrome

Enzyme deficiencies are confined to skeletal muscles. Progressive muscle weakness with cramping pains on exer-

tion. Muscle necrosis and myoglobinuria occurs in half the patients. Diagnosis from characteristic histological appearance of muscle, and enzyme assay.

Galactosaemia

A disorder due to accumulation of galactose and galactose-1-phosphate with resulting tissue damage.

Cause - Disturbance in conversion of galactose to glucose.

Clinical features - Widespread symptoms and signs. Child ill in first week of life with vomiting, failure to thrive. Jaundice and hepatomegaly. Cataracts in about 50%. May be hypoglycaemic. Prone to infection. Evidence of renal tubular dysfunction.

Diagnosis - confirmed by demonstration of absent enzyme activity.

Treatment - Omission of lactose and galactose from diet. Adequate proteins, calories and vitamins.

PURINE AND PYRIMIDINES

Lesch-Nyhan disease - Hereditary hyperuricemia with choreoathetosis, spasticity and mental retardation.

TRACE METAL METABOLISM

Wilson's disease.

LIPID METABOLISM

Familial hyper cholesterolaemia (Deficient LDL receptors).

12. AMYLOIDOSIS

A disorder of protein metabolism characterized by extracellular tissue deposits, localized or systemic, of an abnormal material, consisting of protein fibrils and also a glycoprotein known as amyloid P component (AP). Two main types of amyloid fibril are AL (amyloid light chain proteins) and AA (amyloid A fibril proteins). Clinical significance of amyloidosis depends on its type, and on the site of deposition.

Table 24 Classifies the most common types of amyloid and amyloidosis.

SYSTEMIC AMYLOIDOSIS

Table 25 lists the clinical features of systemic amyloidosis.

Clinical syndromes - based on chemical nature of fibril subunit proteins.

Table 24: Classification of the most common types of amyloid and amyloidosis

Type	Fibril protein precursor	Clinical syndrome
AA	Serum amyloid A protein	Reactive systemic amyloidosis associated with chronic inflammatory diseases
AL	Monoclonal immunoglobulin light chains	Systemic amyloidosis associated with myeloma, monoclonal gammopathy, occult dyscrasia
ATTR	Normal plasma transthyretin Genetically variant transthyretin	Senile systemic amyloidosis with local nodular amyloidosis, prominent cardiac involvement Familial amyloid polyneuropathy, usually with systemic amyloidosis Sometimes prominent amyloid cardiomyopathy or nephropathy
Ab ₂ M	β ₂ -microglobulin	Periarticular and occasionally systemic amyloidosis associated with kidney failure and long-term dialysis
Ab rare	β-protein precursor (and rare genetic variants)	Cerebrovascular and intracerebral plaque amyloid in Alzheimer's disease. Occasional familial cases
AIAPP	Islet amyloid polypeptide	Amyloid in islets of Langerhans in type II diabetes mellitus and insulinoma.

Table 25: Clinical features

Renal disease
<i>Commonly</i>
<ul style="list-style-type: none"> • Proteinuria • Nephrotic syndrome • Renal insufficiency • Hypertension
<i>Occasionally</i>
<ul style="list-style-type: none"> • Microscopic haematuria • Nephrogenic diabetes insipidus • Renal tubular acidosis • Renal vein thrombosis
Cardiac disease
<ul style="list-style-type: none"> • Restrictive cardiomyopathy • Biventricular 'diastolic' failure • Mimics constrictive pericarditis • Rhythm disturbances • Heart block • Apparent angina, myocardial infarction
Respiratory tract disease
<ul style="list-style-type: none"> • Dyspnoea • Haemoptysis • Stridor • Cough
Gastrointestinal disease
<ul style="list-style-type: none"> • Macroglossia (AL) • Dysphagia • Gastrointestinal haemorrhage • Diarrhoea, constipation • Malabsorption • Intestinal perforation, obstruction • Hepatomegaly • Splenomegaly, rupture • Skin disease

Renal disease
<ul style="list-style-type: none"> • Occasionally • Scleroderma-like infiltration • Alopecia • Nail changes • Bullous eruption
Nervous system
<ul style="list-style-type: none"> • Peripheral neuropathy • Autonomic neuropathy and orthostatic hypotension • Enlarged peripheral nerves • Carpal tunnel syndrome
Musculoskeletal system
<ul style="list-style-type: none"> • Bone marrow (AL) • May resemble rheumatoid arthritis • Mono-arthropathy • Bilateral glenohumeral infiltration with 'shoulder pads' • Muscle infiltration • Dialysis arthropathy syndrome (Ab₂M)
Miscellaneous
<ul style="list-style-type: none"> • Lymphadenopathy • Goitre • Isolated clotting factor IX and X deficiency • Haemorrhage with normal clotting factors • Sicca syndrome • Adrenal involvement • Involvement of subcutaneous fat

I. Systemic amyloidosis –

Reactive systemic (AA) amyloidosis – Associated with chronic infections, long-standing inflammatory disease e.g. RA and malignant neoplasms, e.g. myeloma. Usual clinical features are proteinuria, nephrotic syndrome and/or hepatosplenomegaly. Prognosis is poor.

Systemic AL amyloidosis – Usually in patients over 50, associated with multiple myeloma and lymphoma or as ‘benign’ monoclonal gammopathy (Bence-Jones protein). Liver, spleen, kidneys, nerves and gut are commonly involved. Cardiac involvement is in form of restrictive cardiomyopathy and intractable heart failure is the usual cause of death. Prognosis is worse than for AA amyloid.

Hereditary systemic amyloidosis – can manifest as predominantly neuropathic, nephropathic or cardiomyopathic form. *Familial Mediterranean fever* is a distinct group and is characterised by recurrent attacks of fever, polyserositis, arthritis and rashes, which generally resolve in a few days. A number of these patients develop systemic amyloidosis.

Senile systemic amyloidosis – Major deposits occur in the heart, but functional impairment is uncommon. Deposits may also occur in lungs, muscles and blood vessel walls. However, the cerebrovascular and intracerebral amyloid of ‘normal’ aged brains is distinct and derived from β -protein as in Alzheimer’s disease.

II. Localized amyloidosis –

Senile amyloidosis – Deposits in heart, joints, seminal vesicles. No clinical significance as a rule.

Cerebral amyloidosis –

Alzheimer’s disease is the most common form of dementia in older age groups and is characterized by the triad of cerebral amyloid angiopathy, neuritic amyloid plaques and neurofibrillary tangles.

Cerebral amyloid angiopathy is an uncommon cause of haemorrhagic stroke. The fibrils are derived from β -protein.

Prion disorders (e.g. Creutzfeldt-Jakob disease, Gerstmann-Straussler syndrome) are associated with an amyloid change in confirmation of the prion precursor protein (P_rP^C), which is a normal, widely distributed molecule. The altered amyloid form is proteinase resistant and is designated P_rP^{Sc} . This material is the transmissible agent of the spongiform encephalopathies and may accumulate sufficiently to be identified histologically as amyloid. The change from normal autologous P_rP^C to pathogenic P_rP^{Sc} , which seems to occur by chance in sporadic prion disease, is promoted either by inoculation with exogenous P_rP^{Sc} or by genetic variants of P_rP^C .

Subacute spongiform encephalopathy (Creutzfeldt-Jakob disease, transmissible viral dementia, mad cow disease)

Transmission – Infection has been transmitted by consumption of beef from infected cows, from post-mortem and surgical specimens and corneal grafts, and to recipients of human growth hormone (obtained from human pituitary glands removed at autopsy).

Pathology – of CJD is very similar to bovine spongiform encephalopathy of cattle – status spongiosus (presence of ‘bubbles and holes’) in the cortex and sometimes in basal ganglia. Lesions are accompanied by marked fibrillary gliosis in later stages.

Clinical features – Abnormalities of personality and visual spatial coordination are generally first signs of illness. This is followed by a progressive severe dementia with myoclonus.

EEG – is initially normal but then develops sharp waves or spikes against a background of delta or theta slow wave activity.

CSF – is normal except for occasional mild elevation of protein.

Treatment – None. Death usually occurs within 2 years from onset of symptoms.

Kuru – A disorder confined to Fore people in highlands of New Guinea. It is characterized by cerebellar ataxia and a ‘shivering tremor’ which progresses to complete motor incapacity and death from intercurrent infection or malnutrition in less than one year after its onset. Dementia is not a feature.

Haemodialysis associated amyloid – Carpal tunnel syndrome, large joint arthropathy, lytic bone lesions, pathological fractures, soft tissue masses and tendinitis can complicate haemodialysis for end-stage kidney failure, from deposit of b_2M amyloid fibrils.

Endocrine amyloidosis – In APUD organs, APUDomas, medullary carcinoma of thyroid, and in islets of Langerhans.

Isolated massive nodular deposits – in skin, lung, urogenital tract.

Diagnosis

1. **Biopsy** – Full coagulation studies should be carried out to exclude factor X (and IX) deficiency before histological confirmation. Rectal biopsy is positive in majority of cases. Alternatives are labial gland biopsy and aspiration of fat from anterior abdominal wall. If negative, biopsy of organ suspected to be affected, e.g. liver, kidneys or heart. Histological examination is carried out under crossed polarized light after staining with alkaline alcoholic Congo red. Type of amyloid can be determined using immunohistochemical techniques on serum and urine.
2. **Electrophoresis** – and immunophoresis for presence of plasma cell dyscrasia. The monoclonal protein often consists of pure immunoglobulin light chains.
3. **Radionuclide SAP studies** – after IV injection of iodine-123 labelled serum amyloid O component (SAP). Characteristic visual patterns of amyloid can be

visualised after 24 hours in both systemic and localised amyloidosis, permitting the extent and distribution of deposits to be precisely identified.

Management

See Table 26.

13. HYPOTHERMIA

Hypothermia is a fall in core (rectal) temperature to $<35^{\circ}\text{C}$.

CAUSES

- Prolonged exposure to cold or with slow cooling, e.g. accident while mountain climbing, fall into a crevasse, prolonged exposure to low temperatures in homeless individuals.
- Immersion and submersion in ocean, lakes, cold rivers.
- Any kind of snow accident, e.g. avalanches.

See Table 27 for risk factors of hypothermia

PATHOPHYSIOLOGY

1. Low temperatures cause the myocardium to become irritable and multiple rhythm and conduction disturbances appear, e.g. bradycardia, atrial fibrillation, ventricular arrhythmia and non-specific and specific, pathognomonic j-wave ECG changes. At temperature of $<30^{\circ}\text{C}$ ventricular fibrillation or asystole will occur.
2. Hypothermia induces hypokalaemia by shifting extracellular potassium into intracellular compartments.

Extremely high potassium levels reflect transfer of cellular potassium to extracellular space indicate acidosis, cell lysis and tissue damage.

3. With profound hypothermia blood viscosity and haematocrit readings are increased primarily because of loss of intravascular fluid (plasma) into extravascular compartments leading to hypovolemia. Hyperviscosity also favours development of intravascular thrombi and coagulopathy.

CLINICAL FEATURES

Clinical features depend on severity of hypothermia (Table 28).

MANAGEMENT

Of profound hypothermia:

1. *Non-arrested patient* - Haemodialysis provides continuous blood flow rate of 300-450 ml per minute by using a percutaneous dual lumen venous access. Rewarming using forced hot air via a plastic blanket can be used as assisting device.
2. *Cardio-circulatory arrest* - (a) Extracorporeal blood rewarming by cardiopulmonary bypass (CPB) is an efficient method of rewarming and total body perfusion. (b) Extracorporeal circulation (ECC) - Main advantage of this method is the rapid institution by using groin access while closed chest compression continues.

Table 26: Reduction in fibril precursors protein production in systemic amyloid

Disease /Aim of treatment	Example of treatment
AA amyloid Suppress acute phase response	Immunosuppression in RA, Still's disease (chlorambucil) Colchicine for familial Mediterranean fever, surgery for osteomyelitis and uncommon cytokine- producing tumors
AL amyloid Suppress production of immunoglobulin light chains	Chemotherapy and stem cell transplantation for myeloma and monoclonal gammopathy
Hereditary amyloidosis Eliminate source of genetically variant protein	Orthotopic liver transplantation for variant transthyretin- associated familial amyloid polyneuropathy
Haemodialysis amyloidosis Reduce plasma concentration of β_2 - microglobulin	Kidney transplantation

Table 27: Risk factors of hypothermia

- Children and old people
- Hypothyroidism and hypopituitarism
- Hypoglycaemia and adrenal Insufficiency
- Immobile or demented patient
- Drug overdose: Alcohol, hypnotic drugs.
- Trauma, sepsis, shock
- Hepatic or renal failure

Table 28: Clinical features of hypothermia

Mild $32-35^{\circ}\text{C}$	Moderate $28-32^{\circ}\text{C}$	Profound $<28^{\circ}\text{C}$
Amnesia, apathy, impaired judgement. Peripheral vaso- constriction, greyish appearance, tachycardia Shivering	ECG changes, hallucinations, paradoxical undressing, loss of consciousness. Decline in pulse and cardiac output, arrhythmia, prolonged asystole. Hyporeflexia, rigidity, cessation of shivering	Coma. Fall in BP, bradycardia, diminished or absent peripheral pulses, VF, asystole. Apnoea, peripheral areflexia

3. *Treatment of complications*- includes treating arrhythmias class I and class III preferred.
4. Underlying disease needs to be corrected, e.g. hormone replacement in endocrine disease.

14. GENETICS

Two essential features of genetic information are that it is transmitted from generation to generation and that it varies between individuals of species. The understanding of the basic modes of inheritance is fundamental to genetic counselling and prenatal diagnosis.

TERMS USED IN GENETICS

Acquired chromosomal abnormality is derived from stem cells (e.g. the Philadelphia chromosome in CML) as a result of mutagenic or carcinogenic influences.

Allele - An alternative form of gene occupying the same locus on a particular chromosome.

Aneuploidy - The chromosome number is not an exact multiple of 23, e.g. trisomy and monosomy.

Base - The genetic information determining the amino acid sequence in peptide chains (the building blocks of proteins) is stored as the order of four bases adenine (A), guanine (G), cytosine (C) and thymine (T), which constitute each DNA strand.

Chromosome - A single DNA strand is <10 angstroms wide, but one human cell contains just under 2 meters of DNA. Each time a cell divides, this DNA must replicate itself completely and accurately, and the sets must separate quickly, and precisely into two daughter nuclei. This is accomplished by 'packing' the DNA, by coiling, recoiling and folding into discrete parcels known as chromosomes.

A normal human cell contains 46 chromosomes, comprising 23 pairs. In 22 (autosomes), the two members of a pair are almost identical in appearance (i.e. they are homologous). The remaining pair sex chromosomes are identical in females (XX), but of different length and staining characteristics in males (XY).

Chromosome constitution - The autosomes are numbered from the largest (1) to the smallest (22 in humans). The short arm of a chromosome is called 'p' and the long arm 'q'. The chromosome constitution of an individual is written with the chromosome number first, followed by the sex chromosome constitution, followed by description of any abnormalities e.g.:

- 46, XY normal male
- 47, XX + 21 (common form of Down's syndrome, with an extra copy of chromosome 21, in a female)

- 46, XYt [(2; 19) p21; p12] (translocation between chromosomes 2 and 19, breaking at bands p21 and p12, respectively).

Codon - Three nucleosides code for a particular amino acid. Each of these triplets is called a codon.

Combination - Exchange of genetic information between DNA strands (e.g. between diploid chromosomes).

Constitutional chromosomal abnormality is present from early embryogenesis. It may be found in all tissues.

Contiguous gene syndromes involve loss of genes that may be functionally unrelated but are contiguous along the chromosome.

Deletion (del) - A section of chromosome (terminal or interstitial) is lost (a structural chromosomal abnormality).

Exons are sequences codons; they code for polypeptides.

Fragile site (fra) - A chromosomal site showing a tendency to break, producing a structural chromosomal abnormality.

Frameshift mutation is the change in code on usage which results when nucleotides are added to or deleted from a nucleic acid sequence, producing a novel translation of the code locus.

Genes comprise lengths of DNA containing sufficient codons to code for the amino acids in the polypeptide chain of a particular protein. Most genes comprise exons interspersed with introns of variable length which are often longer than the coding regions; for example, globin genes have two introns and three exons and collagen genes may have 50 introns.

Heterozygote - A diploid cell or organism in which the gene at a given locus is different on the two chromosomes.

Homozygote - A diploid cell or organism in which a given locus carries the same genetic variant at both sites.

Hybridization is the technique of using labelled, single-handed nucleic acid sequences (DNA probes) to identify complementary sequences. Use of the technique on an intact metaphase spread is termed in *situ* hybridization.

Introns are sequences of nucleotides that are non-coding.

Inversion (inv) is produced when two breaks occur in one chromosome and the middle piece is rotated by 180° and reinserted, producing a structural chromosomal abnormality.

Linkage is the inheritance of different genetic loci with a frequency greater than would be expected by chance alone.

Table 29: Common constitutional chromosomal syndromes

Syndrome	Karyotype	Major clinical features
Down's	47, + 21	Small head, round face, slanting eyes, epicanthic folds, short stubby fingers, mental retardation
Edwards'	47, + 18	Narrow face, characteristic facies, multiple internal anomalies, overlapping digits, high lethality, very severe handicap
Patau's	47, + 13	Midline craniofacial defects ranging from cyclopia to facial clefts, multiple anomalies, polydactylism, high lethality, very severe handicap
Fragile X (fra(X))	46, XX fra (X) 46, XY fra (X)	Characteristic breakage of Xq, mental retardation predominantly in males, macro-orchidism
Klinefelter's	43, XXX	Male hypogonadism, azoospermia, slightly decreased IQ
Turner's	45, XO	Short stature, amenorrhoea, renal and cardiac anomalies
	47, XYY	Above average stature, slightly decreased IQ
	47, XXX	Increased incidence of nonspecific behavioural disturbance, slightly decreased IQ
Balanced translocations		
Unbalanced translocations		Often mental retardation

Locus – The position of a gene or another well characterized sequence of DNA on a chromosome.

Microdeletion – A deletion too small to be seen by microscopy. Paradoxically, these may be 100s or 1000s of bases in size.

Mosaic individuals have two different cell lines in their constitution, usually as a result of a chromosomal abnormality arising during early cell division after fertilization.

Numerical chromosomal abnormality – Extra or missing chromosomes may occur; for example, trisomy 21 (Down's syndrome), monosomy X (Turner's syndrome).

Phenotype – Physical characteristics displayed by an individual.

'Ploidy' describes the number of chromosome sets:

- 23, haploid (one set)
- 46, diploid (two sets)
- 69, triploid (three sets)

Polymorphism is the existence of different versions of a characteristic in a population. Polymorphism may reflect genetic variation.

'Somy' refers to the number of copies of an individual chromosome per cell. Thus, the term 'trisomy' describes three copies (as in trisomy 21) and 'monosomy X' describes the absence of the second sex chromosome.

Splicing – Reconnection of DNA or RNA at specific sites after segments have been removed.

Structural chromosomal abnormalities include deletions, translocations and inversions. These may be inherited.

Tandem repeat variance – Segments of DNA comprising variable repetitions of short DNA sequences.

Translocation (t) – Two chromosomes break and exchange segments, producing a structural chromosomal abnormality.

Table 29 lists common constitutional chromosomal syndromes

MOLECULAR GENETICS

The human genome – contains as many as 50-100,000 genes varying in size. A typical gene is organized into regions of DNA that encode specific amino acids (exons) with larger regions of non-coding DNA (introns). The function of introns is largely unknown. The great variation in the size of genes mainly reflects differences in the number and size of introns.

Gene expression – In order to produce its protean product, a gene is transcribed and then translated.

Transcription: One strand of the DNA acts as a template for production of messenger RNA. This is then modified before leaving the cell nucleus to form the processed RNA molecule.

Translation: In the cytoplasm, mRNA is translated to form the gene product.

Regulation: In addition to exons and introns, the genome contains regions of DNA that flank genes and have an important role in regulation of gene transcription.

DNA analysis – The three commonly used methods for diagnostic molecular genetics are:

DNA hybridization: Double-stranded DNA is held together by the mutual attraction of paired bases mentioned earlier. **Uses** – (a) Detection of mutations in fragile X syndrome and myotonic dystrophy. (b) For characterizing chromosomal rearrangements and for microdeletions such as those occurring in DiGeorge and Prader-Willi syndromes.

DNA amplification involves producing many copies of a target sequence using PCR. It is fast and efficient and allows analysis of a particular sample (e.g. prenatal diagnosis) to be performed in 24-48 hours. Small amounts of tissue (e.g. a single hair root, a dried blood spot) can be

typed and even a single cell or gamete can be analysed. However PCR analysis can only be applied only to regions of DNA that have been cloned and sequenced.

DNA sequencing is used to determine the specific order of the bases in a given fragment of DNA. The procedure is semi-automated and data analysed by computer.

DNA markers – Human DNA shows much variation between individuals. This variation is the source of DNA markers which can be used to track diseases through families. Different types of variation give rise to different classes of DNA markers. (a) Restriction fragment length polymorphisms: RFLPs are of limited use, because each RFLP has only two forms (alleles). (b) Variable number tandem repeats – If a series of VNTR markers are used simultaneously, they produce a pattern of bands (a ‘fingerprint’) unique for every individual. This is the basis of ‘genetic finger printing’ which is used in forensic science and for paternity testing.

Linkage analysis. The first step in the search for the cause of genetic disorder is to identify the chromosome on which the faulty gene lies. This is achieved using linkage analysis, which follows the segregation of the disease and the DNA markers in a number of large families. When the marker and the disease are inherited together they are said to be linked; this is possible only if key individuals are heterogenous for the marker concerned (i.e. they have a different allele on each chromosome at a given locus).

Once the linkage is clearly established, closer markers can be isolated systematically until the gene itself can be sought. However, linkage analysis is often complicated by genetic heterogeneity, e.g. mutations in at least three different genes have been shown to cause retinitis pigmentosa.

Isolating the gene. Isolating and cloning a disease gene once it has been mapped is the most difficult problem in human genetics. Rarely, patients with a particular disease have chromosomal rearrangements that disrupts the disease gene, cloning the chromosome breakpoints and hence the disease gene is relatively easy.

Mutation analysis – There are three principal types of mutation that can cause loss or change of gene function:

Deletions/duplications – Part of a gene may be deleted, or more often duplicated. Deletions can be identified using PCR. About two thirds of cases of Duchenne muscular dystrophy are caused by partial deletions of the dystrophic gene. Deletions are identified by the absence of a PCR product because males have only one copy of the gene.

Base substitutions – Most changes do not alter restriction of enzyme sites, in which case the changes can be detected by a modification of PCR reaction in which prim-

ers for specific for normal and mutant alleles are used in separate reactions. Amplification in either reaction is indicated whether the normal or mutant allele is present.

Expanding trinucleotide repeats – This form of mutation is the cause of fragile X syndrome, myotonic dystrophy and Huntington’s disease. In these disorders, normally polymorphic trinucleotide repeat sequences at the disease location expand in affected individuals beyond the normal size range. The simplest method of detection is to amplify across the expanding region.

Mendelian disorders

Single gene defects – Result from single abnormal gene of major effect. Those carried on X chromosome are usually recessive, those on the autosomes, dominant or recessive. A dominant mutation implies that the disorder is manifest in a heterozygous state. A recessive mutation requires a homozygous state to manifest clinically.

1. **Autosomal dominant (AD) traits** – Autosomal genes are located on chromosomes other than sex chromosomes. The genotype of such a trait may be AA both dominant alleles homozygous state or Aa one dominant allele – heterozygous state (allele is an alternative form of a gene occupying the same locus on a particular chromosome). Each affected individual must have at least one parent suffering from the disease, and he/she will transmit the disorder vertically to 50% of the offspring. Both males and females are equally affected. These disorders often have a delayed age of onset and vary in severity of manifestations.
2. **Autosomal recessive (AR) traits** – The genotype is a two recessive alleles – (homozygous state). The parents are often normal (heterozygotes) and only siblings are affected. An affected individual may transmit the disorder to all, one half or none of the offspring depending on whether he marries another affected individual, a heterozygous carrier, or a normal person respectively. Unlike AD disorders, these generally manifest early in life and have a uniform degree of expression.
3. **X-linked dominant (XLD)** – The genotype is 46XY or 46XX where X is the dominant mutant gene. Females to male ratio is 2:1. An affected male will transmit the anomaly to all his daughters but not to sons (who inherit his Y chromosome). A heterozygous female transmits the disorder to half her offspring (both sexes).
4. **X-linked recessive (XLR)** – vary from mild to severe. The genotype is 46XY or 46XX, where X is the recessive mutant gene. Usually males are affected, a female

suffers only when she is homozygous for the recessive allele. An affected male does not transmit the disorder to any of the sons, but the abnormal gene is transmitted to all his daughters (who may be carriers if the mother is normal or may manifest the disease if mother is a carrier or is affected by the disease). A carrier female transmits the disease to half her sons or to half her daughters.

- Y-linked inheritance** – Some male Mendelian disorders require exposure to an environmental factor usually a drug, to manifest (pharmacogenetic disorders) e.g. slow acetylation of isoniazid (inherited as AD trait) can cause polyneuritis, G6PD deficiency on exposure to certain drugs, malignant hyperthermia (inherited as AD trait).
- Heterogenicity or variable modes** – Some clinically similar diseases may be inherited in different ways, e.g. Mucopolysaccharidoses (AR, XLR). Ehlers-Danlos syndrome (AD, AR, XLR). Polycystic disease of kidneys (AD, AR). Retinitis pigmentosa (AD, AR, XLR). Ichthyosis (AD, XLR). Deafness (AD, AR, XLR). Spinocerebellar ataxias (AD, AR, XLR), Muscular dystrophies.

Multifactorial genetic disorders – including congenital malformations. Here both environmental and genetic factors combine in varying proportions in different individuals, even within the same family, to reach the threshold beyond which abnormality appears. It is possible to identify candidate genes, such as those encoding the apolipoproteins and the low density lipoprotein involved in cholesterol metabolism. Population studies may then reveal the inheritance of a particular set of these genes (haplotype) which can be correlated with a higher risk of coronary artery disease.

Diseases – (a) *Congenital* – Congenital heart disease, neural tube defects, congenital pyloric stenosis, cleft lip/and/or cleft palate, congenital dislocation of hip. (b) *Adult life* – Diabetes mellitus, IHD, peptic ulcer, essential hypertension, epilepsy, psychoses.

Disorders with mitochondrial inheritance – The mitochondrial DNA (which is of male origin) may transmit traits in a manner that does not follow Mendelian principles. The trait is passed on from a mutant mother to her offspring but not from a mutant father to his children. Examples are Leber's optic atrophy and ragged red fibre myopathy.

Genetic heterogenicity and pleiotropism – Genetic heterogenicity means that a particular phenotype (physical characters displayed by an individual) can result from anyone of separate genotypes, e.g. Marfan's syndrome and homocystinuria are both associated with similar manifes-

tations of subluxation of ocular lenses and skeletal abnormalities. The genotypes, mode of inheritance and prognosis of the two are however different.

Pleiotropism means that a single gene can result in several phenotypic features, e.g. association of melanin spots of buccal mucosa, lips, and digits with jejunal polyps in Peutz-Jegher syndrome.

See Table 30 for mendelian disorders and Table 31 for pre-natal diagnosis

Gene therapy – is the introduction of healthy genes into patients to replace their own defective genes. This concept of delivering genes to specific targets has widened the field from treatment of single-gene defects (e.g. cystic fibrosis and DMD) to alleviation of multigene defects (e.g. neurodegenerative disease, cardiac disease).

Table 30: Mendelian disorders

Autosomal dominant	
Marfan syndrome	Polycystic kidney disease
Tuberous sclerosis	
Achondroplasia	Polyposis coli
Familial hypercholes-terolaemia	Acute intermittent porphyria
Huntington's chorea	Facioscapulo-humeral m. Hereditary
Neurofibromatosis	Dystrophy
Dystrophia myotonica	Spherocytosis
Autosomal recessive	
Sickle cell anemia	Glycogen storage disease
β -thalassaemia	
Cystic fibrosis	α -antitrypsin deficiency
Phenylketonuria	Haemochromatosis
Galactosaemia	
Tay-Sach's disease	
Scapulohumeral m. dystrophy	
Wilson's disease	
X-linked dominant	
Vitamin D-resistant rickets	
Pseudohyperparathyroidism	
X-linked recessive	
Haemophilia	Fabry's disease
G6PD deficiency	Colour blindness
Duchenne muscular dystrophy	Nephrogenic
	Diabetes insipidus
Menke's syndrome	Lesch-Nyhan syndrome
Testicular feminization	

Table 31: Prenatal diagnosis

Technique and timing		Types of disorders detected
Chorionic villous sampling (CVS)	Transcervical 9–11 weeks	<i>Direct analysis of uncultured chorionic villi</i> — Trisomic Down's syndrome and other numerical chromosome abnormalities. Translocation Down's syndrome. Inherited metabolic disorders by enzyme assay. Many single gene defects by DNA analysis. Foetal sexing for X-linked recessive disease.
	Transabdominal 12–16 weeks	
		<i>Cultured cells from chorionic villi</i> — All chromosome abnormalities. Inherited metabolic disorders. Many single gene defects by DNA analysis.
Maternal serum α-fetoprotein	16–19 weeks	Raised – Neural tube defects. Lowered – Down's syndrome, Edwards's syndrome.
Amniocentesis	16–18 weeks	<i>Amniotic fluid cell culture</i> — All foetal chromosome abnormalities, including Down's syndrome. Many metabolic defects by enzyme assay. Many single gene defects by DNA analysis. Foetal sexing for X-linked recessive disease. <i>Amniotic fluid supernatant</i> – α-fetoprotein and α-acetylcholine esterase assays Open spina bifida and encephaly. Anterior abdominal wall defects. Congenital nephrosis. <i>Alkaline phosphatase and α-Glutamyltranspeptidase assay</i> – Cystic fibrosis. <i>Other biochemical assays</i> – Congenital adrenal hyperplasia. Mucopolysaccharidoses.
Foetal blood sampling	18 or more weeks	Inherited immunodeficiencies Platelet disorders Foetal viral infections Chromosome aberrations Haemoglobinopathies. Haemophilia A and B Rapid foetal chromosome analysis in pregnancies at risk for fragile X syndrome of mental retardation, or in pregnancies in which ultrasound has revealed features suggestive of a chromosomal syndrome. For confirming equivocal CVS and amniocentesis results.
Ultrasonography	16–18 weeks	Certain types of skeletal dysplasia – Spina bifida, short limb dwarfism, polydactyly, osteogenesis imperfecta. Severe congenital heart disease. Infantile polycystic disease of kidney, renal agenesis, bladder outflow obstruction. Anterior abdominal wall defects. Hiatus hernia. Duodenal atresia.
Foetoscopy and foetal syndromes tissue sampling	after 18 weeks	<i>Endoscopic visualization of foetal structures</i> – for diagnosis of dysmorphic associated with facial or limb defects not easily identified by ultrasound. <i>Foetal skin biopsy</i> – Skin conditions, e.g. epidermolysis bullosa, ichthyosis, albinism.
		<i>Foetal liver biopsy</i> – Rare metabolic disorders.
Maternal serum screening syndromes,	16–20 weeks	Raised maternal serum AFP levels in open neural tube defects (about 90%). Remainder include anterior abdominal wall defects, chromosomal (trisomies 18 and 13), teratomas, congenital nephrosis, haemangioma of placenta or cord, cardiac monster and hereditary persistence of AFP.

Gene delivery

1. Virus-mediated delivery -
 - a. *Retroviruses* - The wild-virus type is disabled by deleting essential genes so that infection cannot occur without a helper virus. In patients with familial hypercholesterolemia, a normal low density lipoprotein gene can be introduced into liver cells to reduce the serum cholesterol level.
 - b. *Adenoviruses* - have been used for treatment of cystic fibrosis and for introduction of genes into CNS.
2. Non-viral therapy - (a) Liposomes. (b) DNA-receptor complexes. (c) High-energy bombardment of tissue. (d) Direct DNA uptake.

Gene therapy for cancer - (a) Introduction or interleukin-2 (a T cell activator) into a patient's T lymphocyte and reintroduction of these primed cells back into the patient can shrink some cancers (e.g. melanomas). (b) Introduction of a suicide gene into the cell, e.g. the introduction of the enzyme thymidine kinase under the control of α -fetoprotein promoter will result in production of cytotoxic drug in the tumour but not in normal cells.

15. SLEEP DISORDERS

PHYSIOLOGY OF SLEEP

Sleep is a result of activity in certain sleep-provoking areas in the brainstem. States and stages of sleep are defined on the basis of typical EEG, electrooculogram (EOG a measurement of eye-movement activity), and the EMG (see Table 32).

Table 32: Types of sleep and their differentiation

Features	Rapid-eye movement (REM) sleep	Non-rapid eye-movement (NREM) sleep
Eye-movement	Rapid conjugate	No eye-movement
Temp; BP, heart rate, resp.	Fluctuate	No fluctuation
Muscle twitching	Absent	Present
Site of origin	Pontine reticular formation	Midline pontine and medullary nuclei
Mediated by	Noradrenaline	Serotonin
Investigations		
EEG	Low voltage, fast activity	High voltage with slow activity (deep sleep)
EOG	Rapid, conjugate	Absent
EMG	Absent	Reduced

Periods of NREM and REM sleep alternate cyclically through the night at intervals of 60–120 minutes.

CLASSIFICATION OF DISORDERS OF SLEEP

I. Dyssomnias -

1. *Intrinsic sleep disorders* -

- a. Narcolepsy - Tetrad of excessive daytime somnolence, cataplexy (sudden loss of postural tone precipitated by emotion), hypnagogic hallucinations at onset of sleep or upon awakening (hypnopompic hallucination), sleep paralysis (on awakening patient is unable to move for 2–3 minutes).

Treatment - Drugs which inhibit REM sleep such as amphetamine or better methylphenidate or pemoline. Tricyclic anti-depressants for cataplexy, hallucinations and sleep paralysis.

- b. Psychophysiological insomnia - A behavioural disorder in which there is a preoccupied perception of inability to sleep at night, initially triggered by a stressful event.
- c. Sleep apnoea - (OSA) is a part of a spectrum of sleep-disordered breathing characterised by repetitive episodes of partial or complete obstruction of upper airways during sleep, commonly associated with hypoxia and usually terminated by arousal from sleep, resulting in sleep fragmentation and deleterious effect on day time functioning. OSA in association with daytime symptoms such as sleepiness is termed 'OSA syndrome'. An overnight sleep study (polysomnography) is the standard investigation in diagnosis of OSA and other sleep disorders, and in the titration of nasal continuous positive airway pressure (CPAP) therapy.

Treatment - (i) General measures such as avoidance of alcohol or sedatives, weight loss, reduction of nasal resistance. Treatment of underlying cause such as hypothyroidism. (ii) Continuous positive airway pressure (CPAP) in severe cases. (iii) Surgery - Removal of enlarged tonsils or other obstructive tumours.

- d. Restless leg syndrome.
- e. Periodic limb movement disorder (nocturnal myoclonus)

2. *Extrinsic sleep disorders* -

- a. Adjustment sleep disorders - e.g. changes in sleeping environment, anxiety, after an illness.
- b. Altitude insomnia - Exposure to high altitude may give rise to Cheyne-Stokes type of periodic breathing during NREM sleep, but regular breathing pattern during sleep.

- c. Drug-induced sleep disorders – Caffeine, amphetamine, rebound insomnia associated with sudden withdrawal of hypnotics. Levodopa, corticosteroids, theophylline, thyroid hormone.
 - d. Circadian sleep disorders – Jet-lag syndrome, shift-work insomnia.
- II. **Parasomnias** – Behavioural disorders during sleep associated with brief or partial arousals but not marked disruption of sleep.
1. **Arousal disorders**
 - a. Sleep walking (Somnambulism) – Varies from sitting up in bed to walking around the house. Episodes occur during deep or intermediate REM sleep.
 - b. Night terrors (Pavor nocturnus) – Child wakes up in a state of fright, with tachycardia and sweating.
 - c. Sleep enuresis – Bedwetting beyond age of 5-6 years considered abnormal and part of parasomnia manifestation. Treatment mainly consists of badder training exercise and medication consists of oxybutynin and imipramine.
 2. **Sleep-wake transition disorders** – Nocturnal leg cramps, sleep talking.
 - a. Parasomnias usually associated with REM sleep – Nightmares, sleep paralysis, sleep-related penile erections. Behavioural disorders usually in middle aged or old men with violent behaviour during sleep sometimes with self-injury.
Treatment- Clonazepam 0.5–2 mg
 - b. Other parasomnias – (a) *Sleep bruxism* or teeth grinding usually in young adults with risk of dental injury. (b) *Nocturnal enuresis*.
- III. **Sleep disorders with systemic or physiological illness** –
1. **Mental disorders** – Anxiety, depression, obsessive-compulsive disorders. Chronic alcoholism.
 2. **Neurological disorders** – Parkinsonism, cerebral degenerative diseases, sleep-related epilepsy, sleep-related headache (migraine, cluster headache), fatal familial insomnia (hereditary disorder due to degeneration of nuclei in thalamus).
 3. **Miscellaneous medical diseases** – COPD, CHF, hiatus hernia, peptic ulcer, cervical spondylosis, backache, sleeping sickness.

16. PHAKOMATOSIS

A group of hereditary disorders characterised by multi-organ malformations and tumors, also designated as neurocutaneous syndrome because of neurological and cutaneous involvement.

CLINICAL PRESENTATION

1. **Neurofibromatosis** (von Recklinghausen's disease) – inherited as AD.
 - a. Cafe-au-lait spots – Brown macules on trunk (Must be 5 or more with at least one having a long axis >1 cm to be significant).
 - b. Neurofibromas – along peripheral nerves and increasing with age.
 - c. Mollusca fibrosa – Large, pedunculated, pinkish cutaneous fibromas.
 - d. Plexiform neuromas – Diffuse neurofibromatosis with skin and subcutaneous overgrowth and occasional underlying bony abnormality.
 - e. Skeletal – Kyphoscoliosis, macrocephaly, spina bifida, pes cavus and syndactyly.
 - f. CNS – (a) Mental retardation. (b) Epileptic seizures (c) Neoplasms – (i) Cranial nerves particularly VIII, V and II. (ii) Intraspinal (iii) Peripheral nerves. Some neurofibromata may become sarcomatous.
 - g. Hypertension.
 - h. Retinal phakomas may be seen.
2. **Tuberous sclerosis** – AD condition. *Clinical features* – due to masses of glial tissue in various organs.
 - a. Skin – Adenoma sebaceum – Papular rash like severe acne on butterfly area of face. Also lipomas, depigmented naevi and fibromas underneath the nail.
 - b. Neurological – Mental retardation, seizures. Intracranial neoplasms may cause obstructive hydrocephalus. CT scan may show calcium deposits in periventricular areas.
 - c. Renal cysts and tumours may occur.
3. **Sturge-Weber syndrome** –
 - a. Port wine stain (capillary naevus) over one or more divisions of fifth cranial nerve, usually the first.
 - b. Eye involvement – Glaucoma, choroidal angioma.
 - c. Neurological – Epileptic seizures, hemianopia, mental retardation and behavioural disorders.
 - d. Skull X-ray – Typical 'tramline' calcification due to deposits of calcium in middle layers of cerebral cortex.

4. **Ataxia telangiectasia** (Luis-Barr syndrome) – AR condition characterised by mild cerebellar syndrome, or choreoathetotic movements in early childhood. After the age of 4 or 5 telangiectasias appear on face, bulbar conjunctiva and limbs, progressing as the child grows older. Respiratory tract infections common, associated with diminution of IgA and IgE.
5. **von Hippel-Lindau disease** – Autosomal dominant disorder characterised by haemangioblastoma of the neuraxis and cysts in kidney, liver and pancreas.

Clinical features – (a) Cerebellar – Progressive ataxia. (b) Spinal cord – Cord or root compression. (c) Retinal haemangioblastoma seen on fundoscopy. (d) Erythrocytosis – from excessive production of erythropoietin. (e) Pheochromocytoma and renal carcinoma may occur.

17. OCULAR MANIFESTATIONS OF SYSTEMIC DISEASE

Neurological disorders: Most neurological disorders present with visual dysfunction (e.g. loss of vision, diplopia).

1. Ocular vascular disease

- a. **Central retinal artery occlusion** – Sudden, usually painless, monocular blindness. If occlusion is temporary, patient may complain of transient monocular visual loss (amaurosis fugax). Permanent occlusion leads to retinal infarction and blindness. However, if only a branch retinal artery is occluded there may be an altitudinal field defect. Fundoscopy may demonstrate embolic material within blood vessels, retinal oedema and later a cherry-red spot.
- b. **Anterior ischemic optic neuropathy** – from infarction of optic nerve head due to occlusion of posterior ciliary arteries. There is sudden, painless, monocular visual loss, usually altitudinal. Disc is swollen and pale, there may be haemorrhages and cotton-wool spots.

2. **Optic neuropathies** – Non-vascular optic neuropathies usually present as monocular visual disturbance with central scotoma, impaired colour vision and relative afferent pupillary defect. Causes – Optic neuritis, compression of optic nerve. by retrobulbar masses (e.g. tumours or connective tissue swellings as in Grave's disease), metabolic (e.g. vitamin B₁₂, B₆ or B₁ deficiency), drugs or toxins (e.g. ethambutol, isoniazid, lead).

Tobacco-alcohol amblyopia is optic neuropathy caused by tobacco, alcohol or nutritional deficiencies (e.g. vitamin B₁₂, B₆ or B₁).

Optic neuritis – resulting from demyelination is the most common cause of acute optic neuropathy. It presents as progressive visual loss after a few days, improving during subsequent weeks. It may be associated with a dull ache of the eye, exacerbated by eye movement. The optic disc may be swollen (papillitis) or appear normal (retrobulbar neuritis).

3. **Optic disc swelling** – may result from local optic nerve pathology (e.g. inflammation, infiltration, meningioma). Swelling caused by raised intracranial pressure is termed papilloedema. Visual acuity is reduced in optic nerve pathology, but is normal in papilloedema. In papilloedema the blind spot is enlarged because the optic n. head swells.
Raised intracranial tension – consists of papilloedema and increased intracranial pressure. It usually occurs in obese, young women who present with headache and sometimes transient visual obscuration. There is an association with use of oral contraceptives, corticosteroids and several antibiotics including tetracycline. Also dural sinus thrombosis.
4. **Optic chiasm, tract and radiation lesions** – have been described in Chapter 6. Table 33 summarises localization of afferent visual pathway lesions.
5. **Ophthalmoplegia**

Table 33: Lesions in visual pathway

	Optic n.	Optic chiasm	Optic tract	Temporal lobe	Parietal lobe	Occipital Lobe
Acuity	N/-	N	N	N	N	N
Colour vision	–	N/-	N/-	N	N	N
Afferent pupil defect	+	+	+	–	–	–
Disc pallor	+/-	+/-	+/-	–	–	–
Visual field defect	Central scotoma	Bitemporal	Homon. (incongr.)	Homon. sup.	Inf.	Homon.

External ophthalmoplegia is paralysis of external ocular muscles. Causes – Infranuclear (myasthenia gravis, mass lesions within the orbit, cavernous sinus or near brainstem), nuclear (vascular disorders or demyelination affecting brainstem nuclei), of IIIrd, IVth or VIth ns.), or supranuclear (frontal infarcts).

Internal ophthalmoplegia refers to paralysis of sphincter pupillae and ciliary muscles. Causes – Small pontine infarct, in younger patients demyelination is more often responsible for bilateral internuclear ophthalmoplegia. Clinical features. – In right internal ophthalmoplegia when patient attempts to look to the left, abduction of right eye is normal, but right eye is unable to adduct, because the right medial rectus is not activated in concert. The left eye usually displays jerk nystagmus and convergence to a near stimulus may be preserved.

Endocrine disorders

Hypothyroidism – may be lental opacities, blepharospasm, keratoconjunctivitis.

Hyperparathyroidism – Conjunctival flare, corneal calcification.

Tumors of adrenal medulla (Neuroblastoma) – Unilateral or bilateral proptosis, accompanied by orbital swelling in temporal region, ecchymosis of eyelids, and papilloedema in some cases.

Metabolic disorders

Diabetes mellitus – Cataract – Incidence of senile cataract is higher. Retinopathy – (a) Background or non-proliferative – microaneurysms, haemorrhages, hard exudates, venous dilatation. Background retinopathy may progress to proliferative retinopathy or maculopathy. (b) Proliferative retinopathy – Intraretinal microvascular abnormalities (IRMA), venous abnormalities, cotton-wool spots and clusters of haemorrhages. (c) Maculopathy – is the most common cause of visual loss in type 2 DM, and can be exudative or oedematous, or ischemic. Advanced diabetic eye disease includes preretinal and vitreous haemorrhages and rubeotic glaucoma, a painful complication that results from extensive retinal ischemia. (d) Cranial n. affection – Optic, oculomotor, trochlear or abducent nerves.

Inborn errors of metabolism – (a) Corneal haziness or clouding in Hurler's, Morquio's, and Scheie's and beta-glucuronidase syndromes. Tapetoretinal degeneration in Hunter's and Sanfilippo's syndromes. (b) Pigmentation of conjunctiva and sclera in alkaptonuria. (c) Albinism – Translucent iris, nystagmus, photophobia and hypoplasia of the foveae.

Amyloidosis – Hypertrophied conjunctivitis (especially following trachoma), purpura of eyelids, ptosis, nodules in conjunctiva and sclera and vitreous opacities.

Hyperlipoproteinaemia – Lipaemia retinalis, arcus senilis (small retinal vessels appear paler).

Sphingolipidoses – Gaucher's syndrome: Deposits in conjunctiva and sclera.

Tay-Sachs' disease and Niemann-Pick syndrome – Cherry-red macula.

Disorders of mineral metabolism – (a) *Calcium* – Hypo- and hyperthyroidism have been discussed. (b) *Copper* – Chalcosis (deposits in conjunctiva), 'sunflower' cataract, Kayser-Fleischer ring. Iron particles retained in the eye may cause siderosis bulbi, Fleischer's ring (hemoiderin ring round the base of the cone) and Stahl-Hudson line (linear brown pigmentation in cornea).

Systemic infections

Tuberculosis – (i) Orbit: periostitis, rarely tuberculoma with fistula formation. (ii) Tarsitis, dacryoadenitis and dacryocystitis. (iii) Conjunctiva – Allergic (phlyctenular lesion) or infective. (iv) Cornea: Phlyctenular keratoconjunctivitis. Rarely deep keratitis, tuberculous infiltrates and ulcers. (v) Episcleritis, scleritis and keratoscleritis. (vi) Uveal tract: Anterior: Granulomatous iritis, nodular iritis, miliary tubercles on iris or conglomerate tubercle of anterior segment. Posterior: Circumscribed choroiditis, disseminated choroiditis, choroid tubercles miliary or solitary, or tuberculoma. (vii) Retina: Periphlebitis.

Leprosy: (i) Leproma of sclera. (ii) Cornea: Sclerokeratitis. (iii) Subepithelial punctate keratitis. (iv) Interstitial stromal keratitis. (v) Thickening of corneal nerves. and of Descemet's membrane. (vi) Leproma nodules (pearls) at the pupillary borders of the iris, singly or in groups.

Syphilis – (a) Interstitial keratitis. Also keratitis pustuliformis profunda and deep punctate keratitis. (b) Episcleritis and scleritis occasional. (c) Iritis and iridocyclitis, iris atrophy, syphiloma of ciliary body and iris. (d) Choroiditis (more often in congenital syphilis). (e) Visual pathways – Papilloedema, papillitis and optic atrophy. (f) 3rd and 6th cranial ns. involvement. (g) AR pupil, fixed pupil.

IE – Haemorrhages in retina and conjunctiva, Roth's spots.

Diphtheria – Extrinsic nerve palsies and paralysis of accommodation.

Whooping cough – Subconjunctival hemorrhage.

Parasitic infections

Malaria – Pigmentation of conjunctiva and retinal haemorrhages.

Toxoplasmosis – (a) Congenital: Posterior uveitis from activation of quiescent cysts. (b) Chorioretinitis leading to circumscribed glial scar.

Cysticercosis – (a) Cysts in subconjunctival tissue, orbit or AC. Vitreous humor cysticercus may cause exudative uveitis and endophthalmitis. (b) Retinal tear from cysticercus.

Leptospirosis – Photophobia, ocular pain, conjunctival suffusion or hemorrhage.

Haematological conditions

Haemoglobinopathies – Dilatation and tortuosity of retinal vessels, retinal haemorrhages, retinal micro-aneurysms and vitreous haemorrhages.

Polycythemia – Engorged conjunctival and episcleral vessels. Dusky fundus with dilated, tortuous and violaceous veins.

Dysproteinemia – (a) Macroglobulinemia: Sludging of conjunctival circulation, haemorrhages, cotton-wool type exudates, retinal oedema and venous occlusion. (b) Cryoglobulinemia – Retinal haemorrhages, exudates, arterial narrowing, venous thrombosis.

Helminthic infections

Ankylostomiasis – Lid oedema, retinal haemorrhages (from anemia), stellate retinopathy (due to toxic effect), granuloma in vitreous and retina.

Ascaris – Haemorrhages, granulomatous uveitis and oedema (due to direct invasion). Lid oedema and phlyctenulosis due to allergy.

Guinea worm – may be detected in eyelids, conjunctiva and orbit.

Hydatid disease – Cysts may invade the eye or orbit.

Onchocerciasis – Keratitis, microfilaria in AC and vitreous, uveal inflammation, degeneration and atrophy of retina.

Collagen diseases

Rheumatoid arthritis – Refer

SLE – Transient cotton-wool type exudates in macular region. Retinal haemorrhages and oedema, conjunctivitis, episcleritis, keratitis and iridocyclitis.

Polyarteritis nodosa – Scleritis and episcleritis, corneal ulcer, uveitis, retinal exudates and haemorrhages, ocular palsy. Occlusion of central retinal artery may occur.

Progressive systemic sclerosis – Cataract.

Dermatomyositis/polymyositis – Oedema and erythema of eyelids, extrinsic muscle involvement, retinal haemorrhages and exudates.

Wegener's granulomatosis – Proptosis, chemosis, ocular motility impairment and papilloedema.

Diseases of muscles

Myasthenia gravis – Ocular muscles are first to be involved, with resultant ptosis or double vision. Lid twitching.

Ocular myopathy – Progressive external ophthalmoplegia.

Myotonia atrophica – Cataract, bilateral ptosis.

Skin and mucous membrane affection

Muco-cutaneous lesions – Benign mucosal pemphigoid (ocular pemphigus, shrinkage of conjunctiva), pemphigus, erythema multiforme, Reiter's syndrome, Behcet's syndrome, dermatitis herpetiformis, epidermolysis bullosa.

Dermatoses – Rosacea, seborrhoea, eczema, ichthyosis, xeroderma pigmentosum, psoriasis vulgaris, keratosis follicularis.

Vitamin A deficiency – *Signs:* (a) *Primary* – Conjunctival xerosis, Bitot's spots, corneal xerosis, corneal ulceration with xerosis, keratomalacia. (b) *Secondary* – Night blindness, xerophthalmia fundus, corneal scars following keratomalacia.

18. STEM CELL THERAPY

Stem cells are defined as “cells that have clonogenic and self-renewing capabilities and that differentiates into multiple cell lineages”

Characteristic features include

1. Undifferentiated cells
2. Ability for unlimited self-renewal.
3. Infrequent proliferation.
4. Replenish progenitor cells.

TERMINOLOGY

Potency: Some of developmental options available to cell:

- **Totipotent:** Ability to (re)generate an organism in total. In mammals only the zygote and first cleavage blastomere are totipotent.
- **Pluripotent:** Ability to form all lineages of body, e.g. embryonic stem cells.
- **Multipotent:** Ability of adult stem cells to form multiple cell types of one lineage, e.g. haemopoietic stem cells.
- **Unipotent:** Cells from one cell type, e.g. spermatogonial stem cells (can only generate sperms).

Table 34: Stem cells

Intrinsic or Endogenous	Extrinsic
Basal epithelial	
Cells in trachea and larger airways	Adult stem cells
	Embryonic stem cells
Clara cells in smaller airway	
Type II	
Pneumocytes in lung parenchyma	

CLASSIFICATION OF STEM CELLS

Embryonic stem cells – Cells isolated from the inner mass of early developing blastocytes. Embryonic stem cells have the capacity for self-renewal and are pluripotent, having the ability to differentiate into cells of all embryonic lineage and all adult cell types. However, they cannot form extra embryonic tissues such as trophoblast-derm.

Adult stem cells – Cells isolated from adult tissues including bone marrow, adipose tissue, skin, umbilical and blood and placenta that have the capacity for self-renewal. In general, adult stem cells are multipotent, having the capacity to differentiate into mature cell types of the parent tissue. Some adult stem cells such as mesenchymal stem cells exhibit a large range of differentiation that is not limited to a single tissue type.

Adult tissue-specific stem cells – The same as adult stem cells but with defined tissue specificity. A relatively undifferentiated cell within a given tissue that has the capacity for self-renewal through stable maintenance within a stem cell niche. Adult tissue specific (endogenous) stem cells have a differentiation potential equivalent to the cellular diversity of the tissue in which they reside. The haemopoietic stem cells the prototypical adult tissue stem cells.

Progenitor cells – A collective term used to describe any proliferative cell that has the capacity to differentiate into different cell lineage within a given tissue. Unlike stem cells, progenitor cells have limited or no self-renewal capacity. The term “Progenitor cell” is commonly used to indicate a cell that can expand rapidly but that undergoes senescence after multiple cell doubling (see Table 35 and 36).

Table 35: Indications of stem cell therapy

• GI conditions
Achalasia (endoscopic intrasphincteric injection)
• Cardiovascular diseases
Coronary artery disease
Dilated cardiomyopathy
Congestive heart failure
Myocardial infarction
Primary pulmonary hypertension
Peripheral arterial diseases
• Lung disease
Interstitial lung disease
Acute respiratory distress syndrome
Cystic fibrosis
Pulmonary arterial hypertension
Lung cancer
• Neurological disorders
Multiple sclerosis
Parkinson's disease
Alzheimer's disease
Muscular dystrophy (intrathecal of autologous derived bone marrow stem cell)
Stroke
• Spinal cord injuries and nongenetical neurological disorders
Paraplegia
Cerebral palsy
Post traumatic spinal cord injury
• Orthopaedic conditions
Cartilage damage
Sport injury
Bone cysts
Osteoarthritis
Avascular necrosis
Nonunion fracture
Bone regeneration
• Infertility management
Degenerative/poor endometrial development
• Asherman's syndrome
Aesthetic/cosmetic therapies
Stable vitiligo
Face lifting/wrinkles
Breast augmentation
Hair generation
• Dermatological conditions
Diabetic foot ulcer
Nonhealing ulcers
Burns and wounds
Postinflammatory hypo- or depigmentation
• Organ transplantation
Graft versus host disease
• Kidney disease
Acute kidney injury
Chronic kidney disease
Lupus nephritis

Table 36: List of stem cells

Type	Advantages	Disadvantages
Embryonic blastocysts (inner cell mass)	Totipotent and highly expandable	Immunosuppression required, ethical debate, lack of availability and tumour potential
Umbilical Cord Blood Cells (Umbilical cord)	Pluripotent and highly expandable	Immunosuppression required
Foetal Cardiomyocytes	Cardiomyocyte phenotype Electrophysiologically compatible	Immunosuppression required, ethical debate Short survival and limited supply.
Resident cardiac system cells	Cardiac in origin, mechanically and electrophysiologically compatible source of cells for transplantation	In chronic phase of MI, the number of stem cells falls and the remaining cells have less regenerative potential
Skeletal Myoblasts (Satellite cells)	Lack of immunogenicity and autologous transplantation, high yield and fatigue-resistant, slow-twitch fibres	Electrophysiologically incompatible lack of gap junction-arrhythmogenic
Hematopoietic stem cells Bone marrow/Peripheral blood	Lack of immunogenicity and autologous transplantation-different lineage of cells	Quantum of cell population not adequate.
Endothelial Progenitor cells Bone marrow/Peripheral blood	Lack of immunogenicity and autologous transplantation-different lineage of cells	Need for expansion because of limited supply.
Mesenchymal Stem Cells Bone marrow stromal/Muscle, Skin and Adipose Tissue	Lack of immunogenicity, autologous transplantation, pluripotent and cryopreservable for future use.	Requires expansion.

19. PREBIOTICS AND PROBIOTICS

Probiotics are bacterial cultures or living microorganisms upon ingestion in certain quantity promote and enhance health benefits. *Prebiotics* are non-digestible food ingredients such as fructo-oligosaccharides (FOS), lactulose and insulin that beneficially affect the host by selectively stimulating growth and/or increasing the activity of a limited number of probiotic-like bacteria in the colon.

Species – Probiotics can be yeast, bacteria or moulds, bacterial species being predominant. Some of the species are –

1. *Lactic acid bacteria (LAB)* – Lactobacillus, Bifidobacterium, Streptococcus, Lactobacillus species help in production of enzymes to digest and metabolize proteins and carbohydrates. They aid in synthesis of vit. B and vit. K and facilitate breakdown of bile salts.
2. *Nonlactic acid producing bacterial species* – Bacillus propionibacterium. The benefits include metabolism of lactose and synthesis of vitamins, and help in reducing antibiotic associated diarrhoea and traveller's diarrhoea. They relieve constipation, alleviate inflammatory bowel disease and prevent DNA damage, and may prevent or delay onset of cancer.
3. *Nonpathogenic yeasts* – Saccharomyces, Streptococcus thermophilus and Lactobacillus bulgaricus metabolize lactose, improve lactose tolerance and antimicrobial activity.

4. *Nonsporeforming and non-flagellated rod or coccobacilli.*

Mechanism of action and indications for probiotics

1. *Immunity* – Regulatory T lymphocytes (Tregs) are thought to play a role in limiting inflammation in pathogenesis of some intestinal disorders.
2. *Probiotics and HIV* – It has been postulated that probiotic bacteria may slow down AIDS progression.
3. *Probiotics and cancer* – In addition to their conventional use as gut modulators, probiotics play a role in preventing colon cancer. Prebiotics also have the same effect, attributed to production of short chain fatty acids. Butyrate is one such protective agent.
4. *Prevention of Clostridium difficile diarrhoea.* Overall up to one quarter of patients treated with antibiotics develop diarrhoea caused by C difficile. Favourable results have been obtained with Lactobacillus rhamnosus GG or Saccharomyces boulardii.
5. *Functional GI disorders* in children and adults. Lactobacilli and bifidobacteria increase stool frequency and decrease consistency in constipation predominant IBS.
6. *Calcium absorption* – Probiotic given to individuals with lactose intolerance. The milk lactose is hydrolysed by probiotic strains and favours calcium absorption.

7. *Probiotics and oral health.* Probiotics have been successful for treating digestive related disorders. Some of the hypothetical mechanism of probiotic action in oral cavity are – Direct interaction in dental plaque, binding oral micro-organisms to proteins, or reduction of chemicals that inhibit oral bacteria. Indirect probiotic actions include modulating systemic immune function, effect on local immunity, regulation of mucosal permeability, action as antioxidants, production of antioxidants. Probiotic bifidobacterium reduce gingival and periodontal inflammation. Commonly used probiotics are sporolactobacilli, *Saccharomyces boulardii* and yogurt (*L. bulgaricus*), *L. thermophilus*, *Bacillus mesentericus* (genetically modified) as alternate to B complex.

20. CHEMICAL WARFARE

The acquisition of chemical weapons by a number of countries has increased the likelihood of their use by terrorists. Sulphur was used in the Iran-Iraq war. Some time back the release of ricin are examples of actual or potential chemical weapons. Nerve agents: The organophosphorous nerve agents are chemically related to organophosphorous insecticides. Two classes of nerve agents are recognised – G and V. Tabu Tabun, sarin and soman are the G agents. VX is the V agent. G agents are both dermal and respiratory, the V agents, unless aerosolized, are contact poisons.

Clinical features of toxicity: Systemic features may develop following ingestion and dermal and vapour exposure. Features follow most rapidly after inhalation.

Ocular exposure – Miosis, which may be painful and can last for several days. Ciliary spasm may impair accommodation.

Dermal exposure – Contact with liquid nerve agent may produce localized swelling and fasciculations which spread to involve whole muscle groups.

Inhalation – Chest tightness, rhinorrhoea and increased salivation. Ingestion of contaminated food or water may cause abdominal pain, nausea, vomiting and involuntary defecation.

Systemic features – Tremor, restlessness, ataxia and convulsions may follow. Bradycardia, tachycardia and hypotension may occur, dependent on whether muscarinic or nicotinic effects predominate.

Management – Urgent hospitalization. If rhinorrhoea or bronchorrhoea, atropine 2 mg in adults (20 mg/kg in children) IV q5-10 minutes till patient is atropinised. An oxime e.g. IV 30 mg/kg q4h in systemic fea-

tures who require atropine or infusion of pralidoxime mesylate 8–10 mg/hr. Diazepam IV 10–20 mg (child 1–5 mg) for controlling agitation, fasciculation and convulsions.

Ricin is a globular glycoprotein and is readily produced as a by-product of castor oil production. Use of ricin to cause mass casualties would require either aerosolization by means of disposable device or its addition to food and beverages as a contaminant. By inhalation, (breathing in solid or liquid particles) and injection into muscle or a vein, the lethal dose is 5–10 mg/kg. Many of the features seen in poisoning are due to ricin-induced endothelial cell damage which leads to fluid and protein leakage and tissue oedema causing so-called ‘vascular leak syndrome’.

Clinical features

Ricin is toxic via all routes, although features of poisoning varies with both route and dose.

Ingestion – Vomiting, abdominal pain and diarrhoea within a few hours. GI fluid and electrolyte loss may be complicated by haematemesis and melena and result in dehydration and hypovolemic shock. Liver and kidney damage may ensue. Death results from multi-organ failure.

Inhalation – Clinical features are those of an allergic response with conjunctivitis, rhinitis, urticaria and wheeze.

Parenteral administration. (a) In clinical trials of ricin as a chemotherapeutic agent, an IV dose of 0.3 mg/kg caused marked fatigue, myalgia, nausea and vomiting. (b) IM injection – Marked pain at site of injection followed by nausea, vomiting and fever over next 24 hours. GI hemorrhage is followed by hypovolemic shock and kidney failure.

Diagnosis – Detection of arthricin antibodies in individuals exposed to ricin who survive for 2–3 weeks. Antibodies will not be detected in those who die soon after exposure, in this situation, a ribosome inactivation test is more useful.

Management – is symptomatic and supportive for all routes of exposure.

Sulphur mustard is a colourless oily liquid. Its vapour has considerable penetrating ability, and it passes rapidly through clothing to affect the underlying skin and causes a chemical burn. The naturally moist areas of the body (e.g. genitalia, perineal region, groin, lower back, axillae) are often most severely affected. Erythema develops within a few hours and crops of blisters may appear at any time up to 2 weeks after exposure, necrosis is complete 4–6 days after exposure and separation of necrotic slough then begins, followed by scab formation.

Management – No specific treatment. IV fluids since substantial fluid loss may occur once blisters have formed. Bland lotions (e.g. calamine) for areas of erythema and minor blistering. Topical bacteriostatic agents (e.g. 1% silver sulphadiazine).

21. ANTIBACTERIAL CHEMOTHERAPY

Selection of an antibacterial drug – depends on – (a) Spectrum of activity. (b) Its distribution to the site of infection. (c) Clinical proof of efficiency in a given situation.

Indications for combined antibacterial therapy

1. To achieve a synergistic effect, e.g. penicillin and gentamicin for *Strep. faecalis* endocarditis.
2. To reduce likelihood of emergence of drug resistance e.g. treatment of tuberculosis.
3. To treat mixed infections, e.g. both aerobic and anaerobic infections in GI or female genital tract sepsis.
4. To treat severe infection at an initial stage when the causative agent is not known.

Antibiotic resistance – The term ‘antibiotic resistance’ implies that a particular antibiotic is ineffective in a clinical inference. This may be because the organism is inherently resistant to the antibiotic or because it is inaccessible. *In vitro* resistance is defined by measuring the minimum inhibitory concentration (MIC) and the minimum bactericidal concentration (MBC) of the antibiotic against an organism using appropriate controls to define the cut-off points between ‘resistant’, ‘intermediate’ and ‘sensitive’. Low MIC and high MBC imply that an antibiotic is bacteriostatic; that is it inhibits the growth of an organism but is

unable to kill it. Even with bactericidal antibiotics, killing *in vivo* normally requires an intact immune system.

Mechanisms of resistance. Resistance may be inherent (e.g. vancomycin against Gram-negative organisms, nitrofurantoin against *Proteus* spp.) or may be acquired via genetic elements encoding three fundamental mechanisms:

1. **Antibiotic-inactivating enzymes** – may be produced in vast excess, surrounding the organism (e.g. β -lactamase from *Staph. aureus*, or in limited amounts in periplasmic space of Gram-negatives. The effect *in vivo* is similar, but the latter organisms may appear sensitive *in vitro*).
2. **Target site change** may be a structural alteration preventing binding of an antibiotic, or a mechanism whereby the metabolic pathways that is normally inhibited is bypassed by an alternative one. This is seen in sulphonamide resistance and in methicillin-resistant *Staph. aureus*. Important target site changes include topoisomerases II and IV (quinolones), B subunit of DNA-dependent RNA polymerase (rifamycins) and methylation of 23S target (macrolides).
3. **Exclusion of antibiotic** from the target site. Porins are protein structures embedded in the outer bilipid membrane of Gram-negative organisms. They control what passes into and out of the cell on basis of molecular size and charge. Mutations of the genetic elements encoding porins (permeability mutations) may exclude one antibiotic or more commonly multiple antibiotics. *P. aeruginosa* has two outer lipid membranes, produces β -lactamases constitutively, and therefore tends to be more resistant than coliforms. Alternatively, organisms may actively excrete antibiotics, notably tetracyclines, macrolides and quinolones.

Table 37: Main classes of antibiotics and antibacterial drugs

Class, action	Indications	Adverse effects
β-lactams		
Inhibit bacterial cell formation		
Bacteriostatic		
Meropenem Ertapenem		
Penicillins	Clinical Use	
Classifications 1. Bronchospasm. susceptible strains of enterococci penicillin	Penicillin G for infections due to <i>Strep.</i> Aminocillins for upper and lower resp. Tract infections bacterial gastroenteritis bacterial endocarditis, meningitis, UTIs cause by susceptible (i.e. non- β -lactamase producing organisms) and tr. of ulcers and gastric infections cause by <i>H. pylori</i>	1. Hypersensitivity reactions – Rash, fever, Natural penicillins, pyogenes, penicillin- Vasculitis, serum sickness, exfoliation, Stevens Johnson-penicillin G and <i>Strep</i> - pneumonia and syndrome and anaphylaxis. 2. Other – Diarrhoea with oral penicillin, particularly amoxicillin. Interstitial nephritis and encephalopathy with high doses in patients with renal failure. Hypersensitivity?

Contd...

Contd...

Class, action	Indications	Adverse effects
2. Penicillinase-resistant encephalopathy penicillins, methicillin, nafcillin and isoxazolyl penicillins		
3. Aminopenicillins, ampicillin, amoxicillin		
4. Carboxypenicillins, carbenicillin and ticarcillin		
5. AcyH ureidopenicillins, azlocillin, mezlocillin and piperacillin		
Action		
Inhibition of bacterial cell wall synthesis β-lactam and β-lactamase inhibitors combinations		
Action-Inhibition of Class C and class β -lactamases Drugs: Clavulanic acid, sulbactam and tazobactam		
Carbapenems		
Action, Bactericidal Inhibit cell wall synthesis		
Imipenem Meropenem Ertapenem Doripenem	Most anaerobic and aerobic pathogens (except xanthomonas maltophilia and some strains of <i>P. cepacia</i>). Largely used for serious intra-abdominal infections.	Diarrhoea, nausea, vomiting, abdominal pain Contraindicated in patients who are hypersensitive to β -lactams and those with CNS disease, especially in presence of renal failure because of increased risk of seizures.
Cephalosporins		
<i>First generation</i> Oral:	Mainly active against Gram-positive bacteria. Used only if intolerance or resistance to other agents	1. <i>Hypersensitivity reactions</i> as in case of penicillins. 2. <i>Renal tubular necrosis</i> – in case of high doses of cephalothin (less likely with third generation group) 3. <i>Bleeding</i> .
Parenteral:		
• Cephalothin • Cephazolin		
Second generation		
Oral:	Cefuroxime – Active against Staphylo., Strepto., Gram-ve bacteria, e.g. <i>E. coli</i> , <i>Proteus</i> spp., <i>H. Influenzae</i> , <i>N. Gonorrhoea</i> and some <i>Klebsiella</i> spp.	
Parenteral:		
• Cefuroxime • Cefamandole • Cefoxitin • Cefepime • Aztreonam		
<i>Third generation</i>		
Oral:	Aerobic Gram-ve and Gram +ve bacteria, many anaerobic bacteria, including <i>B. fragilis</i> .	
• Cefixime • Cefpodoxime proxetil • Ceftibutin • Cefdinir • Cefditoren		

Contd...

Contd...

Class, action	Indications	Adverse effects
Parenteral: • Cefotaxime • Cefotaxime • Cefoperazone • Ceftazidime • Ceftriaxone • Cefsulodin • Cefodizime	Activity against many Gram-ve bacilli, comparable to aminoglycosides Similar to cefotaxime Most Gram-ve bacteria and P. aeruginosa All forms of gonorrhoea, childhood meningitis P. aeruginosa Most Gram-ve bacilli and Streptococci.	GI side effects
Fourth generation Cefepime Cefpirome	P. aeruginosa and enterococci Also plague and tularemia	
Oxazolidinones Inhibit neuritis protein synthesis Linezolid	Gram +ve bacteria including methicillinresistant Staph. aureus. Vancomycin-resistant enterococci and penicillin resistant S. pneumonia.	Reversible bone marrow suppression, optic neuritis lactic acidosis, headache, hypertension
Quinolones Inhibit bacterial DNA synthesis Bactericidal		
Nalidixic acid Oxolinic acid Fleroxacin Gemifloxacin	Urinary tract infections	Headache, nausea, vomiting, diarrhoea
Ciprofloxacin Pefloxacin Ofloxacin Norfloxacin Levofloxacin Lomefloxacin Gatifloxacin Sitafloxacin Moxifloxacin Plurifloxacin Biofloxacin	Active against aerobic gram-negative bacilli, particularly Enterobacteriaceae, M. catarrhalis, Haemophilus and Neisseria Ciprofloxacin and levofloxacin and gemifloxacin are active against M. tuberculosis, M. fortuitum, M. kansasii and against genital pathogens like C. trachomatis, U. urealyticum and M. hominis	Occasional photosensitivity, GI intolerance and CNS toxicity.
Aminoglycosides Inhibit bacterial protein synthesis Bacteriostatic Streptomycin Gentamicin Kanamycin Tobramycin Netilmicin Amikacin Neomycin	Second line treatment for T.B. Gram-neg. bacilli including P. aeruginosa (resistant to amikacin), Strep. pneumoniae, anaerobic bacteria. Often combined with penicillin or cephalosporin for life-threatening infections and metronidazole if anaerobic infection is likely.	1. <i>Ototoxicity and nephrotoxicity.</i> 2. <i>Other side effects</i> – Neuromuscular blockade (hence not to be prescribed in myasthenia gravis), very occasionally bleeding. 3. <i>Effects in foetus</i> – May cause VIIIth nerve damage (hence to be avoided in pregnancy).
Macrolides Interfere with bacterial protein synthesis Bacteriostatic. Lack activity against most methicillin resistant staphylococci Erythromycin Clarithromycin	Staphylo and Streptococcal infections. As effective as tetracycline for M. pneumoniae and Coxiella burnetti infections. Drug of choice for Legionnaire's disease, and is active against all sero-groups of Legionella pneumophilia and other Legionella-like organisms. More active than erythromycin – M. tuberculosis and M. avium intracellulare, Legionella pneumophilia and other atypical resp. pathogens.	<i>Cholestatic hepatitis</i> – The jaundice is accompanied by elevated aminotransferase enzymes, fever, leucocytosis and eosinophilia

Contd...

Contd...

Class, action	Indications	Adverse effects
Azithromycin	Atypical mycobacteria, Chlamydiae trachomatis. Toxoplasmosis (in patients with HIV).	
Tetracyclines		
Interfere with bacterial protein synthesis Bacteriostatic Oxytetracycline Doxycycline Minocycline	Brucellosis, cholera, chlamydiae and mycoplasma infections. Rickettsial and Coxiella infections.	<ol style="list-style-type: none"> 1. <i>GI side effects</i> – GI irritation and rarely oesophageal ulceration. 2. <i>Renal side effects</i> – Aggravation of pre-existing renal failure (not doxycycline and minocycline). 3. <i>Tooth pigmentation and dental enamel hypoplasia</i> in infants and children under 8 years of age.
Chloramphenicol	H. influenzae meningitis and epiglottitis due to ampicillin-resistant strains or drug sensitivity to cephalosporin. Bacterial meningitis. Typhoid fever and anaerobic	<ol style="list-style-type: none"> 1. Aplastic anemia. 2. Suppression of bone marrow – This is dose-dependent. 3. Grey baby syndrome – of cardiovascular collapse sepsis may develop in neonates
Lacosamide antibiotics		
Lincomycin Clindamycin Action: have same or overlapping 50S ribosomal binding sites as for macrolides	Staphylo, pneumo, S. pyogenes Streptococci Unidamycin has activity against T. gondii, P. jiroveci and P. falciparum	Diarrhoea, kidney or liver impairment
Glycopeptides		
Inhibit cell wall synthesis in dividing bacteria vancomycin	Gram-positive organisms Enterococcus faecalis including all strains of Streptococci	Infusion related (redman syndrome) Pseudomembranous colitis. Deafness.
Lipopeptides		
Daptomycin Antimicrobial activity	Gram-positive pathogens including isolates resistant to methicillin, vancomycin	Myopathy
Polymixin and Colistin Penetrate into cell membranes and disrupt the membranes	Post-antibiotic effect (PAE) for pseudomonas, Gram-negative aerobic bacilli Colistin sulphate po for intestinal decontamination Colistimethate by parenteral, inhalational and intraventricular route to treat infections caused by MDR gram-negative bacilli	Dose-related nephrotoxicity and neurotoxicity
Sulphonamides and Trimethoprim		
Interfere with folate synthesis in bacteria		
Sulphonamides		
Sulphadimidine Sulphathiazole Sulphamethizole	Combination therapy for urinary and resp. tract infections Co-trimoxazole drug of choice for Pneumocystis carinii pneumonia and long-term prevention of this infection in patients infected with HIV.	Stevens-Johnson syn., hemolytic anemia, marrow aplasia, agranulocytosis, thrombocytopenia, hepatotoxicity.
Trimethoprim Trimethoprim Tetroxoprim		
Fusidic acid	Staphylococcal infections such as osteomyelitis and pneumonia usually combined with anti-staphylo. penicillin or erythromycin.	Generally well tolerated. Nausea, hepatotoxicity.
Nitroimidazoles		

Contd...

Contd...

Class, action	Indications	Adverse effects
Metronidazole Tinidazole Secnidazole	Amoebiasis. Trichomoniasis. Anaerobic infections (e.g. intra-abdominal and female genital tract infections, brain abscesses).	Peripheral neuropathy (dose dependent).
Rifampicin	Tuberculosis. Staph. epidermis infections (combined with flucloxacillin to reduce risk of drug resistance). Legionnaire's disease. Chemoprophylaxis of meningococcal and <i>H. influenzae</i> meningitis.	1. Jaundice. Incidence of severe hepatic problems increases when the drug is used in combination with isoniazid. 2. Other side-effects – Thrombo-cytopenia, eosinophilia, transient neutropenia and hemolytic anemia.

22. SOME COMMON SYMPTOMS AND SIGNS

Absent ankle jerks with extensor plantar

1. Subacute combined degeneration.
2. Friedreich's ataxia.
3. Taboparesis.
4. Motor neuron disease.
5. Diabetic amyotrophy.
6. Combined lumbar and cervical spondylosis.
7. Conus medullaris lesion.
8. Meningeal carcinomatosis.
9. Spinal shock.

ACANTHOSIS NIGRICANS

Brown to black hyperpigmented lesions velvety in structure, sites in such as creases of axillae, neck, groins.

A. Benign

1. Hereditary benign (AD)
2. Benign acanthosis nigricans

Endocrine: Acromegaly, Cushing's disease, Addison's disease, insulin-resistant DM, hypothyroidism, Bloom's syndrome, Crouzon's syndrome, hyperandrogenic states

3. Pseudo-AN: Complication of obesity (more common in individuals with dark complexion)

Drug-induced: Nicotinic acid, stilboestrol, oral contraceptives, folic acid antagonists (triazine), methyl-testosterone.

- #### B. Malignant AN:
- Paraneoplastic, usually associated with adenocarcinoma of GI tract or genitourinary tract, rarely lymphoma.

ACUTE ABDOMINAL PAIN

All age groups

- Appendicitis
- Perforated peptic ulcer

- Acute cholecystitis
- Renal colic
- Factitious pain (Munchausen syndrome)
- Diverticular disease
- Acute intestinal obstruction
- Nonspecific abdominal pain
- Dyspepsia

Elderly

- Urinary tract infection
- Vascular (myocardial infarction, aortic aneurysm, mesenteric ischemia)
- Medical causes, e.g. pneumonia

Children

- Intussusception Hernia
- UTI URTI

Women

- Salpingitis Ovarian cyst
- UTI Ectopic pregnancy

ACUTE FLACCID PARALYSIS

1. Poliomyelitis
2. Diplegia (cerebral palsy)
3. Guillain-Barre syndrome
4. Acute motor neuropathy
5. Transverse myelitis
6. Injury to nerves, traumatic neuritis
7. Japanese encephalitis virus
8. Hypokalaemia in malnourished children
9. Hopkins syndrome. Poliomyelitis - like illness with a flaccid paralysis of an extremity during the recovery stage of an asthmatic attack.
10. Miscellaneous
 - a. Viral myositis
 - b. Osteoarticular trauma
 - c. Dystrophies

- d. Acute cerebellitis
- e. Retroperitoneal tumors
- f. Upper motor neuron syndrome
- g. Myopathies
- h. Non-poliovirus enterovirus-induced paralysis

ANGULAR CHEILITIS

1. Riboflavin deficiency.
2. Iron deficiency anaemia.
3. Excessive intake of tobacco, betel nut, alcohol.
4. Herpes labialis at angles of mouth.
5. Ill-fitting dentures.

ANOREXIA

1. *Infections and chronic diseases* – Acute febrile illness, chronic infections like tuberculosis. Hepatic, renal, cardiac, haemopoietic and adrenal disease.
2. *Lessened metabolic function* – Addison's disease, hypothyroidism, Simmond's disease.
3. *Local causes due to decreased hydrochloric acid secretion* – Carcinoma of stomach, chronic gastritis, pernicious anaemia, etc.
4. *Psychic causes* – Mental worry, fear, anorexia nervosa.
5. *Deficiency of vitamins* – particularly B complex.
6. *Physiological anorexia* – Inactive life, irregular eating and drinking, excess of carbohydrate food in between meals.

Management – (a) If symptomatic, the disease must be treated. Gastric lavage if there is pathological retention of food in the stomach. (b) Diet – Appetising food. No sweets between meals. No hurry. (c) Exercise and fresh air. (d) Avoidance of excessive smoking and alcohol. (e) Appetisers – Cyproheptadine hydrochloride – in dose of 2–4 mg. according to age as tablets or syrup b.d. Contraindicated in glaucoma and urinary retention. Produces drowsiness, or rarely agitation and confusion. (f) Vitamin B₁₂' multi-vitamins. (g) Anabolic steroid – Norethandrolone 50 mg. daily by mouth or 25 mg. I.M. once a week.

ASCENDING PARALYSIS (ACUTE)

1. Poliomyelitis
2. Acute myasthenia gravis
3. Snake bite
4. Botulism
5. Tick paralysis
6. Shellfish poisoning

ATAXIA

1. **Sensory ataxia** –
 - a. *Peripheral sensory nerves* – Peripheral neuritis.
 - b. *Posterior roots* – Tabes, syphilitic pachymeningitis.
 - c. *Posterior columns* – Multiple sclerosis, spinal tumours, syringomyelia, subacute combined degeneration.
 - d. *Post-central convolution* – Disorders of parietal lobe.
2. **Cerebellar ataxia** –
 - a. *Cerebellum* – Cerebellar tumour or abscess, cerebellar artery thrombosis, progressive cerebellar degeneration.
 - b. *Cerebellar pathways* – Cerebellopontine angle tumour, encephalitis, Friedreich's ataxia.
3. **Labyrinthine ataxia** – Acute labyrinthitis, haemorrhage into internal ear, acute lesions of vestibular nucleus in medulla, attacks of vertigo of Meniere's disease.

BACKACHE

1. **Diseases of vertebral column** – Pott's disease, tumour, diseased intervertebral disc, sacroiliac arthritis, osteitis fibrocystica, osteitis deformans, osteomalacia, osteoporosis of various types. Congenital malformation, e.g. sacralization of 5th lumbar vertebra. Spondyloarthritis or spondyloarthrosis, multiple myeloma, malignant deposits.
2. **Disease of spinal cord and meninges** – Trauma, infection, neoplasm.
3. **Soft tissue involvement** – Fibrositis (lumbago); acute traumatic injury causing contusion, haemorrhage, rupture of muscle fibres, fascia or ligaments. Acute infections such as influenza, exanthemas, dengue, brucellosis, chikungunya.
4. **Referred pain** – (a) Pancreas – tumour, cyst or sometimes even chronic pancreatitis. (b) Lymph nodes – lymphosarcoma, Hodgkin's disease, lymphatic leukaemia or cancerous metastases. (c) Retroperitoneal hematoma. (d) Aneurysm of abdominal aorta. (e) Kidney disease – Calculi, tumours, tuberculosis, polycystic kidneys, hydro- or pyonephrosis, pyelonephritis, perinephric abscess. (f) Disease of female genital organs (gynaecologic backache). (g) Disease of prostate. (h) Cancer of rectum.
5. **Faulty body posture.**
6. **Depression.**

BASILAR INVAGINATION

1. **Delayed or defective cranial ossification** – Osteogenesis imperfecta, achondroplasia, cleidocranial dysplasia, cranial thinning due to hydrocephalus.
2. **Klippel-Feil syndrome** – Fusion of bodies of some cervical vertebrae.
3. **Generalized bone disease** – Osteomalacia, rickets, Paget's disease, fibrous dysplasia.

CAFE-AU-LAIT SPOTS

(Five or more with at least one with long axis more than 1 cm. to be significant).

1. Neurofibromatosis (von Recklinghausen's disease).
2. Albright's disease (Polyostotic fibrous dysplasia).
3. Watson's syndrome (Pulmonic stenosis).
4. Normal individuals (about 10%).

Calf muscle enlargement or hypertrophy

1. Hereditary – Duchenne or Becker myopathy, Charcot-Marie-Tooth disease.
2. Myositis ossificans.
3. Parasitic – Trichinosis, cysticercosis.
4. Endocrine – Acromegaly, hypothyroidism.
5. Amyloidosis.
6. Traumatic.

CANNON 'A' WAVES

Isolated – Ventricular ectopics.

Regular – (a) At normal heart rate: Nodal rhythm, sinus rhythm with prolonged PR. (b) At rapid rate: Isorhythmic AV dissociation, ventricular tachycardia with 1:1 retrograde conduction.

Irregular – (a) Slow rate: Complete heart block. (b) Fast rate: Ventricular paroxysmal tachycardia.

CAROTENEMIA

1. Excessive intake of carrots
2. Hypothyroidism
3. Diabetes mellitus
4. β -carotene therapy for erythropoietic porphyria
5. Anorexia nervosa.

CARPAL TUNNEL SYNDROME

1. Idiopathic
2. Compression of median nerve by fracture, oedema or tenosynovitis

3. Rheumatoid arthritis
4. Osteoarthritis
5. Myxoedema
6. Acromegaly
7. Palindromic rheumatism
8. Primary amyloid
9. Pregnancy

CHARCOT FOOT

- Diabetes mellitus (major cause)
- Leprosy
- Tabes dorsalis
- Spinal cord tumour
- Charcot-Marie-Tooth disease
- Drugs: Steroids, indomethacin, phenylbutazone, vincristine
- Alcoholism
- Cerebral palsy
- Hereditary insensitivity to pain
- Myelodysplasia
- Poliomyelitis
- Syringomyelia
- Tertiary syphilis

CHYLURIA

1. Primary or idiopathic
2. Secondary –
 - a. *Parasitic* – Filaria, ascaris, trichomonas, echinococcus, tinea and H. nana infestation, Ankylostoma, malaria.
 - b. *Non-parasitic* – Obstruction or traumatic injury of thoracic duct, thrombosis of left subclavian vein, neoplasms, retroperitoneal fibrosis, pregnancy. Congenital lymphangiectasia involving urinary tract.

CLUBBING OF FINGERS

1. **Symmetrical** –
 - a. **ACQUIRED** – (i) *Pulmonary* – Pleural, mediastinal or pulmonary disease due to compression, infection, foreign body or neoplasm. (ii) *Cardiac* – Cyanotic congenital heart disease, SBE, occasionally congestive heart failure. (iii) *Liver disease* – Cholangiolitic cirrhosis. (iv) *Gastro-intestinal* – ulcerative colitis, chronic dysentery, idiopathic steatorrhoea. (v) *Miscellaneous* – Myxoedema, particularly iatrogenic; exophthalmic ophthalmoplegia.
 - b. **Hereditary** – May be familial condition and is often asymmetrical.

- c. **IDIOPATHIC** – Cases without family history or recognizable underlying disease.
2. **Unilateral or unidigital** –
- Aneurysm of aorta or its branches
 - Brachial A-V fistula
 - Subluxation of the shoulder
 - Pancoast tumour
 - Erythromelalgia
 - Local trauma
 - Felon (suppurative nail pulp infection)
 - Tophaceous gout
 - Sarcoidosis

CLAW HAND

1. Leprosy
2. Progressive muscular atrophy, amyotrophic lateral sclerosis
3. Median and ulnar nerve injury
4. Brachial plexus injury
5. Cervical rib or cervical pachymeningitis
6. Syringomyelia.
7. Acute poliomyelitis (rare).

COMA OF VARYING DEPTH

1. On and off gastrointestinal absorption, e.g. with meprobamate which forms concretions in the gut.
2. Enterohepatic circulation.
3. Secondary effect of hypoxia on consciousness.
4. Brief action of narcotic antagonists versus long action of opiates.
5. Brief action of glucose versus long-acting hypoglycaemic agents.
6. Subdural hematoma.

COUGH (PERSISTENT)

1. *Infections* –
 - a. Viral bronchial infection.
 - b. Nasal and sinus infection.
 - c. Chronic bronchitis.
 - d. Pulmonary TB.
 - e. Bronchiectasis.
2. *Bronchial asthma.*
3. *Bronchial carcinoma.*
4. *Pulmonary fibrosis.*
5. *Repeated bronchial aspiration* –
 - a. Oesophageal disorders. GERD

- b. Neurological disease affecting swallowing.
6. *Drug-induced cough* – ACE inhibitors.
7. *Psychogenic.*

CRANIAL BRUITS (IN ADULTS)

1. Transmitted from aortic or carotid artery stenosis.
2. Carotid-cavernous sinus fistula.
3. Arteriovenous malformations of cerebrum.
4. Angiomatous conditions in the orbit.
5. Vascular intracranial tumours, e.g. some meningiomas.
6. Glomus jugulare tumours.

CYANOSIS

1. **Central cyanosis** – is due to diminished arterial oxygen saturation. It is visible in the skin (nose, cheeks and fingers), and in warm areas, viz. those richly supplied with blood vessels (tongue, lips, conjunctivae). Central cyanosis, if severe and of long duration is associated with clubbing of fingers, and polycythemia.

Causes

- a. *Veno-arterial shunts* – e.g. Fallot's tetralogy, Eisenmenger's syndrome.
- b. *Impaired arterial oxygenation* – (i) Impaired diffusion of oxygen due to pulmonary disease, e.g. consolidation, atelectasis, emphysema, fibrosis. (ii) A low partial pressure of the alveolar oxygen as occurs at high altitudes.
2. **Peripheral cyanosis** – is due to a peripheral mechanism, i.e. an increased arteriovenous oxygen difference. It is visible only in the skin (nose, cheeks, fingers) and not in warm areas (tongue, lips, conjunctivae). Clubbing of the fingers and polycythemia do not occur.

Causes

- a. Slowing of circulation due to cold, or excess vasomotor stimulation.
- b. Oxygen deficiency with carbon dioxide accumulation – obstruction to trachea, venous congestion.
- c. Increased venous pressure producing stagnation and cyanosis – right sided heart failure, tricuspid stenosis, acute or chronic constrictive pericarditis, venous thrombosis.
- d. Shock because of vasomotor collapse and stagnation of blood.
3. **Mixed cyanosis** – due to combination of both factors, e.g. in cor pulmonale due to pulmonary emphysema.

DEHYDRATION

1. *Failure of fluid intake* – Unavailable, nausea, psychic disorder.
2. *Failure of absorption* – Diarrhoea, intestinal disorders.
3. *Loss from gastrointestinal tract* – Vomiting and diarrhoea.
4. *Excessive renal loss* – (a) Due to renal factors, e.g. failure of renal absorption. (b) Due to pre-renal factors – Disturbed body fluid chemistry, e.g. diuretics, cathartics.
5. *Excessive perspiration*.
6. *Loss from burns, wounds, etc.*

DELAYED PUBERTY (BOTH SEXES)

1. *Physiological* or constitutional.
2. *Non-endocrine diseases* – Asthma, steatorrhoea, chronic liver disease, helminthic infestation, haemoglobinopathies, chronic malaria, malnutrition.
3. *Chromosomal and endocrine disorders* – Turner's syndrome (in girls), Klinefelter's syndrome (in boys).
4. *Juvenile myxoedema*.
5. *Cushing's syndrome*.
6. *Pituitary failure* – Chromophobe adenoma or craniopharyngioma.

DIPLOPIA

1. *Monocular* – In disease of the eye and hysteria.
2. *Temporary* – Myasthenia gravis, vascular disease affecting brainstem, migraine, post-concussion, acute alcoholism, fever, toxic states. States of nervous tension.
3. *Long-lasting (usually)* – Encephalitis, meningitis, head injury, tumours, subarachnoid haemorrhage, hypertensive encephalopathy, Wernicke's encephalopathy, abscess of brain or cerebellum, cavernous sinus thrombosis, botulism.
4. *Gradually worsening diplopia* – Compression from aneurysm, pituitary tumour, meningovascular syphilis, tuberculous meningitis, post-nasal carcinoma or tumour at base of skull.
5. *Very slowly progressive* – Ocular myopathy, thyrotoxic ophthalmoplegia. Lesions in the orbit such as arteriovenous fistula in cavernous sinus, orbital tumour.

DYSPNOEA

A feeling of laboured, or unnaturally difficult breathing.

1. *Mechanical impairment of ventilation* – (a) Muscular weakness as in poliomyelitis or myasthenia. (b) Skel-

etal fixation, as from marked chest wall deformity or spondylitis. (c) Hydrothorax, pneumothorax. (d) Ascites or marked abdominal distension due to other causes. (e) Tracheal or bronchial obstruction.

2. *Impairment of pulmonary distensibility* – (a) Pulmonary congestion. (b) Pulmonary fibrosis.
3. *Pulmonary insufficiency* (inadequately functioning alveolar tissue) – (a) Emphysema. (b) Extensive inflammatory disease of pulmonary parenchyma.
4. *Inadequate delivery of oxygen to tissues* – (a) High altitude. (b) Anaemia. (c) Cardiac failure.
5. *Hyperventilation of central type, as from acidosis* – (a) Nephritic. (b) Diabetic.
6. *Psychic*.

Time course for onset of dyspnoea –

Seconds –

- Pneumothorax
- Pulmonary oedema due to arrhythmias
- Pulmonary embolism
- Inhalation of foreign body

Hours –

- Asthma
- Left heart failure
- Pneumonia
- Laryngeal oedema
- Hemorrhage
- Hypersensitive pneumonitis

Days –

- Pneumonia
- ARDS
- Left heart failure

Weeks to months –

- Pleural effusion
- Anemia
- Muscle weakness
- Tumours
- Pulmonary fibrosis
- Chronic airways obstruction
- Thyrotoxicosis
- Chest wall disorders

ENLARGED GREAT AURICULAR NERVE

1. Leprosy
2. Amyloidosis

3. Neurofibromatosis
4. Hypertrophic peripheral neuropathy
5. Refsum's disease

EPISTAXIS

1. **Local causes** –
 - a. Spontaneous.
 - b. Trauma to nose, base of skull, or from foreign body.
 - c. Nasal disease – acute ethmoidal sinusitis, nasal diphtheria, rhinitis sicca, tumours of nasal and paranasal sinuses, angiomas.
2. **Systemic disease** –
 - a. *Infections* – Influenza, measles, typhoid fever, malaria, viral infections of upper respiratory tract, viral haemorrhagic fever including dengue fever.
 - b. *Arterial hypertension*.
 - c. *Venous hypertension* – Whooping cough, chronic bronchitis, emphysema.
 - d. *Connective tissue disorders* – Ehlers-Danlos syndrome, pseudoxanthoma elasticum.
 - e. *Bleeding disorders* – Haemophilia, leukaemia, thrombocytopenia, anticoagulants.
3. **Miscellaneous** –
 - a. Mountain or air sickness.
 - b. Hypersplenism.
 - c. Hereditary haemorrhagic telangiectasia.

ERYTHEMA NODOSUM

1. Rheumatic fever.
2. Infections – Streptococcal, tuberculosis (especially primary), toxoplasmosis, histoplasmosis, brucellosis, leprosy, blastomycosis, coccidioidomycosis, lymphogranuloma inguinale, psittacosis, rickettsial infection, cat scratch fever, trichophytosis.
3. Inflammatory bowel disease.
4. Drugs – Sulphonamides, oral contraceptives, barbiturates.
5. Sarcoidosis.
6. Immunological – Behcet's disease.

ERYTHROMELALGIA

A syndrome of red congestion and burning pain in hands and feet.

1. Erythromelalgia associated with thrombocythemia.
2. Primary erythromelalgia – begins in childhood or adolescence as bilateral symmetrical burning distress in feet, ankle and legs, aggravated by warmth and exercise.

3. Secondary erythromelalgia – in association with gout, SLE, RA, cryoglobulinaemia, thromboangiitis obliterans, polyarteritis nodosa, arteriosclerosis, diabetes mellitus, neurological conditions, vascular diseases and secondary to vasoactive drugs.

EXOPHTHALMOS (PROPTOSIS)

Unilateral –

1. *Dysthyroid*.
2. *Orbital neoplasms* – Optic nerve glioma, retinoblastoma, metastases, etc.
3. *Vascular* – A-V malformation, hematoma, carotid-cavernous fistula.
4. *Obstructive lesions* – (a) *Intracranial* – Meningioma, glioma, cavernous sinus thrombosis, infraclinoid aneurysm. (b) *Sinus/bone lesion* – Fibrous dysplasia, neoplasm (carcinoma, osteoma, dermoid), mucocoele (extending from frontal sinus), craniostenosis.

Bilateral –

1. Graves' disease.
2. Cavernous sinus thrombosis.
3. Chronic emphysema (Frog's eyes).
4. Myasthenia gravis.
5. Paget's disease of bone.
6. Orbital myositis.
7. Uraemia.
8. Alcoholism.
9. Malignant hypertension.
10. SVC obstruction.
11. Carcinomatosis.
12. Craniostenosis

FACIAL ERUPTIONS

1. Vasomotor instability – provoked by stimuli such as warmth, hot drinks, alcohol, sun, emotion, pregnancy, odours and fumes.
2. Menopausal flushing.
3. Facial telangiectasia.
4. Carcinoid syndrome.
5. Superior vena caval syndrome.
6. Rosacea.
7. Corticosteroid red face.
8. Perioral dermatitis – Groups of pimples around the mouth.
9. Seborrhoeic dermatitis.
10. Contact dermatitis.

11. Atopic dermatitis (eczema).
12. Psoriasis.
13. Light sensitivity.
14. Lupus erythematosus - (a) Discoid: Slightly, bluish-red, thickened patches on cheeks, nose or chin. (b) SLE - Butterfly eruption.
15. Erysipelas.
16. Port wine stain.

FATIGUE (TIREDNESS)

1. *Psychogenic* - Neurosis or depression.
2. *Organic causes* - (a) *Cardiac* - Congestive failure, atrial fibrillation, hypertension, congenital heart disease. (b) *Respiratory* - Obstructive airways disease. (c) *Neurological* - Myasthenia gravis, myopathy. (d) Hemopoietic - Anaemia, lymphoma. (e) Endocrine - Hypothyroidism, hyperthyroidism, Cushing's syndrome, hypopituitarism, chronic adrenal insufficiency, diabetes mellitus (uncontrolled).
3. *Chronic infection* - Malaria, brucellosis, pulmonary tuberculosis.
4. *Iatrogenic causes* - e.g. diuretics, hypotensive drugs.
5. *Prolonged inactivity*.

FLATULENCE

1. *Aerophagia* (air swallowing) - (a) Faulty dietary habits - Eating fast, excessive consumption of carbonated drinks, or of tobacco, spicy foods, betel leaves, candies. (b) Psychological - Anxiety, grief, nervous tension. (c) Hypersalivation - Gastritis, peptic ulcer. (d) Reflex - Angina pectoris, chronic cholecystitis, hiatus hernia. (e) Dryness of mouth - Dehydration, mouth breathing, anticholinergics.
2. *GI fermentation* - (a) Faulty diet containing inadequately cooked starch or cellulose. (b) Gastrointestinal stasis - Constipation, after vagotomy, intestinal strictures. (c) Intestinal hurry - Diarrhoea, cathartics. (d) Deficiency of digestive enzymes. (e) Malabsorption states. (f) Abnormal bacterial flora, e.g. use of broad spectrum antibiotics.
3. *Mechanical obstruction* - to passage of food and gas - Cascade stomach, intestinal obstruction.

Management

Gastric flatulence - (a) Treatment of aerophagia. (b) Avoid gulping down food, much talking during meals. (c) Chew food thoroughly and eat slowly. (d) Antacid-antiflatulent tablets or liquid after meals. (e) Carminative preparation.

Intestinal flatulence - (a) Avoid gas forming foods such as cabbage, cauliflower, cucumber, beans, peas, onions, raisins, nuts, apples. (b) Rule out amoebic infection. (c) Minimum consumption of sugar if associated diarrhoea. (d) Enzyme digestants after meals.

FOOT DROP (UNILATERAL)

1. *Pyramidal lesion* - affecting lower limb, e.g. hemiplegia, multiple sclerosis.
2. *Lateral peroneal nerve* - palsy.
3. *L5 root lesion* - from prolapsed disc.
4. *Charcot-Marie-Tooth disease*.

GENITAL AND ORAL ULCERATION

1. Reiter's syndrome.
2. Crohn's disease.
3. Pemphigus.
4. Erythema multiforme.
5. Syphilis.
6. Herpes simplex.
7. Behcet's syndrome.

GLOBUS SENSATION

1. Gastrooesophageal reflux disease
2. Anxiety disorder
3. Early hypopharyngeal cancer
4. Goitre

GOITRE

The term goitre is used to describe an enlargement of the thyroid.

1. *Iodine deficiency*.
2. *Idiopathic*.
3. *Physiological* - Puberty, pregnancy.
4. *Graves' disease*.
5. *Goitrogens* - Antithyroid drugs, iodine containing medicine, aminoglutethimide, lithium. Foods - soya-bean, cassava.
6. *Thyroiditis* - Hashimoto's, acute or subacute (de Quervain's), Riedel's septic.
7. *Dyshormonogenesis* - Iodide trapping defect, organification defect (including Pendred's syndrome), impaired thyroglobulin synthesis, coupling or dehalogenase defects, end-organ resistance to thyroid hormone.
8. *Tumours* - Adenoma, carcinoma, lymphoma.
9. *Others* - Sarcoidosis, syphilis.

GUM BLEEDING

1. Gingivitis and gingivostomatitis.
2. Bleeding disorders - Thrombocytopenia, haemophilia, leukaemia, anticoagulants.
3. Abnormalities of vessel wall - Scurvy, Henoch-Schönlein purpura, dysproteinemia, e.g. multiple myeloma.
4. Connective tissue disorders (hereditary) - Ehlers-Danlos syndrome, pseudoxanthoma elasticum.

GYNECOMASTIA

1. **Physiological** -
 - a. Neonatal.
 - b. Pubertal.
 - c. Senile.
2. **Pathological** -
 - a. *Increased oestrogen production* - Cirrhosis of liver, thyrotoxicosis, Leydig cell tumours and adrenal carcinomas. Carcinoma of bronchus and other tumours (from secretion of HCG).
 - b. *Decreased androgen production* (Hypogonadism) - (i) Hypergonadotrophic - Klinefelter's syndrome, castration, orchitis. (ii) Hypogonadotrophic - Isolated or part of panhypopituitarism.
 - c. *Androgen insensitivity* (Testicular feminization).
 - d. *Refeeding gynecomastia* - due to resumption of gonadotrophin production.
 - e. *Miscellaneous* - Leprosy, paraplegia, generalised skin disease, ulcerative colitis, congestive heart failure, hypertrophic pulmonary osteoarthropathy, rheumatoid arthritis, Hodgkin's disease, myotonia dystrophica, leukaemia, chronic renal dialysis, familial.
3. **Pharmacological** -
 - a. *Oestrogen therapy*.
 - b. *Androgens*.
 - c. *Digitalis, tetrahydrocannabinol, and griseofulvin* - bind to oestrogen receptors.
 - d. *Anticancer drugs* - especially alkylating agents (testicular damage).
 - e. *Anti-androgens* - including cyproterone acetate, spironolactone and cimetidine.
 - f. *Other drugs* - Phenothiazines, reserpine, tricyclics, and methyldopa. (Mechanism unknown).

HICCUGH

1. *Abdominal* - Transient following over-distension of stomach with food or drink or irritation of stomach, e.g. from alcohol. Peritonitis, diaphragmatic pleurisy,

intestinal obstruction, after abdominal operations, subphrenic abscess, gastric dilatation, abdominal carcinoma, liver abscess, abdominal Hodgkin's disease, crisis (diaphragmatic) of tabes dorsalis.

2. *Thoracic* - Irritation of phrenic nerve, fibrous mediastinitis, cardiac enlargement, mediastinal tumours, adherent pericarditis, aortic aneurysm, oesophageal tumours.
3. *Cerebrovascular* - Tuberculous meningitis, encephalitis, brain tumour, hydrocephalus, multiple sclerosis, focal epilepsy, chorea, arteriosclerosis.
4. *Toxic* - Uraemia, diabetic ketoacidosis, severe systemic infections, anoxia, alcoholism, electrolyte imbalance.
5. *Functional* - e.g. following bouts of laughter or swallowing; or evidence of hysteria.
6. *Without demonstrable cause*.

Management -

1. *Removal or control of primary cause* - when possible.
2. *Physical or mechanical measures* - (a) Holding the breath. (b) Breathing in and out of a paper bag. (c) Compression of carotid sinus or eyeballs. (d) Stimulation of the pharynx to induce vomiting. (e) Drinking cold water, Valsalva manoeuvre, pull on the tongue. (f) Washing out the stomach if gastric dilatation.
3. *Drugs* - (a) Antispasmodics - (i) Octin - 10-15 drops of 10% solution in water or dragees, or subcutaneous or IM, may be repeated 3-hourly till satisfactory response. (ii) Atropine - 1/100 gr subcutaneously. (b) Chlorpromazine or promazine - 50 mg by mouth or IM. (c) Local anaesthetic orally - Xylocaine viscous one dessertspoon 1/2 hour after preliminary injection of atropine. (d) Baclofen 10 mg b.d. p.o. (e) Basal narcotic - Prolonged IV administration in resistant cases.
4. *Carbon dioxide* - Inhalation of 7% carbon dioxide in oxygen stimulates the respiratory centre.
5. *Phrenic nerve paralysis* - In rare cases, if hiccough tends to exhaust the patient, phrenic nerve block by paravertebral injection of 3-5 cervical roots, or nerve crush.

HOARSENESS OF VOICE

1. *Inflammation of larynx* - (a) Acute - Infection of larynx, acute epiglottitis, laryngotracheobronchitis, (b) Chronic - Nonspecific, polypoid laryngitis, vocal nodules.
2. *Chronic granulomas* - Tuberculosis, syphilis.
3. *Endocrine dysfunction* - Hypothyroidism.
4. *Mechanical interference with function* - Injury to larynx, tumours benign or malignant.

5. *Functional disorders* – Functional dysphonia.
6. *Laryngeal paralysis* – (a) *Central (intracranial) causes* – bulbar lesions, tumours or vascular lesions. (b) *Peripheral (in neck or thorax) causes* – stretching, compression or interruption of the recurrent nerve, usually the left, e.g. aneurysm of aorta, cardiac enlargement, achalasia, anthracosilicosis, bronchogenic carcinoma, carcinoma of oesophagus, thyroid or trachea. Trauma following thyroidectomy. Toxic neuritis – lead, arsenic, alcohol, measles, influenza, diphtheria.

HORNER'S SYNDROME

(According to site of lesion)

1. *Brainstem* – Tumour, vascular lesions.
2. *Spinal cord* – Syringomyelia, tumour.
3. *Spinal roots (T₁, T₂)* – Injury.
4. *Carotid artery* – Thrombosis.
5. *Sympathetic chain* – Apical lung carcinoma, glands.

HYPERPYREXIA

1. Malaria
2. Septicaemia
3. Lobar pneumonia
4. Pontine haemorrhage
5. Encephalitis
6. Heat stroke
7. Malignant hyperpyrexia
8. Dengue
9. Chikungunya fever

Hypersomnia (Attacks of drowsiness or sleep)

1. *Idiopathic narcolepsy*.
2. *Symptomatic narcolepsy* – Lesions in region of hypothalamus, e.g. increased intracranial pressure, encephalitis, brain injuries, multiple sclerosis.
3. *Hysteria*.
4. *Parasomnia* – in diabetic ketoacidosis, uraemia, portal systemic encephalopathy, or overdosage with sedative drugs.
5. *Klein-Levin syndrome* – Periodic attacks of hypersomnia with excessive hunger.
6. *Miscellaneous* – Hypopituitarism, hypothyroidism, severe anaemia, debilitating illness, anxiety neurosis.

HYPERTROPHIC OSTEOARTHROPATHY

1. *Pulmonary* – Ca bronchus, lymphoma, abscess, bronchiectasis, metastases.
2. *Pleural* – Fibroma, mesothelioma.
3. *Cyanotic congenital heart disease*.

4. *GI* – Ulcerative colitis. Crohn's disease, chronic dysentery, coeliac disease, lymphoma, Whipple's disease, biliary cirrhosis.
5. *Nasopharyngeal carcinoma*.

HYPERVENTILATION

1. *Anxiety or hysteria*.
2. *Pain*.
3. *Drugs* – Salicylates, analeptics, adrenaline.
4. *Increased metabolism* – Pyrexia, hyperthyroidism.
5. *Metabolic acidosis*.
6. *Anoxia*.
7. *Lung disease* – Atelectasis, pneumothorax, irritant gases.
8. *Hypotension*.

HYPOTENSION

1. *Symptomatic* – Addison's disease, Simmond's disease, shock, myocardial infarction, emphysema, pulmonary tuberculosis, etc.
2. *Constitutional permanent hypotension* – occurs in about 3% of healthy individuals; more common in females.
3. *Orthostatic hypotension* – Reduction of >20 mm Hg systolic BP and >10 mm Hg diastolic BP on standing from lying within 3 minutes. Causes: Prolonged bed rest, prolonged use of hypotensives or major tranquilizers, β -blockers, vasodilators. Autonomic neuropathy, hyponatremia, Addison's disease, chronic kidney failure.

Management of postural hypotension –

1. Extra pillows under the head at night.
2. Extra sodium chloride in diet because salt causes retention of fluids in tissues which has a sort of binding effect on the capillaries.
3. Abdominal binder may help.
4. Drugs which raise blood pressure such as mephentermine sulphate 20–25 mg b.d. Amphetamine (5–10 mg.) may be useful.

IMPOTENCE

1. **Psychological** –
 - a. *Developmental* – e.g. conflict in parent-child relationship.
 - b. *Affective* – Depression, anxiety, guilt, inter-personal relationship.
 - c. *Cognitional* – e.g. lack of knowledge about sex.

2. Organic -

- a. *Endocrine* - (i) Pituitary - Tumour, acromegaly. (ii) Thyroid - Hypothyroidism or thyrotoxicosis. (iii) Hypoparathyroidism. (iv) Diabetes mellitus. (v) Addison's disease. (vi) Testicular defects - Eunuchoidism, Klinefelter's syndrome, testicular feminization, interstitial cell tumour, ageing.
3. **Local conditions** - Priapism, Peyronie's disease, phimosis.
4. **Others** - (a) Extreme obesity. (b) Surgery, e.g. prostatectomy, bladder surgery. (c) Drug abuse and chronic alcoholism. (d) CNS disease - Parkinsonism, autonomic neuropathy, spinal cord injury. (e) Drugs - e.g. some antihypertensives, anticholinergics. (f) Hepatic or kidney failure. (g) Pelvic trauma.

INCREASED INTRACRANIAL PRESSURE

1. Mass lesion - Tumour, hematoma, abscess.
2. CSF accumulation - Hydrocephalus - Congenital, obstructive, following infection or haemorrhage.
3. Brain oedema -
 - a. *Vasogenic* (vessel damage) - Tumour, abscess, contusion.
 - b. *Cytotoxic* (Cell membrane pump failure) - Hypoxia, ischemia, toxins.
 - c. *Hydrostatic* (High vascular transmural pressure) - e.g. post-brain decompression.
 - d. *Hypo-osmotic* - Hyponatremia.
4. Brain swelling (Increased blood volume) -
 - a. Arterial dilatation and hypertension.
 - b. Venous congestion.
5. Benign intracranial hypertension.
6. Chronic meningitis or adhesive arachnoiditis and/ or aqueductal stenosis.
7. Thrombosis of cervical veins and dural sinus.
8. Addison's disease, hypoparathyroidism.
9. Excessive vitamin A and chloramphenicol therapy in children.
10. Withdrawal of corticosteroid therapy in children.

Intercostal Retraction or Suction**Bilateral:**

1. Foreign body in larynx or trachea
2. Laryngeal diphtheria
3. Angioedema of glottis
4. COPD
5. Bronchiolitis
6. Bilateral diaphragmatic paralysis

Unilateral

1. Lung collapse from bronchial obstruction.
2. Unilateral lung fibrosis.

KAYSER-FLEISCHER RING

1. Wilson's disease.
2. Cryptogenic cirrhosis.
3. Chronic biliary cirrhosis
4. Prolonged cholestasis

KYPHOSCOLIOSIS

1. Congenital.
2. Idiopathic.
3. Rickets.
4. Rheumatoid arthritis.
5. Senile osteoporosis.
6. Neurological causes - Friedreich's ataxia, neurofibromatosis, syringomyelia, cerebral palsy, poliomyelitis.

LEG ULCERS

1. *Venous ulceration* - (a) Deep vein thrombosis. (b) Varicose veins. (c) 'Armchair legs' in elderly persons who sleep in a chair.
2. *Arterial insufficiency* - (a) Arteriosclerosis. (b) TAO.
3. *Neuropathy* - Diabetes mellitus, peripheral neuropathy.
4. *Vasculitis* - SLE, rheumatoid arthritis, PAN, Wegener's granulomatosis, erythema induratum, pyoderma gangrenosum.
5. *Systemic sclerosis*.
6. *Systemic hypertension* (Martorell's ulcer).
7. *Infection* - Leprosy, tuberculosis, tropical ulcer, post-cellulitis, dermal leishmaniasis, syphilis, atypical mycobacterial infection.
8. *Blood disorders* - Sickle cell anemia, polycythemia vera, spherocytosis, DIC.
9. *Plasma protein disorders* - Cryoglobulinemia.
10. *Malignancy* - Basal cell carcinoma, squamous cell carcinoma (Marjolin's ulcer), reticulosis, malignant melanoma, dysproteinemia.
11. *Chilblains*.
12. *Trauma*.
13. *Frost bite*

Livedo Reticularis

A mottled net-like pattern of dilated blood vessels.

1. Idiopathic: Benign, complicated

2. Congenital: Cutis marmorata, telangiectatica marmorata
3. Secondary
 - Vascular disease: Arteriosclerosis
 - Vascular calcification
 - Arteritis: PN, lupus erythematosus, RA, dermatomyositis, allergic granulomatosis
 - Vascular occlusion: Emboli, thrombocytopenia, intra-arterial injections.
4. Miscellaneous
 - Paralysis
 - Cardiac failure
 - Tuberculosis
 - Pancreatitis
 - Syphilis
 - Lymphomas
 - Mycosis fungoides
 - Amantadine therapy

Liver tenderness

1. Acute viral hepatitis
2. Liver abscess: amoebic, pyogenic
3. Congestive heart failure
4. Carcinoma liver
5. Drug-induced hepatitis
6. Infected hydatid cyst of liver
7. Budd-Chiari syndrome

Loin Pain

Renal:

1. Calculus, sloughed papilla.
2. Pyelonephritis, perinephric abscess.
3. Acute glomerulonephritis (esp. proliferative).
4. Vesicoureteric reflux.
5. Hemorrhage into cyst, infected cyst.
6. Segmental infarction (sickle cell disease, embolism).

Extra-renal:

1. Acute cholecystitis.
2. Acute pancreatitis.
3. Leaking duodenal ulcer (Rt. side).
4. High appendicitis.
5. Splenic rupture.
6. Acute porphyria.

7. Ectopic gestation.
8. Ileo-caecal carcinoma.

Loss of Memory

1. Transient – following concussion.
2. Epilepsy (intermittent forgetfulness).
3. Intracranial tumour esp. of frontal lobe, corpus callosum or temporal lobe.
4. Multiple sclerosis.
5. General paralysis and meningo-vascular syphilis.
6. Vitamin B₁₂ deficiency.
7. Vitamin B₁ deficiency with or without Wernicke's encephalopathy, Korsakoff's psychosis.
8. Pellagra
9. Hypothyroidism
10. Huntington's chorea
11. Anticonvulsant and sedative drugs
12. Electroconvulsive therapy
13. Alcoholism
14. Senile cerebral atrophy
15. Hysterical or psychopathic
16. Rare diseases – Cerebral lipoidoses, gargoylism, Jakob-Creutzfeldt disease.

Lump in Left Iliac Fossa

1. Diverticular abscess
2. Ca colon
3. Crohn's disease
4. Pelvic (or transplanted) kidney
5. Lymphadenopathy (Iliac)
6. Faecal masses

Lump in Right Iliac Fossa

1. Appendicular abscess
2. Ileocaecal tuberculosis
3. Carcinoma of caecum
4. Amoeboma
5. Crohn's disease
6. Ectopic right kidney
7. Actinomycosis
8. Intussusception
9. Carcinoid syndrome
10. Lymphoma
11. Tubal pregnancy, ovarian tumour
12. Schistosomiasis

Macroglossia

- | | |
|--------------------|-----------------------------|
| 1. Cretin | 5. Haemangioma of tongue |
| 2. Acromegaly | 6. Lymphangioma of tongue |
| 3. Myxoedema | 7. Amyloidosis |
| 4. Down's syndrome | 8. Mucopolysaccharidosis |
| | 9. Glycogen storage disease |

Mask-like Facies

- | | |
|-------------------|-------------------------------|
| 1. Parkinsonism | 6. Myasthenia gravis |
| 2. Scleroderma | 7. Facial myopathies |
| 3. Hypothyroidism | 8. Bilateral UMN facial palsy |
| 4. Depression | |
| 5. Dementia | |

Melena (Tarry Stools)

1. *Swallowed blood.*
2. *Oesophageal and gastric causes* – (a) Ruptured oesophageal varices – cirrhosis of liver, portal hypertension. (b) Haemorrhagic gastritis. (c) Gastric ulcer or duodenal ulcer, or hiatus hernia.
3. *Intestinal causes* –
 - i. Primary
 - a. Carcinoma of intestinal tract.
 - b. Typhoid fever.
 - c. Crohn's disease.
 - d. Amoebic dysentery.
 - e. Ulcerative colitis.
 - f. Colonic and sigmoid polyposis.
 - g. Peptic ulcer in Meckle's diverticulum.
 - h. Mesenteric infarction.
 - i. Ankylostomiasis.
 - ii. Secondary to systemic disease –
 - a. Purpura and other haemorrhagic disorders.
 - b. Polyarteritis nodosa.

Moon Face

1. Acute nephritis and nephrosis
2. Cushing's syndrome
3. Corticosteroid therapy
4. Superior mediastinal syndrome
5. Angioedema
6. Cri-du-chat syndrome
7. Congenital pulmonary stenosis

Morning Stiffness

1. Rheumatoid arthritis
2. Ankylosing spondylitis
3. Osteoarthritis
4. Myxoedema

Myoglobinuria

1. *Metabolic defects*
 - A. Genetic –
 - a. Deficiencies of glycolytic enzymes: Phosphorylase, LDH, phosphofructokinase, etc.
 - b. Carnitine palmitoyl transferase deficiency.
 - B. Sporadic –
 - a. Exercise in excess of training
 - i. Military recruitment, marathon runners, cross-country skiers
 - ii. Status epilepticus, prolonged myoclonus, prolonged dystonia
 - iii. Agitated delirium
 - iv. High voltage electric shock, lightning stroke, electroshock therapy
 - b. Excessive body temperature

Heatstroke, malignant hyperthermia, malignant neuroleptic syndrome, infections
 - c. Ischemia

Thrombosis and embolism of major arteries and veins, sickle cell trait
 - d. Drugs and toxins

Alcohol, clofibrate and other fibrates, other hypolipidaemic drugs, heroin, LSD, opiates and barbiturates, azathioprine, 5-azacytidine
2. *Muscle necrosis*
 - a. Crush
 - b. Coma
 - c. Toxic
3. *Loss of muscle membrane integrity*
 - a. Toxic
 - Sea snake, tiger snake (Phospholipases myotoxins)
 - Hornet venom
 - Staphylococcal toxic shock syndrome
 - Drugs–succinylcholine
 - b. Salt and water imbalances
 - Hypokalaemia (drugs, aldosteronism, renal tubular acidosis)

- Hyponatremia
- Hypophosphatemia
- Hyperosmolar non-ketotic states
- Acidosis (diabetic, renal tubular)

4. Infections

1. Viral - influenza, coxsackie, ECHO
2. Bacterial - staphylococcal, typhoid, legionella, clostridia
3. Primary myopathies - Dermatomyositis, polymyositis

Nasal Regurgitation of Fluid

1. Bulbar and pseudo-bulbar palsy.
2. Acute bulbar paralysis - Myasthenic crisis, poliomyelitis, diphtheria, rabies, encephalitis, polyneuritis, botulism.
3. Polymyositis and dermatomyositis.
4. Muscular dystrophy.
5. Myotonia dystrophica.
6. Paralysis of tenth nerve by inflammatory, neoplastic or vascular lesion (posterior inferior cerebellar artery thrombosis).

Neck Pain

1. Mechanical disorders
Spasmodic torticollis
Cervical spondylosis
2. Systemic causes
Inflammatory: Ankylosing spondylitis, RA, polymyalgia rheumatica
Malignancy: Myeloma, metastatic Ca
Infection: Staphylococcal or other sepsis, TB
Metabolic: Osteomalacia
3. Whiplash injury
4. Fibromyalgia

Neck rigidity

- | | |
|-------------------|-----------------------------------|
| • Meningitis | • Meningoencephalitis |
| • Tetanus | • Meningism |
| • SAH | • Rabies |
| • Meningomyelitis | • Intracranial haemorrhage (rare) |
| • Parkinsonism | • Post. fossa tumour |
| • Parkinsonism | |

Nodules (Subcutaneous)

1. Rheumatic nodules
2. Rheumatoid nodules

3. Multiple neurofibromatosis
4. Fibroma
5. Gouty tophi
6. Lepromatous leprosy
7. Sarcoid
8. Erythema nodosum
9. Xanthomatous deposits
10. Cysticercosis
11. Calcinosis
12. Heberden's and Bouchard's nodes
13. Haygarth's nodes
14. Osler's nodes
15. Metastatic carcinoma
16. Myositis ossificans progressiva
17. Mycosis fungoides
18. Dermal leishmaniasis
19. Syphilis
20. Tuberculosis cutis
21. Skin cancer

Non-pitting Oedema

1. Myxoedema
2. Elephantiasis
3. Chronic venous oedema
4. Milroy's disease
5. Scleroderma (early stage)
6. Scleroderma

Oculogyric Crisis

Involuntary acute ocular deviation usually upwards.

1. Post-encephalitic.
2. Parkinsonism.
3. Petit mal epilepsy.
4. Drug-induced - Phenothiazines.
5. Neurosyphilis.
6. Following head injury.

Oedema

1. **Oedema of venous origin - Pitting oedema:** (a) Ingestion of excessive salt. (b) Steroids. (c) Premenstrual. (d) Cardiac oedema. (e) Renal oedema. (f) Portal obstruction. (g) Obstruction of inferior vena cava. (h) Anaemia and hypoproteinemia. (i) Beriberi. (j) Epidemic dropsy. (k) Pregnancy. (l) Miscellaneous - Old age, dermatomyositis, Raynaud's phenomenon, disseminated lupus.

If pitting remains for more than one minute (slow oedema), congestion is the most likely cause. If the pitting disappears in 40 seconds (fast oedema), the cause is hypoalbuminemia.

2. **Lymphoedema** - *Non-pitting oedema* - due to lymph stasis.
 - a. Congenital - Milroy's disease (primary lymphoedema), oedema of congenital arteriovenous aneurysm, congenital neurofibromatosis.
 - b. Parasitic - filarial.
 - c. Allergic - angio-oedema.
 - d. Chronic inflammatory - repeated attacks of erysipelas.
 - e. Post-traumatic - following fracture or soft-tissue injury.
 - f. Post-operative - e.g. excision of axillary or inguinal malignant lymph nodes.
 - g. Post-thrombophlebitic.
 - h. Neoplastic - blockage of lymphatics by malignant tissue, e.g. cancer of breast.
 - i. Lymphoedema or erythrocytosis frigida - in young women with stout build whose legs are abnormally fat.
 - j. Idiopathic or spontaneous - more common in females, spontaneous puffiness in ankle or foot, unilateral in majority, gradually extending up the leg over months or years. Oedema pitting at first, later becomes non-pitting.

Oral Manifestations of Systemic Disease

Teeth - (1) *Retarded eruption* - Congenital hypopituitarism or hypothyroidism, Down's syndrome, cleidocranial dysostosis, or after radiotherapy. Local causes, e.g. overcrowded arch. (2) *Loosening or early loss* - Dental caries or inflammatory periodontal disease, Down's syndrome, diabetes mellitus, neutropenia. (3) *Missing teeth* - in ectodermal dysplasia. (4) *Malformed teeth* - Local infection, trauma, radiotherapy. "Screw driver" teeth in congenital syphilis. Peg-shaped teeth in ectodermal dysplasia. (5) *Discoloration* - Tetracycline given during pregnancy or lactation, or to child under 12. Fluoride may cause white specs within the teeth. (6) *Dentinogenesis imperfecta* - may occur in isolation or in osteogenesis imperfecta.

Periodontal (Gingival) - (1) *Bleeding* - Purpura, acute leukaemia. (2) *Redness* - in gingivitis in pregnancy, females taking oral contraceptives, herpetic stomatitis, atrophic lichen planus or mucous membrane pemphigoid. (3) *Swelling* - Drugs, e.g. phenytoin, systemic disease, pregnancy. (4) *Pigmentation* - (i) Congenital - Racial,

naevi, Peutz-Jeghers syndrome. (ii) Acquired - (a) Drugs - Antimalarials, phenothiazines, ACTH. (b) Endocrine - Addison's disease, ACTH producing tumours, Albright's syndrome, Nelson's syndrome. (c) Dental amalgam. (d) Melanoma. (e) Ulcers - Neutropenia.

Oral mucosa - (1) *Blisters* - Pemphigus, pemphigoid. Labial blisters in herpetic infection. (2) *Oral purpura* - Trauma, bleeding diathesis, infectious mononucleosis, rubella, amyloidosis, scurvy. Blood-stained crusting in erythema multiforme. (3) *Telangiectasia* in hereditary haemorrhagic telangiectasia or systemic sclerosis. (4) *Localised red areas* - lupus erythematosus, lichen planus or erythroplasia. (5) *Ulcers* - Infections - Herpetic stomatitis, chickenpox, infectious mononucleosis, tuberculosis, trigeminal herpes zoster, herpangia, syphilis, hand, foot and mouth disease. (i) Blood dyscrasias - Anaemias, leucocyte defects. (ii) Malabsorption - e.g. coeliac disease, Crohn's disease. (iii) Mucocutaneous diseases - lichen planus, pemphigoid, pemphigus vulgaris, erythema multiforme, lupus erythematosus. (iv) Drugs - e.g. cytotoxic drugs. (6) *Angular stomatitis* - Deficiency of vitamin B complex, iron or folic acid; malabsorption. Denture-induced. (7) *Lumps* - Benign tumours, lymphomas (in region of fauces), myeloma, histiocytosis and metastatic deposits.

White Oral Lesions

- | | |
|------------------------|---|
| • Idiopathic keratosis | Infections |
| • Carcinoma | Candidiasis |
| • Physical or chemical | Hairy leukoplakia |
| Friction | Syphilitic keratosis |
| Burns | Papillomas (some) |
| Tobacco | Mucocutaneous disease |
| Snuff | Lichen planus |
| Sanguinarine | Lupus erythematosus |
| | Inherited lesions (such as white sponge naevus) |

Red Oral Lesions

Widespread redness

- | | |
|-------------------------|---------------------|
| • Candidiasis | Candidiasis |
| • Iron deficiency | Erythroplasia |
| • Avitaminosis B | Purpura |
| • Irradiation mucositis | Telangiectases |
| • Lichen planus | Angiomas |
| • Mucosal atrophy | Kaposi's sarcoma |
| • Polycythaemia | Burns |
| | Lichen planus |
| | Lupus erythematosus |
| | Avitaminosis |

Localised red patches

Salivary manifestations - (1) *Dry mouth* - Drugs (anticholinergic or sympathomimetic), severe dehydration, Sjogren's syndrome, irradiation of salivary glands. (2) *Drooling of saliva* - Pharyngeal obstruction, parkinsonism, facial palsy, mental deficiency.

Halitosis - Poor oral hygiene, oral infections, dry mouth, starvation, drugs, e.g. penicillamine, systemic disorders such as lung infection (bronchiectasis, lung abscess), hepatic or renal failure, diabetic ketoacidosis and GI disease.

Changes in oral sensation - (1) *Loss of taste* - Dry mouth, irradiation of head and neck, drugs such as penicillamine, neurosis, maxillofacial injuries, cerebral metastases. (2) *Pain* - Local causes such as infection or dental carries, trigeminal neuralgia, migraine or giant cell arteritis, referred as in angina, or atypical facial pain psychogenic in origin. (3) *Sensory disturbances* - (a) Lingual or inferior alveolar nerve damage from trauma or removal of wisdom tooth, or peripheral or central neuropathies. (b) Intracranial lesions such as tumours, multiple sclerosis, syringobulbia. (c) Paget's disease. (d) Benign trigeminal sensory neuropathy. (e) Drugs - Labetalol, acetazolamide. (f) Hyperventilation or hysteria. (g) Mandibular osteomyelitis, leukaemic deposits or metastases may cause lower labial anaesthesia.

Orthopnoea

1. Cardiac: LV failure, pericardial effusion
2. Respiratory: Bronchial asthma, COPD, bilateral diaphragmatic palsy
3. Intra-abdominal: Large ascites, massive tumour
4. Renal: Nephrosis, acute nephritis, uraemia

Pallor

1. *Anemia* of any aetiology
2. *Peripheral vasoconstriction* - Shock, exposure to cold, common faint (syncope), extreme fright
3. *Dermal* - Thick skin, myxoedema, oedema

Palmar Erythema

- A. **Physiological** - Pregnancy.
- B. **Pathological** -
 1. Liver disease - Viral hepatitis, cirrhosis
 2. Rheumatoid arthritis, SLE
 3. Polycythemia
 4. Beriberi
 5. Mitral regurgitation
 6. Diabetes mellitus

7. Chronic leukaemia
8. Thyrotoxicosis
9. Skin diseases - Tinea, eczematoid dermatitis, psoriasis, pityriasis rubra pilaris.

Palpitation

1. *Cardiac disease* - Ectopic beats, paroxysmal tachycardia, atrial flutter or fibrillation, ventricular tachycardia, heart block, hypertension and aortic regurgitation, associated with transient postural hypotension.
2. *Non-cardiac disease* - Effort syndrome, flatulent indigestion especially gall-bladder dyspepsia, anaemia, pulmonary tuberculosis, thyrotoxicosis, embarrassment of heart due to local pressure, e.g. pleural effusion, pneumothorax, tympanitis, ascites or pregnancy. Hypertensive crisis of pheochromocytoma.
3. *Non-organic disease* - After violent exertion or emotional upset specially in sensitive individuals, convalescence from a debilitating disease, excessive smoking, tea, coffee, or alcohol; functional cardiac arrhythmias, anxiety neurosis.

Paralysis of One Arm

Acute -

1. Cerebrovascular lesion.
2. Encephalitis.
3. Multiple sclerosis.
4. Poliomyelitis.
5. Neuritis.
6. Hysterical paralysis.

Chronic -

1. Tumour in arm area of brain, e.g. meningioma.
2. Lesions of brachial plexus - neoplastic compression, trauma at birth, cervical rib or scalenus anticus syndrome.
3. Syringomyelia.
4. Muscular dystrophy, motor neuron disease, polyneuritis may be confined to one limb for a time.

Paralysis of One Leg

Acute -

1. Thrombosis of paracentral artery
2. Multiple sclerosis
3. Cauda equina lesion
4. Sacral plexus lesion
5. Hysterical

Chronic –

1. Localized lesion of brainstem, e.g. multiple sclerosis
2. Parasagittal meningioma
3. Compressive or infiltrative lesion in dorsal or lumbar region of spinal cord
4. Brown-Sequard syndrome
5. Parkinsonism
6. Femoral or sciatic nerve palsy

Parotid Enlargement

(chronic, bilateral, nontender)

- Sjogren's syndrome
- Sarcoidosis
- Diabetes mellitus
- Cirrhosis
- Alcoholism
- Amyloidosis
- Acromegaly
- Uraemia
- Drugs (iodide, propylthiouracil)
- HIV infection

Pes cavus

1. Idiopathic
2. Spinocerebellar atrophy, e.g. Friedreich's ataxia, peroneal muscular atrophy
3. Spina bifida
4. Myelodysplasia in lumbosacral region
5. Sacral dermoid cyst with affection of cauda
6. Cerebral palsy
7. Poliomyelitis
8. Syringomyelia

Pigmentation of the Skin

1. *Yellow pigmentation* – (a) Jaundice. (b) Carotenemia – (no pigmentation of sclera and mucous membrane) results from excessive ingestion of foods rich in carotene such as carrots, oranges, squash, etc., lowered body metabolism, e.g. myxoedema. Simmond's disease and diminution of androgenic hormonal activity, e.g. the male castrate. (c) Administration of mepacrine. (d) Exposure to yellow industrial chemicals. (e) Ingestion of picric acid or its absorption from ointments applied to open wounds. (f) Diffuse xanthomatosis produces yellowish-orange type of skin discolouration.

2. *Haemoglobin pigmentation* – (a) Cyanosis. (b) Polycythemia. (c) Carbon monoxide poisoning (carboxy-hemoglobinuria). (d) Methemoglobinaemia and sulph-hemoglobinaemia.
3. *Melanin pigmentation* – (see hypermelanosis).

Polyneuritis Cranialis

1. *Acute polyneuritis* – Involvement of several cranial nerves in association with polyneuritis of the nerves of the limbs.
2. *Inflammatory lesions within the skull* – Tuberculous meningitis, chronic syphilitic meningitis, osteomyelitis of the bones at base of skull, otitis media.
3. *Compression* – of multiple Ns. by neoplastic infiltration of meninges.
4. *Painful ophthalmoplegia*.

Priapism

Persistent and abnormal penile erection unaccompanied by sexual desire.

1. *Haematological* – Sick cell disease, thalassemia, leukaemia, thrombocytopenia.
2. *Neurological* – Cerebral vascular accident, spinal cord injury.
3. *Local causes* – Penile trauma, perineal infection, myelomatosis, amyloidosis.
4. *Drugs* – Chlorpromazine, thioridazine, hydralazine, prazosin, reserpine, diazepam, anticoagulants and corticosteroids.
5. Alcoholism.
6. Idiopathic.

Prolonged (hung-up) Ankle Jerks

1. Hypothyroidism
2. Obesity
3. Gross oedema
4. Drugs – β -blockers, reserpine, quinidine, bromides
5. Diabetes mellitus
6. Arteriosclerosis
7. Sarcoidosis
8. Neurosyphilis
9. Parkinson's disease
10. Hypokalaemia
11. Myasthenia gravis
12. Profound hypothermia
13. Postpartum
14. Anorexia nervosa

Protein-losing Enteropathy

1. *Mucosal* - Coeliac disease, sprue.
2. *Inflammatory* - Inflammatory bowel disease, radiotherapy.
3. *Neoplasm* - Ca stomach, colon. Villous adenoma.
4. *Venous obstruction* - Cirrhosis, constrictive pericarditis, IVC obstruction.
5. *Lymphatic obstruction* - Lymphangiectasia, lymphoma, retroperitoneal fibrosis.
6. *Chronic arterial obstruction*.
7. *Infiltrate* - Whipple's disease, eosinophilic enteritis.

Proximal Myopathy

1. Cushing's syndrome.
2. Polymyositis/dermatomyositis.
3. Thyrotoxicosis.
4. Diabetes mellitus.
5. Malignancy.
6. Osteomalacia.
7. Hereditary muscular dystrophy.

Ptosis

1. Congenital.
2. Oculomotor nerve paralysis.
3. Horner's syndrome. (Ptosis less marked than in III n. palsy).
4. Tabes dorsalis.
5. Myasthenia gravis.
6. Ocular myopathy.
7. Myotonia dystrophica
8. Snake bite (Elapidae)
9. Periodic paralysis.

Puffiness of Face

1. Nephritic syndrome
2. Nephrotic syndrome
3. Angio-oedema
4. Myxoedema
5. Congestive heart failure
6. Hypoalbuminemia
7. Cushing's syndrome
8. Superior vena caval syndrome
9. Corticosteroid therapy
10. Lepromatous leprosy
11. Retro-orbital inflammation
12. Allergic dermatitis

Purpura

Non-Palpable Purpura

Ecchymoses: Chronic renal disease, clotting abnormalities, corticosteroids, Cushing's syndrome, primary amyloidosis, senile, trauma, venous stasis.

Dysproteinemia: Cryoglobulinemia, hyperglobulinaemia, macroglobulinemia.

Platelet abnormalities: Thrombocytopenia, thrombasthenia.

Progressive pigmentary purpura: Schamberg's dermatosis, Majocchi's disease, Lowenthal's disease.

Scurvy

Severe physical exertion

Wiskott-Aldrich syndrome., histiocytosis X.

Palpable Purpura

Sparse acral, palpable purpuric lesions

Atheroembolism

RA and SLE

Septicaemia: Gonococcal, meningococcal, candidial, pseudomonal, mucormycosis, staphylococcal

Subacute infective endocarditis

Multiple palpable purpuric lesions

Consumption coagulopathy: Drugs, post-infection, septicaemia, tumour.

Leukocytoclastic vasculitis: Allergy, collagen vascular disease, dysproteinemia, drug-related, Henoch-Schonlein purpura, idiopathic thrombocytopenic purpura, vasculitis, Rocky Mountain spotted fever.

Quadriplegia

1. Brainstem lesion
2. Craniovertebral anomaly
3. High cervical cord compression or trauma
4. G-B syndrome
5. Acute anterior poliomyelitis
6. Myopathy
7. Myasthenia gravis
8. Periodic paralysis

Raynaud's syndrome

1. *Raynaud's disease*.
2. *Collagen diseases* - Rheumatoid arthritis, Sjogren's syndrome, polyarteritis nodosa, dermatomyositis and polymyositis, systemic sclerosis.

3. *Occlusive arterial disease* – Arterial embolism, thromboangiitis obliterans, subclavian compression in costoclavicular syndrome.
 4. *Blood diseases* – Polycythemia vera, paroxysmal cold haemoglobinuria, high titre of cold agglutinins in blood, cryoglobulinaemia in association with lymphoma or myeloma.
 5. *Poisoning by ergot*.
 6. *Syringomyelia*.
 7. *Trauma* (occupational) – pneumatic drill operators, grinders, riveters.
3. *Neurogenic syncope*
 - a. Cerebral arrhythmia: Generalized motor seizures, temporal lobe epilepsy (associated with bradycardia).
 - b. Reduced cerebral blood flow: Vertebrobasilar ischemia (drop attacks), carotid ischemia (in presence of vertebral artery disease).
 4. *Metabolic*
 - a. Systemic hypoxia: Recurrent pulmonary emboli
 - b. Hypoglycemia: Diabetic on insulin/oral hypoglycaemic drugs.

Rectal Bleeding

1. Haemorrhoids.
2. Perianal lesions.
3. Dysentery.
4. Inflammatory bowel disease.
5. Colonic diverticular disease.
6. Colonic polyps or cancer.
7. GI bleeding from drugs.
8. Ischaemic colitis.
9. Pseudomembranous colitis (following antibiotic use).
10. 'Gay bowel' syndrome in male homosexuals.
11. Irradiation proctitis.
12. Others – Ulcer of rectum, angiodysplasia, Meckle's diverticulum.

Recurrent syncope

1. *Cardiac syncope*
 - a. Arrhythmia: Sinus node disease, AV node disease, tachycardia (particularly VT)
 - b. Mechanical causes of reduced cardiac output: Extensive myocardial ischemia, AS, HOCM, rarely PS and pulmonary hypertension.
 - c. Reduced ventricular filling: Pulmonary embolism, cough syncope, atrial myxoma/ball valve thrombus.
2. *Inappropriate vasodilatation*
 - a. Vasovagal syncope: Simple vasovagal faint, malignant vasovagal syncope.
 - b. Carotid sinus hypersensitivity
 - c. Drug-induced: Anti-anginal, antihypertensive, neuroleptic medications.
 - d. Orthostatic hypotension: Diabetes, Parkinson's disease, elderly
 - e. Micturition syncope.

Red face (Flushed Face)

1. Vasomotor instability.
2. Carcinoid syndrome.
3. Alcohol intake (with oral antidiabetic drug).
4. Steroids.
5. Acne rosacea.
6. Postmenopausal.
7. Dermatitis – Perioral, atopic, seborrhoeic, contact.
8. Psoriasis.
9. Lupus erythematosus.
10. Dermatomyositis.
11. Erysipelas.
12. Portwine stain.
13. Light sensitivity.

Restless Legs Syndrome

1. Abnormal iron metabolism
2. Uraemia
3. Diabetes mellitus
4. Rheumatic disease
5. Venous insufficiency
6. Genetic predisposition

Scaly skin

1. Ichthyosis
2. Psoriasis
3. Kwashiorkor
4. Pityriasis
5. Seborrhoeic dermatitis
6. Ring worm
7. Eczema
8. Lichen planus
9. Exfoliative dermatitis

Sialosis

(Painless, diffuse, non-tender, enlargement of parotid glands).

1. Idiopathic.
2. Sarcoidosis.
3. Alcoholic cirrhosis.
4. Diabetes mellitus.
5. Acromegaly.
6. Hyperlipoproteinaemia.
7. Chronic pancreatitis.
8. Drugs, e.g. phenylbutazone.
9. Anorexia nervosa.
10. HIV infection

Spider Naevi

1. Cirrhosis of liver.
2. Virus hepatitis (transient).
3. Pregnancy.
4. Normal individuals especially children (occasionally).
5. Rheumatoid arthritis.

Splinter fingers

1. Occupation trauma
2. Infective endocarditis
3. Trichinosis
4. Rheumatic fever
5. Infectious mononucleosis
6. Cryoglobulinemia
7. Severe hypertension
8. Severe rheumatoid arthritis
9. Widespread malignancy
10. Leukaemia
11. Scurvy
12. Idiopathic

Sterile Pyuria

1. Renal tuberculosis.
2. Drugs - Analgesic nephropathy, diuretics, jectofer.
3. Renal calculus.
4. Urogenital infection inadequately treated with antibiotics.
5. Amoebic infection of urinary tract.
6. Nonspecific urethritis (NSU).

Stridor

Noisy breathing with harsh, crowing sound mainly during inspiration and resulting from partial obstruction or narrowing of larynx, trachea or bronchus.

1. *Supraglottic* - Acute epiglottitis, angioedema, retropharyngeal abscess, infectious mononucleosis.

2. *Subglottic* - Acute laryngotracheitis, croup.
3. *Miscellaneous* - Foreign body aspiration, diphtheria, vocal cord palsy, pressure over main bronchus (from paratracheal and subcarinal lymph nodes).

Swelling in One Groin

1. Femoral hernia
2. Ectopic testis
3. Femoral lymphadenopathy
4. Saphenous varix
5. Psoas abscess
6. Femoral aneurysm

Swollen Leg

Acutely swollen leg

1. Trauma
2. DVT
3. Allergy
4. Cellulitis
5. Snake or insect bite
6. Rheumatological disease

Chronically swollen leg

1. Venous causes: Postphlebotic limb, varicose veins, venous compression
2. Lymphoedema: Primary, secondary
3. Congenital AV malformation
4. Dependency: Paralysis, arthritis, ischaemic rest pain

Tachypnoea

1. Pyrexia
2. Restrictive lung disease
3. Cardiac failure
4. Hypoxia
5. Pleuritic chest pain
6. Lobar pneumonia
7. Elevated diaphragm
8. Shock
9. Acidosis
10. Nervousness or hysterical

Thickened nerves (Hypertrophic neuropathy)

1. **Hereditary** -
 - a. Neurofibromatosis.
 - b. Charcot-Marie-Tooth disease.
 - c. Dejerine-Sottas disease.
 - d. Refsum's syndrome.
 - e. Amyloidosis (Predominantly neuropathic forms).
2. **Acquired** -
 - a. Leprosy.
 - b. Acromegaly.
 - c. Diabetes mellitus.
 - d. Sarcoidosis.
 - e. Relapsing neuropathies of unknown aetiology.

Tinnitus

1. *Ear disease* – (a) External ear – excessive wax, aural polypi or foreign body. (b) Middle ear – acute or chronic otitis media, Eustachian block. (c) Internal ear – Meniere's disease, specific fevers, extension of sup-puration to labyrinth from middle ear, fracture base of skull.
2. *Auditory nerve* – Auditory nerve neuronitis, drugs such as streptomycin, salicylates; pressure from tumours or by new bone formation as in osteitis deformans.
3. *Pons* – Vascular or neoplastic lesions of lateral aspect.
4. *Cerebrum* – Temporal lobe epilepsy.
5. *General diseases* – Anaemia, leukaemia, AR, uraemia, arteriosclerosis with hypertension. During attacks of neuralgia or migraine.

Vascular Gangrene Peripheral, Symmetrical

1. Asplenia
2. Immunosuppression
3. Diabetes mellitus
4. Kidney failure
5. Cold injury to extremities
6. Myoglobulinemia
7. Vasopressor drugs
8. Cerebral malaria
9. Viral gastroenteritis

Vesicular skin rashes

1. Eczema, cheilopompholyx
2. Herpes simplex
3. Herpes zoster
4. Impetigo
5. Scabies
6. Chickenpox
7. Dermatitis herpetiformis
8. Miliaria crystallina and rubra
9. Tinea
10. Drug eruption
11. Insect bites

Visual Failure

Transient monocular visual loss

1. Migraine
2. Retinal artery emboli

3. Recurrent hyphema
4. Recurrent angle closure
5. Optic disc anomaly
6. Blood dyscrasia
7. Papilloedema
8. Retinal vein occlusion
9. Primary antiphospholipid antibody syndrome
10. Compressive optic nerve lesion
11. Other optic neuropathy
12. Uhthoff's phenomenon – Diminution of vision with rise of temperature, e.g. after hot bath or exercise in demyelinating diseases of optic nerves.

Progressive loss of vision

1. Cataract.
2. Glaucoma.
3. Myopia.
4. Diabetic retinopathy.
5. Retinal degeneration – (a) Macular degeneration. (b) Retinitis pigmentosa.
6. Optic atrophy.
7. Toxic amblyopia – Chloroquine, tobacco, methyl alcohol, ergot, lead, arsenic.
8. Uveitis.

Blindness of abrupt onset

1. Assumed blindness usually in one eye.
2. Ischemic optic neuropathy.
3. Retrobulbar neuritis.
4. Leber's optic atrophy.
5. Inflammatory lesions of orbit – Pyogenic infections of paranasal sinuses or acute granulomatous infection of orbit.
6. Intracranial space-occupying lesions.
7. Poisons – Methyl alcohol.
8. Eclampsia.
9. Acute glaucoma.
10. Vascular occlusion of central retinal artery.
11. Cranial arteritis.

Vomiting (and Nausea)

Mechanism – Act of emesis is under the control of vomiting centre situated in the lateral reticular formation in medulla, and chemoreceptor trigger zone in the floor of the fourth ventricle. The vomiting centre receives afferent stimuli from the chemoreceptor trigger zone which can be activated by a number of stimuli such as bacterial toxins,

metabolic disturbances (e.g. uraemia), drugs and radiation. The efferent pathways are the phrenic nerves to the diaphragm, spinal nerves to intercostal and abdominal muscles and visceral efferent fibres in the vagus nerve to larynx, pharynx, oesophagus and stomach.

1. Reflex -

a. Abdominal -

Gastric - (i) Diseases - Acute and chronic gastritis, ulcer or carcinoma, pyloric spasm or stenosis, venous congestion as in portal obstruction and cirrhosis of liver. (ii) Chemical agents and poisons - food poisoning, corrosives and irritants, emetics like hypertonic salt solution, copper sulphate.

Extragastric - Appendicitis, intestinal obstruction, spasm as in lead poisoning, intestinal worms, biliary and renal colic, pancreatitis, and due to stimuli arising from disease of urinary bladder or uterus, migraine.

b. Peripheral - Stimulation of pharynx and fauces, severe trauma to testicle, muscles or joints. Primary shock.

2. Central -

a. Special senses - Offensive smells, tastes, repulsive sights.

b. Brain - Concussion, cerebral tumours or abscess, meningitis, cerebral haemorrhage, middle-ear disease, Meniere's disease, migraine, epilepsy; sea, train, car or air-sickness, radiation sickness.

c. Spinal cord - Gastric crisis of tabes.

3. **Toxic** - Hepatic disease, uraemia, acidosis, alkalosis, hypoglycemia, excessive dehydration, toxemia of pregnancy, cyclic vomiting of childhood. Drugs such as digitalis, emetine.

4. **Functional** or hysterical vomiting.

Morning vomiting -

1. Pregnancy or trophoblastic tumour.
2. Alcoholic gastritis.
3. Migraine.
4. Intracranial space-occupying lesion.

Weight loss (in an adult)

I. Exogenous causes -

1. Inadequate intake -

- i. Anorexia and starvation, dietary fads, perverted appetite, chronic alcoholism, drug therapy, antibiotics.

ii. Inability to swallow due to lesions of - (a) Tongue - paralysis, tumour, inflammation. (b) Palate - paralysis, tumours, inflammation, perforation. (c) Pharynx - paralysis, tumours, inflammation. (d) Oesophagus - stenosis, tumours, achalasia, foreign body, etc.

2. *Inadequate absorption or utilization* - Chronic diarrhoea, lack of enzymes or bile, lack of hydrochloric acid and pepsin, malabsorption syndrome, intestinal parasites.

3. *Excessive elimination or abnormal loss* - Diarrhoea, vomiting, fistulae, burns.

II. Endogenous factors -

1. Endocrine disorders - (a) Addison's disease. (b) Thyrotoxicosis. (c) Diabetes mellitus. (d) Simmond's disease.

2. Hepatic disorders - Cirrhosis of liver, liver abscess.

3. Respiratory diseases - Pulmonary tuberculosis, chronic lung abscess, bronchiectasis.

4. Blood diseases - Leukaemia, Hodgkin's disease.

5. Cardiovascular - Malignant hypertension, subacute infective endocarditis.

6. Kidney diseases - Chronic nephritis, pyonephrosis.

7. Neurological disorders - Progressive muscular atrophy.

8. Malignancy - Cancer stomach, bronchogenic carcinoma, etc.

9. Psychosis - Depression, schizophrenia, anorexia nervosa.

10. Drug addiction.

11. Collagen diseases.

Weight loss in spite of increased appetite

1. Diabetes mellitus
2. Hyperthyroidism
3. Chronic kala-azar
4. Malabsorption syndrome

Xanthomas

1. Disorders of lipid metabolism.
2. Normolipaeamic conditions: Histiocytosis X, xanthoma disseminate, diffuse planar xanthomatosis, juvenile xanthogranuloma, histiocytosis.

Xerostomia

1. Drugs (e.g. anticholinergics, antidepressants)
2. Rheumatoid arthritis

3. Sjogren's syndrome
4. Radiation therapy

Yawning

1. *Physiological*, e.g. boredom.
2. *Pathological* -
 - a. Encephalitis.
 - b. Epilepsy.
 - c. Tumour in posterior fossa.
 - d. Following nalorphine injection for opium poisoning.

23. THE FUNDUS

Changes in retinal vessels and retina -

1. *Hypertensive retinopathy* -

AV ratio	Haemorrhages	Exudates	Papilloedema	
	(Normal 3:4)			
Gr. I	1:2	Nil	Nil	Nil
Gr. II	1:3	Nil	Nil	Nil
Gr. III	1:4	+	+	Nil
Gr. IV	Fine, fibrous cords	+	+	+

Malignant hypertension (Retinopathy) -

- a. Diffuse and marked contraction of retinal arteries.
 - b. Swelling of optic nerve resembling papilloedema.
 - c. Numerous flame shaped superficial haemorrhages.
 - d. "Cotton wool" exudates in retina. (e) Star shaped figure at the macula.
2. **Retinitis** - Exudates and haemorrhages in the retina; the exudate interrupts the vessels. Papilloedema is a late sign. *Causes* - Hypertension, nephritis, diabetes, leukaemia and severe anaemia. In albuminuric retinitis there are large, flame shaped haemorrhages and cotton wool exudates. In diabetic retinitis the haemorrhages and exudates are usually small and round and hard (well defined), a mild degree of papilloedema may be present.
3. **Retinal arteries** -
- a. *Retinal haemorrhages* - (i) *Of haematological origin* - Diabetes mellitus, severe anaemia, bleeding diathesis, leukaemia, hypertension, papilloedema, trauma and retinal detachment, arteritis; rarely in polycythemia vera, and subacute infective endocarditis. (ii) *From venous congestion* - Compression of chest and head especially in newborn

infants. (iii) *Subhyaloid (preretinal)* - Fluid level visible between retina and vitreous. Commonly found in subarachnoid haemorrhage; may be due to trauma to eye, malignant endocarditis, pyemia and septicaemia.

- b. *Embolism of central retinal artery* - Retina in the surrounding area becomes white, and because the choroid shows through the thinnest part of the retina, the macular region remains coloured yellow, orange or red - "cherry red spot".
 - c. *Pulsation of retinal vessels* - In AR and in glaucoma, the arteries are seen to fill with each systole and collapse with diastole.
 - d. *Arteriolar constriction* - Malignant hypertension, central retinal artery occlusion, retinitis pigmentosa, cinchonism.
4. **Retinal veins** -
- a. *Thrombosis of central retinal vein* - Outline of disc lost and large veins seen intermittently in the oedematous and haemorrhagic retina, as if a quantity of red paint had been splashed all over the retina.
 - b. Dilated retinal veins - (i) Polycythemia, hyperviscosity. (ii) CRV thrombosis. (iii) Increased intracranial pressure. (iv) CO₂ retention. (v) Carotico-cavernous fistula.
5. Takayasu's disease - Fragmentation of blood stream in the retinal vessels may be visible particularly when the patient is standing. Later ocular manifestations are atrophy of the retina and iris with neovascularization, the formation of retinal and microaneurysms and peri-capillary arteriovenous anastomoses and the rapid development of cataract.
6. Degenerations - (a) Retinitis pigmentosa - Laurence-Moon-Biedl syndrome, Refsum's disease. (b) Amaurotic family idiocy - Pale fundus with cherry red spot in macula; nerve head pale and atrophied. Similar picture may be seen in Niemann-Pick disease.
7. Septic retinitis - Small, round, white patches (Roth spots) often associated with small haemorrhages near the disc in SIE.
8. Tuberos sclerosi - Pale white mass on or very close to the nerve head, appearing like a small bunch of grapes.
9. Tumours - Neuroblastoma or metastatic tumours. Angiomatosis of retina may be associated with angioma in cerebrum or cerebellum.

10. **Detachment of retina** - may occur in severe inflammatory, exudative or degenerative process affecting the eye, in intraocular tumour and following trauma.
11. **Angioid streaks** - (breaks in Bruch's membrane): Paget's disease, acromegaly, pseudoxanthoma elasticum, Ehlers, Danlos syndrome, hereditary hypophosphatasia, sickle-cell anemia.

Choroid -

1. **Choroiditis** - Irregular areas of white sclera with dark patches of pigment epithelium: (a) Tuberculous - Minute miliary tubercles seen as discrete, widely separated, greyish white masses, pathognomonic of tuberculous meningitis or miliary tuberculosis. (b) Syphilis - Gummatous or multiple greyish-yellow dust-like vitreous opacities. (c) Toxoplasmosis. (d) Sarcoidosis.
2. **Vascular lesions** - Endarteritis may occur in syphilis.
3. **Tumours** - Melanomas or metastatic tumours.

Optic disc -

1. **Papilloedema** (Choked disc) - is a swelling of the nerve head. Diagnostic criteria - (a) Loss of physiological cup. (b) Elevation of disc head. (c) Blurring of disc margins. (d) Distended non-pulsatile veins. (e) Subhyaloid haemorrhages at disc margins.

Causes -

- a. **Increased intracranial pressure** - due to space occupying lesion, or due to circulating block - aqueductal stenosis, intraventricular tumours, or outflow block of 4th ventricle.
 - b. **Cerebral oedema** - After head injury or cerebral anoxia, benign intracranial hypertension, vitamin A intoxication, steroid withdrawal, lead poisoning.
 - c. **Malignant hypertension.**
 - d. **Raised CSF protein or altered blood products** - Subarachnoid haemorrhage, chronic meningitis, Guillain-Barre syndrome, spinal cord tumours.
 - e. **Metabolic disorders** - Hypercapnia, hypocalcemia particularly in childhood, malignant exophthalmos.
 - f. **Circulation disorders** - CRV thrombosis, lateral sinus thrombosis, SVC obstruction, polycythemia rubra vera, multiple myelomatosis, macroglobulinaemia, hyperlipidemia, diabetes mellitus, vasculitis including temporal arteritis.
2. **Papillitis** - (Retrolbulbar neuritis) - Oedema of nerve head, retinal veins engorged and tortuous, and haemorrhages. Poor visual acuity. **Causes** - (a) Infections - (i) Local - retinitis, periostitis. (ii) General - Syphilis, toxoplasmosis, typhoid, mumps, measles. (b)

Toxins (toxic amblyopia) - tobacco, methyl alcohol, contraceptive pill, lead, carbon disulphide, thallium, quinine. (c) Demyelinating diseases - e.g. multiple sclerosis, Devic's disease. (d) Metabolic disorders - Diabetes, vitamin B₁₂ deficiency. (e) Hereditary degenerative diseases - Friedreich's ataxia. (f) Giant cell arteritis.

The difference between papilloedema and papillitis:

- Examiner sees nothing (can't find the disc) but patient sees everything (normal vision) - Papilloedema
 - Examiner sees nothing and patient sees nothing (severe visual loss) - Papillitis
 - Examiner sees everything (normal looking disc) but patient sees nothing - Retrolbulbar neuritis.
3. **Optic atrophy** -
 - a. **Primary** (due to nerve damage) - Compression of optic nerve, post-neuritic, toxic, ischemic, infective (e.g. syphilis), hereditary (Leber's), traumatic.
 - b. **Secondary** (following papilloedema) - Fuzzy appearance of nerve head. Disc appears like a tennis ball.
 - c. **Consecutive** - to retinal disease, e.g. choroiditis, retinitis pigmentosa.
 4. **Tumours of optic nerve head** - Neoplastic, inflammatory such as gumma or tubercle.
 5. **Congenital anomalies** - Vascular, anomalies of pigmentation.

Retinopathy

<i>Hypertensive</i>	<i>Diabetic</i>
A V nipping	Microaneurysms
Flame haemorrhages	Dot and blot haemorrhages
Papilloedema	New vessel formation

24. SOME IMPORTANT LABORATORY VALUES

Haematology

(Also refer Chapter 5)

Reticulocytes - 25,000-75,000/c.mm. $25.75 \times 10^9/1$ (0.5-1.5% of erythrocytes).

Increased - (i) Response to Vitamin B₁₂ therapy in primary macrocytic anaemia, (ii) congenital hemolytic jaundice, (iii) sickle cell anaemia, (iv) slight increase in leukaemia, myelophthisic anaemia, lead and mercury poisoning.

Decreased - Aplastic anaemia, myelodysplastic syndrome.

Mean corpuscular volume (MCV) 78–99 fl Red cell mass

- Males 31–35 mL/kg
- Females 20–30 mL/kg

Red cell half-life 25–33 days

MCV is most important of indices in presence of anaemia. Low – Iron deficiency anaemia, thalassaemia trait, anaemia of chronic disease. High – Vitamin B₁₂ or folate deficiency, or one of the causes of macrocytosis, with normoblastic marrow. Normal MCV in anaemia – Acute blood loss, combined vitamin B₁₂ and folate deficiency with iron deficiency or thalassaemia trait, and in many primary haematological disorders such as hemolytic anaemia, myeloproliferative disorders and marrow infiltration.

Leucocytes**Leucocytosis** (Neutrophilia) -

1. *Physiological* - (i) Newborn infant, (ii) following meals, (iii) strenuous exercise, (iv) convulsive seizures, (v) extreme heat or cold, (vi) pregnancy, (vii) emotional disorders, (viii) ultraviolet exposures, (ix) ether anaesthesia, (x) attack of paroxysmal tachycardia.
2. *Pathological* - (a) Infections - (i) Local - pneumonia, empyema, furunculosis, perinephric or appendicular abscess. (ii) General - septicaemia, infective endocarditis. (b) Toxic neutrophilia - (i) Endogenous intoxications - uraemia, eclampsia, gout, diabetic acidosis, burns. (ii) Drugs and poisons - Digitalis, mercury, lead, adrenaline, potassium chlorate, salicylates. (c) Post-haemorrhagic - especially haemorrhage into serous cavities - peritoneum, pleura, joints, subdural. (d) Associated with tissue destruction - myocardial infarction, postoperative, cancer of liver, gastrointestinal tract or bone marrow; burns, after haemolysis of red cells.

Lymphocytosis

1. *Infants and young children.*
2. *Infections* - (a) Viral: Infectious mononucleosis, infective hepatitis, acute infectious lymphocytosis, mumps, rubella, cytomegalovirus infection, varicella. (b) Bacterial: Tuberculosis, pertussis, brucellosis. (c) Protozoal: Toxoplasmosis.
3. *Lymphoproliferative disorders* - Chronic lymphocytic leukaemia, Waldenstrom's macroglobulinaemia.
4. *Miscellaneous* - Drug reactions, hyperthyroidism, myasthenia gravis, convalescence from any infection.
5. *Occasionally atrial myxoma.*
6. *Malaria.*
7. *Drugs* - Hydralazine, procainamide.

Eosinophilia -

Eosinophil counts up to $1.5 \times 10^9/l$

Common	Rare
Allergic rhinitis	Inflammatory bowel disease
Hay fever	
Extrinsic asthma	Some infectious diseases
Parasitic diseases	Neoplasms
Occupational lung disease	Skin diseases: Pemphigus, pemphigoid, dermatitis herpetiformis and psoriasis.

Eosinophil counts over $1.5 \times 10^9/l$

Common	Rare
Drug reactions	Vasculitis and granulomatous diseases
Intrinsic asthma	Neoplasms
Parasitic diseases	Hypereosinophilic syndromes
Pulmonary eosinophilia	
(including tropical eosinophilia)	

Monocytosis - (i) Certain bacterial infections - Tuberculosis, subacute bacterial endocarditis, brucellosis, typhus, and rarely typhoid. (ii) Protozoal infections - malaria, kala-azar, trypanosomiasis. (iii) Infectious mononucleosis. (iv) Hodgkin's disease. (v) Monocytic leukaemia. (vi) Tetrachlorethane poisoning.

Leukaemoid blood picture

A *leukaemoid reaction* is the occurrence in a patient suffering from a non-leukaemic disorder, of a peripheral blood picture resembling that of leukaemia, i.e. marked elevation of total white cell count or the presence of immature white cells, or both. Leukaemoid reactions may be either myeloid or lymphatic, or at times both (e.g. tuberculosis and carcinoma).

Neutrophilic leukaemoid reaction - (i) Hemolytic crisis in hemolytic anaemia. (ii) Haemorrhage. (iii) Hodgkin's disease. (iv) Infection - Tuberculosis (also lymphocytic), pneumo, meningo or staphylococcus infection, gas gangrene, diphtheria, leptospirosis, malaria, congenital syphilis (also lymphocytic). (v) Burns. (vi) Eclampsia. (vii) Mustard gas poisoning. (viii) Vascular thrombosis and infarction, e.g. mesenteric infarction. (ix) Marrow replacement by tumours including multiple myeloma, myeloid metaplasia.

Lymphocytic - Infectious lymphocytosis, infectious mononucleosis, pertussis, varicella.

Unfavourable signs in leucocytic picture -

(i) Extremely high total number of leucocytes with high percentage of neutrophils. (ii) Failure to develop leucocytosis. (iii) High proportion of immature cells, especially if they outnumber the mature forms. (iv) Absence of eosinophils. (v) Marked absolute reduction of lymphocytes. (vi) Presence of numerous toxic degenerative forms.

Leucopenia -

1. *Starvation or malnutrition.*
2. *Defective production* - (a) Hereditary - Infantile genetic agranulocytosis, familial benign chronic neutropenia, neutropenia with pancreatic dysfunction. (b) Acquired - (i) Ineffective myelopoiesis: Vitamin B₁₂ or folate deficiency. (ii) Marrow infiltration: Leukaemia, myelofibrosis, carcinoma, myeloma, lymphoma. (iii) Drugs or irradiation.
3. *Excessive destruction* - (i) Isoantibody: Neonatal. Blood transfusion. (ii) Autoantibody: SLE, RA. (iii) Drug-dependent antibody: Amidopyrine.
4. *Other causes* - Hypersplenism, haemodialysis.
Immature forms - Myelocytes, myeloblasts or persistent large number of lymphocytes or immature forms indicates leukaemia.

Platelets -

Normal 15,000-350,000/c.mm. $150-350 \times 10^9/l$ (Refer Ch.4).

Positive LE cells in blood -

1. Systemic lupus erythematosus (70-80%).
2. Rheumatoid arthritis (10%) and occasionally other collagen diseases.
3. Active chronic lupoid hepatitis (10%).
4. Atrial myxoma occasionally.

HLA antigens - Commonly associated disorders -

1. *Rheumatic diseases* - Ankylosing spondylitis and related disorders, rheumatoid arthritis.
2. *Neurologic diseases* - Multiple sclerosis, myasthenia gravis, olivopontocerebellar ataxia.
3. *Skin diseases* - Psoriasis, discoid lupus erythematosus, dermatitis herpetiformis, Behcet's disease.
4. *Endocrine diseases* - Insulin-dependent diabetes mellitus, Graves disease, subacute thyroiditis, Addison's disease, hypergonadotrophic hypogonadism, 21-hydroxylase deficiency.
5. *Gastrointestinal diseases* - Gluten-sensitive enteropathy, pernicious anaemia, chronic active hepatitis, hemochromatosis.
6. *Immunopathic diseases* - Atopy, complement deficiencies (C2, C4), SLE, Sjogren's disease.

7. *Malignant diseases* - Hodgkin's, acute lymphoblastic leukaemia, acute myelogenous leukaemia, nasopharyngeal carcinoma.
8. *Occupational disease* - Asbestosis.
9. *Drug reactions* - Hydralazine.

Erythrocyte sedimentation rate (ESR) -

	Adult males	Adult females
Wintergreen	3-5 mm. in 1 hour	4-7 mm. in 1 hour
Wintrobe	0-10 mm. in 1 hour	0-15 mm. in 1 hour

Normal values do not necessarily exclude disease.

Increased - (i) Physiological - pregnancy after the second month and menstruation. (ii) Infective disease - acute generalised and localised infections, chronic active infections like tuberculosis and rheumatic carditis. (iii) Ischemic disease - myocardial infarction. (iv) Metabolic - e.g. acute gout. (v) Traumatic - burns, fractures. (vi) Neoplastic - certain malignant tumours including Hodgkin's disease. (viii) Chikungunya fever.

Grossly abnormal ESR (>100 mm/h)

1. Multiple myeloma.
2. Carcinomatosis esp. active Hodgkin's.
3. Sepsis esp. florid TB.
4. Active vasculitis esp. giant-cell.
5. Severe anemia.
6. Uraemia.
7. Kala-azar.
8. SLE.

Low ESR (< 3 mm/h)

1. Polycythemia vera.
2. Sickle cell anemia.
3. Massive leucocytosis, e.g. CLL.
4. Hypofibrinogenaemia.
5. High-dose steroids or salicylates.
6. Congestive heart failure

No increase - Generalized blood infection without localisation, e.g. influenza, cystitis, sometimes infective process in CNS, fibrotic carcinoma or early sarcoma.

Value of ESR estimation -

- In diagnosis* (of little value) - (i) To distinguish functional from organic disease. (ii) Infective arthritis, acute gout and active rheumatoid arthritis cause an increase in the rate, but in osteoarthritis it is normal or only slightly increased. (iii) The rate is increased by pelvic inflammation but not with an unruptured ectopic gestation. (iv) The rate is always rapid in malignant pelvic tumours but not in simple pelvic tumours.

- b *In prognosis and treatment* - (i) In fevers, a rising ESR suggests progress of the disease or onset of complications. (ii) In rheumatic fever, it is a specially sensitive index of persistent rheumatic infection (Cardiac failure gives falsely low and anaemia falsely high values). (iii) In acute nephritis, the rate remains high in patients passing into the chronic stage.

Ceruloplasmin and copper - Normal - Ceruloplasmin 27-37 mg/100 mL, Copper 70-140 mcg/100 mL (11-22 mol/L).

Elevated - Pregnancy, hyperthyroidism, aplastic anaemia, acute leukaemia, cirrhosis of liver.

Decreased - Wilson's disease.

Gammaglobulins (Immunoglobulins)

Immunoglobulin	Serum conc. mg/100 mL
IgG	800-1500
IgA	150-300
IgM	50-200
IgD	0-40
IgE	17-450 ng/mL

Hypergammaglobulinaemia -

- a. *Diffuse 'broad band' type* - Chronic infection, cirrhosis of liver, collagen vascular disease, ulcerative colitis, Crohn's disease Hashimoto's thyroiditis.
- b. *Narrow 'M band' type* - Multiple myeloma, Waldenström's macroglobulinaemia, 'benign' especially in old age. Leukaemia, Hodgkin's disease, carcinoma.

Hypogammaglobulinaemia -

- a. *Primary* - Physiological in infancy, idiopathic, acquired, congenital sex-linked, alymphocytic, primary lymphopenic, associated with thymoma.
- b. *Secondary* - (i) Protein deficiency - Malnutrition, malabsorption, nephrotic syndrome, protein-losing enteropathy, exfoliative dermatitis. (ii) Defective synthesis - Multiple myeloma, lymphoreticular disease, irradiation, cytotoxic drugs.

Fibrinogen - 0.2-0.4 g/100 ml (5.9-11.7 μ mol/L).

Elevated - Glomerulonephritis, nephrosis (occasionally), and infectious disease.

Decreased - Accidents of pregnancy (placental ablation, amniotic fluid embolism, violent labour), acute and chronic hepatic insufficiency, congenital fibrinogenopenia, and occasionally with prostatic carcinoma.

C-reactive protein - (CRP) - Normal 0-20 g/mL It is an acute phase protein in acute rheumatic fever (unaffected by cardiac failure or anaemia) and most connective tissue diseases but in SLE there is a slight rise in CRP with

disease activity. CRP levels rise normally with infection in SLE patients and this is useful in distinguishing disease activity from infection.

Plasma viscosity - Normal 1.50-1.72 centipoises.

Enzymes -

Alkaline phosphatase - Normal 5-13 KA or 2-5 Bodansky units per 100 mL

Increased - (i) Osteoblastic bone disease, e.g. osteitis fibrosa cystica, Paget's disease, osteogenesis imperfecta, severe osteomalacia, osteogenic sarcoma, metastatic carcinoma of bones. (ii) Hepatic duct or cholangiolar obstruction due to stone, stricture or neoplasm. Hepatic disease resulting from drugs such as chlorpromazine, methyltestosterone. (iii) Myeloid leukaemia. (iv) Hyperparathyroidism. (v) Hyperpituitarism. (vi) Physiological - pregnancy, alimentary hyperglycemia, ultra-violet light exposures, administration of irradiated ergosterol.

Decreased - Hypothyroidism, growth retardation in children.

Acid phosphatase - 0.5-2 units.

Increased - in carcinoma of prostate particularly with bone metastasis.

Amylase - 70-300 IU/L or 80-200 Somogyi units/100 mL

High level

Acute pancreatitis	Perforated peptic ulcer
Carcinoma pancreas	Ruptured ectopic
Mumps	Dissecting aortic aneurysm
Salpingitis	Acute renal failure
Hepatic disease	

Low level

Hepatitis	Pancreatic insufficiency
(Necrotizing)	Severe burns with liver damage
Toxaemia of pregnancy	

Lipase - 0-1.5 units.

Increased - Acute pancreatitis, carcinoma of pancreas, cholelithiasis with jaundice, cirrhosis or carcinoma of liver, intestinal obstruction, duodenal ulcer.

Transaminase enzymes - Glutamic oxalacetic transaminase (SGOT) 5-40 units. Glutamic pyruvic transaminase (SGPT) 5-35 units.

Elevated - (i) Hepatic disease - Hepatitis, cirrhosis of liver, hepatic congestion, metastatic carcinoma. (ii) Cardiac disease - Myocardial infarction. (iii) Miscellaneous - Skeletal muscle disease, haemolysis, acute pancreatitis, renal or cerebral necrosis, shock, pulmonary infarction, dermatomyositis, progressive muscular dystrophy, delirium tremens.

Creatinine phosphokinase (CPK) - 0-12 Sigma units/mL.

Elevated - In presence of muscle damage, e.g. myocardial infarction, trauma to muscle, progressive muscular dystrophy, polymyositis, and severe muscular exertion, delirium tremens, Endocrine causes - hypothyroidism, diabetic nephrotic syndrome. Penicillamine, Dermatomyositis/polymyositis.

Lactic dehydrogenase (LDH) - Normal - 150-450 units/mL.

Elevated - All conditions accompanied by tissue necrosis, particularly those involving acute injury of the heart, red cells, kidney, skeletal muscle, liver, lung and skin. Marked elevations accompany hemolytic anaemias, and the anaemias of vitamin B₁₂ and folate deficiency, and polycythemia rubra vera. Although elevated in acute phase of infectious hepatitis, enzyme activity is seldom increased in chronic liver disease.

Serum aldolase - Normal 0-11 milliunits/ml (I.U.).

Elevated - Skeletal muscle disease, carcinomatosis, myeloid leukaemia, megaloblastic anaemia, hepatitis.

Serum myoglobin - Normal 6-85 pg/mL

Elevated - early in acute myocardial infarction.

Calcitonin - Normal less than 5 ng/mL

Elevated - Medullary carcinoma of thyroid, some patients with hyperparathyroidism.

Brain natriuretic peptide - normal up to 80 pg/mL
Decreased in myocardial depression.

Arterial blood analysis

Analysis	Range
Bicarbonate	21-27.5 nmol/l
Hydrogen ion	36-44 nmol/l
PaO ₂	12-15 kPa
PaCO ₂	4.4-6.1 kPa
O ₂ saturation	97% normally

25. RADIOLOGY

Chest Radiographs

Cardiovascular

Enlarged cardiac silhouette on chest radiograph

- Chamber enlargement including:
 - Bradycardia
 - Athletes

- Pericardial effusion

- Spurious

- Technical (rotated chest radiographs)
- High diaphragm
- Cardiac fat pads
- Skeletal deformity (depressed sternum, scoliosis)
- Racial (Afro-Carribeans)

Enlarged left atrium (Double right heart borders)

- Mitral stenosis.
- Mitral regurgitation
- Congestive cardiomyopathy.
- Ischemic heart disease.
- Shunts (excluding ASD).
- Left atrial myxoma.

Enlarged right atrium

- Volume overload* - ASD, TR, AV canal, APVD
- Pressure overload* - TS, RA myxoma
- Secondary to RV failure*

Enlarged left ventricle

- Volume overload* - MR, VSD, PDA, ASD with shunt reversal.
- Pressure overload* - MS, LA myxoma.
- Secondary to LV failure.*

Enlarged right ventricle

- Pulmonary hypertension.*
- Pressure overload* - PS.
- Volume overload* - ASD, VSD.
- Secondary to LV failure or mitral valve disease.*

Prominent main pulmonary artery

- Increased pressure:* Pulmonary arterial hypertension.
- Increased flow:* Shunts.
- Turbulence:* Pulmonary valve stenosis.
- Increased compliance:* Mycotic aneurysm (rare)
- Spurious:* Displaced by large aortic root, mediastinal mass, corrected transposition, projectional (lordotic/rotated).

Enlarged pulmonary arteries

Both central and peripheral vessels -

- Left-to-right shunt (> 3:1).
- Hyperdynamic circulation.

Only central vessels -

- Vasoconstriction of peripheral vessels -
 - COPD.

- b. Secondary to venous hypertension, e.g. MS.
- c. Secondary to left-to-right shunts.
- 2. Obliteration of peripheral arteries –
 - a. Pulmonary embolism.
 - b. Secondary to left-to-right shunts.
 - c. Tumour emboli.
 - d. Schistosomiasis.
 - e. Primary pulmonary hypertension.
 - f. Vasculitides, e.g. polyarteritis nodosa.

Pulmonary plethora

(Generalized increase in pulmonary vessel size – both arteries and veins)

1. Left to right shunts.
2. Venous-arterial mixing lesions: TAPVD, truncus arteriosus.
3. Cor pulmonale (mildly plethoric).

Globular (massive) cardiomegaly

1. Congestive heart failure.
2. Congestive cardiomyopathy.
3. Pericardial effusion.
4. Multiple valvular defects.
5. ASD with Eisenmenger's syndrome
6. Ebstein's anomaly

Cardiovascular calcification

Pericardium – Infective especially TB pericarditis.

Myocardium – Myocardial infarct, rheumatic heart disease (LA), mitral annular calcification.

Endocardium – Jet lesions.

Within chamber – Thrombus, myxoma.

Valve – Rheumatic heart disease, bicuspid-senile aortic valve, aortic homograft.

Coronary artery – Atheroma.

Pulmonary artery – Pulmonary arterial hypertension.

Aorta – Atheroma, aortitis.

Right sided aortic arch

1. Fallot's tetralogy.
2. Truncus arteriosus.
3. Pulmonary atresia with VSD.
4. Transposition of great vessels.
5. Tricuspid atresia – Rare.
6. Uncomplicated VSD – Rare.

Large aortic arch

1. Unfolding of aorta from atherosclerosis

2. AR: Prominent ascending aorta
3. Hypertension
4. AS: Post-stenotic dilatation
5. PDA

Pulmonary oedema with no increase in heart size –

1. Mitral stenosis.
2. Constrictive pericarditis.
3. Constrictive cardiomyopathy.
4. Blocked lung lymphatics, e.g. pneumoconiosis, silicosis.
5. Viral pneumonias.
6. Inhalation of toxic fumes.
7. Head injury or cerebrovascular accident.
8. Drowning.

Respiratory tract

Air bronchogram – When the normally aerated pulmonary parenchyma is replaced by non-aerated tissue, the bronchi and bronchioles become visible as branching, linear lucencies – the air bronchogram.

Causes of an air bronchogram

1. Pneumonia – infective, eosinophilic
2. Pulmonary oedema
3. Hemorrhage – traumatic/contusion, infarction, diffuse pulmonary hemorrhage
4. Radiation pneumonitis
5. Non-obstructive pulmonary collapse – Compressive atelectasis (e.g. pleural effusion), bronchiectatic collapse
6. Bronchoalveolar cell carcinoma
7. Lymphoma
8. Sarcoidosis
9. Cryptogenic organizing pneumonia
10. Alveolar proteinosis

Infiltrates

Upper zone infiltrates

1. TB, aspergillosis, Klebsiella pneumonia
2. Silicosis
3. Ankylosing spondylitis
4. Histiocytosis X
5. Radiation fibrosis
6. Hypersensitive pneumonitis (long-standing)

Lower zone infiltrates

1. Idiopathic pulmonary fibrosis.
2. Pulmonary fibrosis due to connective tissue disease.
3. Bronchiectasis.
4. Asbestosis.
5. Aspiration.
6. Cytotoxic-induced lung disease.
7. Pulmonary haemosiderosis.
8. Hypersensitivity pneumonitis.

Lung Consolidation

1. *Transudate (oedema)*
 - Cardiogenic, nephrogenic, neurogenic fat embolus
 - Inhalation of toxic or irritant gases, ARDS
 - Drug-induced
2. *Exudate*
 - Infective pneumonia
 - Eosinophilic lung disease (allergic aspergillosis, cryptogenic eosinophilic pneumonia)
 - Radiation damage
 - Connective tissue disorder
3. *Blood*
 - Contusion
 - Infarction
 - Diffuse pulmonary hemorrhage
4. *Alveolar cell carcinoma*
 - Neoplasm
 - Lymphoma
5. *Miscellaneous*
 - Alveolar proteinosis
 - Sarcoidosis
 - Fibrosing alveolitis

Honeycomb lung (Air-containing cysts)

1. Extrinsic allergic alveolitis.
2. Cystic bronchiectasis.
3. Collagen disorders - RA, scleroderma.
4. Pneumoconiosis (esp. asbestosis).
5. Cystic fibrosis.
6. Sarcoidosis.
7. Drugs - Busulphan, cyclophosphamide, bleomycin, melphalan, nitrofurantoin.
8. Histiocytosis X.
9. Tuberous sclerosis.

10. Neurofibromatosis.
11. Cryptogenic fibrosing alveolitis.
12. Lymphangitic carcinomatosis.

Lung Cavities

1. *Infection* - Tuberculosis. *Staph. aureus*, *Klebsiella pneumoniae*. Aspiration. Actinomycosis. Histoplasmosis. Aspergillosis. Hydatid. Amoebiasis.
2. *Neoplastic* - Ca bronchus, metastases, Hodgkin's disease.
3. *Infarction* - more common in lower lobes.
4. *Lung abnormality* - Cystic bronchiectasis, infection of emphysematous bulla, bronchogenic cyst, sequestered lung.
5. *Granulomas* - Rheumatoid nodules, Wegener's progressive massive fibrosis.
6. *Traumatic* - Hematoma, traumatic lung cyst.

Intracavitary Bodies

1. Mycetoma.
2. Hydatid (complicated).
3. Blood (laceration, tuberculosis, infarct).
4. Infection (abscess, necrotizing pneumonia).
5. Necrotic neoplasm (especially squamous).

Non-caseating Granulomas in Lung

1. Sarcoidosis
2. Brucellosis
3. Extrinsic allergic alveolitis
4. Chronic beryllium disease
5. Reaction to foreign body, e.g. IV drug abuse
6. Wegener's granulomatosis
7. Churg-Strauss syndrome
8. Lymphoid granulomatosis
9. Langerhans cell histiocytosis

Multiple Pulmonary Calcification

1. Infections - TB, chickenpox, pneumonia in childhood, histoplasmosis, coccidioidomycosis.
2. Mitral stenosis.
3. Silicosis, Caplan's syndrome.
4. Occupational lung disease.
5. Metastases.
6. Alveolar microlithiasis.
7. Hyperparathyroidism.
8. Hypervitaminosis D.

Hilar Enlargement

Unilateral -

1. Lymph nodes - (a) Infections - Tuberculosis (primary), pertussis, mycoplasma, histoplasmosis, coccidioidomycosis. (b) Lymphoma. (c) Ca bronchus. (d) Sarcoidosis.
2. Pulmonary artery - Post-stenotic dilatation (on left side), aneurysm, pulmonary embolism.
3. Mediastinal mass at hilum.
4. Pneumonia (Perihilar).

Bilateral -

Infection	Tuberculosis Histoplasmosis Infective mononucleosis Toxoplasmosis Mycoplasma, viral including HIV Chlamydial
Neoplasms / Infiltration	Lymphoma Leukaemia Metastasis Amyloidosis Histiocytosis Lymphomatoid lung disease
Inhalation	Silicosis Chronic beryllium disease Extrinsic allergic alveolitis
Obscure	Sarcoidosis

Bilateral Hilar Lymphadenopathy and Diffuse Pulmonary Shadowing or Infiltrates

- | | |
|----------------------------------|--------------------------------|
| • Tuberculosis | • Pulmonary eosinophilia |
| • Sarcoidosis | • Bacterial or viral infection |
| • Lymphoma | • Drug reactions |
| • Carcinoma | • Histiocytosis X |
| • Berylliosis | • Pneumoconiosis |
| • Histoplasmosis | • Pulmonary hemorrhage |
| • Coccidioidomycosis | |
| • Extrinsic allergic alveolitis. | |

Miliary Calcification

1. Tuberculosis
2. Chickenpox
3. Histoplasmosis

Hilar Calcification

1. Tuberculosis.
2. Silicosis.
3. Sarcoidosis ("egg-shell" appearance).
4. Lymph node irradiation.
5. Histoplasmosis
6. Coal miner's pneumoconiosis.

Consolidation with Bulging of Adjacent Fissures

1. Abscess
2. Klebsiella pneumonia
3. Bronchogenic carcinoma

Unilateral transradiancy of hemithorax

Chest wall

- Mastectomy
- Absence of pectoralis major
- Poliomyelitis
- Poland's syndrome

Pleura

- Pneumothorax

Lung

- Emphysema
- Bullae
- Macleod's syndrome
- Compensatory hyperinflation - Post-lobectomy, lobar collapse
- Post-obstructive - has a vasoconstrictive component
- Pulmonary embolus

Bilateral transradiancy of hemithorax

A. *Overexpanded lungs* -

1. Chronic obstructive pulmonary disease.
2. Acute bronchiolitis.
3. Stenoses - Tracheal, laryngeal or bilateral bronchial.

B. *Normal or small lungs* -

1. Congenital heart disease with oligemic lung fields including pulmonary artery stenosis.
2. Multiple pulmonary embolism.
3. Primary pulmonary hypertension.
4. Metastatic trophoblastic tumour.

Increased Density of Hemithorax

- #### A. *No shift of mediastinum* -
1. Massive consolidation.

2. Pleural effusion (in supine position).
3. Mesothelioma.

B. Mediastinal shift away from side of lesion –

1. Massive pleural effusion.
2. Diaphragmatic hernia.

C. Mediastinal shift towards side of lesion –

1. Massive collapse.
2. Pneumonectomy.
3. Lymphangitic carcinomatosis.
4. Pulmonary agenesis and hypoplasia.

Alveolar Opacities (Widespread)

1. Pulmonary oedema.
2. Pneumonia – TB, histoplasmosis, chickenpox, influenza, other viral pneumonias, pneumocystis carinii.
3. Haemorrhage – Trauma, anticoagulants, haemophilia, leukaemia, DIC.
4. Fat emboli.
5. Alveolar cell carcinoma.
6. Metastases (haematogenous).
7. Lymphoma (usually with adenopathy).
8. Sarcoidosis.
9. Loeffler's (Reversed bat's wing).

Nodules

Large nodules (more than 3 cm) –

1. *Neoplasm* –
 - Bronchial carcinoma
 - Metastasis
 - Lymphoma
 - Benign neoplasm (hamartoma).
2. *Granuloma* –
 - Tuberculous, fungal
 - Rheumatoid disease
 - Wegener's granulomatosis.
3. *Abscess* –
 - Pyogenic.
 - Hydatid disease.
4. *Congenital* –
 - Sequestered segment.
 - Bronchogenic cyst.
 - A-V malformation.
5. *Others* –
 - Hematoma
 - Infarct
 - Progressive massive fibrosis
 - Amyloidosis.

Medium-sized nodules (5–10 mm) –

1. Metastases.
2. Sarcoidosis.
3. Tuberculosis (bronchogenic spread).
4. Fungal infections.
5. Chickenpox pneumonia.
6. Abscesses.
7. A-V malformations.
8. Histiocytosis X.
9. Long-standing mitral valve disease (calcific nodules).

Miliary nodules (1–2 mm) –

1. *Soft tissue density* –
 - Miliary tuberculosis.
 - Sarcoidosis.
 - Coal workers' pneumoconiosis.
 - Fungal infections.
 - Extrinsic allergic alveolitis.
 - Haemosiderosis.
 - Oedema.
 - Metastases (uncommon).
2. *Calcific metallic density* –
 - Alveolar microlithiasis.
 - Siderosis.
 - Stannosis.

Solitary pulmonary nodule (coin lesion)

Malignant tumors

- Bronchogenic carcinoma
- Carcinoid
- Pulmonary lymphoma
- Plasmocytoma
- Pulmonary sarcoma
- Solitary metastasis (colon, breast, kidney, head and neck, germ cell, sarcoma, thyroid)
- Melanoma

Benign tumors

- Hamartoma
- Adenoma
- Lipoma

Infectious granulomas

- Tuberculosis
- Histoplasmosis
- Coccidioidomycosis

- Mycetoma
- Ascaris
- Echinococcal cyst
- Dirofilariasis

Noninfectious granulomas

- Rheumatoid arthritis
- Wegener's granulomatosis
- Sarcoidosis
- Paraffinomas

Miscellaneous

- Abscess
- Silicosis
- Fibrosis/scar
- Haematoma
- Pseudotumour
- Spherical pneumonia
- Pulmonary infarction
- A-V malformation
- Bronchogenic cyst
- Amyloidoma

Miliary Pattern

Opacities with soft tissue density

- Miliary tuberculosis
- Fungal infection: Histoplasmosis, blastomycosis, coccidioidomycosis, farmer's lung.
- Coal miner's pneumoconiosis
- Acute extrinsic allergic alveolitis
- Varicella pneumonia
- Hyaline membrane disease in infants

Opacities with greater than soft tissue density

- Pulmonary haemosiderosis (from MS)
- Silicosis
- Siderosis
- Berylliosis

Discrete opacities

- Miliary carcinomatosis (from thyroid, melanoma). Enlarged lymph nodes
- Lymphoma
- Sarcoidosis

Opacities tending to coalesce

- Multifocal pneumonia
- Pulmonary oedema

- Extrinsic allergic alveolitis
- Fat emboli

High density opacities

- Post-lymphography
- Baritosis
- Stannosis

Other opacities

- Bronchiolitis obliterans
- Alveolar microlithiasis
- Wegener's granulomatosis

Multiple rounded pulmonary nodules

1. Pulmonary abscesses
2. Hydatid disease
3. Metastases
4. Coccidioidomycosis
5. Histoplasmosis
6. A-V malformations
7. Progressive massive fibrosis
8. Rheumatoid nodules
9. Caplan's syndrome
10. Wegener's granulomatosis

Pulmonary Cysts

1. Bleb/bulla
2. Bronchogenic cyst*
3. Hydatid cyst
4. Bronchiectasis
5. Laceration
6. Pneumatocoele

*Only when complicated by airway communication.

Unilateral Pulmonary Oedema

A. *On same side as abnormality* -

1. Prolonged lateral decubitus.
2. Rapid aspiration of fluid or air.
3. Lung contusion.
4. Unilateral aspiration.
5. Bronchial obstruction.
6. Shunts (systemic to pulmonary artery).

B. *On opposite side of abnormality* -

1. Congenital hypoplasia of pulmonary artery.
2. Thromboembolism.
3. Unilateral emphysema.
4. Lobectomy.
5. Macleod's syndrome.

Septal Lines

1. Increased pulmonary venous pressure (Kerley's lines).
2. Lymphangitis carcinomatosa.
3. Lymphatic obstruction (hilar/mediastinal).
4. Diffuse fibrosis (pneumoconiosis, sarcoidosis).
5. Pneumonia (e.g. mycoplasma).
6. Pulmonary haemosiderosis.

Kerley's (septal) lines are caused by oedema of interlobular septae.

Kerley's A lines are seen in the upper zone (**Apex**) and also mid zone. They lie away from the pleural surfaces and point to the hila.

Kerley's B lines are more common than Kerley's A lines and occur most commonly in the **Base** region (costophrenic angle). They are straight, short, (1-2 cm) horizontal lines that touch the parietal pleura. Septal B lines can be distinguished from vessels because:

- They do not branch
- They touch the pleura
- They are dense for their width

Kerley's C lines are seen usually near the **Centre** (mid zone) as fine interlacing lines which produce a 'spider web' appearance.

Unilateral Elevation of Hemidiaphragm

A. *Causes above the diaphragm* -

1. Scoliosis
2. Thoracic: Painful pleuritis, atelectasis, pulmonary embolus, rib fracture.
3. Diaphragmatic: Phrenic n palsy, eventration, hernia.
4. Abdominal: Mass, subphrenic infection, surgery.
5. False: Subpulmonic effusion, chest mass.

B. *Diaphragmatic causes* - Eventration, hernia.

C. *Causes below the diaphragm* -

1. Amoebic hepatitis or abscess, subphrenic abscess, splenic abscess and pancreatitis.
2. Distended stomach or splenic flexure (left side).

D. *General causes* - Scoliosis, supine film.

Bilateral Elevation of Diaphragm

A. *Causes above the diaphragm* -

1. Bilateral basal lung collapse.
2. Fibrosis of lung with reduction in lung size.

B. *Causes below the diaphragm* -

1. Ascites.

2. Pregnancy.
3. Hepatosplenomegaly.
4. Large abdominal mass.
5. Pneumoperitoneum.
6. Bilateral subphrenic abscesses.

Bronchial Wall Thickening

1. Recurrent asthma/bronchitis (particularly children).
2. Bronchiectasis.
3. Cystic fibrosis.
4. Allergic aspergillosis.
5. Lymphangitis carcinomatosa.

Bilateral Basal Interstitial Opacities

1. Cryptogenic fibrosing alveolitis.
2. Fibrosing alveolitis: Systemic sclerosis, rheumatoid disease.
3. Asbestosis.
4. Drug-induced alveolitis (including nitrofurantoin).

Predominantly Upper Zone Fibrosis

(Linear and/or interstitial opacity)

1. Tuberculosis
2. Extrinsic allergic alveolitis
3. Silicosis
4. Sarcoidosis
5. Histiocytosis X
6. Ankylosing spondylitis
7. Allergic bronchopulmonary aspergillosis
8. Cystic fibrosis
9. Radiation fibrosis
10. Histoplasmosis, coccidioidomycosis.

Mediastinal Masses

I. *Anterior mediastinum* -

Upper region -

- Retrosternal goitre.
- Thymic mass.
- Aneurysm of ascending aorta.
- Tortuous innominate artery.

Mid region -

- Teratoderms.
- Thymic mass.
- Sternal tumours - Primary or metastatic.

Lower region -

- Pericardial cyst.

- Pericardial fat pad.
- Localized eventration of diaphragm.
- Morgagni hernia.

II. *Middle mediastinum* -

- Aortic aneurysm
- Hilar nodes.
- Bronchogenic cyst.
- Aneurysm of aorta.
- Ca bronchus.

III. *Posterior mediastinum* -

Paravertebral region

- Neurogenic tumors
- Anterior thoracic meningocoele
- Abscesses, metastases, extramedullary haemopoiesis

Superior region

- Aneurysm of descending thoracic aorta
- Dilated oesophagus
- Neurenteric cyst

Inferior region

- Diaphragmatic hernia
- Hiatus hernia

Calcification of Chest

1. *Trachea-bronchi* - Senile.
2. *Pulmonary* - (a) Congenital - (i) Dermoid. (ii) Hamartoma, A-V aneurysm. (iii) Microlithiasis alveolaris pulmonale (familial). (b) Infections - (i) Tuberculosis. (ii) Histoplasmosis. (iii) Parasitic: Guinea worm, cysticercus. (c) Inhalation: Silicosis, asbestosis. (d) Neoplastic - (i) Primary: Bronchial Ca arising near or in TB focus. (ii) Secondary: Osteogenic sarcoma. (e) Broncholiths.
3. *Pleural* - Plaques following empyema, T.B., haemothorax, asbestosis, hyperparathyroidism, metastatic calcification.
4. *Mediastinal* - (a) Lymph glands - TB, sarcoid, pneumoconiosis. (b) Tumours - Thyroid adenoma, aneurysm, teratodermoid cyst.
5. *Cardiac* - Aortic arch, pericardium, valves or valve rings, thrombi, left atrium in MS, coronary arteries, patent ductus.
6. *Chest wall* - (a) Costal cartilage. (b) Healing rib fractures. (c) Tuberculous glands. (d) Osteomas and chondromas. (e) Soft tissue calcification - (i) Parasitic: cysticercosis, guinea worm, armillifer armillatus. (ii) Myositis ossificans. (iii) Breast tumours. (f) Inter-costal arterial calcification (in renal osteodystrophy).

Oesophagus, Stomach, Abdomen

Diffuse Oesophageal Spasm

1. Atypical achalasia.
2. Gastro-oesophageal reflux.
3. Intermediate motor disorders.
4. Symptomatic oesophageal peristalsis.
5. Obstruction at the cardia.
6. Neuromuscular disorders (e.g. diabetes, motor neuron disease).

Malignant Stricture of Oesophagus

1. Short segment stricture with mucosal destruction.
2. 'Shouldering', the hallmark of malignancy in a tubular structure.
3. 'Apple-core' appearance as a result of 1 and 2.
4. No proximal dilatation.
5. Tracheo-bronchial opacification common (due to tracheo-oesophageal fistula, or regurgitation of contrast medium).

Giant Gastric Rugae

1. Malignancy, e.g. lymphoma, leiomyoma.
2. Gastrinoma.
3. Menetrier's disease (hyperproteinaemic hypertrophic gastropathy).

Jejunal Ulcers

1. Ulcerative jejunitis (malignant histiocytosis).
2. Coeliac disease, Crohn's disease.
3. Gastrinoma.
4. Meckel's diverticulitis.
5. Mesenteric ischemia, polyarteritis.
6. Lymphoma.
7. Infection - Typhoid, bacillary dysentery, TB, fungal, actinomycosis, syphilis.
8. Iatrogenic - Digoxin, potassium tablets.

Calcification (Radio-opacities) on an Abdominal X-ray

1. Faecoliths.
2. Phleboliths.
3. Calcified lymph nodes.
4. Calculi - Renal, biliary, prostatic.
5. Liver - Calcified hydatid, tuberculous, amoebic abscess, gumma, histoplasmosis, haemangioma, hepatoma, brucellosis.

6. Renal (urogenital) – Radio-opaque stone, renal tubular acidosis, secondary to hypercalcaemia, cortical necrosis, sponge kidney, tuberculosis, calcification in hypernephroma and polycystic kidneys. Prostatic calculi. Calcification of bladder tumours. Bilharziasis.
7. Spleen – Splenic stones, calcified cyst of spleen.
8. Pancreas – Chronic pancreatitis.
9. Suprarenal – Addison's disease, neuroblastoma or carcinoma.
10. Calcified aorta.
11. Calcified tumour – Dermoid, fibroid.
12. Foetus.
13. Calcification in abdominal wall – e.g. cysticerci.
14. Calcified tablets.
15. Calcified fibroid

Dilated Bowels

Mechanical obstruction of small bowel

Obstruction of large bowel

- Paralytic ileus
- Local peritonitis
- Small bowel infarction
- Toxic dilatation of colon (e.g. Crohn's disease)
- Gastroenteritis

Gas Outside Bowel Lumen

Gas under diaphragm

- Perforation of hollow viscus
- Laparotomy
- Miscellaneous: Pneumothorax, pneumomediastinum

Free Gas in Peritoneum

Gas in peritoneal cavity

- Perforation of GI tract (e.g. perforation of peptic ulcer)
- Laparotomy
- Colonic perforation

Signs

- Double wall sign of Rigler
- Umbilical ligament sign (Inverted V sign)
- Falciform ligament sign
- Urachus sign
- Triangle sign (gas trapped between three loops of intestine)
- Morrison's pouch sign over right. kidney
- Scrotal air sign (in head low position)
- Football sign (air rising to the abdomen, best seen in children).

Gas in Wall of Bowel

- Pneumatosis coli (bubbles of gas)
- Infarction of bowel (linear streaks)
- Necrotizing enterocolitis

Hepatic Calcification

1. Amoebic abscess.
2. Tuberculosis.
3. Hepatoma.
4. Hydatid cysts.
5. Brucellosis.
6. Gumma.
7. Haemangioma.
8. Histoplasmosis.
9. Intrahepatic biliary calculi.

Pancreatic Calcification

1. Alcoholic pancreatitis.
2. Hyperparathyroidism.
3. Pancreatic pseudocyst.
4. Cystic fibrosis.
5. Kwashiorkor.
6. Hereditary pancreatitis.
7. Neoplasms – Cystadenoma and cystadenocarcinoma.
8. Chronic tropical calculous pancreatitis
9. Idiopathic.

Acute Pancreatitis

Plain abdominal radiograph

- Gasless abdomen: Very few gas shadows seen
- Localized ileus in region of maximum inflammation
- Colon cut-off sign: Abrupt cut-off of gas shadow of transverse colon near the flexure
- Left sided pleural effusion may occur
- Obliteration of pro-peritoneal fat line may be seen
- Pancreatic calcification in presence of above signs would suggest acute-on-chronic pancreatitis.

Urinary Tract

Small Kidneys

Unilateral:

1. *Scarred kidney* –
 - Chronic pyelonephritis/Reflux nephropathy.
 - Tuberculosis.
 - Infarction (Lobar).
 - Renal dysplasia.

2. *Smooth kidney* –
 - Post-obstructive atrophy.
 - Ischemia (Renal artery stenosis).
 - Following renal infarction.
 - Radiation nephritis.
 - Congenital hypoplasia.

Bilateral (Small smooth kidneys):

1. Chronic glomerulonephritis.
2. Chronic papillary necrosis.
3. Hypertension.
4. Obstructive uropathy.
5. Renal artery stenosis.
6. Arteriosclerosis.

Large Kidneys

Unilateral:

1. Compensatory hypertrophy.
2. Obstructed kidney.
3. Pyonephrosis.
4. Tumour.
5. Polycystic kidney.
6. Acute pyelonephritis.
7. Hematoma.
8. Renal vein thrombosis.
9. Acute infarction.
10. Duplex kidney.

Bilateral:

1. *Proliferative and necrotizing disorders* – Acute glomerulonephritis, PAN, Goodpasture's syndrome, Wegener's granulomatosis, SLE.
2. *Abnormal protein infiltration* – Amyloid, multiple myeloma.
3. *Fluid accumulation* – Acute tubular or cortical necrosis.
4. *Infiltration* – (a) Neoplastic – Lymphoma, leukaemia. (b) Inflammatory – Acute interstitial nephritis.
5. *Miscellaneous* – Renal vein thrombosis, polycystic kidneys, acute papillary necrosis, bilateral hydronephrosis, sickle cell anaemia, medullary sponge kidneys. Gigantism and acromegaly.
6. *Diabetes mellitus*

Solid Renal Masses

1. Renal cell carcinoma.
2. Metastatic deposits.

3. Transitional cell carcinoma.
4. Haematoma.
5. Unusual masses – Tuberculoma, lymphoma, focal xanthogranulomatous pyelonephritis, angio-myolipoma, juxtaglomerular tumour, sarcoma.

Renal Calcification

1. Renal stones.
2. Due to localized disease – (a) Infections – Tuberculosis, abscess, hydatid. (b) Carcinoma. (c) Renal artery aneurysm.
3. Nephrocalcinosis –
 - a. *Medullary* – Hyperparathyroidism, renal tubular acidosis, medullary sponge kidney, renal papillary necrosis, hypercalcaemia or hypercalciuria, oxalosis.
 - b. *Cortical* – Acute cortical necrosis, chronic transplant rejection, chronic glomerulonephritis (rare).

Skull and Bone Radiographs

Punched-out Translucencies in Skull

Physiological –

1. Arachnoid granulations (parasagittal)
2. Emissary parietal foramina
3. Parietal fenestrae
4. Increased convolutional markings.

Pathological –

1. Myelomatosis.
2. Hyperparathyroidism.
3. Metastatic deposits from thyroid, bronchus, breast or kidney.
4. Leukaemias.
5. Sickle-cell anaemia.
6. Cushing's syndrome
7. Histiocytosis.

Increased Density of Skull Vault

Localized

- Sclerotic metastases
- Paget's disease
- Osteoma
- Hyperostosis
- Fibrous dysplasia

Generalized

- Sclerotic metastases
- Paget's disease

- Acromegaly
- Osteopetrosis
- Myelosclerosis

'Hair-on-end' Skull Vault

1. *Hemolytic anaemias* -
 - Thalassemia
 - Sickle-cell anaemia
 - Spherocytosis
 - Elliptocytosis
2. *Neoplasms* - Haemangioma, meningioma, plasmocytoma, metastases of neuroblastoma, rarely osteosarcoma.
3. *Miscellaneous* - Cyanotic heart disease, severe iron deficiency anaemia in childhood. Hereditary spherocytosis, elliptocytosis, pyruvate kinase deficiency.

Enlarged Pituitary Fossa

1. Intrasellar or parasellar tumour -Pituitary adenoma, craniopharyngioma, prolactinoma, meningioma, aneurysm.
2. Raised intracranial pressure.
3. Empty sella syndrome - Defect or distortion of diaphragma sellae.
4. Nelson's syndrome:

Empty Sella Syndrome

- A. *Primary*
 1. Congenital absence of diaphragmatic sella
 2. Herniation of subarachnoid space into sella
 3. Involution of pituitary (a) Physiological after pregnancy and after menopause. (b) Pathological in Sheehan's syndrome or infarction of pituitary in vasculitis, diabetes, head injury, meningitis.
 4. Rupture of suprasellar or parasellar cyst.
- B. *Secondary*
 1. Pituitary surgery, ablation or radiation.
 2. Ischemia after childbirth.
 3. Head trauma.

Intracranial Calcification

Unifocal -

1. *Familial*
2. *Physiological* - Pineal, choroid plexus.
3. *Pathological* -
 - a. Neoplasms - Glioma, meningioma, craniopharyngioma, chordoma, metastases, pinealoma, lipoma, teratoma, dermoid, etc.

- b. Vascular - Atheroma, aneurysm, A-V malformation, chronic subdural hematoma, healed infarct, Sturge- Weber syndrome.
- c. Infections - Tuberculoma, abscess.
- d. Extracerebral - Foreign body, calcified sebaceous cyst, osteoma of calvarium.

Multifocal -

1. *Infections* - Cysticercosis, toxoplasmosis, hydatid, cytomegalovirus rubella, tuberculoma, histoplasmosis, torulosis, etc.
2. *Metabolic* - Hypoparathyroidism, vitamin D intoxication, chronic renal failure, lead or carbon monoxide poisoning.
3. Tuberosus sclerosis.

Calcification of basal ganglia

1. Secondary hypoparathyroidism, pseudo-hypoparathyroidism.
2. Perinatal asphyxia.
3. Cockayne's syndrome
4. Tubosclerosis
5. Familial idiopathic

Bones

Punched-out erosions in extremity bones

1. Gout
2. Rheumatoid arthritis
3. Psoriatic arthritis
4. Osteoarthritis
5. Sarcoid
6. Multiple myeloma
7. Hand-Schüller-Christian disease
8. Hyperparathyroidism
9. Leprosy
10. Miscellaneous - Gaucher's, Albright's (polyostotic fibrous dysplasia), osteitis fibrosa cystica, aneurysmal bone cysts, non-ossifying fibroma.

Periosteal Calcification

1. Subperiosteal haemorrhage.
2. Following a fracture.
3. Bone infection - Tuberculous, pyogenic or syphilitic.
4. Pulmonary osteoarthropathy.
5. Bone neoplasms and secondary deposits.

Generalized Increase in Bone Density

1. Myelosclerosis.
2. Developmental osteopetrosis (Marble bone disease).
3. Renal osteodystrophy.

4. Fluorosis.
5. Secondary deposits.
6. Paget's disease (Commonly multifocal).

Sacroiliitis

1. Ankylosing spondylitis.
2. Other seronegative arthritides - psoriatic, Reiter's, juvenile chronic arthritis.
3. Inflammatory bowel disease.
4. Infection - septic arthritis, TB, brucellosis.
5. Recurrent polyserositis.
6. Ochronosis.

Expansible Bone Lesions

1. **Non-neoplastic** -
(a) Hydatid. (b) Fibrous dysplasia. (c) Hyperparathyroidism (brown tumour). (d) Haemophilic pseudotumour.
2. **Benign neoplasms** -
a. Giant cell tumour.
b. Aneurysmal bone cyst.
c. Endochondroma.
3. **Malignant neoplasms** -
a. Metastases
b. Plasmocytoma
c. Chondrosarcoma
d. Fibrosarcoma

Distal Phalangeal (tuft) Resorption

1. Neuropathic - Leprosy, syringomyelia, diabetes, myelomeningocele
2. Scleroderma
3. Psoriatic arthropathy
4. Thermal injuries
5. Trauma
6. Hyperparathyroidism
7. Epidermolysis bullosa
8. Raynaud's disease

Rib Notching

- A. **Superior surface** -
1. *Connective tissue diseases* -
▪ Rheumatoid arthritis
▪ SLE
▪ Scleroderma
▪ Sjogren's syndrome

2. *Metabolic* - Hyperparathyroidism
3. *Miscellaneous* -
▪ Neurofibromatosis (Ribbon ribs)
▪ Marfan's syndrome
▪ Restrictive lung disease
▪ Poliomyelitis
▪ Osteogenesis imperfecta
▪ Progeria

B. Inferior surface -

1. *Arterial* -
▪ Coarctation of aorta (4th to 8th ribs)
▪ Aortic thrombosis (bilateral notching of lower ribs)
▪ Subclavian obstruction (first 4 ribs)
▪ Pulmonary oligoemia
2. *Venous* - Superior vena cava obstruction.
3. *Arteriovenous* - Pulmonary or chest wall A-V malformation
4. *Neurogenic* - Neurofibromatosis.

Focal Rib Lesion (Solitary or Multiple)

1. **Neoplastic** -
- *Metastases* - (i) Adult male - bronchus, kidney or prostate. (ii) Adult female -breast. (iii) Child - Neuroblastoma.
- *Primary malignant* - Multiple myeloma, plasmocytoma, chondrosarcoma, Ewing's tumour (child).
- *Benign* - Osteochondroma, enchondroma, histiocytosis X.
2. **Non-neoplastic** -
- Healed rib fracture
- Fibrous dysplasia
- Paget's disease
- Brown tumour of hyperparathyroidism
- Osteomyelitis (tuberculous, bacterial or fungal).

Spine Tuberculous Spine

1. Decreased intervertebral disc space
2. Some degree of collapse of diseased vertebra with anterior wedging
3. Paravertebral soft shadow due to paravertebral abscess.

Radiological classification: Types -

- Marginal type - Paradiscal pattern of involvement. Reduction of disc space is early sign. Formation of

paravertebral abscesses seen as soft tissue shadows in relation to affected vertebra – either fusiform (bird's nest' abscess) or globular in case of tense abscess. Ultimately, destruction of the vertebra causes it to collapse resulting in anterior wedging of the vertebra. A gibbus occurs if more than one vertebra is affected.

- Central type: Normal intervertebral disc but presence of central abscess.
- Anterior type: An anterior located abscess is seen which tracks along the anterior longitudinal ligament. Erosions over anterior surface of the vertebral bodies, resembling erosions due to aortic aneurysms (aneurysmal sign). Ribs near the affected vertebrae show lytic lesions.

Erosion of vertebrae: Scalloping of vertebral bodies –

Anterior:

- Tuberculous spondylitis: Erosion of vertebral bodies, decreased intervertebral disc space, and paraspinal soft tissue shadows, which makes the spinal column appear widened.
- Lymphadenopathy: Well defined margins of erosions (except malignant infiltration of vertebrae).
- Aortic aneurysm: Well-defined margins of erosions. Calcification of the aneurysm may be visualized as an arcuate line. Normal disc spaces.

Posterior:

- Spinal tumors: Meningioma, lipoma, dermoids, ependymoma
- Neurofibromatosis: (a) Posterior scalloping due to mesodermal dysplasia and associated ductal ectasia. (b) Localized scalloping due to pressure of neurofibroma. (c) May be associated widening of adjacent intervertebral foramen and flattening of a pedicle
- Achondroplasia: Breaks in anterior aspect of vertebral bodies, and spinal stenosis
- Acromegaly: Associated osteoporosis, calcified discs, spur formation and increase in anteroposterior and transverse diameters of vertebral bodies
- Syringomyelia
- Hydrocephalus (communicating)
- Marfan's syndrome
- Ehlers-Danlos syndrome
- Hurler's syndrome
- Morquio's syndrome.

Neoplasm

Spinal cord and meninges:

1. Erosion of vertebral body or pedicles
2. Enlargement of intervertebral root of foramina
3. Vertebral: Metastases, haemangiomas, aneurysm, bone cysts, multiple myeloma.

Single Collapsed Vertebra

1. Trauma
2. Infection – Tuberculosis
3. Neoplasm – (a) Benign – Giant cell tumour, haemangioma, bone cyst. (b) Malignant – Metastasis, lymphoma, multiple myeloma
4. Osteoporosis
5. Histiocytosis

Multiple Collapsed Vertebrae

1. Osteoporosis.
2. Neoplasms – Metastases, myeloma.
3. Trauma.
4. Infection – Pyogenic or tuberculous.
5. Histiocytosis.
6. Sickle cell anaemia.
7. Scheuermann's disease.

Metabolic Bone Disease

1. Rigger-jersey spine
Renal osteodystrophy
Osteopetrosis.
2. 'Ivory vertebrae'
Paget's disease
Hodgkin's disease
3. 'Codfish' vertebrae
Osteoporosis
Osteomalacia
Sickle-cell disease

Arthritis Mutilans

1. Rheumatoid arthritis
2. Juvenile chronic arthritis
3. Psoriatic arthropathy
4. Neuropathic arthropathy
5. Leprosy
6. Diabetes mellitus
7. Reiter's syndrome

Fluorosis

Milky white appearance of:

- Atlas and axis (lateral view)
- Pelvic bones, lumbar and sacral vertebra and femur
- Calcification of interosseous membrane and milky white appearance of bones of forearm.

Soft Tissue Calcification

Linear and curvilinear -

1. Nerve - Leprosy, neurofibromatosis.
2. Artery - Atherosclerosis, diabetes, hyperparathyroidism.
3. Ligament - Fluorosis, ankylosing spondylitis, tendinitis, alkaptonuria, diabetes.
4. Parasitic - Guinea worm, cysticerci, Loa loa, armillifer.

Conglomerate -

1. Collagen disorders - Scleroderma, dermatomyositis.
2. Metabolic - Hyperparathyroidism, gout (tophi).
3. Traumatic - Haematoma, myositis ossificans.
4. Tuberculous lymph node or abscess.
5. Neoplasm - (a) Benign - Periosteal lipoma, haemangioma. (b) Malignant - Periosteal osteosarcoma, liposarcoma.

Urinary Tract

Calcified Renal Shadows

1. Renal calculi
2. Tuberculous calcification
3. Renal abscesses
4. Hydatid cyst
5. Renal artery aneurysm
6. Nephrocalcinosis
7. Medullary sponge kidney ('bunch of grapes' appearance)
8. Renal tubular acidosis
9. Xanthogranulomatous pyelonephritis
10. Hyperparathyroidism (renal medullary)
11. Carcinoma: Amorphous, curvilinear or irregular calcification
12. Renal papillary necrosis
13. Acute cortical necrosis ('Tramline' calcification in renal cortex)
14. Oxalosis: Diffuse calcification
15. Hypercalcemia or hypercalciuria
16. Chronic glomerulonephritis (rare)
17. Rejection of renal transplant (cortical calcification).

Miscellaneous

CT scan in first 24 hours of stroke

Hemorrhage is seen within a few minutes as an increased attenuation. In middle cerebral infarct there is subtle loss of distinction between grey and white matter.

Ring enhancement lesions on computerized tomography scan

1. Cerebral abscesses
2. Tuberculoma: Ring enhancement seen with contrast media
3. Metastases with contrast media

Ventilator perfusion lung scan

Perfusion scan: Microaggregates of albumin labelled with technetium 99 m injected I.V. These microaggregates get trapped in pulmonary capillaries and their distribution is imaged by a gamma-camera. This reveals pulmonary perfusion.

Ventilation scan: Radioactive gases (Xenon 133 or Krypton 81m or Technetium 99m) are inhaled by the patient. The distribution of this radioactive gas is imaged by a gamma-camera. This indicates pulmonary ventilation.

Hazards of radiation

Skin: Pigmentation of skin due to melanocyte injury. Scarring may occur.

GI tract: Gut obstruction due to fibrosis. Fistula formation and rectal ulceration.

Bone marrow: (a) Mild-dose - Decrease in number of actively dividing cells. Number of erythroblasts exceeds myelocytes and megakaryocytes. (b) Moderate dose: Bone marrow becomes cellular and is replaced by fat. (c) Large dose: Aplastic anemia.

Bone: Necrosis and fractures

Ureters and bladder: Fibrosis of ureters due to damage to ureteric vessels. Fibrosis of bladder with subsequent contraction.

Female genitals: (a) Ovaries - pyknosis and degeneration of ovary and Graffian follicles. Follicular lining cells phagocytise ova. (b) Uterus: Necrosis and perforation.

Radiological features of hemolytic anemia.

Skull: Thickened diploe. 'Hair on end' appearance. Obliteration of paranasal sinus.

Bones: Thin cortex. Thickened and coarse trabeculae. Osteopenia. Widening of diaphysis and metaphysis. Ribs may be enlarged. Phalanges may appear rectangular with flattening of their concavities. H-shaped vertebrae in

sickle cell anemia. Changes due to infarction – Soft tissue swelling. Flattening and sclerosis at ends of humerus and femur. Periosteal reaction and periosteal new bone formation in shafts of long bones with foci of bony destruction.

Gallbladder: Gallstones on USG.

Mammography (radiological examination of the breast)

- Benign lesions: Well circumscribed and homogenous with surrounding fatty tissue.
- Carcinoma: Poorly defined margins with spiculated or irregular outline. Fine, stippled calcification in periductal region and soft tissue diagnostic.

26. SOME DRUGS WITH MULTIPLE INDICATIONS

ACE Inhibitors

1. Hypertension (essential).
2. Renovascular hypertension.
3. Hypertension in scleroderma.
4. Hypertension with diabetic nephropathy.
5. Hypertension with peripheral vascular disease.
6. Hypertension and hyperuricemia.
7. Refractory heart failure.
8. Cardioprotection after acute myocardial infarction.

Acetazolamide

- Altitude insomnia
- Ataxia
- Catamenial epilepsy
- Drug, toxin-induced epilepsy
- Glaucoma
- Hypokalaemic periodic paralysis
- Metabolic acidosis

Acyclovir

- Bell's palsy
- Cytomegalovirus
- E-B virus
- Encephalitis
- Genital herpes
- Herpes simplex
- Herpes zoster
- Meningitis
- Varicella

Aspirin

1. In atherosclerotic stroke
2. In coronary artery disease and myocardial infarction in primary prevention and revascularization procedures and secondary prevention in unstable angina
3. In Dressler syndrome
4. In fever
5. In headache
6. As analgesic
7. In rheumatic fever
8. In thrombocytopenia, reactive
9. In thrombotic thrombocytopenic purpura

Atropine

1. In advanced life support
2. In A-V block
3. In myocardial infarction
4. In overdose and poisoning from
 - β -adrenergic antagonists
 - Anticholinesterases
 - Calcium channel blockers
 - Organophosphates
5. In sinus bradycardia
6. In COPD (as Nebulizer).

Azathioprine

1. Myasthenia gravis
2. Dermatomyositis
3. Polymyositis
4. Wegener's granulomatosis
5. SLE

Benzodiazepines

1. Generalized anxiety disorders: use benzodiazepines for short-term relief and try to switch to non-pharmacological methods wherever long-term treatment is required.
2. Panic disorders and agoraphobia: alprazolam is the drug of choice.
3. Agitated depression: benzodiazepines are added to antidepressants for first 1–2 weeks or alternatively use an antidepressant with antianxiety effect, e.g. amitriptyline, dothiepin and doxepin.
4. Insomnia: benzodiazepines are used when insomnia is interfering with day-to-day routine. Short-term benzodiazepines (Nitrazepam, Flurazepam and Lorazepam) are preferred for short duration.

5. NREM sleep disorders like enuresis and somnambulism (diazepam reduces duration of stage 4 NREM sleep).
6. Nightmares (diazepam also reduces REM sleep duration).
7. Pre-medication in anaesthesia.
8. Anticonvulsant use: diazepam (I.V.) is the drug of choice for status epilepticus and alcoholic seizures.
9. To produce skeletal muscle relaxation in various surgical procedures.
10. Treatment of alcohol withdrawal syndrome.
11. Acute mania: clonazepam along with lithium controls manic symptoms without much side effects.
12. Antipsychotic induced akathisia.

Beta-blockers

1. Angina and secondary prevention of myocardial infarction.
2. Cardiac arrhythmias.
3. Systemic hypertension.
4. Hypertrophic obstructive cardiomyopathy.
5. Fallot's tetralogy.
6. Thyrotoxicosis.
7. Pheochromocytoma.
8. Schizophrenia.
9. Migraine (prophylaxis).
10. Subarachnoid haemorrhage.
11. Anxiety.
12. Essential tremor.
13. Drug and alcohol withdrawal syndromes.
14. Glaucoma.

Bisphosphonates

1. Paget's disease
2. Hypercalcemia
3. Osteoporosis
4. Bone pain
5. Osteogenesis imperfecta
6. Progressive diaphyseal dysplasia
7. Multiple myeloma

Botulism Toxin A

1. Blepharospasm and hemifacial spasms
2. Cervical dystonia
3. Spasmodic torticollis
4. Axillary hyperhidrosis
5. Palmoplantar hyperhidrosis

6. Hyperfunctional facial lines or wrinkles
7. Focal limb dystonia
8. Sialorrhoea
9. Anal fissures
10. Migraine
11. Meigs' syndrome
12. Essential tremor
13. Tardive syndrome
14. Tourette syndrome

Bromocriptine

1. Parkinson's disease.
2. Acromegaly.
3. Hyperprolactinemia – Prolactin secreting pituitary adenoma. Suppression of lactation.
4. Cyclic benign breast disease.
5. Premenstrual syndrome.
6. Neuroleptic malignant syndrome
7. Obesity in diabetes mellitus
8. Prolactin secreting tumors.

Calcium-channel Blockers

1. Angina.
2. Hypertension.
3. Hypertrophic cardiomyopathy.
4. Subarachnoid hemorrhage (Nimodipine).
5. Raynaud's phenomenon.
6. Systemic sclerosis.
7. Pulmonary hypertension.
8. Migraine prophylaxis.

Carbamazepine

1. Epileptic seizures.
2. Trigeminal neuralgia and other neuralgic pains.
3. Mood disorders (manic and depressive episodes).
4. Bipolar disorder
5. Diabetic neuropathy
6. Multiple sclerosis
7. Peripheral neuropathy
8. Sydenham's chorea
9. Stress disorders

Chloroquine

1. Malaria.
2. Hepatic amoebiasis.
3. Rheumatoid arthritis.

4. Lupus erythematosus, discoid and systemic.
5. Clonorchiasis.
6. Lepra reaction.
7. Porphyria

Colchicine

1. Alcoholic liver disease
2. Gout
3. Primary biliary cirrhosis
4. Amyloidosis
5. Familial Mediterranean fever
6. Behcet's syndrome
7. Myelofibrosis

Corticosteroids

1. *Allergic conditions*

Bronchial asthma	Allergic rhinitis
Contact dermatitis	Urticaria
Atopic dermatitis	Angioneurotic
Serum sickness	Oedema
2. *Cardiac disease*
 - Acute rheumatic fever
 - Heart block (1st degree)
3. *Dermatology*

Pemphigus Stevens-Johnson syndrome	Severe seborrhoeic	Pemphigoid dermatitis
		Severe psoriasis
Mycosis fungoides	Bullous	Lichen planus
Herpetiformis	dermatitis	
4. *Endocrine disease*
 - Adrenocortical insufficiency
 - Congenital adrenal hyperplasia
 - Hashimoto's thyroiditis
 - Hypercalcemia of malignancy
5. *Gastrointestinal disease*
 - Inflammatory bowel disease
6. *Haematological disorders*
 - Immune haemolytic anemia, ITP
7. *Neoplastic diseases*
 - Acute lymphoblastic leukaemia
 - Lymphoma
8. *Ophthalmic disease*

Herpes zoster	Optic neuritis
Uveitis	Keratitis
Allergic	
Conjunctivitis	

9. *Respiratory diseases*
 - Sarcoidosis
 - Berylliosis
 - Fulminating tuberculosis
10. *Rheumatological diseases*

RA	Polymyositis
SLE	Psoriatic arthritis

Dapsone

1. Dermatitis herpetiformis
2. Leprosy
3. Pneumocystis jiroveci infection
4. Leishmaniasis
5. Malaria
6. Toxoplasmosis gondii

Diethylcarbamazine

1. Tropical eosinophilia.
2. Filariasis.
3. Loiasis
4. Onchocerciasis
5. Streptocerciasis

Doxorubicin

1. Follicular lymphoma
2. Hepatocellular carcinoma
3. Kaposi's sarcoma
4. Multiple myeloma
5. Salivary gland tumors
6. Thymoma
7. Zollinger-Ellison syndrome

Doxycycline

1. Acne rosacea
2. Acne vulgaris
3. Actinomycosis
4. Anthrax
5. Brucellosis
6. Cat scratch disease
7. Donovanosis
8. Endocarditis
9. Epidemic typhus
10. Gonococcal infection
11. Legionellosis
12. Lyme borreliosis
13. Lymphatic filariasis

14. Malaria
15. Meningitis
16. Onchocerciasis
17. Pneumonia
18. Psittacosis
19. Q fever
20. Rickettsial pox
21. Staphylococcal infection
22. Tularemia
23. Urinary tract infections

Erythropoietin

1. Anemia of kidney failure
2. Anemia of chronic disease, e.g. RA
3. Aplastic anemia (in combination with other human growth factors)
4. Anaemias of cancer (e.g. breast and colonic cancers, multiple myeloma, non-Hodgkin's lymphoma)
5. Myelodysplastic syndrome
6. HIV infection (Anemia due to zidovudine therapy)
7. Autologous blood transfusion (to boost normal erythropoietic response in preoperative settings to increase number of units of blood that can be safely removed and preserved for autologous transfusion in postoperative patients)
8. Other conditions
 - Anemia in premature infants with low EPO production
 - Poor response to iron therapy in nutritional anemia
 - Iron removal by phlebotomy
 - To reduce requirement of RBC transfusion following conditioning regimen during bone marrow transplantation.

Gammaglobulin (Intravenous)

I. Haematology

Immune disorders

- Idiopathic thrombocytopenic purpura
- Post-transfusion purpura
- Neonatal platelet alloimmunization
- Neonatal thrombocytopenia following ITP in mother
- Autoimmune neutropenia in children
- Autoimmune haemolytic anaemia
- Rhesus-isoimmunization in pregnancy
- Red cell aplasia and pancytopenia

- Thrombotic thrombocytopenic purpura and Haemolytic uremic syndrome
- Coagulation inhibitors (e.g. acquired factor VIII deficiency)
- Virus associated haemophagocytic syndrome
- Guillain-Barre syndrome.

- II. **HIV-Infection** - (a) HIV related thrombocytopenia. (b) CMV infection. (c) Children with HIV because of marked susceptibility to serious bacterial infections.

III. Bone marrow transplantation

Glucagon

1. β -blocker overdose
2. Hypoglycemia
3. Cardiac inotropic for treatment of shock.

Granulocyte Maturation Colony Stimulating Factor

1. Transplant patients who exhibit early graft failure.
2. To mobilize progenitor cells for peripheral bloodstem cell (PBSC) for transplantation after myeloablative chemotherapy.
3. To shorten period of neutropenia and reduce mortality in patients receiving intense cancer chemotherapy.
4. To stimulate myelopoiesis in some patients with cyclic neutropenia, myelodysplasia, aplastic anemia or AIDS associated neutropenia.
5. Therapy for pulmonary alveolar proteinosis.

Growth Hormone

Indications:

1. GH deficient short stature in children.
2. Repeated hypoglycemia in GH deficient infants and children.
3. Turner's syndrome in early childhood.
4. Growth retardation in chronic kidney failure prior to kidney transplant.
5. Adults with GH deficiency following pituitary tumour surgery or irradiation or idiopathic hypopituitarism.
6. Strong evidence of protein catabolism, e.g. burns injury.

Possible indications:

- a. Normal short children. In children the end points of GH therapy include achievement of discardable adult height or growth rate velocity of < 2.5 cm/year.
- b. Short children with miscellaneous syndromes, e.g. skeletal dysplasias, spina bifida, Prader-Willi syndrome, Down syndrome, Russel Silver syndrome, Noonan syndrome.

- c. Short children with X-linked Hypophosphatemic rickets.
- d. Non-GH deficient adults, particularly beyond 6th decade. (Short duration to improve bone density and increase in lean body mass).
- e. Catabolic states – Burns, extensive soft tissue injuries, cachexia (following major trauma, surgery), and septic shock.
- f. AIDS – GH therapy for anabolic effects and potential effects of GH on immune system.
- g. Infertility – GH facilitates ovulation induction in infertile women. GH therapy improves semen profile in patients with abnormalities of sperm maturation.
- h. Osteoporosis – GH increases calcium and phosphate absorption from the gut by increasing 1,25 dihydroxy vitamin D production and by direct effect.
- i. CHF – In patients with dilated cardiomyopathy 14 IU/week increases myocardial mass, reduces LV dilatation and improves haemodynamics.
- j. Tumour hypoglycemia – patients with non-islet cell tumours.

Haemopoietic Growth Factor

- A. *Haematological malignancies*
 1. Therapy-induced myelosuppression
 2. AML –
 - a. Treatment associated neutropenia
 - b. Priming with colony stimulating factors
 3. High dose chemotherapy with rescue –Leukemias, lymphomas, multiple myeloma
 4. Role of other growth factors:
 - a. Erythropoietin: Alleviating chemotherapy induced anaemia and decreasing transfusion requirements.
 - b. Others: (i) Prophylactic use – When chemotherapy is expected to have febrile neutropenia equal to or greater than 40%. (ii) When previous chemotherapy has resulted in febrile neutropenia with life threatening infection. (iii) Use during neutropenia: In infections with high risk factors, e.g. pneumonia, hypotension, multi-organ dysfunction and fungal infections, use of colony stimulating factor along with antibiotics.
 5. Bone marrow transplantation
 6. Myelodysplastic syndromes

- B. *Radiation mucositis*

Human Serum Albumin

1. Plasma volume replacement
2. Burns
3. Extracorporeal circulation during cardiac surgery
4. Nephrotic syndrome
5. Cirrhosis and ascites
6. Therapeutic plasma exchange
7. Neonatal hyperbilirubinaemia

Hyperbaric Oxygen

Acute conditions (where HBO therapy should be given earliest when compared to conventional treatment)

1. Non-healing ulcers, problem wounds, compromised skin grafts and flaps
 2. Crush injury, compartment syndrome, and acute traumatic ischemia
 3. Gas gangrene/clostridial infections
 4. Necrotizing soft tissue infections (subcutaneous tissue, muscle, fascia)
 5. Thermal burns
 6. Exceptional blood loss (anaemia)
 7. Intracranial abscess
 8. Post-anoxic encephalopathy
 9. Burns
 10. Sudden deafness
 11. Ocular ischemic pathology
 12. Air or gas embolism*
 13. Decompression sickness*
 14. Carbon monoxide poisoning and smoke inhalation*
- * Curative/primary line of treatment

Chronic conditions

1. Non-healing wounds/problem wounds (diabetic/venous, etc.)
2. Radiation tissue damage
3. Skin grafts and flaps (compromised)
4. Chronic osteomyelitis (refractory).

Immunoglobulin

1. Hepatitis A, B
2. Measles
3. Myasthenia gravis
4. Parvovirus B19 infection in HIV
5. Varicella zoster virus

6. Rabies
7. Tetanus
8. Thrombocytopenic purpura

Interferon Alpha

1. Hairy cell leukaemia
2. Chronic myeloid leukaemia
3. Multiple myeloma
4. Low grade lymphoma
5. Chronic lymphocytic leukaemia
6. Kaposi's sarcoma
7. Malignant melanoma
8. Others
 - Recurrent glioma (along with tamoxifen)
 - Neuroblastoma (combined with valproic acid).

Interleukin - 2

Infectious diseases

1. HIV infections and AIDS
2. Lepromatous leprosy
3. Disseminated cutaneous leishmaniasis
4. Hypogammaglobulinaemia
5. Chronic viral hepatitis
6. Human papilloma virus infections
7. Relapsing multiple sclerosis
8. Sezary syndrome
9. Essential mixed cryoglobulinaemia
10. Mastocytosis
11. Polycythemia vera

Malignancies

1. Anticancer gene therapy
2. Metastatic renal carcinoma
3. Metastatic melanoma
4. Other malignancies: Thymoma, acute myeloid leukaemia
5. Condyloma acuminatum (intralesional)
6. Carcinoid syndrome
7. Essential mixed cryoglobulinaemia
8. Kaposi's sarcoma
9. Mastocytosis
10. Polycythemia vera
11. Mycosis fungoides
12. Relapsed, remitting multiple sclerosis (INF-B)
13. May be protective in development of GVHD (IFN-r)

Ivermectin

1. Onchocerciasis
2. Lymphatic filariasis
3. Intestinal nematodes - Ascariasis, strongyloidiasis, trichuriasis, enterobiasis.
4. Scabies
5. Head lice
6. Cutaneous larva migrans

Levamisole

1. Recurrent aphthous stomatitis
2. Recurrent herpes infections
3. Recurrent skin and respiratory infections
4. Rheumatoid arthritis
5. Chronic staphylococcal infections
6. Anthelmintic (ascariasis, hookworm, trichuris, strongyloidiasis)
7. Breast carcinoma.

Methotrexate

1. Gastric adenocarcinoma
2. Breast cancer
3. Inflammatory bowel disease
4. Multiple sclerosis
5. Myositis
6. Psoriasis, psoriatic arthritis
7. Reactive arthritis
8. Relapsing polychondritis
9. Rheumatoid arthritis
10. Vasculitis
11. SLE

Metronidazole/Tinidazole/Secnidazole

1. Amoebiasis.
2. Giardiasis.
3. Ulcerative gingivitis.
4. Trichomonas vaginalis (both sexes).
5. Anaerobic infections.
6. Brain abscess.
7. Clostridial associated colitis
8. Skin infections
9. *Helicobacter pylori* gastritis.
10. Subpleural empyema.
11. Rheumatoid arthritis.

Penicillamine

1. Rheumatoid arthritis
2. Wilson's disease
3. Systemic sclerosis
4. Primary biliary cirrhosis
5. Cystinuria
6. As chelating agent for heavy metal poisoning.

Rifampicin

1. Tuberculosis.
2. Leprosy.
3. Brucellosis – Children under 7 years of age and during pregnancy (in combination with Co-trimoxazole).
4. Prophylaxis for contacts of patient with meningococcal meningitis.
5. Prophylaxis of children under 4 years of age who have had close contact with a child with *H. influenzae* type B meningitis.
6. Eradication of nasal carriage in individuals with recurrent furunculosis (with cloxacillin).
7. Endocarditis due to *Corynebacterium* species, *coxiella*, chlamydia.
8. *L. pneumophila* infection which has failed to respond to erythromycin, or in combination with erythromycin.
9. *Mycobacterium kansasii*
10. Staphylococcal infections
11. Streptococcus group A
12. *Streptococcus pneumoniae*
13. Chronic staphylococcal osteomyelitis (with nafcillin or vancomycin).

Rituximab

1. Autoimmune hemolytic anemia
2. B cell chronic lymphoid leukaemia/small lymphocytic lymphoma
3. HIV infection
4. Cerebellar degeneration
5. Cold agglutinin disease
6. Diffuse large B cell lymphoma
7. Epstein-Barr virus
8. Follicular lymphoma
9. Inflammatory myopathies
10. Leukaemia
11. Lymphoma
12. Monoclonal gammopathy of undetermined significance

13. RA
14. Thrombotic thrombocytopenic purpura
15. Waldenstrom's macroglobulinemia
16. Wegner's granulomatosis

Rivastigmine

1. Alzheimer's disease
2. Parkinson's disease

Sodium chromoglycate

1. Prevention of bronchial asthma.
2. Allergic rhinitis.
3. Ulcerative colitis.
4. Food allergies.

Statins

1. Lipid lowering therapy
2. Antiarrhythmic therapy
3. Peripheral arterial disease
4. Non-ischemic cardiomyopathy
5. Neuroinflammatory disorders: MS, Alzheimer's disease, ischemic stroke
6. Psychological well-being: Reduced risk of depression in patients with CAD
7. Cancer: Antitumor effects against melanoma, pancreatic carcinoma, glioma, neuroblastoma and lymphoma
8. Osteoporosis
9. Age-related maculopathy.

Thalidomide

(Used only when no alternatives)

1. Erythema nodosum leprosum
2. Major aphthae of mouth, oesophagus, genital, and anus (in isolation, as part of Behcet's disease, or in HIV infection)
3. Chronic graft versus host disease
4. Dermatological conditions – Discoid lupus erythematosus, prurigo nodularis, actinic prurigo, erythema multiforme, pyoderma gangrenosum
5. Inflammatory conditions – Rheumatoid arthritis, ulcerative colitis, post-herpetic neuralgia
6. Multiple myeloma.

Transfer Factor

1. Varicella-zoster prophylaxis in childhood leukaemia.
2. Wiskott-Aldrich syndrome.

3. Chronic mucocutaneous candidiasis (maintenance therapy).
4. Cutaneous leishmaniasis.
5. Lepromatous leprosy.
6. Steroid-resistant nephrotic syndrome
7. Insulinomas.

Plasmapheresis/Plasma Exchange

Established indications:

1. Hyperviscosity syndrome.
2. Goodpasture's syndrome. (Non-oliguric anti-GBM disease).
3. Myasthenia gravis (crisis or thymectomy).
4. Guillain-Barre syndrome.
5. Homozygous familial hypercholesterolemia.

Anecdotal indications:

1. Severe refractory collagen-vascular disease, e.g. SLE, RA.
2. Essential mixed cryoglobulinaemia.
3. Refractory thrombocytopenic purpura - Idiopathic ITP, thrombotic TTP, post-transfusion.

The **Dyslipidemia** of metabolic syndrome is characterized by elevated triglycerides (VLDL), low HDL and small dense LDL, a triad termed *atherogenic lipoprotein phenotype*.

Vasopressin

1. Diabetes insipidus
2. Haemophilia
3. Hyponatremia
4. Uraemia and bleeding
5. Variceal bleeding
6. Von Willebrand's disease
7. Septic shock (by decreasing catecholamine requirement).

Verapamil

1. AV nodal re-entrant tachycardia
2. Angina pectoris
3. Aortic dissection
4. Hypertension
5. Hypertrophic cardiomyopathy

Notes

Gastroenterology Liver and Biliary Diseases

Normal GI fluid volumes

• Food and drink	1500 ml
• Saliva	750 ml
• Gastric secretion	1250 ml
• Biliary secretion	1000 ml
• Pancreatic secretion	2500 ml

Alcohol-induced recurrent abdominal pain:

1. Alcoholic hepatitis.
2. Alcoholic gastritis/peptic ulcer
3. Acute pancreatitis.
4. Others-Lead poisoning, Hodgkin's disease, acute intermittent (or variegate) porphyria.

Effects of Drugs on Teeth, Oral mucosa and Salivary glands

Discoloration of teeth	Chlorhexidine, tetracyclines, iron
Oral candidiasis	Broad spectrum antibiotics, corticosteroids (systemic and topical), cytotoxic drugs
Oral ulceration	Aspirin applied topically, penicillamine
Gingival hyperplasia	Phenytoin, calcium channel blockers (e.g. nifedipine, diltiazem), cyclosporin
Erythema multiforme	Sulphonamides, barbiturates, penicillin, carbamazepine
Lichenoid reactions	Oral hypoglycemic agents, NSAIDs, beta-blockers, allopurinol, methyl dopa
Mucosal pigmentation	Antimalarials (e.g. chloroquine), phenothiazines, oral contraceptives
Xerostomia (dry mouth)	Antihistamines, tricyclic anti-depressants, MAO inhibitors, diuretics, anti-cholinergic drugs, anti-parkinsonian agents (benzhexol, benztropine)
Salivary gland pain and swelling	Phenothiazines, anti-thyroid drugs, insulin

Recurrent (chronic) GI bleeding:

1. *Local lesions:* Angiodysplasia, hemangioma, hereditary hemorrhagic telangiectasia, diverticulitis (including Meckel's).
2. *Systemic causes:* Polycythemia vera, vasculitis (PAN, Henoch-Schonlein); Behçet's syndrome, amyloidosis, inherited collagenoses, pseudoxanthoma elasticum, type IV Ehlers-Danlos syndrome, Degos disease and miscellaneous—Peutz-Jegher's syn., Gardner's syn., blue rubber bleb naevus syn.

Chronic mesenteric ischemia. Causes:

- Atherosclerosis
- Fabry's disease

- Antiphospholipid antibody syndrome
- Behçet's disease
- Thromboangiitis obliterans
- Takayasu arteritis
- Crohn's disease
- External compression

Conditions associated with small intestinal bacterial overgrowth

- Reduced gastric acid
 - Pernicious anemia
 - Atrophic gastritis
 - Gastric surgery
- Structural abnormalities
 - Small bowel diverticula
 - Surgical anastomosis and diversions
 - Strictures
 - Adhesions
 - Fistula (gastrocolic, coloenteric)
- Dysmotility syndromes
 - Diabetes
 - Scleroderma
 - Acute enteric infection
 - Intestinal pseudo-obstruction syndrome

Elevated serum CA-125 levels should not be relied upon to make a diagnosis of ovarian/peritoneal carcinoma in a case of ascites. CA-125 levels can be elevated in conditions like endometriosis, pelvic inflammatory disease and pleural and peritoneal effusion of many etiologies, such as CKF, cirrhosis, TB, CHF and many malignancies.

Double balloon enteroscopy (DBE) is a useful technique for small bowel diagnosis, for obscure GI bleed. It is a safe method for obtaining tissue for diagnosis, providing hemostasis, and carrying out polypectomy.

Cirrhosis with large liver

1. Alcoholic liver disease
2. Alcoholic hepatitis
3. Alcoholic cirrhosis
4. Postnecrotic cirrhosis with
 - a. Superimposed viral hepatitis
 - b. Superimposed alcoholic hepatitis
 - c. Superimposed hepatocellular Ca
5. Budd-Chiari syndrome
6. Biliary cirrhosis

7. Cardiac cirrhosis
8. Metabolic liver disease
9. Wilson's disease
10. Hemochromatosis
11. Glycogen storage disease

Reduced drug dosage or frequency in liver disease

Analgesics: Pentazocin, dextropropoxyphene.

β-blockers: Propranolol, metoprolol, labetalol

Antidepressants: Imipramine, amitriptyline, desipramine, doxepin, haloperidol.

Sedatives: Chlormethiazole.

Anti-arrhythmics: Verapamil, diltiazem.

Non-alcoholic steatohepatitis (NASH) is a condition histologically similar to alcoholic liver disease but in which alcohol has no part and that is most commonly associated with obesity and/or type 2 diabetes. The condition can lead to cirrhosis and hepatocellular cancer.

NASH is now the most common cause of persistent elevation of liver enzymes (notably ALT) in patients in whom no other obvious cause can be found. Ultrasonography shows widespread fat in the liver.

Ascites

Classification of Ascites as per SAAG*

High gradient	Low gradient
(SAGG > 1.1 gm/dl)	(SAGG < 1.1 gm/dl)
Cirrhosis	Tubercular peritonitis
Alcoholic hepatitis	Peritonitis
Fulminant hepatic failure	Carcinomatosis
Portal vein thrombosis	Pancreatic ascites
Budd-Chiari syn.	Biliary ascites
Congestive heart failure	Serositis
Mixed ascites	Nephrotic syn.
Serum Ascites Albumin gradient*	
Serum albumin (gm/dl)—Ascitic fluid albumin (gm/dl)	

Ascites: Sudden worsening in stable cirrhosis:

1. Spontaneous bacterial peritonitis.
2. Budd-Chiari syndrome.
3. Hepatoma.
4. Acute deterioration of hepatocellular function (due to sepsis, alcoholic indulgence, gut bleeding).
5. Rupture of dilated abdominal lymphatics (chylous ascites).
 - When the ascitic fluid contains more than 250 neutrophils/mm³, diagnosis of spontaneous bacterial peritonitis is made
 - Bloody ascitic fluid occurs in 2% of cirrhotic patients, one-third of whom have hepatocellular carcinoma

- Cirrhotic patients exhibit high concentration of interleukin-6 and tumor necrosis factor in ascites
- High levels of cytokines in ascitic fluid in spontaneous bacterial peritonitis might be related to complications in these patients, particularly impaired circulatory and kidney function
- TIPS should be used in patients who respond poorly to paracentesis and in those who require frequently repeated taps.

Diseases associated with primary biliary cirrhosis

Common (up to 80%)

- Sicca syndrome

Less common (about 20%)

- Thyroid disease. Arthralgia
- Raynaud's syndrome
- Sclerodactyly
- Fibrosing alveolitis

Uncommon (5%)

- CREST syndrome
- Addison's disease
- Coeliac disease
- Glomerulonephritis
- Vitiligo
- Renal tubular acidosis
- Myasthenia gravis
- Hypertrophic pulmonary osteoarthropathy

Liver disease in pregnancy

1. Liver dysfunction in hyperemesis gravidarum is generally mild and resolves as the vomiting settles
2. Obstetric cholestasis usually presents as pruritus of the extremities in the last trimester. Jaundice is uncommon, it may follow pruritus by a few weeks
3. HELLP syndrome. Defining features are:
 - Hemolysis (microangiopathic)
 - Elevated ALT and aspartate aminotransferase
 - Low platelets (100,000 × 10⁹/litre)

The syndrome occurs in the setting of pre-eclampsia, with wt. gain and oedema, hypertension and abdominal tenderness over the liver. Most cases occur in the third trimester. Early delivery is helpful though the condition may progress or even develop *de novo* post-partum, peaking at about 48 hours after delivery. In full-blown eclampsia, rupture of the liver with massive peritoneal hemorrhage can occur.
4. Acute fatty liver of pregnancy is most common in first and multiple pregnancies. Onset is in third trimester, with vomiting, upper abdominal pain, anorexia and malaise. Later, DIC, leucocytosis, hyperglycemia and hyperammonemia develop and progress to fulminant liver failure.

- Ovarian hyperstimulation syndrome is caused by fertility treatment. Ascites may require drainage, and correction of hemoconcentration is vital.
- Other liver diseases: (a) Gallstone formation is increased by pregnancy, particularly in association with obstetric cholestasis. (b) Budd-Chiari syndrome may be seen during pregnancy due to heightened thrombotic tendency. (c) Hepatitis E has a high mortality in pregnancy, for unexplained reasons.

Clinical and laboratory findings which raise suspicion of hepatocellular carcinoma

- New abdominal pain or wt. loss
- Hepatomegaly
- Hepatic bruit
- Acute hemoperitoneum
- Blood-tinged ascitic fluid
- Persistent fever
- Sudden increase in serum alkaline phosphatase
- Increasing ratio of aspartate aminotransferase to alkaline aminotranferase
- Polycythemia or persistent leucocytosis
- Hypoglycemia
- Hypercalcemia
- Hypercholesterolemia

Note: 9-12 are paraneoplastic syndromes associated with HCC.

Hepatic tumour-specific markers

α-Fetoprotein - Levels above 400 ng/ml are suggestive and above 1000 ng/ml are diagnostic of hepatocellular carcinoma or germ-cell tumour. High levels sometimes in chronic hepatitis, acute cirrhosis or during recovery from massive hepatic necrosis. Fucosylated *α*-fetoprotein measurements may help if *α*-fetoprotein levels are equivocal (20-1000 ng/ml) range.

Desgamma carboxyprothrombin (DCP) - Levels (normal 0.1 AU/ml) are increased in 60% of patients with hepatocellular carcinoma.

Consequences of sleep-related GER

Insomnia	Barret's esophagus
Sleep disturbance	Adenocarcinoma of esophagus
Impaired day time functioning	Recurrent pneumonia and aspiration
Impaired quality of life	Nocturnal asthma
Erosive esophagitis	Nocturnal laryngospasm

Groups at risk of opportunistic pneumonias

Dysphagia and oesophageal disease
Stricture Achalasia
Oesophageal pouch
Fistula
Hiatus hernia
Reflux

Eosinophilic ascites. Eosinophilic gastroenteritis. Patients with serosal variant of EGED present with eosinophilic ascites. It mainly affects children and young adults. EGED has three variants - (a) Mucosal disease - Abdominal pain, vomiting, diarrhea, protein-losing enteropathy. (b) Muscle layer disease - Bowel wall thickening, gastric and small bowel obstruction. (c) Serosal disease associated with eosinophilic ascites.

Chronic abdominal pain. Mesenteric ischemia should be suspected in elderly patients with chronic abdominal pain and in those with other risk factors.

Primary ciliary dyskinesia (PCD). Clinical features may be varied including distress in neonates, bronchiectasis, situs inversus, infertility, hydrocephalus singly or in various combinations. Exhaled NO may be used as a screening test with level of NO regulator. Ciliated epithelial cells obtained from inferior or middle turbinate using a sterile cytology brush may be studied for ciliary beat using digital high-speed video imaging when the dyskinetic cilia are seen lack the classical sideways recover sweep.

Respiratory System

Thoracic endometriosis is a rare condition where endometrial cells are seen in pleural lung. Common presentations are recurrent pneumothorax or hemothorax.

Terzidone is WHO categorized group IV anti-TB drug. It has an antibiotic effect against *M. tuberculosis* and also *M. avium* for treatment of tuberculosis. It is classified as a second line drug. Its mode of action is similar to cyclosporin. Dose: 15-20 mg/kg/day. It is to be used with caution in patient with psychiatric comorbidities and epilepsy. Advantages over cyclosporin - Adverse side-events lesser, better tolerated, does not produce hypotension. It has the advantage of usefulness in schizophrenics and alcoholics.

Device to detect drug-resistant TB in 2 hours. The device called gene expert is useful in early diagnosis. The expert WSB test has been found to accurately and quickly detect TB.

Factors predisposing to aspiration pneumonia

Altered consciousness	Neurological disorders
Drug overdose	Pseudobulbar palsy
Anaesthesia	Myasthenia gravis etc.
Epilepsy	Nasogastric tubes
Cerebrovascular accident	Severe dental and upper airways sepsis
Alcoholism	Terminal illness

Groups at risk of opportunistic pneumonias

Primary immunodeficiency	Secondary immunodeficiency
B-cell deficiency (agammaglobulinemia)	HIV infection (AIDS)
T-cell deficiency (Di George syndrome)	Leukemias and lymphomas
	Corticosteroid therapy (particularly following organ

Differential diagnosis of pulmonary-renal syndrome

Disease	Vasculitis	Granulomata	Features
• Wegener's granulomatosis	Present	Present	See text
• Microscopic polyangiitis	Present	Absent	Primary small vessel vasculitis is the most common cause of pulmonary renal syndrome (about 56% of cases)
• Churg-Strauss syndrome	Present	Present	See text
• Goodpasture's disease	Present	Absent	Linear IgG deposition on glomerular basement membrane Antiglomerular antibody positive in patients with ANCA, treatment should be as for primary small vessel vasculitis; prognosis may be better then in those with antglomerular basement membrane antibody alone
• Systemic lupus erythematosus	Present	Absent	Antinuclear factor and anti-dsDNA positive Low C3 and C4.
• Henoch-Schonlein purpura	Present	Absent	Lung involvement uncommon IgA deposition in vessel walls and mesangium
• Behçet's disease	Present	Absent	Diagnosed on clinical criteria Associated with recurrent oral and genital ulceration, eye lesions (including uveitis) and skin lesions; renal involvement usually mild
• Infection	Rarely present (e.g. SLE)	Absent	Pneumonia may be associated with acute tubular necrosis or interstitial nephritis (rarely) Subacute infective endocarditis may be associated with ANCA-negative pauci-immune glomerulonephritis Post-streptococcal glomerulonephritis Blood cultures, atypical serology and antistreptolysin-0 titer should be undertaken

Cardiovascular System

Rheumatic aortitis. RA, ankylosing spondylitis, psoriatic arthritis and inflammatory bowel disorder may all be associated with aortitis involving the ascending aorta. The inflammatory lesion may extend to sinus of Valsalva, mitral valve leaflets and adjacent myocardium. Clinical manifestations are AR, aneurysm, and involvement of cardiac conduction system.

Endomyocardial Fibrosis (EMF) is a variant of obliterative, restrictive cardiomyopathy. Endocardium of either or

Primary immunodeficiency	Secondary immunodeficiency

Pulmonary emboli

Non-specific pneumonitis

both ventricles is markedly thickened with involvement of underlying myocardium

Cardiovascular system

Rheumatic aortitis. RA, ankylosing spondylitis, psoriatic arthritis and inflammatory bowel disorder may all be associated with aortitis involving the ascending aorta. The inflammatory lesion may extend to sinus of Valsalva, mitral valve leaflets and adjacent myocardium. Clinical manifestations are AR, aneurysm, and involvement of cardiac conduction system.

Endomyocardial Fibrosis (EMF) is a variant of obliterative, restrictive cardiomyopathy. Endocardium of either or both ventricles is markedly thickened with involvement of underlying myocardium.

Loeffler endocarditis is a rapidly progressive, aggressive disease affecting principally males and associated with intense thromboembolic phenomena.

Infective endocarditis caused by nutritionally variant streptococci (NVS) is associated with increased incidence of complications, both embolization and cardiac failure.

High-dose Statin therapy provides cardiovascular benefit beyond conventional (low to moderate dose) statin therapy in patients with acute coronary syndrome by substantially reducing not only LDL but also the level of atherogenic APO and oxidized LDL.

	Tetralogy of Fallot	Trilogy of Fallot
Onset of cyanosis	At birth or within a year	After few years
Squatting	Common	Rare
Facies	Not typical	Often moon face
'a' waves	Small or none	Usually large
RV heave	Absent	Present
Systolic murmur	Rarely loud	Loud with thrill
X-ray chest	Oligaemic lung fields Good pulmonary bay Right sided aortic arch (25% cases) RV hypertrophy not marked	Oligaemic lung fields but no pulmonary bay No right-sided aortic arch RV hypertrophy ++
ECG	No RBBB	RBBB may be present
Echo	Small P pulmonale Shunt across VSD	Large P. pulmonale Shunt across ASD
Catheterization	Marked reduction of oxygen saturation in LV No giant 'a' waves Stenosis more often infundibular	Slight to moderate fall in oxygen saturation Giant 'a' waves Stenosis more often valvar

Romano – Ward syndrome is an AD inherited disorder with prolonged QT interval that predisposes to VT, torsades de pointes, syncopal attacks and sudden death.

Valsalva manoeuvre: It consists of forceful expiration of air against the closed glottis with the mouth shut and nose held closed.

Normal response: Initially a small rise in the arterial pressure which results from sudden emptying of the pulmonary bed into the left atrium. After 10 seconds, when the manoeuvre is halted, there is a sudden increase in RV and LV filling causing an overshoot in the BP which results in reflex bradycardia.

Abnormal response: Arterial pressure does not fall when the venous return to RA is arrested, and there is no change in pulse rate or pressure during and after the period of strain. This response is labelled 'square wave' response because it also occurs in addition to early heart failure, in patients with large left to right shunts, tight MS or AS, and large volume of blood in the lungs. Diabetic neuropathy, tabes dorsalis, and adrenergic neuron-blocking drugs can all give abnormal response.

Muller's manoeuvre: It is opposite of Valsalva and consists of forced inspiration against closed glottis, with the mouth shut and nose held closed. It results in decrease in intrathoracic pressure.

Myocardial perfusion scintigraphy: Scintigraphy is particularly advisable in patients who have a suboptimal

dilation and should be performed 2 to 4 weeks post angioplasty when vascular reactivity has subsided. Patients with persistent ischemic defects after angioplasty are known to be at high risk for restenosis, whereas those without ischemia have a very low restenosis rate.

Reversible cardiomyopathy may be found with alcohol use, pregnancy, selenium deficiency, hypophosphatemia, hypocalcemia, thyrotoxicosis, cocaine use and chronic uncontrolled tachycardia.

Postural orthostatic tachycardia syn. (POTS). Also known as orthostatic intolerance, it is defined as long standing reproducible symptoms in adequate cerebral perfusion on assumption of upright posture with insignificant change in BP but significantly elevated heart rate in absence of medications, dehydration, prolonged bed rest, neuropathy, or substantial wt. loss. It is commonly a disorder of young women.

Holiday heart syndrome: The syndrome consists of paroxysms of arrhythmias occurring particularly after a holiday or weekend bout of drinking alcohol in a chronic alcoholic. It is commonly associated with alcoholic cardiomyopathy but can occur in absence of vious cardiac disease. The common arrhythmias are supraventricular tachycardias of which atrial fibrillation is the commonest.

Sudden cardiac death:

1. **Coronary artery disease**
Acute ischemic events

- Chronic ischemic heart disease
2. *Cardiomyopathies*
Dilated Hypertrophic
 3. *Valvular inflammation/infiltration*, e.g. AS, myocarditis, sarcoidosis, amyloidosis
 4. *Uncommon, subtle, ill-defined lesions*, e.g. RV dysplasia, cardiac tumours
 5. *Lesions of molecular structure*, e.g. congenital long QT syndrome
 6. *Definable functional anomalies*, e.g. WPW syndrome, idiopathic VF

Causes of upper extremity DVT

I Primary

- A. Traumatic
 - Effort thrombosis
 - Blood vessel injury
- B. Increased distal venous pressure
 - Cervical ribs
 - Long transverse processes of cervical spine
 - Musculofascial bands of subclavius muscle and costoclavicular ligament
 - Clavicular or 1st rib anomalies
- C. Hypercoagulable state
 - Antiphospholipid antibodies
 - Factor V Leiden
 - Antithrombin III deficiency
 - Protein C & S deficiency
 - Prothrombin gene mutation
 - Hyperhomocystinemia
 - Pregnancy and oral contraceptive use

II Secondary

- A. Central venous catheters
 - B. Malignant disease
 - Lymphoma/Leukaemia
 - Pancreas cancer
 - Breast cancer
 - Chest disorders: lung, pleura and oesophagus
 - Gastrointestinal tract
 - C. Pacemakers
 - D. Intravenous Drug Abuse
- III *Idiopathic may be associated with occult cancer*

Hematology

Aggressive natural killer (NK) cell leukemia affects younger patients who present with general poor condition, fever and disseminated disease and often die within a short time from systemic disease or complications such as multiorgan failure.

Reed-Sternberg cell is characteristic cell of Hodgkin's disease. It is a large cell with multilobulated nuclei

and abundant cytoplasm and has been postulated to arise from the germinal central B cell population in most cases. An infiltrate of apparently normal lymphocytes, plasma cells and eosinophils surround the RS cell with various degrees of fibrosis.

Differential diagnosis of acquired aplastic anemia

	Examples	Differential features
Inherited	• Fanconi's anaemia	Chromosome fragility, dysmorphism, family history
Malignant	• Dyskeratosis congenita	Nail/skin changes, leukoplakia, X-linked, family history
	• Hypoplastic myelodysplastic syndrome	Blood cell morphology, cytogenetics
	• Acute leukaemia (presenting as aplastic anaemia)	Spontaneous remission followed by leukaemic relapse
Toxic	• Irradiation	History of exposure
	• Chemotherapy	
Antibody-mediated	• Autoimmune pancytopenia	Multiple auto antibodies

Acute reversible kidney failure is a complication of multiple myeloma - MM should be considered as a case of unexplained ARF in middle aged and elderly patients.

Prurigo nodularis in Hodgkin lymphoma. Pruritus and prurigo nodularis have been associated with the disease. Other neoplastic skin manifestations are eczema, mycosis fungoides and erythema nodosum.

Paraneoplastic syndromes are rare disorders triggered by an altered immune system response to a neoplasm. They are defined as clinical syndromes with non-metastatic systemic effects that accompany malignant disease. Causes - CML, myasthenia gravis, long-term treatment with 6-mercaptopurine.

Patients with hematological malignancies are of increased risk of fungal infections particularly by aspergillus, zygomycoses and may progress rapidly and by highly destructive to local tissues.

Evan's syndrome is an autoimmune disorder characterized by simultaneous or sequential development of Autoimmune hemolytic anemia and Idiopathic thrombocytopenic purpura and/or immune cytopenia in absence of any cause.

Dyskeratosis congenita is a rare progressive bone marrow disorder associated with triad of skin pigmentation, nail dystrophy and mucosal leukoplakia.

Non-infectious causes of peripheral eosinophilia

Atopy	Haematological	Vasculitis	Dermatological	Drug	Other
Asthma Eczema Hay fever	Hodgkin's and non-Hodgkin's lymphoma Chronic eosinophilic leukaemia Systemic mastocytosis Chronic myelomonocytic leukaemia Chronic myeloid leukaemia Acute myeloid leukaemia Myelodysplastic syndrome	Churg-Strauss syndrome Polyarteritis nodosa Wegener's granulomatosis Other connective tissue diseases and vasculitides	Immunobullous disorders: dermatitis herpetiformis and pemphigoid Atopic dermatitis	NSAIDs β-Lactam antibiotics Sulfa-containing antibiotics Tetracycline Acetylsalicylic acid Carbamazepine Colchicine Nitrofurantoin Dapsone Minocycline	Allergic bronchopulmonary aspergillosis Sarcoidosis Addison's disease Eosinophilic myocarditis Familial eosinophilic syndromes Heavy metal poisoning Idiopathic eosinophilic pneumonias

Severity of acquired aplastic anaemia

	Peripheral blood	Bone marrow
Very severe	<ul style="list-style-type: none"> Neutrophils $< 0.2 \times 10^9/\text{litre}$ Platelets $< 20 \times 10^9/\text{litre}$ Reticulocytes $< 20 \times 10^9/\text{litre}$ Transfusion-dependent 	<ul style="list-style-type: none"> $< 25\%$ normal cellularity Moderately hypocellular ($< 30\%$ of remaining cells haemopoietic)
Severe	<ul style="list-style-type: none"> Neutrophils $0.2\text{--}0.5 \times 10^9/\text{litre}$ Otherwise as for very severe 	<ul style="list-style-type: none"> As for very severe
Non-severe	<ul style="list-style-type: none"> Neutrophils $0.5\text{--}1.5 \times 10^9/\text{litre}$ Platelets $20\text{--}100 \times 10^9/\text{litre}$ Reticulocytes $20\text{--}60 \times 10^9/\text{litre}$ 	<ul style="list-style-type: none"> Hypocellular

Bone marrow changes in aplastic anaemia are often patchy, and the assessment of cellularity, even with a good trephine, may be difficult.

Combination of cyclosporin and menabol in treatment of aplastic anemia

Immunoglobulin IV in thrombotic thrombocytopenic purpura.

Endocrine

Hypothyroidism with persistent constipation may exacerbate hyperammonemic portosystemic encephalopathy in patients with well compensated liver disease.

Primary hyperparathyroidism myopathy is relatively less common girdle muscle disease which presents with exaggerated tendon reflexes and is completely reversible with surgery of parathyroid adenoma.

Pheochromocytoma. The triad of headache, palpitation and sweating in a patient with hypertension should arouse suspicion of pheochromocytoma.

Gynecomastia can occur physiologically in 3 phases of life – Neonatal period, puberty and old age. Maternal oestrogens are responsible for the first phase, reduction of endogenous testosterone synthesis for the latter two phases.

Mechanisms by which hyperinsulinemia contributes to hypertension.

- Vasodilatation
- Increased sympathetic nervous system activity directly and from vasodilatation
- Increased renal salt sensitivity, sodium retention
- Increased renal sodium/hydrogen exchange
- Lowered free fatty acids stimulating aldosterone secretion
- Vascular smooth muscle cell proliferation
- Atherosclerotic coronary vascular rigidity

DM. Initiating insulin therapy with insulin as part or switching over to basal insulin in patients with poor glycaemic control leads to improvement in glucose control with no major hypoglycemia.

Drugs which are potentially hypoglycemic

Class of Drugs	Drug	Action
Oral antidiabetics	Sulphonylureas Glinides	• Insulin secretion
Anti-inflammatories	Aspirin Indomethacin	• Drug interactions by linkage with proteins
Antiarrhythmics	Acetaminophen Flecain Quinidine Disopyramide	• Decrease in insulin resistance • Insulin secretion
Antibiotics or Antimicrobials	Sulphamethoxazole Pentamidine Tetracyclines	• Insulin secretion
Antihypertensives	Beta blockers ACE inhibitors	• Interaction with hepatic gluconeogenesis • Sensitivity to insulin
Hypolipidemics	Fibrates	• Sensitivity to insulin
Antidepressants	Fluoxetine	• Stimulation of beta cells

Non-Diabetic Renal Disease (NORD) in patients with type 2 DM

Clinical clues:

1. Short duration of diabetes.
2. Rapid loss of kidney function.
3. Heavy proteinuria with normal kidney function.
4. Significant kidney dysfunction with minimal/normal albuminuria.
5. Active urinary sediment
6. Absence of retinopathy.

Lipoatrophy at insulin injection site is likely to be an immunological phenomenon as postulated that tissue necrosis factor α (TNF- α), which in turn inhibits the adipocyte and consequently resulting in lipoatrophy.

Common causes of ectopic ACTH syndrome

1. Ca lung (esp. small cell)
2. Carcinoid tumour of thymus
3. Medullary Ca of thyroid
4. Ca of colon
5. Pheochromocytoma

Lactic acidosis

- I. Type A: any cause of severe tissue hypoxia.
- II. Type B:
 1. 'Idiopathic'. Onset in elderly diabetics.
 2. Alcohol abuse and/or liver disease.
 3. Uremia.
 4. Leukemias (some), myeloproliferative disorders.
 5. Diabetes mellitus: Metformin, ketoacidosis.

Euthyroid hyperthyroxinemia is a condition in which thyroid hormone levels T4 and or T3 are elevated in the absence of thyrotoxicosis. It can occur in familial disalbuminemic hyperthyroidism (FDH), familial or acquired excess of transthyretin and drugs like propranolol and amiodarone. Also in states of resistance to thyroid hormone.

Causes of abnormal serum TSH concentrations, TSH below normal

- Primary hyperthyroidism
- Pituitary/ hypothalamic disease
- Prolonged thyrotrophic cell suppression after hyperthyroidism
- Old age
- **Drugs:** Glucocorticoids, dopamine
- Problems with T4 treatment e.g. overdose, altered GI absorption, altered T4 clearance because of drugs
- Severe systemic illness (Sick euthyroid state)

TSH above normal

- Primary hypothyroidism
- Pituitary thyrotroph adenoma, pituitary resistance to thyroid hormone
- Thyrotoxicosis from rapid correction of severe hypothyroidism with parenteral T4
- Old age
- **Drugs:** e.g. amiodarone
- Problems with T4 treatment
- Recovering phase after severe systemic illness

Renal Disorders

- Psoriatic nephropathy—Mesangioproliferative GN with IgA deposits in RA, amyloidosis and membranous nephropathy are relatively common. Drug-related nephropathy can be due to high dosage of NSAIDs in psoriatic arthropathy.

In Fabry's disease, an inborn error of glycopospholipid metabolism, urine microscopy shows typical "mulberry cells".

Uremia — Cardiovascular risk factors

Uremic vasculopathy	Uremic cardiomyopathy
• Smoking	• Hypertension
• DM	• Anemia
• Hypertension	• Volume overload
• Dyslipidemia	• DM
• Hyperhomocysteinemia	• A-V fistula
• Increased oxidative stress	
• Elevated calcium phosphate	
• Inflammation	

Systemic disease in which GN may be a feature

- Connective tissue disease, particularly SLE
- Systemic vasculitis
- Infective endocarditis
- Other infections – Methicillin resistant Staph. aureus, malaria, hepatitis B virus, HIV
- Drug reactions – NSAIDs, gold, penicillamine
- Carcinoma, lymphoma, myeloma

Tubulointerstitial disorders

Acute tubulointerstitial disorders

- Acute interstitial nephritis
- Acute tubular necrosis
- Acute urate nephropathy (and other crystal nephropathies)

Chronic tubulointerstitial disorders

- Chronic interstitial nephritis
- Reflux nephropathy
- Analgesic nephropathy
- Toxic nephropathies (uric acid, heavy metals)
- Radiation nephritis
- Balkan nephropathy
- Nephronophthisis
- Medullary sponge kidney

Primary tubular disorders

- Fanconi's syndrome
- Renal glycosuria

- Aminoacidurias (including cystinuria)
- Familial X-linked hypophosphatemic rickets
- Renal tubular acidosis
- Gittleman's and Barter's syndromes
- Nephrogenic diabetes insipidus

Systemic disease affecting the tubulointerstitium

- Myeloma
- Sarcoidosis
- Sjogren's syndrome
- Systemic lupus erythematosus
- Sickle cell anemia
- Hyperoxaluria
- Cystinosis

Interpreting creatinine and urea

Creatinine	Urea
<i>Raised</i>	<i>Raised</i>
• Large muscle bulk	• Reduced glomerular filtration rate (including dehydration)
• Acute rhabdomyolysis	• Gastrointestinal bleeding
• Reduced tubular secretion (trimethoprim, cimetidine, potassium-sparing diuretics, probenecid, triamterene)	• Corticosteroids/tetracycline
	• Catabolic state
	• High-protein diet
<i>Reduced</i>	<i>Reduced</i>
• Small muscle mass	• Liver disease
• Pregnancy	
• Raised antidiuretic hormone	• Starvation/anabolic state
	• Pregnancy
	• Raised antidiuretic hormone

Causes of rapidly progressive glomerulonephritis

- Antineutrophil cytoplasm antibody-associated vasculitis (including isolated antineutrophil cytoplasm antibody-associated glomerulonephritis)
- Antiglomerular basement disease (Goodpasture's disease)
- Lupus nephritis
- Crescentic phase of primary glomerulonephritis (e.g. IgA nephropathy)
- Post-infectious glomerulonephritis
- Cryoglobulinemic glomerulonephritis

Clinical features that may be present when renal dysfunction is part of a systemic disease

Diabetic microvascular disease

- Diabetic nephropathy

Evidence of an underlying infection

- Acute infection with renal involvement (e.g. *Leptospira*, hantavirus)
- Chronic infection with associated glomerulonephritis (e.g. hepatitis B/C, HIV, *Filaria*, *Schistosoma mansoni*)
- Infection followed by post-infectious glomerulonephritis (e.g. *Streptococcus*)

Multi-organ inflammation

- Systemic lupus erythematosus with glomerulonephritis
- Antineutrophil cytoplasm antibody-associated vasculitis with glomerulonephritis
- Sarcoidosis with interstitial nephritis

Rashes, fever and joint pains caused by allergy

- Drug-induced acute interstitial nephritis

Diagnostic definition of normo-, micro- and macroalbuminuria

Condition albumin excretion rate	24-h urinary albumin excretion rate	Overnight urinary albumin excretion rate	Albumin: creatinine ratio*
Macroalbuminuria (overt nephropathy)	> 300 mg/day	> 200 µg/min	> 25 mg/mmol
Microalbuminuria	30-300 mg/day	20-200 µg/min	2.5-25 mg/mmol (for men) 3.5-25 mg/mmol (for women)
Normoalbuminuria	< 30 mg/day	< 20 µg/min	< 2.5 mg/mmol (for men) < 3.5 mg/mmol (for women)

Tropical Infections**Abdominal Pain in Falciparum Malaria****Causes**

- Acalculous cholecystitis
- Splenic rupture
- Splenic infarction
- Splenic torsion
- Hepatitis, hepatomegaly
- Acute pancreatitis

Plasmodium vivax is known to be benign nature but now life-threatening complications, such as ARDS, have been known to occur. The non-sequestration complications are anemia and thrombocytopenia. Severe manifestations include cerebral malaria, hepatic and renal dysfunction, ARDS, severe anemia, pulmonary oedema and hemoglobinuria. The rapid blood test is negative for falciparum malaria but positive for parasite malarial antigen.

Anemia, the most common complications in malaria is due to accelerated RBC removal by the spleen, obligatory RBC destruction of parasite schizogony and ineffective hemopoiesis. A proportion of patients develop immune hemolytic anemia due to multifactorial factors, e.g. antibodies

Evidence of underlying malignancy

- Paraneoplastic glomerulonephritis
- Urinary tract obstruction
- Renal failure caused by hypercalcemia
- Myeloma with cast nephropathy

Features of generalized vascular disease

- Renal artery stenosis or occlusion
- Renal atheroemboli

Organomegaly and organ dysfunction from infiltrative disease

- Amyloidosis

Neurological abnormalities

- Neuropathic bladder with infection, stone or renal failure

directed to parasite antigens sticking to red cells, immune complex deposition leading to hemolysis due to parasite antigen or drug antibody complex, etc.

Malaria due to co-existent *P. falciparum* and *P. vivax* infection in areas where both species co-exists. In mixed infection, *P. vivax* malaria has a protective effect against the severity of falciparum malaria.

Tetany in malaria. Alteration of calcium phosphate and magnesium metabolism can occur in malaria. Also quinine should be used cautiously in patients with severe malaria associated with hypocalcemic and prolonged QT interval.

Leptospirosis - Renal manifestations include oliguric renal failure due to acute tubular necrosis or tubulointerstitial damage leading to non-oliguric kidney failure, renal potassium wasting and hypokalemia.

Hemorrhagic complications of falciparum malaria: SAH, cerebral hemorrhage, bilateral subdural hematoma.

Polymerase chain reaction (PCR) by DNA amplification has 100% specificity and sensitivity for diagnosis of leptospiral infection.

Crimean congo hemorrhagic fever (CCHF) is caused by a virus. Humans get the infection by bite of an infected tick

or contact with infected blood of animals. It can also be transmitted from an infected human to another by contact with infectious blood or body fluids. *Cl.Fs.*-1. Prehemorrhagic phase - Sudden onset of fever, chills, severe myalgia, arthralgia, rash, photophobia. 2. In severe cases 3-6 days after onset of symptoms, hemorrhagic manifestations ranging from petechiae to ecchymosis, red eyes, hematemesis, hematuria. Patients can develop hypovolemic state, DIC, prerenal failure and multiorgan dysfunction syndrome *Lab diagnosis* - ELISA and PCR. Tr. Supportive. Anti-viral agent Ribavirin.

Diseases of Children

Neonatal critical care

Persistent pulmonary hypertension (PPHN) is basically a failed transition of fetal circulation to neonatal circulation.

Pathophysiology: Normal cardiorespiratory adaptations at birth are aeration of lungs, fall in pulmonary vascular resistance, closure of various fetal shunts, i.e. patent foramen ovale, ductus venosus and arteriosus. Alterations in this normal process leads to PPHN.

Pathological mechanisms leading to PPHN in various disease processes:

- Maladaptation of pulmonary vessels (perinatal asphyxia, meconium aspiration syndrome)
- Maldevelopment of pulmonary vessels (PPH)
- Underdevelopment of pulmonary vasculature (congenital diaphragmatic hernia)
- Structural/functional obstruction to pulmonary blood flow

Clinical features

- Cyanosis inspite of high supplemental O₂
- Tachypnoea 80-100/min
- Minimal signs on auscultation
- Mild tachycardia
- Loud P₂
- Pre and post-ductal O₂ gradient (-20 mmHg)
- Hypotension
- Hyporexia and hyperventilation test to differentiate it from cyanotic heart disease

Diagnosis: 2D echo - Structurally normal heart with supra-systemic PA pressures, right to left shunting at level of PFO and PDA. Dilated RV, TR.

Management:

1. Restore functional residual capacity of the lung using conventional or high frequency oscillatory ventilation (HTOV), and optimum PEEP.

2. Reduce peripheral vascular resistance (PVR). Maintain oxygenation > 80 mmHg. Nitric oxide is a selective pulmonary vasodilator. Other adjuvant therapies include avoiding hypercapnia, maintaining pH in range of 7.4-7.5, optimal sedation and muscle relaxation. Inhaled nitrous oxide (iNO) decreases PVR and extrapulmonary venoarterial shunting. It is contraindicated in severe IVH, platelets < 50,000 and irreversible pulmonary pathology.

Cold blanket for asphyxial neonates

Hypothermia arrests the extent of brain damage. The neonate's body temperature is lowered by a couple of degrees from the normal 37°C for 72 hours by using the blanket. The baby's temperature is then gradually raised to normal. The cold environment stops the damaging brain activity - like release of excitatory aminoacids that results in the newborn not crying in the first place.

Excessive crying in a baby

1. Hunger
2. Heat
3. Mosquito bites
4. Wet clothes
5. Blocked or stuffy nose
6. Infantile colic, e.g. from windiness
7. Pain anywhere in the body, e.g. earache
8. Restlessness at night, e.g. from darkness
9. Serious illness, e.g. raised intracranial pressure or brain damage.

Persistent crying in babies. Excessive crying is defined medically as crying that lasts atleast 3 hours a day, for 3 days a week, for atleast 3 weeks.

Nature of the crying: Babies cry for a variety of reasons, including hunger and thirst, being hot or cold, wanting attention, tiredness, discomfort and pain. The pattern of crying may indicate the problem, e.g. infantile colic (excessive crying in an otherwise healthy baby may manifest as long bouts of crying in the early evening).

Other symptoms: Difficulty in feeding may be due to a blocked nose, vomiting may indicate a GI problem, excessive straining may be due to constipation, and eczema suggests discomfort from itching.

Feeding: An underlying cause may be overfeeding or premature weaning. The baby may be inadvertently swallowing air, particularly at the end of a bottle feed.

Psychiatry

Drugs causing confusion in elderly:

1. Digoxin (also fatigue, euphoria).
2. Propranolol (also nightmares, insomnia).
3. Methyldopa.
4. Indomethacin (also vertigo, headache).
5. Cimetidine (esp. if renal or hepatic insufficiency).
6. Amantadine, L-dopa (esp. if used with anticholinergics).
7. Sedative-hypnotics, tricyclics, phenothiazines, alcohol.

Tardive dyskinesia:

Clinical features:

1. Orofacial dyskinesia.
 - a. 'Fly-catcher' tongue.
 - b. 'Bon-Bon' sign.
 - c. Rumination, pouting.
2. Glottal dyskinesia - grunting.
3. Blepharospasm, increased blink frequency.
4. Torticollis.
5. Upper limbs.
 - a. 'Piano-playing' fingers.
 - b. Choreiform or ballistic movements.
 - c. Shoulder shrugging.
6. Lower limbs.

Writhing of lower legs

Distinguishing delirium from dementia

	Delirium	Dementia
Onset	Acute or subacute	Insidious
Course	Fluctuating, usually revolves over days to weeks	Progressive
Conscious level	Often impaired, can fluctuate rapidly	Clear until later stages
Cognitive defects	Poor short term memory, poor attention span	Poor short term memory, attention less affected until severe
Hallucinations	Common, especially visual	Often absent
Delusions	Fleeting, non-systematised	Often absent
Psychomotor activity	Increased, reduced, or unpredictable	Can be normal

Autism: Three areas of impairment that characterize autism:

1. Social impairment
 - Lack of social interest
 - Lack of eye contact and gesture

Obsessive-compulsive disorder. Non-psychiatrists are likely to see patients with OCD:

Professional	Reason for consultation
Family physician	Depression, anxiety
Dermatologist	Chopped hands, eczema, trichotilomania
Cosmetic surgeon	Concerns about appearance (body dysmorphic disorder)
Oncologist	Fear of cancer
Genitourinary specialist	Fear of HIV
Neurologist	OCD associated with Tourette's syndrome
Obstetrician	OCD during pregnancy or puerperium
Gynecologist	Vaginal discomfort from douching

Types of Munchausen's syndrome

Abdominal: Patients travel to various hospitals undergoing repeated operations, only to discharge themselves against advice (even with wounds still healing and I.V. drips in place).

Bleeding: Characterized by bleeding symptoms anticoagulant subtype, anemia subtype, pretended bleeding subtype.

Neurological: Unusual yet often convincing fits, spells, faints and anaesthesias.

Miscellaneous: Pyrexia. Dermatological. Endocrine. Munchausen's syndrome by proxy: A form of child abuse in which a parent or carer feigns illness in a child.

2. Poor peer relationship
2. Repetitive and routinized behaviour
 - Stereotype
 - Reference for routine
 - Unusual preoccupation

3. Communications of an impairment
 - Echolalia or non-communicative speech
 - Language delay
 - Stereotyped or repetitive speech

Postpartum psychosis: Presents with severe depression, mania, high suicidal drive, schizophrenia symptoms, persistent crying, lack of appetite, self and harm to within three months of delivery.

Voluntary and smooth muscle and skeletal disorders caused by alcohol misuse.

- Proximal metabolic myopathy (principally affecting type II).
- Neuromyopathy secondary to minor motor nerve damage
- Atrophy of smooth muscle of GI tract leading to motility disorders
- Osteopenia
- Gout
- Avascular necrosis (e.g. femoral head)
- Fractures - Malunion

Common differential diagnosis of depressive illness

Other psychiatric disorders	Alcohol misuse
	Amphetamine (and derivatives) misuse and withdrawal
	Borderline personality disorder
	Dementia
	Delirium
	Schizophrenia Normal and pathological grief
Organic (secondary) affective illness	Cushing's syndrome
	Thyroid disease (sometimes depression persists even after treatment)
	Hyperparathyroidism
	Corticosteroid treatment
	Brain tumor (rarely without other neurological signs)

Alice in Wonderland syndrome (Todd's syn.) is a type of psychiatric affection in which the individual has a disturbed assessment of self and suffers from fast forwarding of intrapsychic time. This may be encountered in some cases of migraine and of epilepsy.

Poisoning

Barium carbonate: Most cases of acute toxicity occur due to ingestion of barium carbonate (mostly suicidal), food contaminated by or carelessness in 'handling of rat poison'.

Cl. Fs. Abdominal pain, nausea, vomiting, flaccid paraplegia and respiratory paralysis which can develop within a few hours. Hypertension and cardiac arrhythmia. CNS - Myalgias, anxiety, headache, confusion and seizures. Hypokalemia occurs as a result of redistribution of body potassium. *Tr.* Gastric lavage, administration of sodium sulphate. IV potassium (upto 400 mEq).

Acute organophosphorus poisoning. Phases of neurological involvement:

- I. Acute paralysis secondary to continued depolarization at the neuromuscular junction.
- II. Intermediate syndrome develops 24 to 96 hours after resolution of initial phase, characterized by weakness of proximal muscles, cranial nerve palsies, and may require mechanical ventilation. Extrapyramidal symptoms — Dystonia, cogwheel rigidity and Parkinsonian facies.
- III. Organophosphorus delayed polyneuropathy (OPIDP) occurs 2 to 3 weeks after exposure. Chronic OP induced neuropsychiatric disorders have also been reported.

Neurology

Transient Ischaemic Attacks. In the new definition of TIA, emphasis is laid on the fact that MRI must not show evidence of acute ischaemia, irrespective of the time period of recovery.

Temporal arteritis

- If ESR is normal, but CPR is high temporal arteritis should be suspected.
- MRI of temporal vessel. Ensure that skipped areas are not biopsied resulting in false negative biopsy.

Painful ophthalmoplegia

Common causes:

Herpes zoster

Intracranial aneurysm

Diabetes mellitus

Paranasal mucocele

Parasellar neoplasm

Carotid cavernous fistula

Tolosa-Hunt syn.

Ophthalmoplegic migraine

Arteritis

Ophthalmic Grave's disease

Congenital myopathy (myotubular variety)

Migraine: Sublingual Piroxicam 40 mg in migraine without aura has significant analgesic effect in acute management with excellent tolerability.

SAH: The two most common sites are proximal portion of anterior communicating artery and at the origin of

the posterior communicating artery from the stem of the internal carotid.

Sturge Weber syndrome is characterized by cutaneous angioma (portwine stain) typically involving the ophthalmic division of trigeminal nerve and an ipsilateral brain angioma with gyral calcification in parieto-occipital lobe. Principal neurological manifestations are epileptic seizures and focal neurological deficiency. Some patients may present with repeated episodes of facial weakness similar to TIAs.

Tension pneumocephalus is the term used to describe trapping of air intracranially. Usually, it occurs in patient whose brain does not expand after removal of subdural hematoma. Simple procedure like burr hole and air drainage can be life saving.

Pisa syndrome refers to axial dystonia with severe tonic lateral flexion of the trunk. Disproportionate anticollis often seen as chin on chest, whereas rest of the body is normal.

Disorder of voltage-gated ion channels are responsible for a group of neurological and muscular diseases now called channelopathies. They are characterized by increased or decreased excitability of nerve or muscle.

Causes of acute facial palsy which are not idiopathic

- Suppurative otitis media
- Head injury (onset may be delayed by a few days)
- Herpes zoster
- G-B syndrome - Facial palsy may be an early predominant feature
- Sarcoidosis may present with isolated facial palsy
- Multiple sclerosis
- Lyme disease
- HN infection - Lymphadenopathy

Neurodegeneration with brain iron accumulation (NBIA) is characterized by progressive extrapyramidal degeneration presenting as a spectrum of cervical dystonia, dysarthria. MR brain is suggestive of characteristic 'eye of the tiger' appearance.

Reflex sympathetic dystrophy following pacemaker insertion an RSDS (Sudeck's atrophy) usually follows minor trauma or surgery or may occur spontaneously. The syndrome begins with spontaneous pain associated with vasomotor and sudomotor disturbances.

Clinical fMRI: The patient is given specific task to perform (motor, visual, language, etc.) while MR sequences are able to detect increased O₂ delivery and blood flow to the areas of the brain that are responsible for those specific tasks are shown in color on the MRI images, e.g. if the

patient is asked to do a right finger tap, then the functional area for the right hand in left cerebral hemisphere is seen as an activation.

Demyelinating diseases

CNS

- MS or its variant
- Transverse myelitis
- Devic's disease
- Acute disseminated encephalopathy
- Optic neuritis

Peripheral nerves

- G-B syndrome
- Chronic inflammatory demyelinating polyneuropathy
- Anti-MAG (myelin associated glycoprotein) peripheral neuropathy

Pantheothenate-kinase neurodegeneration (PKAN) with iron accumulation is characterized by progressive extrapyramidal dysfunction and associated features like corticospinal involvement, intellectual impairment, retinitis pigmentosa, optic atrophy and seizure and 'eye of tiger' appearance on neuroimaging.

Parkinson's disease and Huntington's chorea

	<i>Parkinsons disease</i>	<i>Huntington's chorea</i>
Site of neuronal loss	Substantia nigra	Caudate nucleus
Neurotransmitter loss	Dopamine	Acetylcholine (and GABA)
Excess of	Acetylcholine	Dopamine
Levodopa therapy	Improvement	Exacerbation of chorea
Phenothiazine	Exacerbation	Improvement of chorea

Pathological classification of syringomyelia:

Type I: With obstruction of foramen magnum and dilatation of central canal:

- With type I Chiari malformation.
- With other obstructive lesions of foramen magnum

Type II: Without obstruction of foramen magnum (idiopathic).

Type III: With associated disease of spinal cord—tumors, arachnoiditis, traumatic myelopathy.

Type IV: Pure hydromyelia with or without hydrocephalus.

Bladder involvement is late in syringomyelia because lesions is lateral.

Nonmotor symptoms of Parkinson's disease

1. Neuropsychiatric symptoms

Depression, apathy, anhedonia, anxiety, panic attacks, attention deficit.

Hallucinations, illusions, delusions (could be drug induced), obsessional behaviour.

Dementia, confusion, delirium (could be drug induced).

2. Sleep disorders

Restless legs and periodic limb movements, REM sleep behaviour disorder (RBD).

Insomnia, excessive daytime somnolence.

Vivid dreaming, sleep disordered breathing.

3. Autonomic symptoms

Bladder disturbances: Urgency, nocturia, frequency. Sexual dysfunction: Hypersexuality (likely to be drug induced), erectile dysfunction.

Abnormalities of sweating, orthostatic hypotension, dry eyes (xerophthalmia), dry mouth.

4. Gastrointestinal symptoms

Dribbling of saliva (sialorrhoea).

Delayed gastric emptying, ageusia, dysphagia, choking, reflux.

Vomiting/nausea (usually drug related).

Constipation/unsatisfactory voiding of bowel/faecal incontinence.

5. Sensory symptoms

Pain/paraesthesia, olfactory disturbance (hyposomnia).

6. Other symptoms

Fatigue, diplopia, blurred vision, seborrhoea.

Weight loss, weight gain (possibly drug induced).

Parkinsonian tremor

Parkinsonian tremor	Essential tremor
Tremor faster	Tremor slower
At rest	Non-resting
Usually unilateral	Usually bilateral
Affects hands and legs	Affects hands, head and larynx
Starts in later life	Often present from childhood
Rapidly progressive	Slowly progressive
Reduced by ingestion of levodopa	Reduced by ingestion of alcohol
Signs of Parkinson's disease	No evidence of parkinsonism

Mitochondrial medicine

Mitochondrial diseases are extremely heterogeneous multisystem disorders predominantly affecting tissues or organs with high oxygen consumption like skeletal muscles, brain, endocrine glands, myocardium, etc.

Mitochondrial diseases

Neuromuscular system: Facial dysmorphism, mental retardation, dementia, impaired visual acuity, visual field, dry mouth, reduced gag reflex, exaggerated masseter reflex, gaze paresis, ophthalmoparesis, weakness, wasting, hypotonia, reduced deep tendon reflexes, long tract signs, fasciculation, myoclonus, cogwheel rigidity, dystonia, ataxia, brady/dysidiadochokinesia, sensory and gait disturbance.

Eye: Pigmentary retinopathy, optic atrophy, squint, cataract and glaucoma.

Endocrine system: Short stature, developmental delay, polyphagia, failure to thrive, hypopituitarism, diabetes mellitus, diabetes insipidus, hypoglycemia, thyroid and parathyroid dysfunction, amenorrhoea, hypogonadism, delayed puberty.

Gastrointestinal: Paraodontosis, dysphagia, gastrointestinal dysmotility, pseudo obstruction, recurrent vomiting, hepatopathy (acute liver failure), recurrent pancreatitis, villus atrophy, malabsorption, diarrhea, weight loss, anorexia.

Kidneys: Renal cysts, tubulopathy, Toni-Debre-Fanconi syndrome.

Blood: Anemia, leucopenia, thrombocytopenia, eosinophilia.

Congenital crocodile tears with congenital cranial dysinnervation syndrome. Lacrimation occurs while taking food. There is limitation of convergence, with narrowing of palpebral fissure. The likely cause is a defect in normal developmental cells forming abducens nucleus and superior lacrimal nucleus in brain stem.

Autonomic dysfunction

Clinical manifestations: of primary autonomic failure:

CVS	Postural hypotension
Urinary bladder	Frequency, urgency, incontinence, retention
Large bowel	Constipation, occasionally diarrhoea
Genital tract	Impotence in males
Sweat glands	Anhidrosis
RS	Stridor, respiratory gasps, apnoeic periods
Pupils	Anisocoria, Homer's syndrome
Other neurological defects	Parkinsonism, cerebellar and pyramidal signs

Moyamoya disease

It is progressive veno-occlusive disease of unknown cause involving arteries of the Circle of Willis. It presents as

ischemic stroke in children and intracranial hemorrhage in adults. It is associated with renal artery stenosis and renovascular hypertension in some.

Neurological conditions with a psychiatric presentation

1. Degenerative disorder, e.g. dementia
2. Head injury
3. Stroke
4. Epilepsy and non-epileptic fits
5. Parkinson's disease
6. Intracranial tumors
7. Intracranial infections
8. Nutritional, toxic or endocrine disorders.

Diseases causing fever with involvement of the CNS

Leptospirosis
 Malaria
 Scrub typhus
 Typhoid Rabies
 Arboviral encephalitis
 Japanese encephalitis
 Tick-borne encephalitis
 Dengue
 East African trypanosomiasis
 Acute human immunodeficiency virus infection

Dermatology

Skin conditions of the male genitalia

Prominent sebaceous glands: Tyson's glands, sebaceous hyperplasia and ectopic sebaceous glands are common normal variants of skin of scrotal sac and penile shaft.

Erythroplasia Queyrat is squamous cell carcinoma of penile mucosa, presenting as red, shiny, possibly eroded patch. It is associated with infection with oncogenic HPV types.

Squamous cell carcinoma: Itch, irritation, pain, bleeding, discharge, ulceration or discovery of a tumor may herald squamous cell carcinoma.

Kaposi's sarcoma was rare before the advent of AIDS. HIV-related Kaposi's sarcoma has a predilection for the mucosa, and penis and foreskin are common sites of patch, papulo, nodular and hemorrhagic forms. Phimosis can occur.

Angiokeratomas are blue-purple, smooth papules on scrotum and penile shaft that appear and multiply during life.

Pearly penile papules are present as flesh-coloured, smooth, rounded papules, predominantly around the coronal margin of the glans, often arranged in parallel rows or concentric rings.

Molluscum contagiosum is usually sexually acquired infection and present as small, flesh-coloured, monomorphic, dome-shaped papules indented with a central 'umbilicus'.

Chronic idiopathic penile oedema is uncommon and thought to result from chronic/recurrent staphylo/ streptocellulitis/lymphangitis of the prepuce, penis and sometimes lower abdominal wall.

Zoon's balanitis is a disorder of middle-aged and older uncircumcised men. Well demarcated, moist, shiny, bright red or brown patches involve glans and prepuce (often opposed in a 'kissing' distribution).

Psoriasis: Anogenital skin is a common, and sometimes the only site of psoriasis. The Kohner phenomenon may contribute to this distribution. 'Inverse-pattern psoriasis' refers to the appearance of the disease on intertriginous skin in the natal cleft, gluteal folds and groins, between the dependent flaccid penis and preputial sac, and on the glans of uncircumcised men.

Lichen sclerosus: Lilac, slightly scaly, atrophic white patches or plaques with telangiectasia, purpura, bullae, erosions and ulcerations may be seen on penis. Other presentations are phimosis and paraphimosis.

Lichen planus manifests as itchy, red-purple, patches or plaques. Occasionally, a micropapular (lichen nitidus) or erosive form is seen.

Pyoderma gangrenosum is very rare. It may occur as a Kohner reaction to local trauma such as urological surgery, or may be associated with Behcet's disease, ulcerative colitis or CLL.

Bowen's disease is a squamous cell carcinoma of the glans or prepuce presenting as a red, shiny, scaly patch. Extra genital disease may be associated with HIV infection, sunlight exposure and internal neoplasia.

Bowenoid papulosis is analogous to other manifestations of penile intra-epithelial neoplasia (PIN), e.g. Bowen's disease, and present as multiple warty lesions in younger sexually active males. The lesions are often pigmented in keratinized sites, and multiple and more inflamed in mucosal site.

Splinter hemorrhage. Causes:

Systemic diseases

Subacute infective endocarditis
 Hypertension
 Mitral stenosis
 Diabetes mellitus
 Rheumatoid arthritis
 Internal malignancy
 Systemic lupus erythematosus

Thrombocytopenia
 Thyrotoxicosis
 Trichinosis
 Langerhans cell histiocytosis
 Scurvy

Skin diseases

Psoriasis
 Reiter's syndrome
 Dermatitis/eczema
 Exfoliative dermatitis
 Onychomycosis
 Mycosis fungoides
 Pityriasis rubra pilaris
 Pemphigus
 Osler-Weber-Rendu disease

Drugs

Tetracyclines
 Drug reactions (in general)

Miscellaneous

Hemodialysis
 Peritoneal dialysis
 Idiopathic

Calcinosis cutis presents as multiple, non-joint subcutaneous swellings over various sites. It has been classified into four types - metastatic, dystrophic, iatrogenic and idiopathic. The nodules can become painful and disfiguring with ulcerative, infective and mechanical complications. Dermatomyositis, SLE and CREST classically manifest with dystrophic classification.

Diseases with dermal rash

1. SLE
2. Dermatomyositis
3. Psoriasis
4. Rheumatic fever
5. Reactive arthritis
6. Cryoglobulinemia
7. Still's disease
8. Sarcoidosis
9. Rubella
10. Dengue
11. Henoch-Schonlein purpura
12. Lyme disease
13. Iatrogenic

Uncommon genital conditions

Psoriasis on shaft of penis produces dull, red plaques covered with scale.

Lichen planus may affect the glans and prepuce, but seldom the vulva. The lesions are flat, shiny, violaceous papules and are often itchy.

Lichen sclerosus et atrophicus may be seen on the prepuce, causing atrophy, depigmentation and contraction (which may lead to phimosis). Vulvar involvement may present with pruritus, and later produce contraction at the introitus.

A *fixed drug eruption* lesion is usually ovoid. The affected site is marked with post inflammatory hyperpigmentation.

Fever-Rash

Though a rash is usually generalized and pathognomonic of exanthemata, the term is often used to include all cutaneous eruptions.

Causes:

- I. Acute illness of short duration
 1. Exanthemata: Measles, rubella, scarlet fever, enteric fever, generalized vaccinia, Kaposi's varicelliform eruption.
 2. Pyogenic: Erysipelas
 3. Allergic rashes: Acute allergy, drug rash, serum sickness, Henoch-Schonlein purpura
 4. Herpes zoster
 5. Rheumatic fever
 6. Infectious mononucleosis
 7. Dermatomyositis
- II. Subacute or chronic illnesses of long duration
 1. SLE
 2. TB of skin - Miliary TB, papulonecrotic
 3. Erythema nodosum
 4. Lepra reaction
 5. Secondary syphilis
 6. PAN
 7. Panniculitis: Common form is characterized by nodules and plaques of dusky colour with relapsing fever and constitutional symptoms.

Sweets' syndrome: Acute febrile, neutrophilic dermatosis is characterised by sudden onset of fever, leucocytosis and cutaneous eruption. Tender, erythematous and well demarcated papules, plaques.

Cutaneous anthrax should be considered in differential diagnosis in cases presenting with ulcers vesicles or eschars with a recent history of exposure to animal or animal products.

Cutaneous manifestations due to occult tumor

- Acanthosis nigricans (mainly ca of stomach)
- Thrombophlebitis migrans (pancreatic carcinoma)

- Dermatomyositis (Tumors of female reproductive organs)
- Ichthyosis (lymphoma mainly)
- Pachydermoperiostosis (cancer lung)
- Pemphigus neoplastic type (myeloproliferative disorders)
- Bullous pemphigoid (malignancy of stomach, breast, lungs)
- Hypertrichosis lanuginosa (lung and colon cancer)
- Tripe palms - Accentuated palmar creases (lung cancer)

Differential diagnosis of psoriasis

Types of psoriasis	
<i>Psoriasis vulgaris</i>	<ul style="list-style-type: none"> • Discoid eczema - well defined, itchy circular lesions with crusting rather than scaling; the lesions show a predilection for the legs • Seborrhoeic eczema - ill-defined, browner lesions with greasy scale affecting the scalp, face, upper chest and flexures • Tinea corporis - well-defined, slightly itchy circular lesions with red, scaly margins and central clearing, with an asymmetrical distribution • Lichen simplex - ill-defined, itchy lesions with marked skin thickening, purplish colour and increased skin markings (lichenification)
<i>Guttate psoriasis</i>	<ul style="list-style-type: none"> • Pityriasis rosea - starts with a large herald patch, over several weeks, develops numerous small pink papules with a fine peripheral scale over the trunk and upper limbs; the papules fade within 6 weeks • Lichen planus - purple papules covered with white lines (Wickham's striae) with possible mouth and nail involvement
<i>Napkin psoriasis</i>	<ul style="list-style-type: none"> • Irritant dermatitis - weeping, erythematous lesions confined to the nappy area, but sparing body folds • Seborrhoeic dermatitis - erythema and scaling of the nappy area, often with lesions of scalp, face and axillae • Candidiasis - macerated, erythematous lesions with pustulation and satellite lesions
<i>Nail psoriasis</i>	<ul style="list-style-type: none"> • Onycholysis can occur in fungal nail infections, thyrotoxicosis, hypothyroidism, Raynaud's phenomenon and trauma • Nail pitting occurs in alopecia areata and occasionally in lichen planus
<i>Erythrodermic psoriasis</i>	<ul style="list-style-type: none"> • Drug reactions, eczema and cutaneous T cell lymphoma can all lead to erythroderma; these conditions are distinguished from psoriasis by the clinical history and skin biopsy changes
<i>Palmoplantar pustulosis</i>	<ul style="list-style-type: none"> • Hand eczema - ill-defined, itchy areas with vesicles rather than pustules • Fungal infection - unilateral or asymmetrical erythema with scaling, involvement of the toe clefts, nails and palmar creases

Infectious diseases and Infections

Meningitis: CSF protein > 200 mg means TBM unless proved otherwise. Acute polymorph reaction can occur in initial phase of TBM.

Measles: House-hold contacts (over 9-12 months) of measles patients should be vaccinated against measles within 3 days of exposure.

Anemia in malaria: Possible factors -

1. Hemolysis of infected RBCs
2. Hemolysis of uninfected RBCs
3. Dyserythropoiesis
4. Splenomegaly causing RBC sequestrations and hemodilution
5. Depletion of folate stores

Lptospirosis

1. Hemorrhagic fever with renal syndrome
2. Weil's syndrome. Severe leptospiremia with jaundice, azotemia, hemorrhage, anemia and disturbed consciousness. Hepatic or renal manifestations predominate.

3. Atypical pneumonia syndrome resembling bilateral bronchopneumonia or ARDS. Leptospirosis should be suspected in cases of rapidly developing pneumonia with severe myalgia.

4. Aseptic meningoenzephalitis.

5. Myocarditis.

Lepto dipstick stick test is highly sensitive and specific test for diagnosis

Clinical syndromes of neurocysticercosis

Cerebral cysticercosis

- Seizure disorder
- Syndrome of increased intracranial tension
- Syndrome of intracranial space occupying lesion
- Syndrome of meningoencephalitis
- Psychiatric syndrome
- Stroke syndrome.

Ocular cysticercosis

Spinal cysticercosis

- Syndrome of compressive myelopathy
- Syndrome of radiculopathy.

Muscular cysticercosis

- Pseudohypertrophy of muscles.

Dengue vaccine: Dengue is not one virus but for 4 different viruses, or serotypes, each of which must be neutralized by the vaccine. Efforts to develop a therapeutic antibody for dengue are to focussed on a part of the virus called the envelop protein.

Chikungunya fever

Arthralgia refractory to other drugs - Use hydroxy chloroquine 200 mg od or Chloroquine phosphate 300 mg day for 4 weeks. Before using chloroquine, peripheral blood smear examination must be done to rule out malaria.

Since an immunologic etiology is suspected in chronic case, a short course of steroids may be useful.

Clinical features in Chikungunya fever

Common	Infrequent	Rare in adults but seen sometimes in children
Fever	Rash	Photophobia
Arthralgia	Stomatitis	Retro-orbital pain
Backache	Oral ulcers	Vomiting
Headache	Hyperpigmentation	Diarrhoea
	Exfoliative dermatitis	Meningeal syndrome Acute encephalopathy

Osteoarticular problems in chronic phase: Usually subside in one or tow weeks. In about 20% case they disappear after a gap of few weeks. In < 10% cases, they tend to persist for months. In<10% cases, the swelling disappears, the pain subsides but only to reappear with every other febrile illness for many months. Each time, the same joints get swollen with mild effusion and symptoms persist for a day or two after subsidence of the fever. Destroyed metatarsal head has been observed inpatients with persistent joint swelling.

Differential diagnosis

1. **Leptospirosis:** Severe myalgia localized to calf muscles with conjunctival congestion/or subconjunctival hemorrhage with or without oliguria or jaundice in a person with history of contact to contaminated water might suggest leptospirosis.
2. **Dengue fever:** Severe back pain with purpura or active bleeding might suggest dengue fever. Confirmatory laboratory diagnosis is possible.
3. **Malaria:** Periodicity for fever and alteration of consciousness/seizures should prompt a diagnosis for malaria.
4. **Meningitis:** High fever with neck stiffness or alteration of consciousness should prompt a through about meningitis. All cases of meningoencephalitis during an outbreak of CF must be suspected to have CF.
5. Rheumatic fever is more common in children and presents with fleeting (migratory) polyarthritis predominantly affecting the large joints. Modified Jones criteria should be the basis for diagnosis. Raised ASO titre and a history of recurrent sore throat are other points to be noted.

Management of osteoarticular problems**Rickettsial Diseases**

Rickettsiae comprise a group of organisms that occupy a position between bacteria and viruses. A general characteristics of rickettsiae is that mammals and arthropods are natural hosts. Rickettsioses caused by organism within the genus of rickettsiae can be divided into the following sub-groups.

1. **Typhus group:** Causing classical epidemic typhus caused by *Rickettsia prowazekii* and *Rickettsia typhi* transmitted by human body louse and rat flea respectively.
2. Spotted fever groups containing a large number of species *Rickettsia rickettsii* transmitted from rodents and other animals by ticks. Rocky mountain spotted fever is a prototype.
3. Scrub typhus caused by *Rickettsia tsutsugamushi* and transmitted by larval trombiculidae bites. New rickettsioses are tick borne lymphadenopathy (TBLA) and Dermacentor - borne - necrosis - eschar lymphadenopathy (DEBONEL).

HIV-AIDS

Fungal meningitis: Apart from *C. neoformans*, other fungi also cause meningitis. If facility for fungal culture is not available and if CSF smear shows evidence of fungal infection, then standard therapy with amphotericin can be started earlier to reduce mortality.

Resistance to Antiretroviral therapy

There is no ARV combination as yet to stop HIV replication. The effective ART most result in undetectable (< 50 copies/ml). The must common cause of therapeutic failure is a viral resistance as it indicates ongoing viral replication in presence of the inhibitory drugs. During ART the virological failure appears first. Immunological failure becomes evident much later, followed by clinical failure. Therefore, viral load monitoring is essential to detect virological failure so as to switch the therapy.

Recommendations for ART in pregnancy

1. **Pregnant females on ART:** Continue same ART. Efavirenz can be switched panarine or PI in first trimester.
2. Pregnant females with CD4 <250 cells/camm: Initiate ART as per adult ART guideline avoiding Efavirenz in first trimester (due to fetal teratogenic risks).

- Pregnant females with CD4 > 250 cells/cumm, short course regimen for 28 weeks till delivery. Zidovudine + Lamivudine + Lopinavir/Ritonavir.

Radiology and Imaging

Differential diagnosis of bilateral upper lobe fibrosis

- Old healed tuberculosis
- Subacute silicosis
- Chronic sarcoidosis
- Coal worker's pneumoconiosis
- Ankylosing spondylitis
- Rheumatoid disorders
- Berylliosis
- End stage histiocytosis
- Late manifestation of radiation therapy for carcinoma breast
- Idiopathic upper lobe pulmonary fibrosis

Abnormal intraluminal gas

- Large bowel obstruction and paralytic ileus.
- Small bowel obstruction.

Comparison of large and small bowel obstruction features

Feature	Obstruction	
	Small bowel	Large bowel
• Bowel diameter	<3 and > 5	> 5
• Position of loops	Central	Peripheral
• Number of loops	Many	Few
• Fluid levels	Many, short	Few, long
• Bowel markings	Valvulae (all the way across)	Haustra (Partially across)
• Large bowel gas	No	Yes

- Volvulus: (a) Sigmoid volvulus: An extremely dilated loop of sigmoid bowel forms two large compartments which look like a coffee bean (coffee bean sign). (b) Caecal volvulus - Caecum is displaced to upper left abdominal quadrant. This leaves the right lower quadrant area empty ('empty caecum' sign). Distal to the volvulus the large bowel is empty.
- Toxic megacolon: Grossly dilated large bowel, typically the transverse colon, with 'thumb printing' evident.
- Acute pancreatitis: A small sentinel loop (a collection of intraluminal gas) of bowel may be seen; the inflamed pancreas paralysing the adjacent bowel, making it adynamic.
- Duodenal obstruction (congenital or acquired), gives the appearance of two gas bubbles, one in the duodenum and the normal gastric air ('double bubble' sign).
- Meteorism: Although there are prominent bowel loops, there is no cut off point; the bowel has been likened to crazy paving.

Calcification on abdominal X-rays

Normal structures that calcify

- Costal cartilage
- Mesenteric lymph nodes
- Pelvic vein clots (phlebolith)
- Prostate gland.

Pathological calcification

- Pancreatic: Chronic pancreatitis, parenchymal tissue
- Renal: Hyperparathyroidism. Renal tubular acidosis
Renal calculi
Medullary sponge kidney
- Vascular: Atherosclerosis, abdominal aortic aneurysm
- Gallbladder
Biliary calculi,
gallbladder fibroids
(Leliomyoma)
- Appendix: Appendicolith
- Bladder: Calculi
- Teratoma
- Uterus: Fibroids.

Biliary gas seen as branching 'tree-like' streaks of black projected in the liver shadow.

Causes: (a) After ERCP with sphincterotomy, gas may travel from the duodenum into biliary tree as the sphincter of Oddi in the second part of duodenum is incompetent. Similarly after a gallstone has been passed, the sphincter may become dilated. Fistulation between gallbladder and adjacent bowel allows a route for gas into the biliary system. (b) Cholangitis — If the biliary ducts are infected with gas forming organisms, it will be found in the duct, creating a negative contrast to the surrounding soft tissue of the liver.

Mount Fuji sign: In hyperostosis frontalis interna. The sign is an imaging observation in case of tension pneumocephalus and occurs due to surgery or trauma and the air gets trapped in bilateral frontal dural spaces, with a ball valve mechanism. In anterior cranial fossa the dura is thin and closely applied to bone, and the arachnoid is adherent to frontal bones; hence the air being trapped in subdural space of anterior cranial fossa. As the accumulation occurs more, it compresses the frontal lobes on both sides, making the CT of the brain resembling the silhouette of a volcano such as Mount Fuji.

Pneumatoceles are thin-walled, air-filled cysts that develop within the lung parenchyma. They can be simple emphysematous lesions, more often multiple thin-walled, air-filled cyst like cavities. Staph. pneumonia with pneumatocele is common in children, uncommon in adults.

Tree-In-Bud sign is a CT scan finding of chest with visibility of small airways. Dilatation of bronchioles due to luminal impaction with mucus or pus, and thickening of their walls due to peribronchiolar inflammation lead to visibility of bronchioles on thin section CT scan. Histopathologically, terminal tufts of tree-in-bud opacities represent inflammation with caseous material in respiratory bronchioles, whereas the stalks represent caseous material in terminal bronchioles. Tree-in-bud opacities are focal or multifocal, unilateral or bilateral. It is commonly associated with bronchopneumonia, invasive aspergillosis, viral bronchiolitis, endobronchial tuberculosis, pneumocystis pneumonia, bronchoalveolar cell carcinoma. Rare causes include RA, Sjogren's syndrome, Sjogren's cell histiocytosis, sarcoidosis, inhalation of toxic fumes or gases. Congenital causes include cystic fibrosis, dyskinetic cilia syndrome, yellow nail syndrome, or congenital immunodeficiency disorders.

Temporal arteritis: Evidence of a dark shadow halo on ultrasonography, arterial wall oedema is considered to be a specific sign of active disease.

Hot cross bun sign on MRI is due to loss of pontine neurons and myelinated transverse, pontocerebellar fibres with relative preservation of corticospinal tracts which run craniocaudally. The sign can occur in multisystem atrophy-cerebellar (MSAC).

Miscellaneous

Poland's syndrome: or anomaly consists of unilateral absence or hypoplasia of pectoral muscle, most commonly involving the sternocostal portion of pectoralis major and a variable degree of hand digit anomalies including symbrachy.

Musculoskeletal problems associated with malignancy:

- Arthropathies
- Muscular disorders including polymyositis/dermatomyositis
- Scleroderma, panniculitis and fasciitis
- Vasculitides
- Miscellaneous rheumatic syndrome

Behcet syndrome must be suspected in all cases who present with orogenital mucosal ulceration, scleritis/uveitis and also considered in DD of PUO.

Immunodeficiency and low mannose-binding levels
Common variable immunodeficiency syndrome (CVID) characterized by failure of B-cell differentiation and defective IgG production leading to recurrent bacterial infection particularly of respiratory tract. ML deficiency increases infection susceptibility to a disease (e.g. meningococcal disease) or alters the natural history of disease, e.g. cystic fibrosis. CVID and chronic granulomatous disease.

Low serum ceruloplasmin level

- New born and infants
- Severe malnutrition
- Nephrotic syndrome
- Protein-losing enteropathy
- Congenital ceruloplasminemia
- Severe hepatic insufficiency
- Acute hepatic infections

Kikujii-Fugimoto's disease is a rare self-limiting disorder characterized by fever and cervical lymphadenopathy. Diagnosis established by excision lymphnode biopsy and histopathology which shows histiocytic necrotizing lymphadenitis.

Maliedosis caused by *B pseudomalle*, has been referred to as the 'remarkable imitator' because of varied clinical presentations. Infections may range from subclinical towards a fulminant disease. Infections may be acute or chronic, localized or disseminated. Humans acquire the infection by inhalation of contaminated dust or when soil contaminated with bacteria comes in contact with abraded skin. The primary focus of infection may be the lung, skin and subcutaneous tissue.

PICA: Doctors must inquire about PICA whilst taking dietary history in case of unexplained hypokalemia and nutrient deficiency.

Hyperhomocystinaemia. Causes:

Primary

Inherited enzyme deficiencies

- Cystathionine beta-synthase deficiency
- C₆₇₇ T mutation of methylene tetrahydrofolate reductase
- Methionine synthase deficiency
- Methylene tetrahydrofolate hornocysteine methyl transferase deficiency

Secondary

Physiological

- Age
- Male gender
- Menopause
- Lifestyle factors
- Tobacco use
- Coffee consumption

Vitamin deficiency

- Folic acid deficiency
- Cobalamin (vitamin B12) deficiency
- Pyridoxine (vitamin B6) deficiency

Systemic disorders

Hepatic impairment
 Kidney impairment
 Diabetes mellitus
 Systemic lupus erythematosus
 Psoriasis
 Anorexia nervosa
 Hypothyroidism
 Malignancies: breast, ovary, pancreas, acute lymphoblastic leukemia
 Solid organ transplantation

Drugs

Methotrexate, phenytoin, anticonvulsants, azathioprine, theophylline, metformin, thiazide diuretics, colestipol, nicotinic acid, oral contraceptives.

Epicardial adipose tissue: Indicator of metabolic syndrome. Epicardial fat tissue tends to be higher in subjects with metabolic syndrome than in normal subjects and correlates well with raised triglycerides. Hence echocardiographic assessment of epicardial adipose tissue can be used as an easy method of screening patients with cardiovascular risk.

Osteopoikilosis: An uncommon familial condition of unknown etiology characterized by uniform punctate, round or oval or linear streaks of bone in the epiphysis and metaphysis of long bones and pelvic bones. The condition can be distinguished from skeletal metastasis by the characteristic distribution, normal alkaline and acid phosphatase and by bone scan.

Summary of approved current gene therapy protocol

Disorder	Objective	Target cell	Mode of delivery
• ADA deficiency	ADA replacement	Blood	Retrovirus
• Alpha-1 antitrypsin deficiency	Replacement	Resp. epithelium	Liposome
• AIDS	Antigen presentation HIV inactivation	Blood, marrow Blood	Retrovirus
• Cancer	Immune function enhancement Tumor ablation	Blood, marrow, tumor Tumor	Retrovirus, liposome electroporation Retrovirus, non-complexed DNA
• Cystic fibrosis	Cystic fibrosis regulatory; trans membrane regulatory	Respiratory epithelium	Adenovirus , liposome
Familial hypercholesterolemia	Replacement of low density lipoprotein receptor	Liver	Retrovirus
Fanconi anemia	Complement group C gene delivery	Blood, marrow	Retrovirus
Gaucher's disease	Glucocerebrosidase deficiency replacement	Blood, marrow	Retrovirus
Hemophilia B	Factor IX replacement	Skin, fibroblasts	Retrovirus
Rheumatoid arthritis	Cytokine delivery	Synovium	Retrovirus

Non-vertiginous dizziness: Causes.

1. Pre-syncope (light headache due to transient cerebral hypoperfusion and not typical cerebral ischemia).
2. Migraine
3. Psychological dizziness, stress.
4. Multisensory dizziness.

Acute febrile encephalitis. Common causes are viral meningoencephalitis, tubercular and bacterial meningitis, sepsis associated encephalopathy and cerebral malaria. Meningitis is an important cause of febrile encephalopathy, especially in patients with HIV-AIDS.

Paraneoplastic plantar fasciitis and polyarthritis. Syndrome has been reported mainly with ovarian cancer and is thought to be a tumor associated autoimmune disease. It is characterized polyarthritis and flexion contractures of hands with palmar nodules due to palmar fasciitis. It has been reported to be due to metastatic gastric adenocarcinoma.

Pulmonary rheumatoid nodules in RA: They may be asymptomatic, regress with or without treatment, enlarge or persist. They may lead to complications like empyema, pleural effusion and pneumothorax and bronchopleural fistula.

Vulvar tuberculosis: An unusual presentation of disseminated tuberculosis.

Autoimmune polyglandular syn. type I is a rare disorder characterized by mucocutaneous candidiasis, hypoparathyroidism and adrenal insufficiency.

INH induced lichenoid eruptions: INH may be the causative agent in different CDAR, and must be considered while confronting drug-induced cutaneous eruptions.

Occupational infection

Veterinary surgeons – Leptospirosis, Q fever.

Farm workers – Ringworm, leptospirosis, tetanus, BSE.

Poultry workers – Ornithosis, histoplasmosis, Newcastle disease.

Health workers – Hepatitis, HIV

Construction workers – Tetanus

Signs and Symptoms of Anaphylaxis

Organ or organ system	Characteristic signs and symptoms
Skin	Pruritus, flushing, urticaria, angioedema
Eyes	Ocular pruritus, excessive lacrimation, conjunctival injection
Respiratory system	Nasal congestion, rhinorrhoea, cough, hoarseness, stridor, wheezing, laryngeal oedema
CVS	Weakness, palpitation, tachycardia, hypotension, arrhythmias, shock, cardiac arrest
GI system	Cramping, nausea, diarrhoea, vomiting, abdominal distension, metallic taste

Elevated serum CA-125 levels

- Ovarian / peritoneal Ca
- Endometriosis
- Pelvic inflammatory disease
- Chronic kidney failure
- Cirrhosis

Fat embolism syndrome (FES) is a serious manifestation of fat embolism phenomenon characterized clinically by triad of dyspnoea, petechiae and mental confusion.

Conditions associated with fat embolism

- **Trauma-related**
 - Long bone fractures
 - Pelvic fractures
 - Fractures of other marrow-containing bones
 - Orthopaedic procedures
 - Soft tissue injuries (e.g. chest compression with or without rib fractures)
 - Bums
 - Liposuction
 - Bone marrow harvesting and transplant
- **Non-trauma related**
 - Pancreatitis
 - Diabetes mellitus
 - Osteomyelitis and panniculitis
 - Bone tumor lysis
 - Steroid therapy
 - Sickle cell haemoglobinopathies
 - Alcoholic (fatty) liver disease

Lipid infusion

Cyclosporin A solvent

Multiple connective tissue disease (MCTD)

1. Common symptoms:
 - Raynaud's phenomenon
 - Swollen fingers or hands
2. Anti U1 RNP antibody
3. Mixed findings
 - A. SLE-like
 - Polyarthritis
 - Lymphadenopathy
 - Facial erythema
 - Pericarditis or pleuritis
 - Leucopenia or thrombocytopenia
 - B. Scleroderma-like
 - Sclerodactyly
 - Pulmonary fibrosis
 - Esophageal dysmotility
 - C. Polymyositis-like
 - Muscle weakness
 - Increased serum levels of CPK
 - Myogenic pattern of EMG

Requirements for diagnosis

1. Positive in either of two common symptoms
2. Positive anti-U1 RNP antibodies
3. Positive in one or more findings in two or three disease categories of A, B, C

Joint migration represents loss of normal congruity of the joint. It may result from severe damage to periarticular structures (e.g. ligaments and tendons in RA) or from severe joint damage in septic arthritis, osteomyelitis or a Charcot joint. Collapse of the acetabulum results in migration of the femoral head centrally in RA and superolaterally in osteoarthritis.

Vertigo with hearing loss. Causes:

- Acoustic neuroma
- Cholesteatoma
- Herpes zoster oticus (Ramsay Hunt syn.)
- Meniere's disease
- Otosclerosis
- Perilymphatic fistula
- TIAs or stroke involving anterior inferior cerebellar artery or internal auditory artery

Inflammatory ankle arthritis

Patients with isolated inflammatory ankle arthritis could be classified into (i) Lofgren's syndrome: Acute form of

arthritis which is the most common manifestation of sarcoidosis, often being the presenting symptom. (ii) Poncet's disease: Positive Mantoux test and mediastinal lymphadenopathy with or without unilateral hilar lymph nodes with central necrosis.

Symptoms and signs of inflammatory response

Clinical features

Fever or hypothermia
Tachypnoea
Altered mental state
Unexplained hyperglycemia
Inflammatory variables
Leukocytosis or leucopenia
Increased CRP
Increased procalcitonin
Tissue perfusion variables
Unexplained hyperlactatemia
Decreased capillary refill or
Skin mottling.
Oran dysfunction variables
Unexplained hypoxemia
Acute oliguria
Coagulation abnormalities
Ileus
Hyperbilirubinemia
Thrombocytopenia

Pathologic events in different organs

Organ/System	Presentation
Lungs	ARDS
Kidneys	Acute tubular necrosis
Brain	Encephalopathy
Coagulation system	DIC
CVS	High cardiac output, decreased ventricular ejection fraction, dilated ventricle, vasodilation, microcirculatory abnormality
Liver	Liver cell failure, canalicular dysfunction

Gardner's syndrome — is an autosomal disorder with features of colonic polyposis, dermal tumors, fibromas and neurofibromas. Congenital hypertrophy of retinal pigment epithelium manifests as black spots in the ocular fundus. Other manifestations include epistaxis, GI hemorrhage, cirrhosis due to liver telangiectasia, and high output cardiac failure from A-V malformations.

Dress Syndrome (Drug rash or reaction with eosinophilia) is drug hypersensitivity syndrome which begins

around 2-6 weeks after exposure to a drug. It is a rare but severe type of reaction, most commonly with aromatic anticonvulsants, some antibiotics, antiviral and immunotherapeutic agents. It usually presents with fever, maculopapular rash, generalized lymphadenopathy, hypereosinophilia and hypogammaglobulinemia.

Influenza vaccine is an inactivated vaccine containing 3 strains of influenza of which the influenza A (H1N1) vaccine virus is derived from 2009 pandemic influenza A virus.

Mixed acid-base disorders: Common clinical settings:

1. Metabolic acidosis/resp. acidosis — Severe pulmonary, cardiopulmonary arrest.
2. Metabolic acidosis/Resp. alkalosis — Kidney failure with vomiting, severe liver disease.
3. Metabolic acidosis/Metabolic alkalosis — Kidney failure with vomiting, alcoholic ketoacidosis with vomiting.
4. Metabolic alkalosis/Resp. acidosis — COPD with vomiting or diuretic use.

Micronized Folvite 15-30 mg tab. o.d. for Euvolemic and Hypervolemic hyponatremia.

Urinary anion gap is used to differentiate between renal and extrarenal cause of non anion gap (NAG). The urinary NAG is defined as $(UNa^+ - U_{Cl}^-)$ and is indirect estimate of urinary ammonium excretion. Normal range is 10 to +10. In extra-renal causes of NAG acidosis, the kidney produces a large amount of ammonium chloride and urinary anion gap is largely negative (> -10), in renal causes of NAH metabolic acidosis the kidney is not able to generate ammonium and unable to excrete acid, hence the anion gap is largely positive ($> +10$).

Osmolar gap: Plasma osmolality can be calculated by the formula $2 \times \text{sodium (mg/l)} + \text{glucose (mg/dl)}$ divided by 18 + urea (mg/dl) divided by 2.8. If the calculated osmolality differs from the measured osmolality by 15/mSom/kgH₂O, it is called as osmolar gap.

Causes of osmolar gap: Ethanol, isopropyl alcohol, methanol, glycine, mannitol, ethylene glycol, glycerol, chronic kidney failure.

H. pylori is an important factor for high blood ammonia concentration in hepatic encephalopathy in chronic liver disease.

Roth spots have been traditionally linked with infective endocarditis, but have also been seen in leukemia and anaemia.

Circulation of RBCs through the normal spleen removes DNA from younger cells (Howell-Jolly bodies), sclerotic granules (Pappenheimer bodies) and target cells, their appearance therefore is marker of splenic atrophy (e.g.

in coeliac disease or sickle cell disease) or removal. Traumatic splenic rupture leads to seeding of splenic tissues and cells, giving rise to splenunculus in the peritoneal cavity retaining some immunological protection.

Body iron stores are regulated by iron absorption, this is where the defect lies in haemochromatosis. In secondary iron overload excessive breakdown of RBCs releases amounts of iron in excess of that required to synthesize new Hb (about 20 mg daily) and that absorbed from the gut (1 mg daily), resulting in damaging iron deposition in other organs such as liver, endocrine organs, pancreas and heart.

Rubella: Clinical diagnosis of rubella could be missed because (a) Rubella is a mild erythematous infectious disease which follows typically a benign clinical course. (b) The infection may present atypically with minimum lymphadenopathy and an evanescent rash.

(c) Typical rubelliform rashes may also be induced by other viruses like Chikungunya, Parvovirus B19 and Ross river virus.

Diagnosis: Acute rubella infection is usually established by demonstration of seroconversion of paired sera or by demonstration of rubella specific IgM antibodies in a single specimen. IgM antibodies usually attain their maximum concentration within 10 to 14 days after onset of illness.

Causes of rash and fever — tropical cosmopolitan infections

Organism/disease	Vector/Exposure risk	Associated features
Dengue	<i>Aedes</i> mosquito, urban and rural	Myalgia, haemorrhage, shock
Chikungunya	<i>Aedes</i> mosquito, urban and rural	Polyarthralgia
Rickettsia	Ticks	
African tick typhus	<i>Amblyomma</i> ticks rural/wilderness	Eschar common, headache
Mediterranean spotted fever	<i>Rhipicephalus</i> dog ticks, urban, suburban	Eschar common
Rocky mountain spotted fever	Ticks, rural/wilderness	Eschar rare
Scrub typhus -	Larvae trombiculid mites	Eschar common
<i>Orientia tsutsugamushi</i>	(Chiggers), rural	
Typhoid fever -	Faecal — oral, poor sanitation	Prolonged fever, splenomegaly
<i>Salmonella typhi/paratyphi</i>		
Leptospirosis	Exposure to rat/rodent urine (freshwater)	Conjunctivitis, myalgia
Schistosomiasis	Freshwater snails	Eosinophilia
Yellow fever	Mosquito-borne urban/rural	Jaundice
Lassa fever	<i>Mastomys</i> rodent urine, rural	Pharyngitis, retrosternal pain, encephalitis, hemorrhage
Ebola/Marburg	Unknown, ? monkeys/bats, rural/wilderness	Abdominal pain, D + V, hemorrhage
South American haemorrhagic fever		
West Nile virus	<i>Culex</i> , <i>Aedes</i> mosquitoes, urban	Encephalitis

Symmetrical peripheral gangrene (SPG)

Causes:

- Infection like streptococcus pneumoniae
- Meningococemia
- Falciparum malaria
- Viral gastroenteritis
- DIC
- Low cardiac output states
- SLE
- Vasopressors
- Reaction to drugs (sulfamethazine, penicillin)
- Ergotism
- Acquired haemolytic anaemia
- Decreased levels of vitamin C
- Antiphospholipid syndrome

Severe magnesium depletion

Adequate Mg concentrations are required for release of PTH from parathyroid gland and also as an activator for adenylyl cyclase. Severe hypomagnesemia (< 0.4 mmol/L) may be seen in any severe and prolonged diarrhoeal illness, but Crohn's disease is the most common association. IV magnesium chloride 20 mmol over 24 hours for a few days, restores parathyroid responsiveness.

Prion disease has a long incubation period, which can last for years but ultimately is fatal within weeks to months of its onset.

Organism/disease	Vector/Exposure risk	Associated features
Measles		Cough, conjunctivitis, Koplik's spots Coryza, pneumonitis,
Varicella — Zoster virus		Pharyngitis, lymphadenopathy,
Epstein — Barr virus		splenomegaly Pharyngitis,
Cytomegalovirus	Blood, body fluids	Pharyngitis, lymphadenopathy splenomegaly
Toxoplasmosis	Cats	Lymphadenopathy, myalgia, hepatosplenomegaly
HIV	Sexual, IVDU	Pharyngitis, lymphadenopathy, splenomegaly
Rubella	Human	Coryza, arthralgia
Staphylococcus aureus	Human, IVDU	Shock, murmur
Staphylococcus pyogenes	Human	Pharyngitis, cellulitis, shock
Neisseria meningitis	Human	Shock, meningitis
Neisseria gonorrhoeae	Sexual	Septic arthritis
Syphilis, Treponema pallidum	Sexual	Genital ulceration

Factors increasing statin-induced myopathy

- Major illness
 - Trauma
 - Severe infection
 - Hypoxia
 - Hypothermia
 - Uncontrolled seizure
- Chronic illness
 - Chronic kidney failure
 - Chronic liver disease
- Endocrine and metabolic disorders
- Viral infections
- Hypothyroidism
- Metabolic acidosis
- Drugs
 - Fibrates
 - Azole antifungals
 - Calcium channel blockers
 - Cyclosporin
 - Warfarin
 - Antidepressants (fluoxetine)

Differential diagnosis of joint pain

Life-threatening conditions

- Malignancy (leukemia, lymphoma, bone tumor)
- Sepsis (septic arthritis, osteomyelitis)
- Non-accidental injury

Joint pain with no swelling

- Hypermobility syndrome

- Idiopathic pain syndromes (e.g. sympathetic dystrophy, fibromyalgia)

Coronary artery media thickness and coronary artery disease: Coronary artery intima-media thickness can be determined by high resolution B mode ultrasonography. This provide information about the severity of atherosclerosis. Reduction in degree of atherosclerosis with statin therapy as observed in the carotid artery correlates with coronary angiographic observations.

Management of Gestational Hypertension

Stage I HT (BP > 140 mmHg systolic or > 90 mmHg diastolic)	Methyldopa 250-500 mg tds Calcium channel blockers e.g. Amlodipine 5-10 mg od Nifedipine 5-10 mg qds Diuretics e.g. Furosemide 20-40 mg bd β blockers (labetalol, atenolol) can cause IUGR (labetalol is safer compared to atenolol) hence should be used with caution
Stage II HT (BP > 160 mm Hg systolic or > 100 mmHg diastolic)	Combination of 2 or more drugs from the above (one from each group) as required
Hypertensive crises (BP > 180 mmHg systolic or > 110 mmHg diastolic)	Nifedipine 10 mg orally can be repeated every 20 min to max of 30 mg.
	OR
	Nitroglycerine 5 /min IV as a continuous drip with BP monitoring

	Hydralazine 5mg IV bolus which can be repeated every 20-30 mins to a max. of 25 mg
	OR
	Labetalol 20 mg IV bolus followed by 40 mg every 10 mins till a max of 220 mg
	OR
	Sodium nitroprusside 0.25 g/kg/ min to a max. of 5 g/kg min. (Used rarely due to fear fetal cyanide poisoning)

Sarcoidosis is the commonest inflammatory condition to affect the heart and present with abnormal, focal areas of enhancement in RV and LV with wall motion abnormalities on cardiac MRI.

Takotsubo cardiomyopathy also known as the transient LV apical ballooning syndrome is a recently described acute coronary syndrome.

Sildenafil in pulmonary hypertension: Sildenafil selectively inhibits cyclic guanosine monophosphate specific phosphodiesterase-5 which is found abundantly in the lung. By this action it enhances nitrous oxide mediated pulmonary arterial pressure. It is useful adjunct to thrombolytic therapy in pulmonary embolism.

Flash pulmonary oedema is a condition characterised by sudden and recurrent episodes of dyspnoea at rest resulting from acute pulmonary venous congestion in the presence of a normal or well preserved LV systolic function. This is usually associated with bilateral renal stenosis or stenosis of a single survival kidney.

Mitral valve prolapse.

Echocardiographic mitral valve prolapse has been defined as single or bileaflet prolapsed atleast 2 mm beyond the long-axis annular plane, with or without leaflet thickening. The classical auscultatory finding is a dynamic, mid-to-late systolic click, frequently associated with a high-pitched, late systolic murmur. Specific manoeuvres (Valsalva, squatting and leg raises) demonstrates that click moves within systole as LV volume and loading conditions change. Reduction of end-diastolic LV volume (squatting), decreasing contractility, or increasing after load (hand grips) will shift the click later into systole.

Patients with MVP have a higher risk of developing infective endocarditis. Factors include male sex, age > 45 years, presence of a systolic murmur and leaflet thickening and redundancy.

Alcohol septal ablation for HCM. A vessel supplying blood to the vessel, muscle is assessed through a thin plas-

tic tube. A small balloon is inserted through the tube and inflated to prevent backflow of alcohol. 1-1.5 ml of alcohol is then injected which causes clotting of the blood and blocks the supply to the part. There is over 50% reduction in muscle thickness post-procedure.

Transplant of stem cells in foetuses. Stem cell transplantation which uses mother's bone marrow to inject in the developing foetus to cure blood diseases. The donor cells are accepted by the foetus growing immune system. Many genetic diseases can be diagnosed in first 12 weeks of pregnancy.

Crimean-Congo hemorrhagic fever (CCHF). A particular variety of ticks, Hyalomma which is known to act as both a reservoir and a vector for several diseases is known to be present in the environment. Primarily found in cattle, sheep, goats and hare as amplifying hosts for the virus, transmission to humans occurs through contact with infected animal blood or ticks. Human to human transmission occurs by contact with infectious blood or body fluids. Documented spread of CCHF has also occurred in hospitals due to improper sterilization of medical equipment, reuse of injection needles and contamination of medical supplies. Cutting meat infected with the virus can also lead to spread to humans.

Cl.Fs. : Sudden onset with high fever, headache, backache, arthralgia, abdominal pain, vomiting. Other features include lymphadenopathy, rash and hemorrhagic phenomena such as petechiae. As the disease progresses, severe bruising, nose bleed, bleeding gums, bleeding from upper bowel, and at injection sites occur on about the fourth day and last for about 2 weeks.

Diagnosis: Detection of antibodies against the virus.

Tr.: Ribavirin oral or IV. Supportive therapy.

Post-Chikungunya Chronic Arthritis (PCCA)

Chronic inflammatory polyarthritis can occur after acute chikungunya infection in some patients. It is seronegative and AntiCCP positive in majority.

Tr. with sulfasalazine with or without methotrexate is effective.

Distinguishing Parkinson's disease from Parkinsonism form of Multiple System atrophy

Urinary incontinence or orthostatic symptoms within one year history of motor symptoms suggests a diagnosis of MSAP and their absence suggests PD.

Mycophenolate mofetil

The drug is useful in renal transplantation and lupus nephritis. It has advantage of relatively less side-effects

and no nephrotoxicity. In primary nephrotic syndrome, though not the first line drug, it can be considered in those who fail to respond to corticosteroids or immunomodulatory medication, or relapse.

Heel pad sign

Though not pathognomonic, a heel pad thickness > 23 mm on radiograph may indicate acromegaly.

Joint pain with swelling

- Juvenile idiopathic arthritis
- Trauma
- Infection
 - Septic arthritis and osteomyelitis (viral, bacterial, mycobacterial)
 - Reactive arthritis (post-enteric, sexually acquired)
 - Infection related (rheumatic fever, vaccination related)
- Inflammatory bowel disease
- Psoriatic arthritis
- Connective tissue disease (systemic lupus erythematosus, scleroderma, dermatomyositis)
- Sarcoidosis
- Metabolic (e.g. osteomalacia, cystic fibrosis)
- Hematological (haemophilia, hemoglobinopathy)
- Crystal arthropathy
- Tumor (benign/malignant)
- Developmental/congenital (e.g. spondyloepiphyseal dysplasia)

Rheumatic disease with subcutaneous nodules

1. Rheumatoid arthritis
2. Rheumatic fever
3. Erythema nodosum
4. SLE
5. Gout
6. Drug-induced (methotrexate)
7. Multicentric reticulohistiocytosis

Stem cell therapy

1. Infusion of heart's own stem cells can repair the damage caused to the organ after an attack and lead to cardiac regeneration.
2. Stem cells can be obtained from an individual's own body fat taken from one part of the body by liposuction.
3. Stem cell therapy for spinal cord injuries. The replacement cell therapy is based on the replacement of cell, with a view to regenerate axons and myelination of the regenerated axons.
4. Milk and wisdom teeth can be source of stem cells.

Urine in aminoaciduria

Maple syrup disorder	Burnt sugar smell
PKU	Musty or mousy odour
Tyrosinemia	Cabbage-like odour
Alkaptonuria	Urine turns black on standing

What's New

- **New guidelines for brain death.** The possibility of brain death being irreversible can be eliminated by continuous observation of the patient for a minimum of 5 minutes to confirm absence of the circulation before being declared death.
- Tenofovir (anti-viral drug) taken once daily reduces HIV risk to nearly half in injectable narcotic drug users.
- **Breastfeeding** helps protect against Attention Deficit hyperactivity, commonly diagnosed behavioural condition in children.
- **TMS therapy** involves using magnetic field externally to stimulate new cells in the brain. An electromagnetic coil is placed on the scalp at a predetermined site. This device then delivers focussed magnetic pulse to the brain.

Indications:

- Major depression
- Tr. resistant depression
- Auditory hallucinations
- Schizophrenia
- Bipolar disorder
- Obsessive compulsive disorder
- Eating disorders such as anorexia and bulimia

Advantages:

(1) Quick onset of therapeutic effect usually 2 to 4 weeks. (2) Painless procedure. (3) No anaesthesia required. (4) Outpatient therapy. (5) Fewer or no side effects.

- **Sono-thrombolysis:** The used of ultrasound waves along with the fibrinolytic agent has been shown to improve the outcome of patients with stroke. Application of ultrasonic waves can be done through intravascular route or transcutaneous route. The exact mechanism of benefits of sono-thrombolysis is not known, however the nitric acid released by vibrating endothelial cells and opening of collateral channels have been suggested.
- **Stem cell therapy in AMI:** Intracoronary infusion of either circulating progenitor cell (CPC) or bone marrow derived progenitor cells in patients with AMI have shown a reduction in infarct size and an increased ejection fraction.
- **Dental caries:** No more root canals. Stem cell therapy can regenerate the dentin pulp complex and consequently totally regenerate the tooth structure and function.
- **From skin to stem cells:** Human stem cells can be reprogrammed to become embryonic stem cells without the use of fertilised embryos. Embryonic cells start to divide and eventually become stem cells which are capable of transforming into any other cell type to cure several diseases.
- **Stem cells harvested from urine:** Urine derived stem cells can be directed to become multiple cell types. These cells can also form bone, cartilage, fat and skeletal muscle, nerve and endothelial cells which line blood vessels. These stem cells represent virtually a limited supply of urology related conditions such as kidney disease, urinary incontinence and erectile dysfunction.
- **Down's syndrome:** Scientists have shown that a naturally acting X chromosome "off switch" can be rerouted to neutralise the extra chromosome responsible for trisomy 21 (Down's syn.).
- **Ultrasound via a skin patch** helps venous ulcers significantly and accelerate tissue repair. The ultrasound patch weighs 100 gm and is connected to two lithium batteries which are fully rechargeable.
- **Intramuscular ACTH stimulation test** for assessment of adrenal function. 25 units of ACTH is injected IM and blood samples taken after 60 minutes for estimation of cortisol. Patients with post-ACTH cortisol <18.0 mg/dl are diagnosed as having adrenal insufficiency.
- **Regenerative therapies:** Infusion with allogeneic mesenchymal stem cells have the potential to regenerate alveolar tissue by themselves or by secreting growth hormones. Specifically, vascular-endothelial growth factor (VEGF).
- **Oral diarrhoeal vaccine (ETEC):** A vaccine against E. coli, a primary cause of diarrhoea in children.
- One shot immunity against flu strains. A vaccine that could protect against most or all influenza strains without the need for annual vaccinations.
- **Wegener's granulomatosis:** Antineutrophil anticytoplasmic antibody (CANCA) is very specific for WG and is being used for diagnosis and monitoring the disease.
- **Intravenous Ulinastatin in severe pancreatitis** prevents new organ dysfunction and reduces mortality in subjects with severe pancreatitis.
Dose: IV infusion of 200,000 IU over one hour every 2 hours for 5 days with standard supportive care.
- **Single glucose challenge test for diagnosis of Gestational DM:** In the antenatal clinic, a pregnant woman is given 75 gm of oral glucose without regard to the time of last meal. A various blood is collected after 2 hours for estimating plasma glucose. GDM is diagnosed if 2 hours plasma glucose is ≥ 140 mg/dl. The test is economical and the patient need not come fasting.
- **Takotsubo cardiomyopathy:** LV apical ballooning is a novel acute coronary syndrome. It is characterized by regional systolic dysfunction involving apex and mid section of LV. This can be seen in left ventriculogram. It is not associated with any obstructive CAD.

New conjugate typhoid vaccine: (for children and adults) gives longer period of immunity.

Microneedle patch to replace TB skin test: A patch with tiny biodegradable needles that can penetrate the skin with the test there is little room for user error, because the depth of delivery is determined by the microneedle length rather than the needle insertion angle. The test is painless and easy to deliver.

Dental CBCT is a three dimensional imaging modality for dental use, dedicated specifically to maxillo facial imaging.

Routine applications

- Evaluation of the height, width and nature of bone available for implant placement.
- Providing virtual implant simulation and assessing their proximity of implant to vital structures.
- Localization of impacted teeth and assessing their proximity to vital structures.

Other applications

- Endodontic applications: Identification of accessory canals, anomalous/atypical canals, calcified canals, elucidation of root resorption, periapical pathosis, etc.
- Periodontal applications: Detection and characterization of the bony aspects of periodontal disease.
- Postoperative applications: Implant evaluation, assessment of endodontically restored teeth for overextended obturation material, broken instruments within the canal or perforations.
- Evaluation of dentoalveolar trauma: Root fractures, luxation, displacement of teeth, and alveolar fractures.
- Evaluation of jaw lesions: Localisation and characterisation of various jaw cysts, tumors, fibro-osseous conditions, etc.
- Imaging of the temporomandibular joint: Evaluation of osseous changes of the TMJ.
- Caries detection: For those incipient, mild, proximal caries which are not visualised on OPG and IOPA.

Tr. of HIV: A combination of Decitabine and Gemcitabine is an effective treatment for HIV virus. The drug combination has been shown by lethal neutrogenesis could obliterate HIV by causing the virus to mutate to a point when it was no longer infectious.

H1N1 encephalopathy: Apart from exacerbation of underlying chronic disease, pulmonary and cardiac complications of H1N1 influenza, also cause seizures, encephalopathy and status epilepticus.

Malarial vaccine: Contains live malaria parasites collected through a process of dissecting the salivary glands of mosquitoes. These immature parasites (sporozoites) are then weakened so that they cannot cause illness and incorporated into a vaccine.

Carotid bodies and hypertension: Removing one of the carotid bodies located at the bifurcation of the carotids could dramatically reduce BP in patients who do not respond to medicines.

Vaccine against MERS (Middle East respiratory syndrome). (COV) has been developed against the illness, which can spread from person to person and has high mortality rate.

Tr. of DM: DDP-4 inhibitor that does not require dose adjustment in adults with DM2. Linagliptin 5 mg tab. OD is the only drug which is not associated with cardiovascular events.

Pacemaker implant for treatment resistant GERD.

Vaccine for Japanese B encephalitis now available.

Implanted catheters: Multiple drug resistant bacterial biofilms on implanted catheters including vascular and Foley catheters. This suggests that catheters should be removed as early as possible to prevent biofilm development in them.

Single test to detect cancer: Tumor prefilling (TP) test will help search for genetic alteration which is driving the growth of tumor-lung, breast, biliary tract, ovarian, thyroid and urinary tract cancer.

Tooth transplant for an injured blind eye. During the technique osteo-odonto-keratoprosthesis, one of patient's front tooth and a part of jaw were removed and used as a cradle holder for a false lens.

Chronic Hepatitis B infection

Telbivudine plus Tenofovir in combination exhibited significant biochemical responses over the period of one year however it was not higher than that seen with monotherapy.

Renal Sympathetic denervation for resistant hypertension

Uncontrolled hypertension (HTN) accounts for significant morbidity and mortality. Renal denervation therapy can improve the control of high BP.

Drug to cure Hepatitis C

The drug combination of Sofosbuvir and Ledipasvir stopped the virus replicating in 97% of patients. An increasing number of people infected with virus are developing cirrhosis and liver failure.

Nitrous oxide gas therapy (with help of a ventilator) to treat meconium aspiration syndrome in the new born. It dilates the pulmonary arteries and the pressure in the arteries goes down.

What's New

Dabigatran can be used as anticoagulant for stroke prevention in AF. Dose: 150 mg for patient with low risk of bleeding 110 mg if high risk of bleeding. Contraindicated in vascular heart disease and in those with prosthetic valves.

Echocardiography in pulmonary embolism

Acute PE may lead to RV pressure overload and disturbed RV ejection pattern (so called 60–60 sign), or on depressed contractility of the RV free wall compared with RV apex (McConnell)

Takotsubo cardiomyopathy Broken heart syndrome or stress induced cardiomyopathy is typically a transient heart dysfunction of the apical or midsegments of the LV that occurs in presence of acute emotional stress. It mimics acute MI with concomitant rise in biomarkers, ECG, 2 D Echocardiography abnormalities such as LV dysfunction with regional wall motion abnormality, no significant coronary artery disease on angiography. It is a variant of dilated cardiomyopathy.

Artificial pancreas endocrine: A device which monitors blood glucose in patients with diabetes and automatically adjusts levels of insulin entering the body. Currently available insulin pumps deliver insulin after taking readings from glucose meters, but these two components are separate. It is the joining together of both parts into a “closed loop” that makes an artificial pancreas.

Diabetes with Vitamin D Deficiency may be at higher risk of vascular complications including coronary artery disease.

Rhabdomyolysis is a syndrome characterized by muscle necrosis which causes the release of myoglobin into the blood stream. The manifestation range from asymptomatic elevation of muscle enzymes to lifethreatening cases with extremely high enzyme levels, electrolyte imbalance and acute kidney failure.

Symptoms include dark urine, muscle weakness and fatigue.

Laryngopharyngeal reflux disorder: An abnormal amount of reflux of the contents of the stomach passes all the way through the upper oesophageal sphincter into the back of the throat reaching the larynx and pharynx. Symptoms include hoarseness, frequent throat clearing, bitter taste in the mouth, referred ear pain and postnasal drip. Treatment for severe LPR is fundoplication which tightens lower oesophageal sphincter.

Endobronchial ultrasound: EBUS combines an endoscopic image with an ultrasound probe giving sonographic images through the airway wall. Indications, for EBUS (1) Staging of lung cancer, (b) Mediastinal lymphadenopathy, (c) Therapeutic uses (d) Assessment of airway wall infiltration and peripheral nodule. Anticoagulants should be stopped a week before the procedure. Benign granulomatous disorders like TB and sarcoidosis are most common cause of mediastinal lymphadenopathy. EBUS helps to reach these nodes as a minimally invasive procedure to take aspirations under real-time ultrasound guidance.

Hypocalcemic cardiomyopathy: Due to severe Vitamin D deficiency. The physiological basis is impaired intracellular calcium metabolism which plays an important role in the pathogenesis of CHF.

Haematology

Patients with pernicious anemia have a higher risk to develop GI malignancies such as gastric adenocarcinoma, carcinoid tumors and oesophageal squamous cell carcinoma.

Trans-sternal mediastinal biopsies—smaller masses and nodes may be difficult to approach directly. While it is often possible to use a trans-pulmonary route. The chances of pulmonary complications makes it more desirable to use extra-pulmonary approaches, one such is trans-sternal route and the simplest method is to lightly tap the needle into the manubrium sternum which is a thin bone and then enter the lesion posterior to the sternum and biopsy it.

New drug for leukaemia: Cells when they are born are destined to die and cancer of leukaemia cells, delays that death by using a protein called BCL2 that stops the normal time of death. The drug Venetoclax works by specially blocking the action of BCL2. The drug is given orally everyday as a pill. 20 mg/d increased to 400 mg over a five week period.

Drugs with multiple action.*Danazol*

- Aplastic anemia
- Dyskeratosis congenital
- Endometriosis
- Gynecomastia
- Benign fibrocystic breast disease
- Menorrhagia
- Hereditary angioedema
- Idiopathic thrombocytopenic purpura

Renal

Measurement of renal function: It has been noted that serum creatinine is the least accurate, while the radionuclide GFR test is the most accurate.

Renal calculi: DECT allows to differentiate urate from monourate cystals. Uric acid can be managed medically, while non-uric acid calculi need ESWL or surgery.

Pollution trigger Alzheimer's, magnetic particles produced by car engines release free radicals in brain and disrupt cellular functions.

Lower blood flow, first sign of Alzheimer's: Using techniques such as MRI and PET show a decrease in the blood flow in the brain. The study also found that changes in cognition begin earlier in the progression.

Eating epilepsy: In the rare variety of seizures eating is a precipitating factor. The affected area in such patient's brain is located in the left dominant lobe that controls comprehension and expressive speech. By a surgery called multiple subpial transection, brain tissues are not removed, only holes are made on the brain to stop the electrical impulses. The seizures may not completely disappear but the frequency is considerably reduced. The patient is advised to continue the drugs for one to two years.

Expanded dengue: The term has been carried by WHO to describe cases which do not fall into either dengue shock syndrome or dengue hemorrhagic fever. The typical manifestations noted in dengue can be multisystemic and multifocal. In clinical practice the occurrence of a typical should prompt the clinician to investigate for dengue.

Unusual manifestations of patients with severe organ involvement such as liver, kidneys, brain or heart have been increasingly reported in DHF and also in dengue patients who do not have evidence of plasma leakage.

These unusual manifestations may be associated with co-infections or complications of prolonged shock and can be clubbed under the expanded dengue syndrome.

Fast acting drug against rabies.

The drug, rabies human monoclonal antibody (RMAB) Rabishield automatically precludes chances of transmitting blood-borne infection that are present in rabies immunoglobulin, the current line of treatment for severe dog bite cases. WHO defines category III animal bites as single or multiple transdermal animal bites a scratches contamination of mucous membrane with saliva from licks or broken skin and exposure to bats.

Aquaholism: Causes by water glut can be deadly. It can bring about a condition like hyponatremia. It can also cause secondary hypokalemia.

Single pill a day treatment for HIV/AIDS patients life long. Doltegravis (DTC) + Abacavir + Lamivudine is the most promising regime.

CNS

Implantable capsule for Alzheimer's disease: One of the hypothesised causes of the disease is the over-accumulation of the protein amyloid beta (A beta) in different areas of the brain. This results in the deposition of aggregated protein plaques that are toxic to neurons. One of the most promising ways is to 'tag' the Abeta proteins with antibodies that signal the patient's own immune system to attack and clear them.

The capsule contains cells that have been genetically engineered to produce antibodies against Abeta. The implant can deliver a steady and safe flow of antibodies. It is implanted in the tissues under the skin.

Moyamoya disease: It is an idiopathic cerebrovascular occlusive disorder characterized by progressive stenosis of the distal internal carotid arteries and by collateral vessel formation. On conventional X-ray, angiography, these collateral vessels have the appearance of a puff of smoke described as moyamoya in Japanese. Treatment involves creating stents to improve the circulation and prevent brain ischemia.

Radiology

X-ray—The Golden S sign: In case of carcinoma of the lung when the peripheral lung collapses and the central portion is prevented from collapsing by the presence of a mass. The relevant fissures resemble an S. The Golden S sign can CT scans.

Although typically seen with right upper lobe collapse, the S sign can also be seen with collapse of the other lobes and has been demonstrated on lateral chest radiography.

Boomerang sign: MRI of the brain shows hyperintense signal in the splenium of corpus callosum.

Dual energy CT: It is a technique where patient is scanned at two or more different energies. There are a number of applications for this technique e.g., Gout.

The DECT shows crystal deposition in the joint. It is also possible to quantify the overall tophus burden and can be used for follow up to document response to treatment. Differential diagnosis of pulmonary infiltrates in HIV infection.
