Golwalla's Medicine for Students

Twenty-Fourth Edition: 2014

Twenty-Fifth Edition: **2017**

ISBN: 978-93-5152-474-8

PREFACE

The purpose and scope of this widely read book at times referred to as a Bible in Medicine remains the same when it was first published in the year 1952 namely to help the undergraduate medical students with necessary information presented on easily imbibable form for the final MBBS examination both for Theory and Viva.

Over the years, the book has spread its wings. To add to this its aim is the acceptance by the students of Homeopathy, Dentistry, Physiotherapy and even Ayurveda, where the question papers in the subject of Medicine have found wide approval.

The original author of the book has been aging but the younger author is aware that new vigour and fresh ideas are needed to ensure that every aspect in the text is kept up-to-date.

The authors welcome the Editor, a pupil of the senior author in yesteryears and now a distinguished head of the leading monthly journal in the country and other literary achievements as a collaborator in this revised edition, and also for such future revisions that will be called for.

Illustrations have been used freely whenever it was thought they would be purposeful in pathogenesis and diagnosis of diseases. There are more number of tables and figures introduced in this edition.

There might be room for improvement in some aspects, notwithstanding the amount of time and labour bestowed upon it.

Criticisms and suggestions are invited and will be received with gratitude by the authors and Editor.

Date of Publication

December 2016

CONTENTS

1. Gastroenterology	1
▶ Investigations of gastrointestinal disease	1
▶ The tongue in diagnosis	4
▶ Stomatitis and oral ulceration	7
▶ Dysphagia	7
▶ Gastro-oesophageal reflux disease	11
▶ Achalasia of the cardia	12
▶ Hiatal hernia	14
▶ Dyspepsia	14
▶ H. pylori infections	15
▶ Gastritis	17
▶ Peptic ulcer	17
▶ Gastric cancer	23
▶ Hematemesis and melaena	24
▶ Lower gastrointestinal haemorrhage	27
▶ Diarrhoea	29
▶ Constipation	32
▶ Malabsorption	33
▶ Coeliac disease	36
▶ Abdominal tuberculosis	38
▶ Irritable bowel syndrome	39
▶ Diverticular disease	41
▶ Inflammatory bowel disease	42
▶ Ischemic bowel disease	47
▶ Drug-induced gastrointestinal disorders	48
▶ Factitious gastrointestinal symptoms and Munchausen	49
2. Hepatobiliary and Pancreatic Disease	51
▶ Investigating and imaging the liver, biliary tract and pancreas	51
▶ Viral hepatitis	55
▶ Autoimmune liver disease	61
▶ Metabolic liver disease	64
▶ Hepatic encephalopathy	67
▶ Acute liver failure	69
▶ Jaundice	71
▶ Cirrhosis of liver	78
▶ Ascites	84
▶ Portal hypertension	90
▶ Hepatomegaly	92
▶ Liver disease in pregnancy	95
▶ Drug-induced liver disease	95

- ▶ Liver transplantation 95
- ▶ Gallstones 97
- ▶ Pancreatic disease 99

3. The Respiratory System.....103

- ▶ Investigations of respiratory disease 103
- ▶ Cough and expectoration 110
- ▶ Haemoptysis 112
- ▶ Inflammation of the bronchial tree 114
- ▶ Bronchial asthma 119
- ▶ Chronic obstructive pulmonary disease (COPD) 124
- ▶ Cystic fibrosis 129
- ▶ Pneumonia 130
- ▶ Lung abscess 136
- ▶ Pulmonary tuberculosis 139
- ▶ Pulmonary eosinophilia 147
- ▶ Lung cancer 150
- ▶ Pulmonary oedema 154
- ▶ Pulmonary thromboembolism 155
- ▶ Fungal infections of the lung 157
- ▶ Airway problems in children 160
- ▶ Pulmonary sarcoidosis 161
- ▶ Diffuse parenchymal lung disease 162
- ▶ Occupational lung disease 166
- ▶ Lobar collapse of the lung 168
- ▶ Sleep apnoea syndrome 169
- ▶ Respiratory failure 171
- ▶ Acute lung injury and acute respiratory distress syndrome 173
- ▶ Severe acute respiratory syndrome (SARS) 175
- ▶ Systemic diseases and the lungs 176
- ▶ Pleural disease 178
- ▶ Therapeutic aerosols 192
- ▶ Drugs and the lungs 193
- ▶ Respiratory problems in immunosuppressed patients 193
- ▶ Lung transplantation 193
- ▶ Miscellaneous 195

4. The Cardiovascular System.....196

- ▶ Investigations in cardiovascular diseases 196
- ▶ Pulse 204
- ▶ Cardiac arrhythmias 207
- ▶ Cardiac murmurs 230
- ▶ Congenital heart disease 233
- ▶ Valvular heart disease 249
- ▶ Infective endocarditis 265
- ▶ Cardiovascular syphilis 270
- ▶ Ischaemic heart disease 271
- ▶ Cardiac arrest 289

▶ Heart failure	291
▶ Shock	296
▶ Hypertension	298
▶ Heart muscle disease	307
▶ Neurocirculatory asthenia	312
▶ Pericardial disease	313
▶ Pulmonary hypertension	319
▶ Heart disease and pregnancy	321
▶ Paroxysmal dyspnoea	322
▶ Diseases of vessels	324
5. Haematology	335
▶ Laboratory diagnosis in haematology	335
▶ Haematopoiesis	342
▶ Anaemias	345
▶ Bone marrow failure	363
▶ Amegakaryocytic thrombocytopenia	366
▶ Porphyrias	366
▶ Disorders of haemostasis	366
▶ Anticoagulant drugs	376
▶ Myelodysplastic syndromes	378
▶ Leukemias	382
▶ Lymphomas	391
▶ Blood transfusion	400
▶ Antiplatelet drug therapy	402
▶ The spleen	403
▶ Bone marrow transplantation	409
▶ The blood in systemic disease	410
6. Endocrine Disorders	412
▶ Pituitary gland	412
▶ Obesity	421
▶ Thyroid disease	424
▶ Thyroid goiter	433
▶ Parathyroid disorders	435
▶ The adrenals	439
▶ Pancreas	445
▶ Hypoglycaemia	466
▶ Multiple endocrine neoplasia men	468
▶ Carcinoid syndrome	468
▶ Miscellaneous	470
7. Neurology	471
▶ Investigations in neurology	471
▶ Disorders of speech	480
▶ The cranial nerves	483
▶ Pupillary disorders	491

- ▶ Sensory impairment 493
- ▶ The reflexes 494
- ▶ Neurological disturbances of bladder and bowel 495
- ▶ Involuntary movements 497
- ▶ Gaits 501
- ▶ Headache 503
- ▶ Epilepsy 507
- ▶ Cerebrovascular diseases 514
- ▶ Coma and brainstem death 530
- ▶ Neurosyphilis 537
- ▶ Tuberculosis of the central nervous system 539
- ▶ Intracranial tumours 542
- ▶ Disorders of the spinal cord 546
- ▶ Deficiency disorders of the nervous system 561
- ▶ Extrapyrmidal syndromes 562
- ▶ Hereditary and degenerative disorders 567
- ▶ Cerebellum and its disorders 571
- ▶ Myopathies 574
- ▶ Myasthenia gravis 580
- ▶ Muscular wasting 583
- ▶ Peripheral neuropathy 584
- ▶ Root and plexus syndromes 592

8. Renal Disorders597

- ▶ Investigations in renal disease 597
- ▶ Hematuria 606
- ▶ Glomerular diseases 608
- ▶ Acute renal failure (ARF) 615
- ▶ Chronic kidney disease (CKD) 619
- ▶ Urinary tract infection (UTI) 627
- ▶ Polycystic disease of kidneys 630
- ▶ Tubulo-interstitial disorders 631
- ▶ Urinary calculi 633
- ▶ Incontinence of urine 634
- ▶ Kidney in systemic disease 636
- ▶ Adverse effects of drugs on the kidney 637
- ▶ Renal disease and pregnancy 637
- ▶ Urinary catheterization 639
- ▶ Stem cell therapy for kidney disease 641

9. Rheumatology642

- ▶ Investigations 642
- ▶ Rheumatoid arthritis 645
- ▶ Spondyloarthropathies 653
- ▶ Joint and bone infections 660
- ▶ Osteoarthritis 662

▶ Metabolic and crystal athropathies	664
▶ Autoimmune diseases	669
▶ Vasculitides	680
▶ Bone disorders	686
▶ Miscellaneous	691
10. Infectious Diseases and Infections	693
▶ Diphtheria	693
▶ Meningitis	695
▶ Viral infections	698
▶ Acute childhood exanthemas	708
▶ Mumps	714
▶ Whooping cough (pertussis)	715
▶ Enterovirus infections	716
▶ Toxoplasmosis	720
▶ Tetanus and other clostridial diseases	720
▶ Lyme disease	724
▶ Legionnaires' disease	724
11. Tropical Diseases	727
▶ Protozoal infections	727
▶ Protozoal GI infections	736
▶ Gastroenteritis	741
▶ Plague	746
▶ Brucellosis	747
▶ Leprosy	749
▶ Rickettsial diseases	752
▶ Rabies	753
▶ Dengue	755
▶ Chikungunya	757
▶ Hantavirus infection	758
▶ Japanese B encephalitis	758
▶ Rat-bite fever	759
▶ Leptospirosis	759
▶ Anthrax	760
▶ Filarial infections	761
▶ Tropical polymyositis	763
▶ Intestinal helminths	763
▶ Schistosomiasis (bilharziasis)	768
▶ Hydatid disease	770
▶ Dracunculiasis (guinea-worm disease)	772
▶ Tropical sprue	773
▶ Effects of heat	774
▶ Endemic fluorosis	775
12. Diseases of Children	777
▶ Newborn infants	777
▶ Diseases of the newborn	780

- ▶ Congenital syphilis 793
- ▶ Gastroesophageal reflux disease 794
- ▶ Infant feeding 794
- ▶ Growth and development 796
- ▶ Prematurity and low birth weight 798
- ▶ Failure to thrive 801
- ▶ Malnutrition in infants and children 803
- ▶ Deficiency diseases 804
- ▶ Infantile diarrhoea 808
- ▶ Acute gastroenteritis in children 810
- ▶ Pica 810
- ▶ Indian childhood cirrhosis (ICC) 812
- ▶ Wheezing infant 813
- ▶ Bronchiolitis and bronchopneumonia 814
- ▶ Acute rheumatic fever 815
- ▶ Tuberculous meningitis 820
- ▶ Infantile convulsions 823
- ▶ Skull 825
- ▶ Hydrocephalus 826
- ▶ Cerebral palsy (Little's disease) 827
- ▶ Breath-holding spells 828
- ▶ Childhood enuresis 828
- ▶ Down's syndrome (mongolism) 829
- ▶ Immunization in children 830

13. Psychiatry.....834

- ▶ Introduction 834
- ▶ Diagnosis and investigation of a psychiatric patient 835
- ▶ Delirium, dementia, amnestic and other cognitive disorders 836
- ▶ Psychosis 840
- ▶ Mood disorders 843
- ▶ Psychoneurosis or neurosis 848
- ▶ Antipsychotic drugs 856
- ▶ Psychological factors affecting medical conditions 857
- ▶ Personality disorders 858
- ▶ Sexual and gender personality disorders 861
- ▶ Perinatal psychiatry 864
- ▶ Substance use disorders 865
- ▶ Chronic fatigue syndrome (CFS) 872
- ▶ Deliberate self-harm 872
- ▶ Eating disorders 873
- ▶ Child psychiatry 875
- ▶ Drug-induced psychiatric disorders 880
- ▶ Treatment methods in psychiatry 880

14. Acute Poisoning.....887

- ▶ Diagnosis of acute poisoning 887
- ▶ Principles of management 888
- ▶ Poisoning with pesticides 890

▶ Petroleum distillates	892
▶ Poisoning with psychotropic drugs	892
▶ Poisoning by alcohols	894
▶ Anticonvulsants	895
▶ Analgesic poisoning	896
▶ Poisoning with cardiorespiratory drugs	897
▶ Stimulants and hallucinogens	898
▶ Corrosives	899
▶ Metallic poisoning	900
▶ Poisonings from inhaled gases	901
▶ Miscellaneous	902
▶ Venomous bites and stings	904
▶ Chemical and biological warfare and terrorism	907
15. Dermatology	908
▶ Structure and functions of normal skin	908
▶ Dermatological history and examination	909
▶ Dermatological pharmacology	911
▶ Hair and nails	912
▶ Skin problems in pregnancy	917
▶ Tuberculosis of the skin	918
▶ Infections	920
▶ Cutaneous fungal infections	923
▶ Acne and other facial eruptions	935
▶ Dermatitis/Eczema	937
▶ Drug reactions and the skin	941
▶ Photosensitivity disorders	944
▶ Papulosquamous eruptions	946
▶ Blistering disorders	949
▶ Urticaria and angio-oedema	952
▶ Pruritus	955
▶ Disorders of pigmentation	956
▶ Disorders of sweat glands	961
▶ Skin manifestations of systemic disease	962
▶ Genetic skin disorders	965
▶ Cutaneous anthrax	966
▶ Skin cancer	966
▶ Benign skin tumors	967
▶ Skin problems in transplant patients	968
▶ Fever with rashes	969
16. Sexually Transmitted Infections, HIV and AIDS	974
▶ Bacterial infections	974
▶ HIV and AIDS	985
17. Miscellaneous	997
▶ Prolonged pyrexia	997
▶ Vertigo	1000

- ▶ Syncope 1002
- ▶ Nutrition 1003
- ▶ Antioxidants 1007
- ▶ Metabolic syndrome 1012
- ▶ Disorders of water and electrolyte metabolism 1013
- ▶ Acid-base disturbances 1019
- ▶ Lymphadenopathy 1022
- ▶ Hyperlipoproteinaemias 1025
- ▶ Inborn errors of metabolism 1027
- ▶ Amyloidosis 1030
- ▶ Hypothermia 1033
- ▶ Genetics 1034
- ▶ Sleep disorders 1039
- ▶ Phakomatosis 1040
- ▶ Ocular manifestations of systemic disease 1041
- ▶ Stem cell therapy 1043
- ▶ Prebiotics and probiotics 1045
- ▶ Chemical warfare 1046
- ▶ Antibacterial chemotherapy 1047
- ▶ Some common symptoms and signs 1051
- ▶ The fundus 1072
- ▶ Some important laboratory values 1073
- ▶ Radiology 1077
- ▶ Some drugs with multiple indications 1091

18. Notes	1099

<i>Index</i>	1131

Gastroenterology

1. INVESTIGATIONS OF GASTROINTESTINAL DISEASE

STOOL EXAMINATION

Naked eye—Consistency, presence of blood, mucus, helminths. Occult blood if positive suggests – GI bleeding, growth, tuberculous lesion or inflammatory bowel disease. Some patients on aspirin, mesenteric vascular disease, vegetative forms and cysts of *E. histolytica*.

Microscopic—For RBCs, pus cells in bacillary dysentery and inflammatory bowel disease. Presence of ova of *Ascaris* or *Ankylostoma*.

Stool culture in selected cases of chronic infective diarrhoea and pseudomembranous colitis.

HEMATOLOGICAL AND BIOCHEMICAL TESTS

RBC count, Hb, MCV, blood film, serum iron, iron binding capacity, red cell folate, serum B₁₂, serum albumin, serum electrolytes.

GASTRIC ACID SECRETIONS

Are usually not measured, but sometimes provide useful corroborative information. In normal people, basal acid output is about 2–4 mmol/hour rising to about 10–30 mmol/hour in the hour after s.c. injection of Pentagastrin 6 mcg/kg. Pentagastrin not available nowadays (An endoscopic method for measuring gastric acid output has been developed but requires further validation). Gastric acid measurements are of diagnostic value:

- (i) When a gastrinoma is suspected.
- (ii) An ulcer has recurred after surgery.
- (iii) To detect achlorhydria in case of gastric ulcer. Occurrence of gastric ulcer in presence of achlorhydria is indicative of malignancy since most cases of benign gastric ulcer have some acid secretion.

FASTING SERUM GASTRIN LEVELS: INDICATIONS

Multiple ulcers or ulcers in unusual locations associated with severe oesophagitis, resistant to therapy, preoperative family history of peptic ulcer disease, postoperative ulcer recurrence, basal hyperchlorhydria, unexplained diarrhoea or steatorrhoea, hypercalcaemia, prominent gastric or duodenal folds.

RADIOLOGY

Plain films of abdomen. Supine and erect films are taken for diagnosis of any acute abdominal condition especially obstruction or perforation. It can also reveal changes in soft tissues produced by masses or inflammation, pneumoperitoneum, gallstones, calcification of gallbladder wall, liver calcification, urinary calculi, appendoliths.

Chest radiographs can reveal a small pneumoperitoneum, level of the diaphragm, intrathoracic conditions, e.g. pneumonia.

BARIUM STUDIES

With advances in endoscopy, the role of barium studies has now become restricted to barium swallow for the oesophagus and small bowel enema/enteroclysis for the jejunum and ileum. Now the CT scan has also become an important modality for small bowel pathology, especially with the use of CT enteroclysis (Fig. 1). Table 1 enumerates various conditions that can be diagnosed on barium studies.

ENDOSCOPY

Diagnostic indications for endoscopy are listed in Table 2.

Colonoscopy is gold standard for diagnosis of colonic mucosal disease.

Fig. 1: Enteroclysis CT abdomen

Contraindications for colonoscopy—Perforated intestine, acute diverticulitis, deep ulcerations, severe ischemic necrosis, fulminant colitis, severe cardiac or pulmonary diseases.

Capsule endoscopy. CE is performed by ingestion of a small, disposable battery powered pill containing a metal oxide semi-conductor camera. Four light emitting diodes illuminate the lumen of the bowel.

Indications—1. Obscure GI bleeding. 2. Small bowel Crohn's disease. 3. Diagnosis of coeliac disease and its complications. 4. Screening for polyps for small bowel polyposis syndromes and small bowel tumours. 5. NSAIDs enteropathies.

Contraindications—1. Patients with known or suspected obstruction, strictures, fistulas. 2. Patients with cardiac pacemaker or other implanted electromedical devices. 3. Patients with swallowing disorders. 4. Pregnancy.

Endosonography

USG of GI tract

USG is an important modality in abdominal imaging.

Indications. 1. Congenital—Hypertrophic pyloric stenosis, malrotation. 2. Acute bowel pathology—Appendicitis, obstruction, intussusception, colitis, sigmoid diverticulitis. 3. Tumours. 4. Miscellaneous—Ileocaecal tuberculosis, duodenal ulcer, round worms.

Endoscopic Ultrasonography

With EUS, lesions located in the gut wall as well as those immediately outside it can be well seen. Endoscopic ultrasonography is useful in diagnosis of submucosal tumours and in assessing the infiltration and depth of malignancy

Table 1: Conditions diagnosed on barium studies

<i>Barium swallow</i>
Oesophageal filling defects
Strictures (sensitivity greater than that of endoscopy)
Gastro-oesophageal reflux
Oesophageal varices
Achalasia
Scleroderma
Oesophageal webs
Candidiasis
<i>Barium meal</i>
Peptic ulcer
Gastric ulcer
Outlet obstruction
Disorders of gastric emptying
<i>Barium meal with follow-through</i>
Abdominal pain
Persistent GI bleed
Malabsorption
Partial bowel obstruction
Crohn's disease
<i>Small bowel enema</i>
Same as barium follow-through
<i>Barium enema (Double-contrast)</i>
<i>Narrowing of lumen</i>
Strictures (colonic diverticulitis, Crohn's disease)
<i>Dilatation of lumen</i>
Obstruction, volvulus, paralytic ileus, ulcerative colitis, megacolon, Hirschsprung's disease.
<i>Miscellaneous</i>
Filling defects
Ulceration
Diverticular disease
Displacement of colon (Hepatosplenomegaly, pelvic tumours)

of GI tract, and also in detection of metastasis in nearby lymph nodes.

Indications—Cancer of oesophagus, mediastinal masses, submucosal tumours, bile duct stones, pancreatic tumours, pancreatic pseudocysts, gallbladder microlithiasis, ampullary growths. Colorectal stenting.

Contraindications for colonoscopy—Perforated intestine, acute diverticulitis, deep ulcerations, severe ischemic necrosis and fulminant colitis, severe cardiac or pulmonary diseases.

Table 2: Diagnostic indications for endoscopy

Upper GI endoscopy		
Oesophageal	Hiatal hernia	Cancer (Figs. 2A and B)
	Reflux oesophagitis	Barrett's oesophagus
	Strictures	Oesophagitis
	Webs	Varices
	Cancer	Mallory-Weiss syndrome
Stomach	Corrosive ingestion (Fig. 3)	
	Gastritis	Polyp
	Ulcers (including biopsy for <i>H. pylori</i>)	Menetrier's disease
	Tumours	
Duodenum	Infiltration (Lymphoma)	
	Duodenitis	Tumours
	Ulcer	Polyps
Miscellaneous	Dyspepsia	Upper GI bleed
	Gastric outlet obstruction	Post-op. stomach
Lower GI endoscopy		
Colonoscopy	Radiological abnormality anastomosis	Inspection of colon
Lower GI bleed	Follow up of polyp or cancer	Some cases of colitis
(Barium enema does not adequately visualise this area).		

Proctoscopy—For examination of middle and lower parts of anal canal, e.g. haemorrhoids, fissures, carcinoma of anorectal region.

Sigmoidoscopy—To evaluate rectum or sigmoid colon before anorectal surgery or in a patient in whom barium enema is indicated. (Primarily used for evaluation of diarrhoea and rectal outlet bleeding)

MUCOSAL BIOPSY

Mucosal biopsies can be obtained under direct vision with endoscope (oesophagus, stomach, duodenum, rectum, colon). Small intestinal biopsy can be obtained with pinch biopsy forceps. Normal histology with a well-formed villous pattern almost excludes diffuse small intestinal mucosal disease. In difficult cases, jejunal biopsy with a suction (e.g. Crosby) capsule may provide further information, and allows examination of dissecting microscopic appearances.

GI MOTILITY

Oesophageal Motility

Barium swallow with video fluoroscopy:

- Upper oesophageal sphincter disorders
- Body motility
- Non-propulsive (tertiary contractions)
- Uncoordinated or weak post-swallow contractions

Manometry:

Upper oesophageal sphincter—Tone of the sphincter and relaxation during swallowing.

Lower oesophageal sphincter tonic pressure and relaxation.

Gastric emptying—Amount of radioisotope retained in the stomach against time, carried out following a test meal containing labelled solids and liquids with different isotopes.

Figs. 2A and B: Carcinoma of oesophagus

Fig 3: Oesophagitis due to corrosive ingestion

Small Intestinal Transit

Barium follow-through—Noting the time taken for contrast to reach terminal ileum (normal about 90 minutes)

Lactulose-hydrogen breath test—Measuring serial breath hydrogen samples following ingestion of a non-absorbable carbohydrate. Rise in breath hydrogen concentration suggests arrival of poorly digested carbohydrate due to fermentation by colonic bacteria.

Colonic transit. Plain radiograph of abdomen on day 5 after ingestion of different shapes of inert pellets on days 1–3. The test is useful in evaluation of chronic constipation due to slow transit.

RADIOISOTOPE TESTS

Radionuclide imaging becomes necessary when barium studies and endoscopy are not conclusive.

- **Gastric emptying time**—for gastroparesis
- **Urea breath test** for diagnosis of *H. pylori*
- **Meckel's scan** for diagnosis of Meckel's diverticulum
- **Labelled red cell scan** for recurrent or obscure GI bleeding.
- **Labelled leucocyte scan** for localised abscess collections in inflammatory bowel disease.
- **SeHCAT scan** for diagnosis of diarrhoea (bile acid-related)
- **Triolein scan** for diagnosis of malabsorption
- **Epithelial permeability test** for investigation of protein-losing enteropathy.

ANGIOGRAPHY

Transfemoral triple vessel angiography (coeliac axis, superior and inferior mesenteric arteries) is used when the site of bleeding cannot be determined by endoscopy. Endoscopic ultrasonography is useful in diagnosis of sub-mucosal tumours and in assessing the infiltration and depth of malignancy of GI tract, and also in detection of metastasis in nearby lymph nodes.

SCANNING METHODS AND THEIR USES

Ultrasound

- Abdominal masses (cysts, tumours, abscess, hepato/splenomegaly)
- Ascites
- Depth of invasion of tumours (endoluminal endoscopic scan)
- Aspiration biopsy

CT Scan

- Bowel wall thickening
- Large colonic carcinoma
- Depth of invasion of tumours

2. THE TONGUE IN DIAGNOSIS

CONGENITAL LINGUAL DISORDERS

Apart from developmental anomalies such as tongue tie, following variations are without clinical significance:

1. **Fissured tongue** (Scrotal tongue)—Deep fissures mostly in longitudinal direction.
2. **Geographical tongue** (Benign migratory glossitis or the wandering rash of the tongue)—For no apparent reason the filiform papillae disappear in oval patches and leave smooth red areas which look like the boundaries of countries on a map.
3. **Median rhomboid glossitis**—Rhomboidal or oval, red, slightly elevated area on the dorsum of the tongue due to failure of fusion of lateral segments of the tongue. (It may be a chronic hypoplastic candidiasis rather than a developmental anomaly).
4. **Furred tongue**—Fur is formed continuously and normally removed by food and saliva. Fur is quite marked if the tongue is not used much, and in smokers.

5. *Rough clean tongue*—Rather large tongue with unusually well-marked fungiform papillae.
6. *Horny tongue* (Crocodile or toad tongue)—Various types of cornification of the mucosa.
2. Red raw, 'angry looking' tongue in sprue, pellagra, severe and untreated diabetes, prolonged febrile illness.
3. White tongue
Lichen planus—Multiple white plaque-like areas.
White patches or flakes on tongue due to curdled milk, thrush, syphilitic patches.

Size

Macroglossia

Acute—(i) Inflammatory. (ii) Non-inflammatory in angioedema.

Chronic—Acromegaly, myxoedema, Down's syndrome, cretinism, amyloid disease or Von Gierke's glycogen storage disease. Other rare causes are congenital arteriovenous fistula between lingual artery and vein, pachydermoperiostosis, and lymphangioma circumscripta superficialis due to hyperplasia of lymphatic vessels.

Microglossia

Dehydration, atrophic glossitis, wasting due to hypoglossal nerve involvement, facial hemiatrophy, or pseudobulbar palsy (small pointed compact looking tongue). In myasthenia gravis atrophy of the tongue may give rise to triple longitudinal furrowing. Bilateral atrophy (with fasciculations) in progressive bulbar paralysis.

ULCERS

1. *Traumatic*—(a) At margins of tongue in epilepsy. (b) Ulcer of frenum (sublingual ulcer) in whooping cough. (c) Dental—opposite a carious tooth.
2. *Tuberculous ulcer*—associated with pulmonary tuberculosis. It is painful and tends to occur near the tip of the tongue.
3. *Recurrent aphthous ulcers*—of unknown aetiology, or at times with idiopathic steatorrhoea or ulcerative colitis. Rarely from Stevens-Johnson syndrome (erythema multiforme) and Behcet's syndrome (recurrent oral, genital and eye ulceration with neurological signs).
4. *Epitheliomatous ulcer*—deep and indurated.
5. *Syphilis*—(a) Primary: Indurated painless ulcer, lymphadenopathy. (b) Secondary: 'Snail track' ulcers with greyish slough or mucus patches and lymphadenopathy. (c) Tertiary: Often midline, punched out ulcers.
6. *Hand, foot and mouth disease*—Round or ovoid ulcers anywhere on mucosa (with vesicular rash on extremities).
4. Magenta colour—in riboflavin deficiency.
5. Blue tongue—denotes central cyanosis.
6. Purple tongue in polycythemia.
7. Dark red or bluish red tongue—in polycythemia vera, riboflavin deficiency, broad spectrum antibiotics.
8. Strawberry tongue—Red tongue with the papillae standing out as white dots in scarlet fever, Kawasaki's disease and toxic shock syndrome.
9. Raspberry tongue—In early stages of scarlet fever, the tongue shows scattered red dots on a grey background. It is due to red fungiform papillae sparsely dotted over the grey tongue.
10. Excessively furred tongue—(a) In all febrile conditions especially typhoid. (b) Poor oral hygiene and mouth breathing. (c) Trismus as from a carious tooth.
11. Yellow tongue—Rarely in jaundice, or due to irritants like nitric or hydrochloric acid.
12. Black tongue—Due to fungus infection, iron, bismuth, opium or tobacco.
13. Slate-blue tongue—in hemochromatosis.
14. Oral hairy tongue—Yellowish brown or black furry patches made up of hypertrophied and densely matted papillae usually from antibiotic ingestion or excessive smoking. Oral hairy tongue should be differentiated from oral hairy leukoplakia which is a white lesion caused by EB virus.

COLOUR

1. Pale tongue in anemia. Blotting paper-like pallor with pigmented margins in Ankylostoma infection at times.

15. Brownish fur with dry tongue (Parrot tongue)—in chronic kidney failure.
16. Small red lesions in hereditary telangiectasia.

MOISTURE

The tongue in health is moist. Dryness of the tongue may be part of general dehydration as in diarrhoea, vomiting and diabetes mellitus. It is worsened by mouth breathing. Certain atropine-like drugs may cause appearance of dry tongue and mouth. Bone-dry tongue in Sjögren's syndrome.

PIGMENTATION

1. *Congenital*—Naevi, Peutz-Jeghers syndrome (circumoral and intraoral melanosis with intestinal polyposis), racial.
2. *Acquired*—(a) Malabsorption or chronic cachexia. (b) Drugs—ACTH, phenothiazines, amodiaquine. (c) Endocrine—Addison's disease, ACTH producing tumours, Albright's syndrome, polyostotic fibrous dysplasia, Nelson's syndrome (hyperpituitarism following adrenalectomy). (d) Dental amalgam. (e) Neoplastic—melanoma, acanthosis nigricans.

SURFACE

1. *Smooth or bald tongue* (atrophic glossitis)—Atrophy of papillae resulting in glossy or varnished tongue may be due to iron deficiency anemia, pernicious anemia, B complex deficiency or malabsorption.
2. *Fissured tongue*—Vitamin B complex deficiency, Mongolian idiocy, acromegaly, acute glossitis, dental trauma, senility or bad oral hygiene, congenital scrotal tongue.
3. *Scarred tongue*—Scars on the tongue may be traumatic, secondary to ulcers from 'tongue-biting' as in epilepsy.
4. *Mushroom-like tongue*—Sore tongue covered with whitish slough in acid poisoning.

MOVEMENTS

1. *Tremors*—(a) Slow rhythmic tremor stopping on voluntary extrusion of tongue in Parkinsonism. (b) Backward and forward 'trombone' tremor of GPI. (c) Miscellaneous causes—multiple sclerosis, prolonged fevers, wasting diseases, senility, chronic alcoholism and excessive smoking and thyrotoxicosis.
2. *Lizard tongue* (Jack-in-the-box or wormian tongue) in rheumatic chorea. After protrusion, the tongue is shot back into the mouth.

3. *Deviated tongue* with tip and median raphe curving round towards the affected side in hypoglossal nerve paralysis. Also in malignant infiltration, scarification after burns or severe ulceration, facial paralysis.
4. *Immobile tongue* (Paretic tongue)—Bilateral lingual paralysis, advanced malignancy of tongue, bulbar palsy, syringomyelia. Sluggish and slow protrusion in mental retardation. Increasingly slow movements in myasthenia gravis.
5. *Rolling movements*—in cretins, Mongols and frontal lobe tumours. In case of Mongols, cretins and in macroglossia, a part of the tongue remains permanently protruded outside the mouth.
6. *Chewing tongue*—Movements of the tongue as in act of chewing in athetosis.
7. *Myotonic reaction*—After a sharp tap on the protruded tongue in myotonia atrophica.
8. *Spasm of the tongue* may be tonic with the tongue becoming small, rigid, conical as in anxiety and general debility, or clonic (the tongue displaying sudden jerks) as in chorea, epilepsy, habit spasm, multiple sclerosis, GPI, hysteria and stuttering.

MISCELLANEOUS DISORDERS

Amyloid tongue—Enlarged tongue with mottling of dark purple areas with translucent matter as part of generalised amyloidosis.

Purpuric spots on the tongue may appear in senile purpura.

Painful tongue—Paroxysms of agonising pain in glossopharyngeal neuralgia.

Alligator tongue—Dry, thick, furrowed and irregular tongue in diabetes mellitus.

Cotton wool patches on dorsum of tongue may be seen in xerostomia in graft-versus-host disease. These are areas of amorphous keratinization as seen in lichen planus.

Truncated tongue—Rarely a tuberculous ulcer at tip of tongue with oedema of the rest of the tongue may impart a truncated, amputated look to the tongue.

Frenulated tongue in Oro-facial-digital syndrome.

Fatiguability of tongue—In myasthenia gravis weakness of muscles of the tongue leads to difficulty in articulation.

Caviar lesions—Varicosities of sublingual veins may be seen on under surface of the tongue in elderly individuals, as also in mediastinal obstruction.

Secondary deposits—Small, yellowish grey nodules rarely in medullary carcinoma of thyroid.

3. STOMATITIS AND ORAL ULCERATION

Causes of stomatitis and oral ulcerations are listed in Table 3.

4. DYSPHAGIA

Dysphagia indicates a delay in the passage of solids or liquids from the mouth to the stomach. Dysphagia should be

Table 3: Causes of stomatitis and oral ulcerations

Stomatitis	Causes	Clinical features	Treatment
Catarrhal	Local: Excessive tobacco, alcohol, spices, antibiotics, drugs (gold, iodide) Systemic: Debility, infectious disease	Red mucous membrane with increased exudate	Elimination of cause. Hexidine or iodine mouth wash. Vit. B complex
Recurrent aphthous stomatitis (RAS)	Possible etiological factors: Positive family history in 1/3. Stress, local trauma, food allergy, in association with menstrual cycles. Episodic mouth ulcers in cyclic neutropenia and HIV infection. Also Behcet's disease, and Sweet's syndrome, Coeliac disease.	Tiny shallow ulcers on erythematous base covered with a greyish white exudate	Systemic: Oral steroids Topical: Mouth washes: Sodium chlorid. Compound thymol glycerin. Antiseptics: Chlorhexidine 0.2%. Povidone iodine 1%. Kamillosan-N mouth spray t.d.s. before meals. Tooth brushing with hydrogen peroxide sodium bicarbonate paste. Immunomodulators: Tetracycline 250 mg capsule in 10 ml water. Swirl then spit qds Triamcinolone acetonide 0.1% Paste qds. Betamethasone 500 µg soluble tabs. swirl and swallow b.d. Beclomethasone dipropionate 100 µg. aerosol sprayed directly qds.
Infection Bacterial (Vincent's angina)	Predisposing factors—pre-existing gingivitis or local trauma, tobacco use	Ulcer surface covered by a grey pseudo-membranous slough demarcated from surrounding mucosa by linear erythema. Increased salivation, foetid odour, spontaneous gingival bleeding, lymphadenopathy and fever.	Metronidazole 200 mg tds for 3 days. After control of acute phase, oral hygiene and surgical correction of distorted gingivae.
Viral	Herpes simplex	Common in children. Severe ulceration of oral mucous membrane with fever, malaise and lymphadenopathy. Initial formation of discrete, spherical grey vesicles which rupture after few hours to form ulcers. Course 2–3 weeks.	Bed rest. Mouth washes. In severe cases acyclovir
	Herpes-varicella zoster	Painful oral ulcer. Tear drop rash of chickenpox.	Symptomatic treatment
	Infectious mononucleosis	Ulcers particularly on fauces.	Symptomatic treatment
	Hand, foot and mouth disease	Round or oval ulcers anywhere on buccal mucosa with rash on extremities.	Symptomatic treatment
Fungal	Thrush (Pseudomembranous candidiasis) Occurs in infants, debilitated adults such as heroin addicts, elderly and after antibiotic and steroid therapy. Early feature of AIDS.	White slightly raised patches resembling milk curds, easily removed leaving a raw bleeding surface.	Ketoconazole 200 mg (for children under 12, 1/4 dose). In infants 0.5% gentian violet applied tds.

Contd...

Stomatitis	Causes	Clinical features	Treatment
Spirochaetal	Secondary syphilis	Circular, mucous patches, often greyish white with red areola	Treatment of syphilis
Drug-induced	Hypersensitivity, cytotoxic drugs (e.g. Methotrexate)	Stomatitis and ulceration of buccal, labial and palatal mucosa.	Symptomatic treatment Vitamin B complex
Vitamin deficiency	Nicotinic acid deficiency	Raw red tongue in pellagra	
GI disorders	Crohn's disease Coeliac disease		
Blood disorders	Acute leukaemia or neutropenia		
Dermatological	Erythema multiforme and Stevens-Johnson syndrome, Lichen planus, Pemphigoid, SLE	See appropriate section	
Systemic disease Neoplasia	Behcet's syndrome, HIV Carcinoma Kaposi's sarcoma		

distinguished from odynophagia which is discomfort or pain on swallowing hot or cold liquids, and occasionally alcohol. In general, mechanical causes lead to dysphagia for solid foods, whereas patients with motility disorders tend to complain of non-progressive dysphagia for both liquids and solids from the onset.

CAUSES OF DYSPHAGIA

Causes of dysphagia are enumerated in Table 4.

Investigation of a case of Dysphagia

HISTORY

- I. Age and sex—*Children* - Cleft palate, foreign body or diphtheritic paralysis. *Young females* - Hysterical spasm. 30-40 - Achalasia. *Menopause* - Sideropaenic dysphagia. *Above 50* - Carcinoma oesophagus particularly in males.
- II. Symptoms—Oropharyngeal dysphagia is usually distinguished from oesophageal dysphagia by the patient's awareness of inability to initiate swallowing properly and occurrence of nasopharyngeal regurgitation, there may also be aspiration of swallowed fluid into the airway.
 - (1) **Dysphagia**—(a) *Onset* - Acute in foreign body, encephalitis, thrombosis of cerebellar artery or hysterical. Gradual in stricture, malignancy, achalasia, etc. Onset after shock or emotional upset common in achalasia. (b) *Type of distress* - (i) Difficulty in swallowing both liquids and solids particularly if there is nasal reflux suggests a

neurological condition. (ii) Difficulty in transferring bolus of food from mouth to gullet is usually caused by *local disorders* of throat, pharynx or larynx. (iii) Sensation of food sticking retrosternally is as a rule due to *oesophageal abnormalities*. (c) *Progress* - Long history with intermittent symptoms in achalasia. Dysphagia first with solids and subsequently fluids suggestive of mechanical obstruction. (d) *Position at which food sticks* - may provide a guide to the site of obstruction as the lesion is either at that level or higher up. (e) *Relation of distress to posture* - If distress at night when patient is in reclining position and relieved in upright position, it suggests oesophageal hiatus hernia. (f) *Deglutition with strangulation or cough* - means central lesions of bulbar type, myasthenia gravis or disease irritating 9th or 10th cranial nerves.

(2) **Pain**—(i) *Burning, substernal contact pain* is felt when hot, acid, spicy or alcoholic material passes through the inflamed oesophagus. This symptom is virtually diagnostic of oesophagitis. (ii) A prolonged history of heartburn preceding the onset of dysphagia is suggestive of peptic stricture and, less commonly, esophageal adenocarcinoma.

(iii) *Impact pain*—Severe pain substernally when a bolus 'impacts' above a narrowed oesophagus. This type of pain together with sudden dysphagia is characteristic first symptom of encircling carcinoma, occurring less commonly with benign stricture.

(iv) *Spasm pain*—This is severe type of oesophageal pain usually related to muscular spasm (oesophageal colic). Causes are diffuse oesophageal spasm, achalasia, reflux oesophagitis, 'nutcracker oesophagus'.

Table 4: Causes of dysphagia**Acute**

- Inflammatory conditions – Pharyngitis, tonsillitis, aphthous ulceration
- Foreign body – Meat bolus, bone or other objects
- Ingestion of caustic substance

Chronic**1. Oropharyngeal****Neurological**

- Cerebrovascular accident
- Motor neuron disease
- Parkinsonism
- Myasthenia gravis
- Multiple sclerosis
- Bulbar palsy
- Polyneuropathy
- Dermatomyositis

Infection

- Candida (Fig. 4)
- Herpes

Mechanical or compressive

- Intervertebral disc degeneration
- Postcricoid carcinoma
- Thyroid enlargement
- Aortic aneurysm
- Mediastinal mass
- Mucosal webs
- Pharyngeal pouch

Psychosomatic

- Globus hystericus

2. Oesophageal**Mechanical block**

- Carcinoma oesophagus or cardia (Fig. 5)
- Oesophageal stricture
- Mediastinal neoplasm
- Schatzki ring (Fig. 6)
- Zenker's diverticulum (Fig. 7)
- Aberrant great vessels (dysphagia lusoria)
- Eosinophilic oesophagitis

Muscular incoordination

- Achalasia
- Scleroderma
- Diffuse oesophageal spasm
- Chaga's disease
- Oesophagitis – peptic, monilial

**Fig. 4: Oesophageal candidiasis**

(3) **Regurgitation**—Characteristic of long standing achalasia; can occur with stooping or straining in hiatus hernia.

(4) **Hematemesis**—Oesophagitis, carcinoma.

(5) **Nasal twang** and nasal regurgitation of fluids suggests palatal paralysis.

(6) **Hoarseness of voice**—Carcinoma of larynx. The presence of hoarseness may be another important diagnostic clue. When hoarseness precedes dysphagia, the primary lesion is usually laryngeal; hoarseness that occurs after the development of dysphagia may result from compromise of the recurrent laryngeal nerve by a malignancy.

III. PAST HISTORY – (a) Of swallowing corrosives or of instrumentation suggests benign stricture formation. (b) Of psychoneurotic disorder may suggest globus hystericus. (c) Of cholecystitis or peptic ulcer may point to reflex cardiospasm.

PHYSICAL EXAMINATION

1. **Mouth and throat**—For stomatitis, malignancy tongue and abnormalities of pharynx.
2. **Neck**—Enlarged lymph glands, goitre, malignancy of thyroid.
3. **Chest**—For evidence of aneurysm, mediastinitis or mediastinal tumour, pericarditis, marked cardiac hypertrophy, emphysema, and pulmonary abscess.
4. **Nervous system**—For evidence of bulbar paralysis or myasthenia gravis.
5. **Spine**—Cold abscess to exclude chronic retro-pharyngeal abscess.

Fig. 5: Carcinoma of oesophagus

Fig. 6: Schatzki's ring

Fig. 7: Zenker's diverticulum

6. *Sideropenic dysphagia*—in Plummer-Vinson syndrome. Dysphagia to solids, iron deficiency, koilonychia, glossitis. Dysphagia is due to a thin web in the precricoid area. The web is formed of degenerated epithelial cells.
7. *Skin*—changes in the skin may suggest a diagnosis of scleroderma or mucocutaneous diseases such as pemphigoid and epidermolysis bullosa, all of which can involve the esophagus.

INVESTIGATIONS

1. *Laryngoscopy*—Ulceration or growth of larynx.
2. *Barium swallow*—Cardiospasm, stricture, growth, congenital shortening of oesophagus, oesophageal diverticulum.

Cineradiography with liquid barium and bread soaked in barium may give functional as well as anatomical information about the pharynx and cricopharyngeal segment.

Videofluoroscopy to investigate chronic dysphagia. It is essentially a modified barium swallow. The three phases of swallowing are observed on a screen and videotaped.

3. *Barium meal*—For hiatus hernia or peptic ulceration.
4. *X-ray chest*—Mediastinal tumour, aneurysm, mitral valve disease. Evidence of lung infection from repeated aspiration in achalasia.
5. *Endoscopy* is the best way to determine the cause of dysphagia because of high diagnostic accuracy and opportunity to take biopsies.
6. *Manometry*—Neither radiology nor endoscopy alone can exclude a treatable motility defect which can readily be demonstrated by intraluminal manometry and pH monitoring. These measure the vigour and coordination of oesophageal muscle contraction patterns, amount of gastro-oesophageal reflux, and the relationship of symptoms to oesophageal luminal events.
7. *Biopsy*—It is recommended that esophageal mucosal biopsies be obtained routinely in the evaluation of unexplained dysphagia even if endoscopically identified oesophageal mucosal lesions are absent.

TREATMENT

1. Treatment of dysphagia depends on both the focus and the specific etiology.

- Oropharyngeal dysphagia most commonly results from functional deficits caused by neurologic disorders. In such circumstances, the treatment focuses on utilizing postures or maneuvers devised to reduce pharyngeal residue and enhance airway protection learned under the direction of a trained swallow therapist.
- Dysphagia resulting from a cerebrovascular accident, Parkinson's disease and amyotrophic lateral sclerosis, may manifest with severe oropharyngeal dysphagia, feeding by a nasogastric tube or an endoscopically placed gastrostomy tube may be considered.
- Surgical intervention with cricopharyngeal myotomy is used in specific disorders such as the idiopathic cricopharyngeal bar, Zenker's diverticulum and oculopharyngeal muscular dystrophy.
- The majority of causes of esophageal dysphagia are effectively managed by means of esophageal dilatation using bougie or balloon dilators.
- Cancer and achalasia are often managed surgically although endoscopic techniques are available for both palliation and primary therapy, respectively.
- Infectious etiologies respond to antimicrobial medications or treatment of the underlying immunosuppressive state.
- Eosinophilic esophagitis has emerged as an important cause of dysphagia that is amenable to treatment by elimination of dietary allergens or administration of swallowed, topically acting glucocorticoids.

5. GASTRO-OESOPHAGEAL REFLUX DISEASE

Gastro-oesophageal reflux disease (GORD) is caused by recurrent reflux of gastric contents into the distal oesophagus. The pathophysiology is multifactorial, but dysfunction

Table 5: Factors which facilitate reflux

Mechanism	Causes
• Relaxed or hypotonic sphincter	Diabetes mellitus, sliding hiatus hernia, fatty meal
• Decreased LOS pressure	Prolonged gastric tube intubation, scleroderma Drugs – Anticholinergics, β -adrenergic agents, calcium channel blockers, nitrates
• Raised intra-abdominal pressure	Ascites, obesity, pregnancy
• Impaired oesophageal mucosal function	Alcohol, smoking
• Delayed gastric emptying	Pyloric obstruction, fatty foods, gastroparesis
• Increased gastric contents	Large meals, Z-E syndrome

of the lower oesophageal sphincter (LOS) has a primary role. Motility disorders of the distal oesophagus (e.g. reduced peristaltic amplitude, decreased velocity and increased duration of peristaltic contractions) cause prolonged exposure of the oesophagus to refluxed gastric contents.

Factors which facilitate reflux are listed in Table 5.

SYMPTOMS AND CONDITIONS ASSOCIATED WITH GERD

Typical symptoms: Heartburn, acid regurgitation.

Atypical symptoms: Dysphagia, globus sensation, non-cardiac chest pain, dyspepsia or abdominal pain.

Extraoesophageal symptoms: Hoarseness or sore throat, or both, sinusitis, otitis media, chronic cough, laryngitis or polyps on the vocal cords or both, dental erosions, non-atopic asthma, recurrent aspiration or pulmonary fibrosis, or both.

Sleep related GER can present with multiple awakenings. Substernal burning and/or chest discomfort, indigestion or heartburn. Other symptoms include a sour or bitter taste in the mouth, water brash, coughing or choking.

Malignancy: Oesophageal adenocarcinoma, head and neck cancer.

Barrett's oesophagus is found in 10–20% of patients with reflux oesophagitis, the squamous epithelium is injured by chronic gastro-oesophageal reflux and repair is effected by columnar instead of squamous cells. Upper GI scopy (Fig. 8) can be diagnostic assisted by biopsy. This columnar epithelium may undergo malignant transformation.

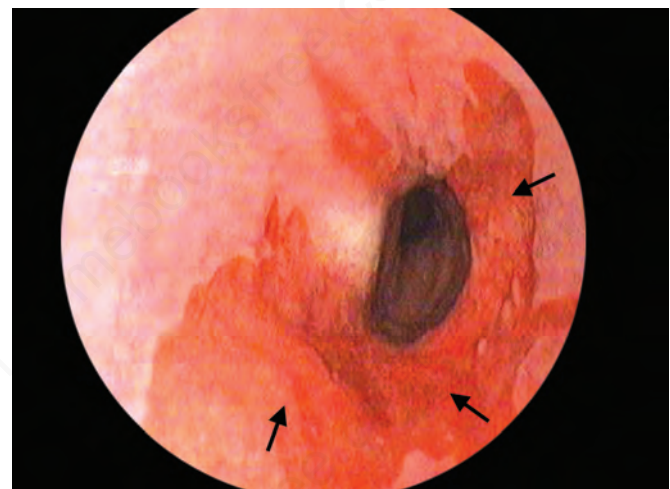

Fig. 8: Barrett's oesophagus

INVESTIGATIONS

1. Radiology

Barium swallow with fluoroscopy

Upper oesophageal sphincter disorders

Defective opening of pharyngo-oesophageal segment

Airway aspiration.

Body motility

Non-propulsive (tertiary contractions)

Uncoordinated or weak post-swallow contractions.

Identification of hiatus hernia, mucosal ulceration, stricture, oesophageal dilatation.

2. Upper oesophageal endoscopy

Indications: GI bleeding, iron deficiency anemia, progressive unintentional weight loss, progressive difficulty swallowing, persistent vomiting, epigastric mass on palpation, suspicious barium meal result or other suspicious imaging result.

3. Manometry

- Upper oesophageal sphincter
- Tone of upper oesophageal sphincter and relaxation during swallowing.
- Coordination between relaxation of upper oesophageal sphincter and contraction of the pharynx.
- Body motility
- Evaluation of amplitude, duration and velocity of waves.
- Lower oesophageal sphincter tonic pressure and relaxation.

4. Oesophageal pH testing—The ideal standard for oesophageal pH probe replacement is manometric determination EES. Newer technology monitoring of oesophageal pH using a wireless system allowing for data collection for up to 48 hours.

- Acid reflux time
- Number and duration of reflux episodes
- Symptom index. (Percentage of symptom episode associated with reflux episode). Special indications—Atypical symptoms, patient unresponsive to medical therapy, preoperative assessment and follow-up of patient undergoing reflux surgery.

5. Scintigraphy. Introduction of technetium⁹⁹ (⁹⁹Tc) into stomach followed by abdominal compression and radiographic counting over oesophagus. This technique can demonstrate reflux as well as provide quantitative measure of its presence.

MANAGEMENT

1. Conservative measures

- Abstain from eating within 2 hours of bed time
- Elevate head of bed by 6 inches
- Sleep in left lateral decubitus position
- Avoid—Caffeine, nicotine, alcohol, chocolate, mints, carbonated beverages, high-fat foods, tomato or citrus - based products. Avoidance of acidic foods which are inherently irritating.
- Avoid if possible medications that can worsen GER - Anticholinergic, theophylline, prostaglandin, calcium channel blockers, alendronate.
- Weight loss if obese (most important of all)
- Consider nasal CRAP if OSA is present
- Rabeprazole, esoprazole provide superior gastric acid suppression.

2. Acid suppression—(a) Proton pump inhibitors provide rapid symptomatic relief and healing of oesophagitis in majority of patients. (b) Prokinetic agents such as Tegaserod maleate 6 mg b.d. or Levosulpiride 50 mB.D.d. or Clebopride 0.5 mg b.d. improve motility by increasing LES pressure, accelerating oesophageal acid clearance mechanism and improving gastric emptying.

3. If no response or relapse—Test and treat for *H. pylori*. Distal gastritis increases production of gastric acid. In this condition eradication of *H. pylori* reduces risk of acid reflux. Conversely, generalized atrophic gastritis decreases production of gastric acid, as a result *H. pylori* eradication may increase severity.

4. Surgery—If persistent non-acid reflux. Antireflux surgery augments the reflux barrier by a full or partial wrap of the gastric fundus (fundoplication) around the lower oesophagus.

6. ACHALASIA OF THE CARDIA

Achalasia (Cardiospasm, Megaesophagus) is a primary motor disorder of the oesophagus. Failure of relaxation of lower oesophageal sphincter on swallowing is a characteristic feature. Degeneration of neuronal cell bodies in the myenteric plexus is thought to be the primary abnormality.

CLINICAL FEATURES

1. Dysphagia—is the dominant symptom. Feeling of obstruction usually of the cardia or sometimes high in the oesophagus. Sensation of food sticking in the oesophagus at first intermittent, later continuous and at every meal, and more with solids.

Fig. 9: Chest radiograph showing gross enlargement of the oesophagus due to achalasia

Fig. 10: Barium-filled oesophagus showing distension above (arrow head) the narrow gastro-oesophageal junction

Note: The abrupt narrowing of the lower end of oesophagus (bird beak sign)

2. **Regurgitation**—In initial stages, food is regurgitated almost immediately following ingestion but as oesophagus becomes dilated, food and secretion may be retained for hours and days followed by delayed regurgitation.
3. **Chest pain**—Spontaneous retrosternal pain which occurs equally during night and day, is often severe and is relieved by drinking cold water. Patients describe a squeezing, pressure-like retrosternal pain, sometimes radiating to the neck, arms, jaw, and back. Paradoxically, some patients complain of heartburn that may be a chest pain equivalent. Other sensations may be bursting feeling provoked by drinking fast, or sensation of food sticking, and heart burn by lying down or stooping.
4. **Respiratory symptoms**—(a) Cough and dyspnoea due to pressure on trachea and bronchus by dilated oesophagus. (b) Aspiration may result in aspiration pneumonia, bronchiectasis or lung abscess.
5. **Asymptomatic**—Occasionally the condition is discovered as a mediastinal swelling on routine chest film.

COMPLICATIONS

1. **Pulmonary**—Fibrosis due to recurrent chest infection.
2. **Carcinoma**—Commonest in mid-oesophagus due to irritation from chronic stasis oesophagitis.
3. **Malnutrition**—Rare.

INVESTIGATIONS

1. **Radiology**—(a) *Plain chest radiograph* will show enlarged mediastinal shadow and oesophageal dilatation

with poor emptying and air-fluid level (Fig. 9) (b) *Barium swallow* - Oesophageal dilatation and slow flow into the stomach across a smoothly tapered gastro-oesophageal junction (bird beak sign) (Fig. 10). Absent stomach gas bubble.

2. **Endoscopy**—Usually reveals a chronically inflamed oesophageal mucosa. It has minimal role.
3. **Manometry**—Failure of lower oesophageal sphincter to relax on swallowing. It is the most sensitive diagnostic test.

MANAGEMENT

Pharmacotherapy—Isosorbide dinitrate 5 mg sublingually before meals or nifedipine 10–20 mg have a direct relaxant effect on the muscle of lower oesophageal sphincter. They may be of value while patient is awaiting definitive treatment.

Pneumatic dilatation and extramucosal oesophagomyotomy endoscopy—The aim of both procedures is to effect partial disruption of lower oesophageal sphincter, by stretching it using an inflatable balloon positioned within the oesophageal lumen, or by surgical myotomy at the cardia (Heller's operation). The most significant complication of the operation is gastro-oesophageal reflux.

Endoscopic LES myotomy (per oral esophageal myotomy)—This technique involves the creation of a tunnel within the esophageal wall through which the circular muscle of the LES and distal esophagus are transected with electrocautery.

Endoscopic intrasphincteric injection of botulinum toxin—As an alternative to pneumatic dilatation or surgery. It may be of advantage in elderly or frail patients. Multiple treatments are needed over a period of time, but the effect tends to last longer with successive injections.

7. HIATAL HERNIA

Protrusion of the stomach above the diaphragm.

Aetiology—Most common in middle-aged, obese females. It may be congenital or due to conditions which raise intra-abdominal pressure, e.g. obesity, pregnancy, ascites or abdominal tumours, or may follow surgical operations like partial gastrectomy or vagotomy.

TYPES

1. Type I *Sliding*—Commonest variety. Simple upward slide of fundus of stomach with oesophago-gastric junction through the hiatus into the chest.
2. Type II *Rolling* (Paraesophageal)—The oesophago-gastric junction is within the abdominal cavity, but part of the gastric fundus protrudes through the hiatus into the thoracic cavity.
3. Type III combined sliding and paraesophageal hernia.
4. Type IV hiatal hernias, viscera other than the stomach herniate into the mediastinum, most commonly the colon.

CLINICAL FEATURES

1. **Asymptomatic**
2. **Symptoms due to reflux**—(a) Retrosternal chest pain or discomfort especially on stooping or lying down soon after meals. (b) Heart burn or regurgitation of acid fluid, or food on bending or stooping. Nocturnal regurgitation may cause choking attacks and aspiration pneumonia. (c) Dysphagia due to oesophageal muscle spasm, oesophagitis.
3. **Symptoms due to pressure**—Either of dilated oesophagus and/or gastric pouch on surrounding structures – (a) From pressure on mediastinum – Dyspnoea, palpitation, cough, anginal pain. (b) From pressure on diaphragm – Hiccup, spasmodic pain.
4. **Symptoms due to hemorrhage**—Iron deficiency anemia due to massive hematemesis or oozing from oesophageal ulcers.
5. **Symptoms due to associated diseases**—Peptic ulcer at level of diaphragmatic hiatus, cholecystitis, ischemic heart disease.

In contrast to a sliding hernia, paraesophageal hernia may lead to serious complications, especially strangulation or hemorrhagic anemia.

INVESTIGATIONS

1. **Radiology**—(a) X-ray chest – If a sliding hernia is large, it may be seen as retrocardiac shadow with fluid level. (b) Barium swallow to assess hernia size and development of complications.
2. **Endoscopy and biopsy**—Mainly of value in assessment of oesophagitis and of consequent bleeding, ulceration and stricture formation.
3. **Manometry** is the only sensitive method, as in absence of dilation, barium meal may be reported as normal.

MANAGEMENT

A. Medical

1. **To minimise gastro-oesophageal reflux**—(a) Elevate bed head by 20 cm. (b) Avoid posture precipitating reflux, e.g. bending or stooping forwards, sitting in a low chair. (c) Avoid large meals. (d) No food or drink for 3–4 hours before bedtime. (e) Reduce weight if obese. Stop non-steroidal anti-inflammatory drugs. (f) Avoid foods which provoke symptoms, e.g. pastries, coffee.
2. **Reduce gastric acidity and pepsin secretion** – with ranitidine or famotidine or antacids.

B. Surgical

Surgical correction in resistant cases.

8. DYSPEPSIA

Dyspepsia refers to upper abdominal symptoms usually following intake of food which appears to arise from upper GI tract.

CLASSIFICATION

1. **Organic dyspepsia**: Erosive oesophagitis, gastric erosions, acute or chronic gastritis, gastric ulcer, duodenal ulcer, duodenitis, malignancy (carcinoma, lymphoma). It is suspected in presence of alarm symptoms (wt. loss, anemia, bleeding or positive occult blood, loss of appetite).
2. **Functional or non-ulcer dyspepsia** (see later).

3. *Drug-related*: Aspirin, NSAIDs, antibiotics, bisphosphonates, oestrogens, steroids, digoxin, chloroquine, iron, potassium supplements.
4. *Extra intestinal systemic disease*: Diabetes mellitus, hypothyroidism, hyperparathyroidism, Addison's disease, uremia.

Symptoms of dyspepsia can be divided into:

1. *Reflux type*: Retrosternal burning, regurgitation.
2. *Ulcer type*: Epigastric pain on empty stomach. Relieved with bland food, antacids or acid suppression.
3. *Dysmotility type*: Postprandial fullness, distension, early satiety, nausea.

ROME III DIAGNOSTIC CRITERIA FOR FUNCTIONAL DYSPESIA

At least 3 months, with onset at least 6 months previously, of one or more of the following:

- Bothersome postprandial fullness
- Early satiation
- Epigastric pain
- Epigastric burning
- No evidence of structural disease (including upper endoscopy) that is likely to explain the symptoms.

CRITERIA FOR DIFFERENTIATING POSTPRANDIAL SYNDROME AND EPIGASTRIC PAIN SYNDROME

Postprandial Distress Syndrome

1. Bothersome postprandial fullness, occurring after ordinary sized meals, at least several times per week AND/OR
2. Early satiation that prevents finishing a regular meal, at least several times per week.

Table 6: Potential causes of non-ulcer dyspepsia

- Duodenogastric reflux
- Duodenitis
- Carbohydrate malabsorption (lactose, fructose, sorbitol)
- Cholelithiasis or choledocholithiasis
- Chronic pancreatitis
- Systemic disorders (diabetes, thyroid, parathyroid, hypoadrenalism, connective tissue disease)
- Intestinal parasites
- Psychiatric disorders
- Visceral hypersensitivity
- Gastric/small intestinal dysmotility
- Gallbladder/biliary dysmotility

Supportive Criteria

1. Upper abdominal bloating, postprandial nausea or excessive belching can be present.
2. Epigastric Pain Syndrome may coexist.

EPIGASTRIC PAIN SYNDROME

1. Pain or burning localized to the epigastrium of at least moderate severity at least once per week AND
2. The pain is intermittent AND
3. Not generalized or localized to other abdominal or chest regions AND
4. Not relieved by defecation or passage of flatus AND
5. Not fulfilling criteria for gallbladder and sphincter of Oddi disorders.

Supportive criteria

1. The pain may be of burning quality but without a retrosternal component.
2. The pain is commonly induced or relieved by ingestion of a meal but may occur while fasting.
3. Postprandial distress syndrome may coexist.

Potential causes of non-ulcer dyspepsia are listed in Table 6.

Differential diagnosis of dyspepsia is given in Table 7.

9. H. PYLORI INFECTIONS

H. pylori is a small curved (comma shaped), highly motile Gram-negative organism that colonises only the mucus layer of the human stomach. Multiple strains of the

Table 7: Differential diagnosis of dyspepsia

- Non-ulcer dyspepsia
- Gastro-oesophageal reflux disease
- Peptic ulcer disease
- Medication related: non-steroidal anti-inflammatory drugs, antibiotics, iron, potassium supplements, digoxin
- Carbohydrate malabsorption (lactose, fructose, sorbitol)
- Cholelithiasis or choledocholithiasis
- Chronic pancreatitis
- Systemic disorders (diabetes, thyroid, parathyroid, hypoadrenalism, connective tissue disease)
- Intestinal parasites
- Abdominal malignancy (especially pancreatic and gastric cancer)
- Chronic mesenteric ischaemia

organism exist. It also has considerable genetic heterogeneity, no strains being identical.

Transmission appears to be predominantly via oral faecal route, including contaminated water supplies. Transmission by endoscopy is possible. *H. pylori* infection can be picked up from siblings, older children, or parents predominantly via gastro-oral route.

CLINICAL FEATURES

1. **Gastritis**—Gastric infection with *H. pylori* is the main cause of gastritis. Infection in infancy is thought to lead to pangastritis, whereas in later childhood to predominantly central gastritis.
2. **Peptic ulcer** associated with *H. pylori*. Only a minority of individuals infected with *H. pylori* develop ulcers. Risk of ulceration is increased by cigarette smoking, and by the presence of more aggressive strains of the bacterium that carry the CAGA gene and the S₁ variant of the gene encoding a vacuolating toxin.

PATHOGENESIS

Possible mechanisms for ulcer development:

1. Bacillus secretes urease which converts into ammonia, thus alkalisng the surrounding acid medium for its survival but simultaneously producing ammonia-induced mucosal damage. Production of ammonia by bacteria prevents D cells in antral glands from sensing the level of acidity, leading to inappropriate release of somatostatin and an increase in gastrin and thus excess of acid secretion.
2. Neural pathways are affected by *H. pylori* which results in downregulation of acid production.
3. *H. pylori* produces inflammatory response in gastric mucosa with induction of epithelial derived cytokines. Influx of neutrophils and macrophages into gastric mucosa with release of lysosomal enzymes and leukotrienes impairs mucosal defence.
4. *H. pylori* expresses adhesins (OMPs like BabA), which facilitate attachment of the bacteria to gastric epithelial cells.

Role in development of MALT (mucosal associated lymphoid tissue), lymphoma, gastric adenocarcinoma, GERD and dyspepsia.

Mechanisms of gastric ulcer are less well defined, but probably include—1. Local *H. pylori* related inflammation leading to epithelial damage. 2. Inhibition of synthesis of protective prostaglandins by inhibition of cyclooxygenase-1 by NSAIDs. 3. Bile reflux, which is increased in these patients.

INVESTIGATIONS

Non-invasive Tests

Serology. The main use of serology is for testing dyspeptic patients in primary care and patients with known ulceration but unknown *H. pylori* status in secondary care. Serology may remain positive for many years after successful eradication of *H. pylori* and is therefore not used for checking the success of treatment.

Urea breath test is a simple, non-invasive test based on the fact that *H. pylori* possesses a powerful urease. It is particularly useful for checking the success of treatment. It must be performed at least 4 weeks after any proton pump inhibitors, bismuth compounds or antibiotics, if not, false-negative results may be obtained.

Biochemical basis of the urea breath test is described in Figure 11.

Stool antigen test is used as ELISA to detect presence of *H. pylori* antigens shed in the faeces. The main advantage of the test is in large scale epidemiological studies of acquisition of *H. pylori* infection in children.

Invasive Tests

Antrum Biopsy

- (a) **Biopsy urease testis** based on liberation of ammonia by action of *H. pylori* urease. One or two biopsies are placed on a gel or into a solution containing urea with a pH indicator. A colour change is produced if the pH

Fig. 11: Urea labelled with the non-radioactive isotope ¹³C, or very small dose of radioactive ¹⁴C, is drunk by the patient. If *Helicobacter pylori* is present in the stomach, its powerful urease catalyses hydrolysis of urea, and labelled carbon dioxide can be detected in breath samples.

Table 8: Eradication of *H. pylori* infection

First-line treatments		
Triple therapy		
1. Bismuth subsalicylate 2 tab qid plus	X 14 days	
Metronidazole 250 mg qid plus		
Tetracycline 500 mg qid		
2. Omeprazole 20 mg b.d. plus		
Clarithromycin 250 or 500 mg bid plus		
Amoxicillin 1g b.d. or		
Metronidazole 500 mg b.d.		
3. Ranitidine bismuth citrate 400 mg bid plus		
Tetracycline 500 bid plus		
Clarithromycin or Metronidazole 500 mg bid		
Quadruple therapy		
Omeprazole 20 mg b.d.		
Bismuth subsalicylate 2 tab qid		
Metronidazole 250 mg qid		
Tetracycline 500 mg qid		

Note: An alternative to 'blind' second-line therapy is to culture *H. pylori* and be guided by antibiotic sensitivities.

increases. When *H. pylori* is present, the urea is hydrolysed by its urease, resulting in a colour change. Most tests are read at 24 hours.

- (b) **Histology**—*H. pylori* infection can be diagnosed with special stains. Multiple biopsies should be taken from the antrum and corpus.
- (c) **Culture**—Endoscopic mucosal biopsy specimens can be cultured for *H. pylori*. This is not useful as a single diagnostic test, but it enables antibiotic sensitivity testing.

TREATMENT

Eradication of *H. pylori* infection is achieved by regimens given in Table 8.

10. GASTRITIS

Gastritis is inflammation of the gastric mucosa. It can be active or chronic. Gastritis is seldom symptomatic, but can have important clinical sequelae, principally duodenal and gastric ulceration, gastric adenocarcinoma and primary gastric lymphoma. The three important causes of gastritis are *H. pylori* infection, NSAIDs and autoimmunity. Classification of gastritis is given in Table 9.

Table 9: Classification of gastritis

Type of gastritis	Aetiology
Non-atrophic	<i>H. pylori</i>
Atrophic	
Autoimmune	Autoimmunity
Multifocal atrophic	<i>H. pylori</i> , ± environmental insults
Special forms	
Chemical	NSAIDs, bile, alcohol
Radiation	Radiation injury
Lymphocytic	Idiopathic, gluten, drugs
Non-infectious granulomatous	Crohn's disease, sarcoidosis, Granulomatous polyangiitis and other vasculitides
Eosinophilic	Food sensitivity
Other infections	Bacteria other than <i>H. pylori</i> (particularly other gastric helicobacter, mycobacteria and syphilis), viruses (cytomegalovirus), fungi (<i>Candida</i> spp., <i>Histoplasma</i>) <i>Capsulatum</i> and <i>Mucoraceae</i>

Chronic gastritis is of two types—Type A and Type B
Type A—Autoimmune gastritis is virtually confined to the corpus and is associated with antiparietal cell and other intrinsic factor antibodies. It may result in vitamin B₁₂ deficiency and pernicious anemia and is a risk factor for gastric adenocarcinoma.

Type B—*H. pylori* can cause antral predominant gastritis, which predisposes to gastric ulceration and distal gastric adenocarcinoma.

NSAIDs/Aspirin cause gastritis characterized by mucosal hyperplasia and oedema but little inflammatory cell infiltration. It may be associated with gastric or duodenal ulceration.

Chemical gastritis due to chemical irritation e.g. reflux of bile or duodenal contents (reflux gastritis).

Treatment—Eradication of *H. pylori*. Patients with pernicious anemia will require parenteral vitamin B₁₂ supplementation on a long-term basis.

11. PEPTIC ULCER

The term peptic ulcer applies to mucosal ulceration near the acid bearing regions of the gastrointestinal tract. Most ulcers occur in the stomach or proximal duodenum but they may also occur in the oesophagus (due to acid reflux), in jejunum (at site of gastrointestinal anastomosis), and rarely in relation to ectopic gastric mucosa (near a Meckel's diverticulum).

Table 10: Causes of gastric ulcer

Causes of gastric ulcer	
Causes of gastric ulcer	
•	H. Pylori infection
•	NSAIDs
•	Neoplasm (carcinoma, lymphoma, lymphosarcoma)
•	Stress
•	Crohn's disease
•	Infections (herpes simplex, cytomegalovirus)
Causes of duodenal ulcer	
Common causes	
•	H. pylori infection
•	NSAIDs
Uncommon causes	
•	Zollinger-Ellison syndrome (Gastrinoma)
•	Hypercalcemia
•	Granulomatous diseases (Crohn's disease, sarcoidosis)
•	Neoplasia (carcinoma, lymphoma, leiomyoma)
•	Infections (tuberculosis, herpes simplex, cytomegalovirus)
•	Ectopic pancreatic tissue

AETIOPATHOGENESIS OF PEPTIC ULCER

1. Heredity and strong family history.
2. Peptic ulceration results from digestion of the mucosa with acid and pepsin of gastric juice. Acid secretion is more important in aetiology of duodenal ulcer than gastric ulcer.
3. Mucosal resistance (Gastric mucosal barrier). Mechanism: (a) Secretion of bicarbonate by surface epithelial cells under the influence of mucosal prostaglandins. These cells also secrete mucus that impedes diffusion of ions and molecules such as pepsin. (b) The tight intercellular junctions and surface lipoprotein level provide a mechanical barrier. (c) The submucosal area provides micronutrients and oxygen while removing toxic metabolic products of gastric epithelial cells. (d) Factors reducing mucosal resistance - Drugs like aspirin, NSAIDs, *H. pylori* infection, reflux of bile and intestinal contents into stomach due to poorly functioning pyloric sphincter.

Causes of peptic ulcer are enumerated in Table 10.

Pathogenesis of duodenal ulceration is depicted in Figure 12.

SYMPTOMS – PAIN

1. *Character and intensity*—Variable, usually gnawing, moderate, very mild or severe.

Fig. 12: Antral inflammation leads to reduced somatostatin production and, because somatostatin has a negative feedback effect on gastrin production, this results in hypergastrinemia. Gastrin acts on parietal cells, resulting in high stimulated acid production, increased duodenal acid load and the formation of protective gastric metaplasia in the duodenum, *Helicobacter pylori* cannot colonize the normal duodenum, but can colonize gastric metaplasia, causing inflammation and ulceration

2. *Location and radiation*—Characteristically sharply circumscribed to an area about one inch in diameter between xiphoid and umbilicus. Can occur anywhere in the abdomen, retrosternally, or with a posterior ulcer in the back.
3. *Relation to food*—Rhythmic occurrence and disappearance. Pain invariably absent in morning. Pain usually comes 2–3 hours after meals and is eased by food. Characteristic nocturnal distress between 12 and 2 am. Freedom from pain for about two hours after rising. In gastric ulcer pain is precipitated by food.
4. *Aggravation and relief*—Aggravated by coarse foods, alcohol, nervous tension, undue fatigue. Relief by antacids or after vomiting of acid fluid.
5. *Periodicity of pain*—Most characteristic feature. Even when pain is absent, recurrent bouts of heartburn, anorexia, nausea and vomiting suggest possibility of ulcer.
Nausea and weight loss occur more commonly in gastric ulcer patients.

Variations in Clinical Picture

1. *From high pain threshold*—Little or no pain, only sensation of fullness or bloating.
2. *Increased reflex activity in gastrointestinal tract*—(a) Oesophageal spasm - Excessive salivation and acid regurgitation (water brash). (b) Pylorospasm - Heartburn.

Fig. 13: Barium study demonstrating duodenal ulcer

Fig. 14: Barium study of gastric ulcer

(c) Colonic spasm - Features of irritable colon syndrome - Constipation, abdominal pain not related to food and most marked on left side of abdomen.

3. *From complications*—(a) Penetrating ulcer - may cause continuous pain, pain in unusual sites such as back or shoulder and refractoriness to agents formerly yielding prompt relief. (b) Bleeding - acute hematemesis or anemia due to insidious bleeding. (c) Pyloric obstruction - Nausea, anorexia, loss of weight and vomiting. (d) Perforation of ulcer - into lesser sac may cause back pain, malaise and fever.
4. *Postbulbar ulcer*—Mostly back pain, or insidious bleeding.
5. *From associated disease*—Such as gallstones or hiatus hernia.
6. *From neurosis*—Multiple gastrointestinal symptoms due to anxiety.
7. *Acute and stress ulcers*—Aspirin, head injury (causing ulcer by acid hypersecretion, burns and shock), reflux of duodenal contents and mucosal ischemia, severe sepsis, surgery, trauma.

SIGNS

“The history is everything, the physical examination nothing”.

1. *Tenderness*—Deep tenderness to the right of the middle in epigastrium. Localised over the site of lesion on deep palpation. Superficial tenderness may be present.
2. *Muscle guarding or rigidity*—may be present with active ulcer or deeply penetrating ulcer.

3. *Peristaltic waves* may be observed in presence of obstruction. Gastric splash may suggest gastric retention due to duodenal ulcer near pylorus.

4. *Occult blood* in stools.

INVESTIGATIONS

1. **Endoscopy** is the ideal method of diagnosing duodenal ulcer. The ulcer often appears like a severe aphthous ulcer with a creamy base.

2. **Barium meal**

Acute stage

- Ulcer crater. Persistent pool of barium.
- Ulcer niche. Crater jutting beyond margins, shown to be on anterior or posterior wall on rolling the patient.
- Irritable duodenal cap seen as spasticity of the cap or a hurry of the barium as it passes through the cap (Fig. 13).

Healing stage

- Radiating folds. Mucosal folds radiating away from the ulcer.
- Scarred and deformed duodenal cap (trifoliate deformity) with multiple ulcers and healing.

Radiographic criteria for benign gastric ulcer (Fig. 14).

- Ulcer crater extending beyond gastric wall
- Gastric folds radiating into base of ulcer
- Thick radiolucent collar of oedema (Hampton's line) surrounding ulcer base.
- Smooth, regular, round or oval ulcer crater
- Pliable and normally distensible gastric wall in the area of the ulcer.

(Up to 8% of GUs that appear to be benign by radiographic appearance are malignant by endoscopy or surgery)

3. **Gastroscopy.** In addition to allowing direct visualization of the mucosa, photographic documentation of a mucosal defect and tissue biopsy to rule out malignancy.
4. **Tests for *H. pylori*.** (Refer)
5. **Gastric studies** include measurement of basal secretion, or response to injection of histamine, pentagastrin or insulin. Not necessary for assessment of uncomplicated DU, but required only for hypersecretion when patient has continuing DU after gastric surgery.
6. **Fasting plasma gastrin concentration**—Elevated in Z-E syndrome. Fasting gastrin levels are usually <150 pg/mL. Virtually all gastrinoma patients will have a gastrin level >150–200 pg/mL. Inj. of Secretin in normal individuals causes fall in plasma gastrin, in Z-E syndrome there is immediate rise.
7. **Hb and MCV**—To exclude anemia of iron deficiency.

COMPLICATIONS

1. Bleeding—Most common
2. Perforation—Acute or chronic perforation into surrounding organs – pancreas, liver, bile duct, colon.
3. Pyloric stenosis.
4. Malignancy at site of ulcer.
5. Pancreatitis due to posterior penetration of ulcer.

DIFFERENTIAL DIAGNOSIS OF DUODENAL ULCER (EPIGASTRIC PAIN)

I. Gastric lesions

1. **Gastric ulcer:** See Table 11 for differences between gastric and duodenal ulcer.

Table 11: Differences between gastric and duodenal ulcer

	<i>Gastric ulcer</i>	<i>Duodenal ulcer</i>
Course of illness	Less remittent	More remittent
Pain	Longer duration	Shorter duration
Food	Provokes the pain	Relieves the pain
Heart burn	Less common	More common
Antacids	Relief of pain not instant	Prompt relief of pain
Anorexia, nausea	More common	Less common
Spontaneous perforation	Less common	More common

2. **Gastric carcinoma** : Clinical features—(a) Dyspeptic symptoms in patient over 45 years. (b) Daily discomfort or pain. (c) Anorexia or undue fullness after meals. (d) Vomiting of small quantities of fresh or altered blood. (e) Weight loss. (f) Unexplained anemia. (g) Previous history of chronic gastritis. (h) Family history of gastric cancer. (i) Known pernicious anaemia. (j) Presence of physical signs such as epigastric mass or jaundice suggest advanced disease. Barium meal examination is useful only for detection of mucosal abnormalities. Neoplastic infiltration causes blunting, fusion, clubbing or tapering of mucosal folds. *Endoscopy and biopsy* with brushing for further confirmation.
3. **Chronic gastritis:** Table 12 gives differentiation between chronic gastritis and peptic ulcer.

II. Duodenal lesions

1. **Pseudoulcer syndrome** (Pyloroduodenal irritability) —Discomfort later after meals, relieved temporarily by food or antacids, and in many cases typical periodicity of remissions and relapses. Often hyperchlorhydria. X-ray studies show pylorospasm and extreme irritability of duodenal cap. No evidence of ulcer.
2. **Duodenitis**—Often no pain but nausea and sensation of fullness in upper right part of abdomen. Maximum intensity several hours after ingestion of food. Symptoms are usually not intermittent but continuous. Endoscopy shows inflamed, hemorrhagic or friable duodenal mucosa.
3. **Duodenal diverticula**—Pain in epigastrium, may arise ½ to 2½ hours after meals. Not relieved by diet or antacid. Diverticula seen on barium meal X-ray.

Table 12: Differentiation between chronic gastritis and peptic ulcer

<i>Chronic gastritis</i>	<i>Peptic ulcer</i>
History of repeated attacks of acute gastritis	History of ingestion of NSAIDs
Pain slight, more soreness	Pain usually severe
Pain intensified by food, no pain if meal is delayed	Food may relieve pain
Pain relatively constant	Intermissions
Symptoms of indigestion	Few symptoms of indigestion marked
Slight or no hemorrhage	Profuse hematemesis
Endoscopy – Patchy mucosal irregularity	Endoscopy – Ulcer with creamy base

4. *Carcinoma of duodenum*—Very rare. Older patient. Symptoms of short duration and severe. No intermittency of symptoms; no relief by medical treatment. Later signs of obstruction, hemorrhage or jaundice. Mass may be felt.

III. Gallbladder disease

Chronic cholecystitis—Vague upper abdominal distress and fullness after meals. Belching and eructations. Intolerance of fat. Attacks of epigastric pain with tenderness over gallbladder. No occult blood in stools. Biliary colic and jaundice due to complicating gall-stones. Symptoms tend to be more irregular and less periodic. Ultrasound confirms diagnosis.

IV. Pancreatic disease

1. *Chronic calcifying pancreatitis*—Upper abdominal pain continuous or intermittent, weight loss, steatorrhoea, diabetes. Jaundice due to involvement of common bile duct late manifestation. Plain radiograph of abdomen may show pancreatic calculi.
2. *Carcinoma of pancreas*—Mid-epigastric pain steady and dull, or paroxysmal colicky pain. Relief from pain may be obtained by stooping or bending or lying in bed with knees tightly drawn up into the abdomen (jack-knife position). Jaundice may be present. Peripheral oedema and thrombophlebitis are recognised presentations. Weight loss and anorexia. Rapidly progressive. Evidence of metastasis in liver or elsewhere.

V. Diseases of colon

1. *Carcinoma*—Pain on right side below level of umbilicus. Lump may be palpable. No response to medical regime. Filling defect on radiography.
2. *Chronic appendicitis*—Dyspepsia more or less continuous. Irregular short attacks of sharper pain. Nausea common. Vomiting. Pain worse on exertion, unrelated to ingestion of food. Pain mid-epigastric but often radiates to right iliac fossa.
3. *Ileocaecal tuberculosis*—May produce reflex dyspeptic symptoms. Constipation alternating with diarrhoea. Thickening or lump in right iliac fossa.
4. *Irritable bowel syndrome*—Postprandial type of pain related to meals may occur. Pain often relieved by defecation. May be accompanied by abdominal fullness, bloating or flatulence. Alternating constipation and diarrhoea in majority. Faeces characteristically ribbon-like with often excessive mucus.

- VI. **Superficial or radicular pain**—Pain usually constant. Hyperaesthesia of abdominal skin. Flexion of abdominal wall reveals situation of pain.

- VII. **Functional dyspepsia**—Postprandial fullness, early satiation, epigastric pain or burning in absence of causative disease to explain the symptoms.

VIII. Miscellaneous

1. *Hiatus hernia*—Chronic heart burn, intermittent regurgitation, dysphagia and substernal or epigastric pain aggravated by stooping or lying flat. Duodenal ulcer is often found with hiatus hernia which is also more common in women. Barium examination will show intrathoracic herniation of stomach.
2. *Ankylostomiasis*—Mild but continuous epigastric pain or discomfort. Anemia. Hookworm ova in stool.
3. *Epigastric hernia*—Eructations, nausea and vague abdominal discomfort. Epigastric pain may be aggravated or relieved by change of posture. Hernia in the linea alba above the umbilicus.
4. *Visceroptosis*—Symptoms variable and many. Pain worse after food. Pain arises during meals and increases as more food is taken. Accompanying sensation of fullness, distension, feeling of weight or dragging in epigastrium. Discomfort persists for hours often with belching and regurgitation. Antacids without effect. Weak abdominal wall. Glennard's test—On standing behind the patient, raising lower abdomen with both hands and holding it up in that position, there may be some relief.
5. *Abdominal angina*—Due to chronic intestinal ischemia. As in effort angina, the pain of intestinal ischemia develops with maximal work load following meals: (i) Occurs usually in patients over 40 years of age. (ii) Post-prandial abdominal pain, usually cramping and referred to the back, develops 20 to 30 minutes after meals and lasts 1 to 2 hours. (iii) Progressive weight loss due to anorexia and malabsorption. (iv) Constipation common, may be interrupted occasionally by steatorrhoea. (v) Central abdominal bruit with at times absent peripheral pulses. (vi) X-ray studies with barium may show puddling of barium in small bowel as a result of impaired motility. (vii) Stool—Excessive fat and often occult blood. (viii) Aortography with exposure of the film in the lateral projection will demonstrate the occlusive process in the coeliac and superior mesenteric arteries.
6. *Gastrinoma*—Triad of abdominal pain, weight loss and diarrhoea.

Medical management of peptic ulcer

INDICATIONS

- Short history (less than 5 years) and few relapses.
 - Mild symptoms.
 - Good social and economic position.
 - No radiological evidence of penetrating ulcer, pyloric stenosis or marked duodenal deformity.
 - General condition unsuitable for surgery.
 - Few chances of recovery after removal of organic lesion due to marked neurosis.
- Rest:** Physical and mental. Rest in bed during acute phase and for one week after subsidence of pain.
Indications for hospitalization—(i) Tarry stools or strongly positive occult blood reaction. (ii) Constant pain replacing previous ulcer rhythm. (iii) Gastric retention. (iv) Uncontrollable night pain or vomiting. (v) Suspicion of impending perforation.
 - Diet:** Bland diet. Duration of particular phase of diet will depend on severity of symptoms, constitution, response to treatment and co-operation of patient. 3-hourly feeds throughout the day – small, digestible, but of adequate caloric value form the basis of treatment.
 - Pharmacotherapy**
See Table 13 for drug treatment of peptic ulcers.
 - Relief from anxiety and mental stress:** Ulcer symptoms get aggravated during periods of mental stress. Psychotherapy and antidepressant like Doxepin 7.5 mg/day.
 - Avoidance of gastric irritants and stimulants**—Tobacco, alcohol, coffee, tea, sour fruits, meat extracts, ulcerogenic drugs.

PREVENTION OF RECURRENCE

- Education of patient**—(a) About recurrent nature of disease. (b) Avoid tobacco, coffee, tea, alcohol, hurried meals, raw vegetables and fruits, fried food, meat extracts, condiments and spices. (c) No emotional stress. (d) Regular hours of rest and sleep. (e) Avoid excessive fatigue. (f) Avoid drugs which might reactivate ulcers, such as aspirin, NSAIDs, steroids.
- Dietary management**—With interval feedings. Snacks between breakfast and lunch and lunch and dinner and a glass of milk before retiring. Snacks may consist of biscuits, toast, or chapattis with or without butter, sandwiches, light cake, curds, butter milk, milk, ice cream, custard or pudding.

Table 13: Treatment of peptic ulcers

<i>Drugs used for peptic ulcer</i>		
<i>Drug</i>	<i>Dosage</i>	<i>Side effects</i>
<i>H₂-receptor antagonists</i>		
Ranitidine	150 b.d. or 300 mg nocte	Headache, confusion (reversible)
Famotidine	40 mg b.d. or 80 mg nocte	Headache, dizziness
<i>Antacids</i>		
Aluminium hydroxide	300 mg 2–3 hours after	Constipation. Long-term use
Magnesium hydroxide	40 mg a meal	depletes body of phosphates
Alginic acid	500 mg	Laxative effect
<i>Mucoprotective drugs</i>		
Prostaglandin analogues		Contraindicated in women of child bearing age.
Misoprostol	200 mg qds.	Abdominal pain, diarrhoea (more useful for NSAIDs induced gastritis)
Sucralfate	1 g qds. before meals	Constipation
Mosapride	5 mg b.d.	Headache
Colloidal bismuth	240 mg b.d. before meals	Stains tongue and teeth
<i>Proton-pump inhibitors</i>		
Omeprazole	20 mg	
Lansoprazole	20 mg	
Pantoprazole	20 mg on empty	Hypergastrinemia,
Rabeprazole	20 mg stomach o.d.	diarrhoea. Headache
Esmoprazole	40 mg	Skin rash
Eradication of H. pylori	(see H. pylori)	
<i>Anticholinergics</i>		
Probanthine	15 mg t.d.s.	Dryness of mouth.
Pirenzepine	50 mg b.d.	Blurring of vision
		Given as adjuvant to H ₂ -receptor antagonists as bedtime dose

- Psychotherapy**—When indicated.
- Preparedness**—Intensified therapeutic regime on exposure to circumstances known to aggravate ulcer – (a) Acute respiratory infection. (b) Excessive work or severe fatigue. (c) Insomnia and nervous irritability due to emotional tension.

Table 14: Indications for surgical treatment of peptic ulcer

- Pyloric stenosis
- Perforation, acute and chronic
- Recurrent bleeding or severe hemorrhage
- Evidence of penetrating or adherent ulcer
- Intractability and relapses
- Severe persistent hour-glass deformity
- Very large ulcers
- Combined gastric and duodenal ulcers
- Suspicion of malignancy
- Economic consideration

Indications for Surgical Treatment

Table 14 lists indications for surgical treatment of peptic ulcer.

ZOLLINGER-ELLISON SYNDROME

Severe peptic ulcer secondary to gastric acid hypersecretion due to unregulated gastrin release from a non β -cell gastrinoma. Gastrinomas are classified into sporadic tumors (more common) and those associated with multiple endocrine neoplasia (MEN) type 1. Gastrin stimulates acid secretion through gastrin receptors on parietal cells by inducing release of histamine from ECL cells. Hypergastrinemia is responsible for the clinical manifestations of ZES.

Clinical Features

(a) *Peptic ulcers* with atypical locations (second part of duodenum and post bulbar (jejunum). Ulcers resistant to medical therapy, recurrence after acid-reducing surgery. Ulcers presenting with complications (bleeding, perforation or obstruction). (b) *Oesophagus* – Mild oesophagitis to frank ulceration and Barrett's mucosa. (c) *Diarrhoea* results from volume overload on small intestine, inactivation of pancreatic enzymes by acid which also damages intestinal epithelial surface. (d) *Signs of hyperparathyroidism* or hypophyseal or pancreatic tumour (MEN 1 syndrome).

Diagnosis: Biochemical Tests

Fasting gastrin level >150 – 200 pg/mL (Normal <150 pg/mL). If normal or elevated requires additional tests. (b)
 1. Gastrin provocative tests—An increase of 120 pg within 15 min of secretin injection has very high sensitivity.
 2. Barium meal shows coarse mucosal folds and ulcers.

**Fig. 15:** Gastrinoma in D2 wall

3. Tumour localization—EUS and imaging of pancreas with endoscopic exploration of duodenum for primary tumours. Localization of gastrinomas by measuring the uptake of the stable somatostatin analogue ^{111}In -pentreotide (OctreoScan) is possible. CT scan (Fig. 15), MRI to exclude metastatic disease.

Management

- Omeprazole 60 mg/day in divided doses over 24 hours.
- Octreotide as adjuvant therapy if peptic symptoms difficult to control with PPI.
- Surgical resection of tumour.
- Chemotherapy for metastasis.

Table 15 lists hormones secreted by alimentary system.

Table 16 lists causes of intestinal ulcers.

12. GASTRIC CANCER

The most common malignancy of the stomach is gastric adenocarcinoma. Factors associated with gastric cancer are listed in Table 17.

CLINICAL FEATURES

Patient may present with:

- Indigestion (most common presentation)
- Weight loss
- Nausea
- Vomiting
- Hematemesis
- Melena

Table 15: Alimentary hormones

Hormone	Physiological role
Gastrin	Stimulates acid, maintains mucosal growth, causes gastric motor activity
Secretin	Stimulates pancreatic bicarbonate
Cholecystokinin	Stimulates GB contraction and pancreatic enzyme secretion
Motilin	Causes upper alimentary motor activity
Glucose-dependent insulin releasing hormone	Stimulates insulin release
Neurotensin	Unknown
Enteroglucagon	Maintains mucosal growth. Slows intestinal transit
Pancreatic polypeptide	Inhibits GB contraction and pancreatic enzyme release

Table 17: Factors associated with gastric cancer

<i>Genetic factors</i>
• Family history (10% of patients)
• Blood group A
<i>Environmental and dietary</i>
• Salted pickles and smoked meat and fish.
• Environmental nitrates/nitrites [#]
• High concentration of lead and zinc in drinking water
• Cigarette smoking
• Consumption of neat spirits
• Poor-quality diets low in vitamin C and high in starch
• Workers in metal, clay and paint industries
<i>Infection</i>
• <i>H. pylori</i> [§]
<i>Premalignant conditions</i>
• Chronic atrophic gastritis
• Intestinal metaplasia
• Benign gastric ulcer
• Gastric adenomatous polyps
• Previous gastric surgery
[#] converted to nitrosamines by gastric bacteria.
[§] high gastric pH encourages bacterial overgrowth, converting nitrites to nitrosamines.

- Profound anorexia
- Flatulence
- Metastatic disease—Palpable left supraclavicular node, metastatic nodules to the ovary (Krukenbergs

Table 16: Causes of intestinal ulcers

• Amoebiasis
• Inflammatory bowel disease
• Bacillary dysentery
• Tuberculosis
• Z-E syndrome
• Malignant ulcers
• Mesenteric artery occlusion
• Ischemic colitis

tumour), periumbilical region (“Sister Mary Joseph node”) or peritoneal cul-de-sac (Blumer’s shelf palpable on rectal or vaginal examination), ascites, jaundice, palpable abdominal mass, enlarged liver.

INVESTIGATIONS

1. *Radiology*—Double contrast studies to detect mucosal abnormalities due to neoplastic infiltration.
2. *Endoscopy*—Multiple biopsies from the margins and brush cytology from the base and under the edges (Fig. 16).
3. *Laparoscopy*—For detection of local and peritoneal spread, and endoluminal ultrasonography for assessing local invasion and lymph node metastasis.
4. Abdominal CT—This and delineate and show metastatic spread (Fig. 17).

MANAGEMENT

Surgery—In early cases local gastric resection, in more advanced disease subtotal or total gastrectomy. Chemotherapy in patients with inoperable disease.

13. HEMATEMESIS AND MELAENA

Hematemesis indicates a site of bleeding proximal to duodenal-jejunal junction, because blood entering the gut distal to this point seldom returns to the stomach (Table 18). The colour of the blood depends on whether the blood has been in the stomach, a large volume of bright red blood suggests a rapid and sizable hemorrhage, whereas a small amount of dark blood (coffee grounds) is more suggestive of a smaller bleed that has been altered by contact with gastric acid.

Melena stools have a characteristic black, tarry appearance and foul smell. Melena occurs when more than 60 mL

Fig. 16: Carcinoma of stomach

Fig. 17: Linitis plastica: stomach wall thickening

Table 18: Causes of haematemesis and melena

Oesophagus

- Oesophageal varices
- Mallory-Weiss tear
- Oesophageal carcinoma
- Reflux oesophagitis
- Foreign body

Stomach

- Peptic ulcer
- Erosive gastritis
- Portal hypertensive gastropathy
- Gastric carcinoma
- Lymphoma
- Leiomyoma
- Angiodysplasia
- Dieulafoy's erosion (ruptured ectatic submucosal artery)

Duodenum/jejunum

- Peptic ulcer
- Erosions/duodenitis
- Vascular anomalies (AVMs)
- Hemobilia
- Polyps (including Peutz-Jeghers syndrome)
- Aortoduodenal fistula
- Mesenteric arterial occlusion

of blood is lost into the upper GI tract. Melena indicates that blood has been present in the GI tract for at least 14 hours (and as long as 3–5 days). Lesions in the

Table 19: Causes of massive upper GI bleeding

- Oesophageal or gastric varices
- Gastric ulcer
- Duodenal ulcer
- Stress ulceration
- Dieulafoy's erosion
- Aortoenteric fistula

oesophagus, stomach and duodenum are responsible for most cases, but occasionally hemorrhage into small intestine, or even the right colon can cause melena if GI transit is slow. Massive upper GI bleeding (Table 19) may result in passage of dark red stools because of rapid transit.

Dieulafoy's disease is a rare cause of massive upper GI hemorrhage in previously asymptomatic individuals. The disease is characterised by a large thickened artery which follows a tortuous course towards the surface mucosa of gastric fundus, duodenum or jejunum. At endoscopy, the appearance of arterial spurting from otherwise normal mucosa is typical.

MANAGEMENT OF BLEEDING

Primary care (before hospital admission)

- IV access with infusion of normal saline
- Oxygen
- Early hospitalization

Hospital management

- **Resuscitation**

Insertion of large bore cannula into a substantial vein.

If pulse rate > 100/min or systolic BP falls below 100 mm Hg – infusion of crystalloids such as normal saline is started.

If blood transfusion is required, 2–4 units of whole cross-matched blood. Aim is to maintain Hb concentration of 10g/dL.

After resuscitation

- *Endoscopy* must be done within 24 hours and is necessary for—Diagnosis in order to plan treatment.

Prognosis—Endoscopic stigmata are very useful by defining risk of further bleeding.

Investigation of upper GI bleeding

HISTORY

- *Vomiting or retching*—Before the episode characteristic of Mallory-Weiss syndrome (Fig. 18).
- *Heart burn and regurgitation*—Reflux oesophagitis.
- *Dysphagia and weight loss*—Oesophageal malignancy
- *History of peptic ulcer or abdominal pain*—History of peptic ulcer is useful. However, bleeding can be the first manifestation of an asymptomatic ulcer.
- *Drugs*—Intake of aspirin or NSAIDs.
- *Alcohol intake*—Questioning for alcohol consumption and other risk factors for chronic liver disease.
- *History of easy bleeding or bruising*—Coagulation or platelet disorders.
- *Haematemesis with melena*—Indicates that the source of bleeding must be proximal to the jejunum.

EXAMINATION

Rapid assessment of hemodynamic state

- Does the patient look pale or shocked?
- Pulse rate and BP.
- Postural hypotension.
- Presence of purpura or petechiae—Telangiectasia of Rendu-Osler-Weber syndrome. Palpable purpura characteristic of systemic vasculitis, and perioral pigmentation of Peutz-Jeghers syndrome (uncommon causes).
- Splenomegaly, dilated abdominal veins or ascites—Signs of portal hypertension in patients bleeding from gastric or oesophageal varices. A congested gastric mucosa (portal hypertensive gastropathy) can also be a site for GI hemorrhage in patients with liver disease.
- Presence of jaundice—Triad of biliary colic, jaundice and melena suggests hemobilia.

Fig. 18: Mallory-weiss tear

INVESTIGATIONS

Blood tests

- *Hemoglobin concentration*—In first few hours after a bleed is a poor indicator of blood volume loss, because dilution by extracellular fluid recruited into the intravascular space may continue for more than 24 hours Low Hb at presentation usually signifies chronic blood loss.
- *Urea and electrolytes*—Elevated blood urea suggests severe bleeding.
- *Liver function tests*
- *Prothrombin time*

Further investigations—In a few individuals endoscopy does not define the cause of bleeding, because blood in the lumen prevents adequate inspection of the mucosa. If no cause is found – endoscopy can be repeated. If there is still no diagnosis and bleeding continues –

Small bowel imaging. Capsule endoscopy is recommended as a diagnostic test after a normal endoscopic evaluation of upper and lower GI tract after a negative gastroscopy and colonoscopy in patients with obscure GI bleeding.

Labelled RBC scan can detect rates of blood loss as low as 0.1 mL/min.

Angiography/CT angiography does not detect bleeding at rates below 1mL/min, but occasionally reveals underlying vascular abnormalities. Both investigations may fail to localise the site of hemorrhage if it is intermittent.

MANAGEMENT

Procedures to stop bleeding are listed in Table 20.

Table 20: Procedures to stop bleeding

Non-variceal hemorrhage	Variceal hemorrhage												
<p>1. Endoscopic therapy to seal the arterial defect created by the ulcer. Indications: (a) Bleeding oesophageal varices. (b) Peptic ulcer with major stigmata of recent hemorrhage. (c) Vascular malformations, including actively bleeding AVMs, gastric antral vascular ectasia and Dieulafoy's lesion. (d) Rarely, active bleeding from a Mallory-Weiss tear.</p> <p><i>Injection:</i> (a) Adrenaline 1:10,000 (b) Fibrin glue, a mixture of thrombin and fibrinogen (injected through separate channels) and human thrombin are effective and have a low complication rate.</p> <p><i>Heat energy:</i> Devices are applied directly to the bleeding point to cause coagulation and thrombosis. The heater probe is pushed firmly on to the bleeding lesion to apply tamponade and defined pulses of heat energy are then given to coagulate the vessel.</p> <p><i>Mechanical devices</i>—'Endoclips' can be applied to bleeding vessels and are the best treatment for major bleeding ulcers.</p> <p><i>Re-bleeding after endoscopic therapy</i> requires operative interavention.</p>	<p><i>Vasoactive drugs</i></p> <table border="1"> <tr> <td>Vasopressin</td> <td>20u over 20 min + 0.4u/min. infusion</td> </tr> <tr> <td>Glypressin</td> <td>2 mg every 6 hrs</td> </tr> <tr> <td>Octreotide</td> <td>50 mg bolus + 50 mg/h infusion</td> </tr> <tr> <td>Somatostatin</td> <td>250 mg bolus + 250 mg/h infusion</td> </tr> <tr> <td>Glyceryltrinitrate</td> <td>40–400 mg/min infusion</td> </tr> <tr> <td>Terlipressin</td> <td>2 mg bolus every 4-6 hours.</td> </tr> </table> <ul style="list-style-type: none"> • Modified Sengstaken Blakemore (Minnesota) tube insertion (Both temporary measures) • Propranolol up to a dose to reduce pulse rate by 20% to reduce risk of rebleeding 	Vasopressin	20u over 20 min + 0.4u/min. infusion	Glypressin	2 mg every 6 hrs	Octreotide	50 mg bolus + 50 mg/h infusion	Somatostatin	250 mg bolus + 250 mg/h infusion	Glyceryltrinitrate	40–400 mg/min infusion	Terlipressin	2 mg bolus every 4-6 hours.
Vasopressin	20u over 20 min + 0.4u/min. infusion												
Glypressin	2 mg every 6 hrs												
Octreotide	50 mg bolus + 50 mg/h infusion												
Somatostatin	250 mg bolus + 250 mg/h infusion												
Glyceryltrinitrate	40–400 mg/min infusion												
Terlipressin	2 mg bolus every 4-6 hours.												
<p>2. Drug therapy—To reduce risk of further bleeding.</p> <p><i>Gastric acid lowering drugs</i>—Omeprazole 80 mg bolus followed by 8 mg/hr infusion for 72 hours.</p> <p><i>Tranexamic acid</i>—A antifibrinolytic agent can improve stability of the clot and reduce risk of re-bleeding.</p>	<ul style="list-style-type: none"> • Endoscopic treatment Injection sclerotherapy – Intravariceal injection of sclerosant (5% ethanolamine, 1% olidocanol). Complications include oesophageal ulceration, fever, pleural effusion, pericarditis. Injection of fibrin glue. 												
<p>3. Emergency surgery if: (a) Active bleeding cannot be controlled by endoscopic treatment. (b) Re-bleeding follows initially successful endoscopic treatment.</p>	<ul style="list-style-type: none"> • Variceal banding Oesophageal band ligation. Banding obliterates varices more efficiently and has few complications, but may be more difficult to perform in patients with active bleeding. • Shunt surgery. Use of small-bore 8 mm interposition H-graft portocaval shunt reduces incidence of encephalopathy. • Devascularization surgery if failure of non-operative treatments and patients who cannot undergo shunt surgery or TIPSS. • TIPS reduces rebleeding rates compared to endoscopic therapy. Covered stents are used to improve patency. 												

14. LOWER GASTROINTESTINAL HAEMORRHAGE

Table 21 lists causes of acute lower GI haemorrhage.

CLINICAL FEATURES AND DIAGNOSIS

Initial assessment: Patients usually present with bright red rectal bleeding (signifying a distal lesion) or dark red rectal bleeding which may be mixed with mucus in case of inflammatory or neoplastic lesion.

Past history of abdominal pain and alteration of bowel habit may suggest a neoplastic lesion, diarrhoea and urgency of defecation inflammatory lesion. Radiotherapy for genitourinary malignancy can cause radiation colitis. Elderly patients with cardiovascular disease may have ischemic colitis.

Table 21: Causes of acute lower GI haemorrhage

<i>Anorectal conditions</i>
• Haemorrhoids
• Anal fissure
• Mucosal prolapse (Solitary rectal ulcer syndrome)
<i>Children</i>
• Meckel's diverticulum
• Juvenile polyps
• Inflammatory bowel disease
<i>Adults</i>
• Inflammatory bowel disease
• Adenomatous polyps (Fig. 19)
• Carcinoma

Contd...

Contd...

- A-V malformation
- Meckel's diverticulum

Elderly

- Diverticular disease
- Angiodysplasia
- Adenomatous polyps
- Carcinoma
- Ischemic colitis
- Inflammatory bowel disease

Fig. 20: Rectosigmoid growth

History of dyspepsia, alcoholism, NSAID ingestion or weight loss may give clues to the causative lesion.

MANAGEMENT

Initial Management

1. Hospitalization if suspicion of significant bleed.
2. Correction of hypovolemia with plasma expanders followed by blood transfusion. Central venous pressure or Swann-Ganz monitoring helps prevent over transfusion in the elderly and is a sensitive indicator of continued or recurrent bleeding.
3. Blood for Hb, clotting screen and urea and electrolyte estimation.

Investigations—May be planned after resuscitation. Digital anorectal examination and proctosigmoidoscopy (Fig. 20) to exclude local anorectal conditions and rectal

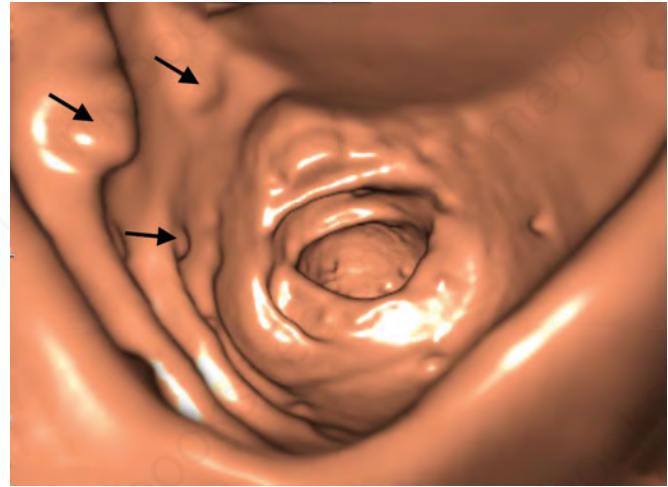

Fig. 19: Virtual colonoscopy showing colonic polyps

Fig. 21: Lower GI bleed: Non-enhanced CT abdomen showing rectal haematoma

biopsy plus stool microscopy and culture. Upper GI endoscopy if a local cause is not found. Capsule endoscopy is useful in detection of small bowel lesions in Crohn's disease, non-steroidal anti-inflammatory drug enteropathies, small bowel polyposis syndromes and small bowel tumours.

CT angiography may be helpful in locating bleeder (Figs. 21 and 22).

Emergency laparotomy if hemorrhage is massive and patient is deteriorating; this should be combined with on-table colonoscopy.

Occult GI bleeding—Bleeding that is not visible and is manifested by positive faecal occult blood (FOB) testing or iron deficiency anemia.

Fig. 22: Lower GI bleed: Contrast CT abdomen showing bleeding spur in rectum

Physical examination findings which might provide a clue about the source or bleeding:

Facial or oral telangiectasia can suggest hereditary telangiectasia. Acanthosis nigricans in axilla suggest possible malignancy.

Perioral pigment spots are associated with Peutz-Jeghers syndrome. Purpura or ecchymosis implies possible bleeding disorder.

False positive FOB can result from pseudoperoxidase in various foods e.g. red meat, raw broccoli, turnips, cauliflower, radishes. A sensitive, quantitative measure is estimation of faecal concentration of ^{51}Cr -labelled RBCs.

15. DIARRHOEA

Diarrhoea is decrease in consistency or increase in liquidity of stools.

Diarrhoea may be further defined as acute if <2 weeks, persistent if 2–4 weeks and chronic if >4 weeks in duration.

ACUTE DIARRHOEA

Table 22 enumerates causes of acute diarrhoea.

Chronic Diarrhoea

Table 23 enumerates causes of chronic diarrhea.

Eosinophilic gastroenteritis is a non-parasitic inflammatory disease of GI tract with various degrees of eosinophilic infiltration in tubular intestinal tract and biliary tree in absence of vasculitis or significant extraintestinal tissue eosinophilia.

Investigations for assessment of acute diarrhoea

Table 22: Causes of acute diarrhea

• Infections
Viruses (adenovirus, astrovirus, calicivirus (e.g. rotavirus, Norwalk agent), herpes simplex virus)
Bacteria (e.g. Campylobacter spp., C. difficile, E. coli, Salmonella enteritidis, Shigella spp.)
Parasites (e.g. E. histolytica, Giardia)
• Food poisoning/toxins
Bacillus cereus
Salmonella spp.
Staphylococcus spp.
Vibrio spp.
• Drugs
Antibiotics (e.g. amoxicillin)
Antihypertensives (e.g. angiotensin converting enzyme inhibitors)
Antineoplastic drugs
Digoxin
Antidepressants (e.g. Fluoxetine, lithium)
CNS drugs (e.g. L-dopa, valproic acid)
Cholesterol lowering drugs
GI drugs (e.g. magnesium containing antacids, prostaglandin analogues, H ₂ - antagonists, sulphasalazine, prokinetic drugs)
Others: Theophylline, diuretics, oral hypoglycemic drugs, thyroxine, colchicine
• Poorly absorbed sugars: Fructose, mannitol, sorbitol
• Faecal impaction
• Intestinal ischemia

- Spot stool specimen
 - Occult blood
 - Leucocytes
 - Ova, cysts and parasites
 - Culture and sensitivity
 - Giardia antigen
 - Clostridium difficile toxin
 - DNA probes
- Blood tests
 - Full blood count and differential
 - Urea and electrolytes
 - ESR and C-reactive protein
 - Blood culture
- Rigid sigmoidoscopy and biopsy
- Plain abdominal radiograph
- Flexible sigmoidoscopy
- Duodenal aspirates

Table 23: Causes of chronic diarrhea

• Dietary factors
Excess ingestion of fructose, sorbitol, caffeine
• Infections
Giardia lamblia
E. histolytica
Campylobacter enteritidis
Various organisms in immunocompromised (e.g. AIDS)
• Drugs
Antacids (magnesium trisilicate)
Antihypertensives (methyldopa, propranolol)
Theophylline
Fruzemide
Methotrexate
Antibiotics (Amoxicillin, lincomycin)
Digoxin
Iron preparations
NSAIDs
• Lactose intolerance
• Malabsorption
Chronic pancreatitis
Bacterial overgrowth
Short bowel syndrome
• Inflammatory bowel disease
• Radiation colitis
• Neoplasms
Pancreatic cancer
Neuroendocrine tumours (carcinoid, gastrinoma), vasoactive intestinal polypeptide secreting tumour, medullary carcinoma of thyroid).
• Idiopathic secretory diarrhoea
Microscopic colitis
Collagenous colitis
Idiopathic bile salt diarrhoea
Post-cholecystectomy
Large - volume nonspecific secretory diarrhoea
• Endocrine disorders
Diabetes mellitus
Hyperthyroidism
Hypoadrenalism
• Functional bowel disorder
Purgative use and abuse
• Faecal incontinence
Autonomic neuropathy (e.g. diabetes)
Anorectal surgery
Latrogenic sphincter damage

MANAGING A CASE OF CHRONIC DIARRHOEA

History, Symptoms and Signs

- History - (a) *Age*—Early life—Parasitic, dysentery, abdominal tuberculosis, genetic or biochemical abnormalities. Middle life—Colonic carcinoma, inflammatory bowel disease, pancreatic disease, laxative abuse. (b) *History of allergy*. (c) *Family history*—In hereditary pancreatitis, multiple neoplasia with multiple carcinoma of thyroid.
- symptoms -
 - Type of diarrhoea*—(i) *Size of stool*—Large stool (with little mucus) suggests small bowel disease. Small stool (with usually excess mucus) suggests large bowel involvement. (ii) *Constipation alternating with diarrhoea*—Carcinoma of colon, irritable bowel syndrome, diverticulosis, laxative habit, intestinal tuberculosis. (iii) *Relation to ingestion of food*—If of gastric origin diarrhoea immediately after each meal. Diarrhoea recurring after certain foods suggests allergy. (iv) *Time of day*—Urgent desire to evacuate in morning common in steatorrhoea. Nocturnal diarrhoea suggests presence of organic disease.
 - Chronic bloody diarrhoea with systemic upset* is probably caused by ulcerative colitis, colonic Crohn's disease or infectious colitis (e.g. amoebic or bacillary dysentery). Less commonly ischemic colitis, radiation colitis or gut vasculitis (e.g. Behcet's disease, SLE, polyarteritis nodosa).
 - Weight loss*—Diarrhoea associated with anorexia and weight loss suggests significant organic disease. Diarrhoea for many years without significant weight loss or systemic upset suggests irritable bowel syndrome. Diarrhoea with weight loss in spite of good appetite suggests thyrotoxicosis.
 - Abdominal pain*—Colicky lower abdominal pain associated with bouts of diarrhoea may suggest colonic obstruction or diverticulitis. Abdominal pain with fatty diarrhoea in recurrent pancreatitis, tuberculosis or Crohn's disease.
 - Abdominal distension*—Malignant disease, Crohn's disease, intestinal tuberculosis, or irritable bowel syndrome.
 - Rectal tenesmus*—Cause in rectum or lower sigmoid. Also in ulcerative colitis or diverticulitis.
 - Sense of urgency*—To pass frequent, small stools, that may be formed, loose or even pellety in irritable bowel syndrome.

3. Signs -

- (a) *Abdominal tenderness*—Diffuse in intestinal tuberculosis, over colon with diffuse colonic lesion.
- (b) *Doughy feel*—With abdominal tuberculosis.
- (c) *Abdominal bruit*—May be heard with stenosis of superior mesenteric artery.
- (d) *Mass*—Carcinoma, tumour or diverticulitis.
- (e) *Anal abnormalities*—Fissures, perianal or ischio-rectal abscesses and fistulae may present as a complication of ulcerative colitis or Crohn's disease.

4. Type of faeces -

1. *Mucus and blood*—Amoebic and bacillary dysenteries.
2. *Profuse purulent discharge*—Chronic ulcerative colitis.
3. *Mucus*—Irritable bowel syndrome, chronic constipation, following ingestion of strong purgatives, rarely in ulcerative colitis.
4. *Fatty stools*—Voluminous, pale pasty stools in steatorrhoea.
5. *Frequent soft, non-fatty stools*—Diarrhoea of gastric origin.
6. *Large fermentative stools*—Sprue, nutritional deficiency states, fungus infections, intestinal carbohydrate dyspepsia.
7. *With excessive bile*—Gastrointestinal hypermotility induced by vigorous purgatives or after severe gastro-enteritis, fistula between biliary tract and alimentary canal in a patient who has suffered from biliary colic attacks.
8. *Watery stools*—Emotional diarrhoea, internal fistulae, reflex diarrhoea, extensive Crohn's disease, ulcerative colitis. In carcinoid syn. the secretory diarrhoea is profuse.

Differentiation of small bowel from large bowel diarrhoea is given in Table 24.

Investigations

Tests used in assessment of chronic diarrhoea

*Initial Evaluation**Spot stool examination*

- Gross characteristics
- Faecal occult blood
- Methylene blue stain for leucocytes
- Sudan stain for fat

Table 24: Differentiation of small bowel from large bowel diarrhoea

Feature	Small bowel diarrhoea	Large bowel diarrhoea
Timing of diarrhoea	Any time	Usually on getting up in morning
Frequency of stools	Increased frequency of small stools	Normal to increased frequency of large stools
Pain if any	Central abdominal, not relieved by defecation	Often in left iliac fossa, relieved by defecation
Stool	Watery, or pale, fatty and offensive	With mucus or fresh blood, or watery

- Microscopy for ova, cysts and parasites

- Culture and sensitivity

Quantitative stool collection

- 3-day stool weight/volume

Blood tests

- FBC and differential
- Urea and electrolytes, liver biochemistry, calcium and phosphate
- ESR, C-reactive protein
- Thyroxine and TSH
- Antigliadin, endomysial and reticulum antibodies
- Amoebic serology

*Rigid sigmoidoscopy and biopsy**Further Evaluation**Spot stool examination*

- Laxative screen
- *Giardia* antigen
- Acid-fast stain
- Faecal elastase
- Faecal chymotrypsin
- Sulphate/phosphate/magnesium concentration

*Quantitative stool collection on 100 g/fat/day**Blood tests*

- Haematinics
- INR
- Immunoglobulin
- Fasting 9 a.m. cortisol
- Fasting gut hormones

Urine

- Alkalinization
- Laxative screen 24-hour 5-hydroxyindole acetic acid
- 24-hour catecholamines
- Urinary indicans

Flexible sigmoidoscopy and biopsies

Gastroscopy and duodenal biopsies

Imaging

- Barium meal and follow-through
- Small bowel enema
- Abdominopelvic ultrasonography
- Barium enema
- CT of abdomen and pelvis

Breath tests

- Lactose hydrogen breath tests
- Glucose hydrogen breath test
- ¹⁴C glycolic acid breath test

Others

- Anorectal physiology studies

Trial of empirical treatment

- Restrictive diets (low-fat, lactose-free) (avoiding lactose for lactase deficiency or gluten for celiac sprue)
- Metronidazole
- Cholestyramine
- Pancreatic enzyme supplements
- Octreotide
Clonidine, an 2-adrenergic agonist, may allow control of diabetic diarrhoea

16. CONSTIPATION

Constipation can be defined as infrequent or difficult passage of faeces. It can also refer to hardness of stools or feeling of incomplete evacuation. Table 25 lists various causes of constipation.

HISTORY

1. Determine number of stools per week and duration of the problem. Ask about straining, pain, pressure and sense of obstruction to defecation, also consistency of stools. Note any associated complaints like abdominal pain and its location, bloating, gas and audible bowel sounds.
2. Any symptoms that might indicate an underlying disorder (secondary constipation).
3. Dietary and habitual fluid intake.
4. An acute or subacute onset of constipation should raise possibility of mechanical obstruction. In female patients the number and type and difficulty of deliveries since rectocele and pelvic problems can be associated with constipation.

Table 25: Causes of constipation

Gastrointestinal	Non-GI disease
<i>Dietary</i>	<i>Medications</i>
Insufficient fibre	Antacids containing aluminium or calcium
<i>Obstruction</i>	Tricyclic antidepressants
Tumours	Diuretics
Inflammation	Analgesics: Opioids, NSAIDs
Ischemia	Calcium channel blockers:
Diverticular disease	Verapamil
Congenital abnormality (e.g. Hirschsprung's disease)	Antipsychotics: Risperidone
<i>Motility disturbance</i>	Anticholinergic: Belladonna alkaloids
Irritable bowel disease	Antiparkinsonian drugs:
Hirschsprung's disease	Amantadine
<i>Anorectal disease</i>	<i>Metabolic/endocrine</i>
Crohn's disease	Diabetes mellitus
Anal fissures	Hypothyroidism
Haemorrhoids	Hypercalcemia
<i>Disorders of rectal evacuation</i>	Pregnancy
Pelvic floor dysfunction	<i>Neurological</i>
Anismus	Spinal or pelvic nerve injury
Descending perineum syndrome	Cerebrovascular accident
Rectal mucosal prolapse	Parkinsonism
Rectocele	Multiple sclerosis
	<i>Gynaecological: Pregnancy, ovarian cancer</i>
	<i>Psychiatric disorders</i>
	Depression

PHYSICAL EXAMINATION

- Abdominal size and girth
- Abdominal tenderness—Local or general
- Organomegaly
- Masses, including palpable left colon
- Perianal examination for excoriations, fissures and haemorrhoids
- Internal rectal examination—masses, gross or occult blood
- Ask the patient strain to expel the index finger during a digital rectal examination. Motion of the puborectalis posteriorly during straining indicates proper coordination of the pelvic floor muscles.
- Clinical examination to identify signs of an underlying medical illness, e.g. hypothyroidism.

INVESTIGATIONS

Barium enema: To exclude obstruction if constipation of recent onset.

Water-soluble contrast media: If megarectum or megacolon is suspected.

Fig. 23: Colonic growth

Flexible sigmoidoscopy plus barium enema or colonoscopy alone: Particularly in patients >40 years, to exclude structural diseases such as cancer or strictures (Fig. 23). Colonoscopy alone is most cost-effective in this setting because it provides an opportunity to biopsy mucosal lesions, perform polypectomy or dilate strictures.

Anorectal physiological studies to elicit anorectal inhibitory reflex and to exclude Hirschsprung's disease to assess pelvic floor coordination.

Upper gut barium studies: To exclude pseudo-obstruction if lower bowel is dilated.

Upper gut transit studies: if patient has upper gut symptoms or surgery for constipation is contemplated.

Proctography if a large rectocele is suspected.

Abdominal CT scan: This can identify even small masses and delineate the extent of spread and metastasis (Fig. 24).

Balloon expulsion test: A balloon-tipped urinary catheter is placed and inflated with 50 mL of water. Normally, a patient can expel it while seated on a toilet or in the left lateral decubitus position. In the lateral position, the weight needed to facilitate expulsion of the balloon is determined; normally, expulsion occurs with <200 g added.

If positive, an anatomic evaluation of the rectum or anal sphincters and an assessment of pelvic floor relaxation are done.

MANAGEMENT

- Increase in dietary fibre, bulking agents such as isabgol and laxatives. If continued use of laxatives is

Fig. 24: Carcinoma of rectum: CECT showing narrowing of rectal canal due to mass

unavoidable, rectal stimulants e.g. glycerine or bisacodyl suppository, or oral senna preparation or oral bisacodyl. 5-HT₄ (serotonin⁴) agonists may have a role initiating peristalsis when laxatives have failed or are poorly tolerated.

- Behavioural techniques—Such as 'biofeedback' and bowel retraining in those with abnormal pelvic floor coordination.
- Surgery—Subtotal colectomy or ileorectal anastomosis as a last resort, but results unpredictable.

Idiopathic megarectum and megacolon—Symptoms may be present from birth, childhood or adulthood. Aetiology is unknown.

Hirschsprung's disease has variable pattern of inheritance and the major susceptibility gene is *RET* proto-oncogene. It should be excluded by contrast studies of the large bowel, elicitation of the recto-anal inhibitory reflex or full-thickness rectal biopsy taken 2 cm above dentate line.

Management—(a) Faecal disimpaction using enemas. Life-long laxatives may be required. (b) Behavioural therapy can improve defecatory behaviour in some. (c) Colectomy with ileorectal anastomosis achieves a normal bowel frequency in 80%.

17. MALABSORPTION

Malabsorption is a failure of normal absorption of nutrients. Principal types of malabsorption are generalized and specific.

Generalized malabsorption affects all classes of nutrients. It usually results from small intestinal disease

or conditions in other organs (Table 26). When severe, it is manifested by one or more clinical features of malabsorptive stage. Because fat absorption is most affected, excess undigested fat in the stool (steatorrhea) is strong evidence of generalized malabsorption.

Specific malabsorption is a failure of the processes governing absorption of one class or type of nutrients, e.g. genetic or acquired failure to absorb disaccharide sugars (e.g. lactase or vitamin B₁₂ deficiency).

HISTORY

- Diarrhoea and weight loss
- Family history may suggest coeliac disease, Crohn's disease or familial pancreatitis
- Previous surgery may lead to short gut syndrome or create other abnormalities predisposing to bacterial overgrowth
- Immunodeficiency may lead to frequent infections
- Radiation treatment may cause radiation enteritis
- Obvious heavy steatorrhea (oily stools) may indicate pancreatic insufficiency
- Abdominal pain though uncommon, suggests a diagnosis of pancreatitis, intestinal strictures or small intestinal ischemia

INVESTIGATIONS

Blood Tests

Tests for Evidence of Malabsorption

- Full blood count
- Mean cell volume, mean corpuscular hemoglobin
- Serum iron/total iron-binding capacity (or ferritin)
- Vitamin B₁₂
- Serum (or RBC) folate
- Prothrombin time
- Plasma proteins

Table 26: Causes of generalized malabsorption

I. Conditions within gut lumen

A. Defective substrate hydrolysis

- Pancreatic enzyme deficiency
 - Chronic pancreatitis
 - Cystic fibrosis
 - Cancer of pancreas
 - Z-E syndrome
 - Hypothyroidism (also villous atrophy)
- Enzyme inactivation
 - Z-E syndrome

Contd...

Contd...

- Intestinal hurry
 - Gastroenterostomy
 - Postgastrectomy
 - Thyrotoxicosis
- B. Lack of solubilising bile salts (failure of micelle formation)
 - Reduced bile salt synthesis
 - Parenchymal liver disease
 - Cholestatic jaundice
 - Bile salt deconjugation
 - Z-E syndrome
 - Bacterial overgrowth
 - Increased faecal loss of bile salts
 - Terminal ileal disease
 - Tuberculosis
 - Crohn's disease

C. Deficiency of certain factors

- Achlorhydria
- Lack of intrinsic factor
 - Pernicious anaemia
- Increased consumption of Vit. B₁₂ in intestine
 - Blind loop or stagnant loop syndrome

D. Immunological

- Immunoproliferative small intestinal disease (IPSID)

E. Drugs (Refer to Drug-induced GI disease)

II. Conditions in gut mucosa

(Reduced absorptive area)

- Normal mucosa
 - Lactase difficile
- Abnormal mucosa
 - Coeliac disease
 - Tropical sprue
 - Giardiasis
 - Whipple's disease
 - AIDS

III. Disorders of transport from mucosal cell

- Lymphatic obstruction
 - Tuberculosis
 - Lymphangiectasia
 - Lymphoma (abdominal)
- Epithelial processing defect
 - Abetalipoproteinemia

IV. Systemic diseases

- Thyrotoxicosis
- Hypothyroidism
- Diabetes mellitus
- Collagen vascular diseases
- Addison's disease

Note: Tropical sprue continues to be the commonest cause following coeliac and Crohn's disease.

Tests for Cause of Malabsorption

- C-reactive protein, ESR
- Immunoglobulins (hypogammaglobulinemia)
- Endomysial and antigliadin antibodies (coeliac disease).

Small intestinal biopsy at endoscopy with punch biopsy forceps. Normal histology with well-formed villous pattern almost excludes diffuse intestinal mucosal disease. In difficult cases, endoscopic small intestinal biopsy may provide information, and allows dissecting microscopic appearance to be examined readily.

Capsule endoscopy as alternative to biopsy of small intestine to detect villous atrophy in patients suspected of coeliac disease.

- Total or subtotal villous atrophy in coeliac disease.
- Mucosal lesions or trophozoites in mucus layer in giardiasis.
- Lipid-filled vacuoles distending villous epithelium in Abetalipoproteinemia.
- PAS positive engorged macrophages filling lamina propria and dilated vacuoles in Whipple's disease.
- Other diseases—Diffuse small bowel Crohn's disease, intestinal lymphangiectasia, diffuse intestinal lymphoma, and various allergic gastroenteropathies (e.g. soya protein intolerance) can also be diagnosed.

Radiology

Barium Meal Follow-through

- Delayed transit time
- Abnormal small intestinal pattern:

Fig. 25: Fragmentation and clumping of barium in the small intestine indicating malabsorption

- (a) Smooth appearance of margins of barium-filled intestine.
- (b) Clumping of barium (Fig. 25) or transformation of a normal feathery appearance to a ladder pattern resembling a stack of coins.
- (c) Radiological anatomical abnormality in stagnant loop syndromes, small intestinal resection, Crohn's disease, systemic sclerosis.
- (d) Nodular lymphoid hyperplasia suggests immunoglobulin deficiency and possibility of an enteric infection such as giardiasis. In older individuals radiology may reveal multiple diverticulae leading to bacterial overgrowth.

PHYSICAL FINDINGS

Physical findings in malabsorption are related to malabsorption of specific nutrients (Table 27).

Table 27: Physical findings in malabsorption

Malabsorbed nutrients	Symptoms and signs
<i>Fat soluble vitamins</i>	
Vitamin A	Hyperkeratosis
	Night blindness
Vitamin D	Osteomalacia
	Proximal myopathy
	Rickets in children
Vitamin K	Bruising
	Bleeding
<i>Water soluble vitamins</i>	
Vitamin B ₁	Beriberi
	Fluid retention
	Brainstem lesions
	Ataxia
	Wernicke's encephalopathy
Niacin	Pellagra
	Dermatitis
	Diarrhoea
	Dementia
Vitamin C	Petechial hemorrhage
	Swollen gums
	Hyperkeratosis
	Follicular congestion
Folic acid	Glossitis
	Macrocytic anaemia

Contd...

Contd...

<i>Haematinics</i>	
Folic acid	Macrocytic anaemia
Vitamin B ₁₂	SCD
Iron	Microcytic anaemia
	Koilonychia
<i>Minerals</i>	
Calcium	Paraesthesias
Magnesium	Tetany
Zinc	Acrodermatitis
	Poor wound healing
	Defective taste
<i>Proteins</i>	
	Muscle wasting
	Peripheral oedema
<i>Bile salts</i>	
	Watery diarrhoea

PANCREATIC DISEASE

- **Radiograph**—Pancreatic calcification
- **Ultrasonography**—(Calcification and complications, e.g. pseudocysts, duct dilatation)
- **CT**—(Calcification, gland atrophy, cysts and duct dilatation)
- **ERCP or MRI**

Investigations

Table 28 enumerates various absorption tests.

18. COELIAC DISEASE

In coeliac disease, the mucosa of small intestine is abnormal. The condition improves morphologically and symptomatically with a gluten-free diet and relapses

Table 28: Absorption Function tests

<i>Test</i>	<i>Method</i>	<i>Interpretation</i>
<i>Carbohydrate malabsorption</i>		
Hydrogen breath test	After overnight fast, basal samples taken and 50 g lactose in 200 mL in water. End-expiratory blood samples analysed at 15 or 30 min interval for 2 hours	If bacteria in upper gut, or lactose absent, increased excretion of H ₂ in breath. Positive test is increase of 200 ppm or more
<i>Fat malabsorption (Pancreatic function)</i>		
Triolein test	Oral dose of labelled fat and measurement of ¹⁴ CO ₂ in expired breath	Tests ability to digest fat
3-day faecal fat collection	Adequate amount of fat intake (70 g/d)	Normal amount of fat in stool <5 g/day. More fat excretion confirms steatorrhea.
Tubeless test	Pancreolauryl test links a fluoresceinated probe to a carrier by a link that is sensitive to pepsin	Low proportion of ingested dye recovered from urine when luminal trypsin is reduced in pancreatic insufficiency
N-benzoyl-tyrosyl paraamino-benzoic acid test	After fasting, oral dose of 500 mg NBT-PABA is given with 250 mL water	Normal subjects excrete more than 57% in 6 hours. Test relies on hydrolysis of NBT-PABA by trypsin and subsequent excretion of paraamino-benzoic acid and its metabolites.
<i>Ileal function</i>		
SeHCAT test scan	Patient's 7-day retention of oral dose of labelled bile acid (Se-homo-cholytaurine) after whole body scan	Low (<7%) in extensive ileal disease or bile salt malabsorption.
Schilling test (Vitamin B ₁₂ absorption)	Ingestion of radioactive B ₁₂ and measurement of urinary recovery	If cause of abnormal B ₁₂ absorption is gastric, it can be corrected by co-administration of B ₁₂ , if cause is terminal ileum it cannot be corrected.
D-xylose absorption test	5 g D-xylose p.o. to fasting patient and urine collected at 30 min. intervals for next 5 hours.	An abnormal test (<4.5 g excretion) primarily reflects the presence of duodenal/jejunal mucosal disease, blind loop syndrome.
Tests of small bowel contamination	Aspiration Uncontaminated small bowel aspirate with pre-sterilized, sheathed aspiration cannula. Aerobic and anaerobic culture of aspirate	Total aerobic and anaerobic count of 10 ⁵ or more suggests bacterial overgrowth.

Table 29: Presenting features of coeliac disease

• Diarrhoea (most common)	• Infertility, recurrent miscarriage
• Lassitude	• Severe anemia and/or unexplained diarrhoea in pregnancy
• Weight loss	• Mild microcytic anaemia with persistent low serum or RBC folate
• Osteomalacia	
• Aphthous ulceration	
• Glossitis	
• Myopathy	
• Skin complains (e.g. eczema)	

when gluten is re-introduced. It was previously called non-tropical sprue, idiopathic steatorrhea or primary malabsorption.

CLINICAL FEATURES

Presenting features of coeliac disease are given in Table 29. Patients with coeliac disease are usually short, and 60% of children are below the third centile for age. Development of secondary sex characteristics is often delayed. Delayed eruption of teeth, finger clubbing and koilonychia may be seen and oedema and ascites occur occasionally in severe cases due to hypoproteinemia.

INVESTIGATIONS

Hematology—Mild hypochromic microcytic anemia. Blood film may show Howell-Jolly bodies, siderocytes, irregular and crenated RBCs, Heinz bodies, microspherocytes, acanthocytes and occasionally erythroblasts.

Laboratory tests—Patients with untreated coeliac disease have IgA anti gliadin, IgA antiendomysial, and IgA anti-tTG antibodies. Elevated tTG antibody titres are 90–95% sensitivity and 90–95% specificity

Bone densitometry for osteoporosis.

Endoscopic small intestinal biopsy. Classical changes are villous flattening of small intestinal mucosal epithelium, inflammation of lamina propria, reduced epithelial surface cell height, increased intra-epithelial lymphocyte count.

Radiology—With barium follow-through or small bowel enema often reveals small intestinal segmentation, dilatation and loss of the normal, fine feathery pattern of the

mucosa. CT and MRI may reveal small bowel dilatation with hyposplenism, and are useful in diagnosing complicating malignancy and caseating mesenteric lymph nodes.

MANAGEMENT

Diet—Gluten-free diet avoiding wheat, rye and barley products. Strict dietary restriction not only reduces the increased incidence of small intestinal T cell lymphoma, but also of autoimmune disorders including diabetes mellitus and thyroid disease. The diet is low in fibre, so regular addition of rice bran and ispaghula husks is useful. Specific dietary deficiencies (e.g. iron, folic acid, occasionally B₁₂) should be corrected.

Corticosteroids can control coeliac disease, leading to rapid cessation of diarrhoea, weight gain and improved fat absorption. However, symptoms usually return within a few days after stopping treatment. Corticosteroids should therefore be reserved for severe illness, a coeliac crisis or otherwise unresponsive disease.

Follow-up—After a gluten-free diet for 3–4 months, a repeat small intestinal biopsy should be taken to determine whether the mucosal morphology has improved. If there is no improvement, other causes of villous atrophy (e.g. giardiasis, cow's milk allergy, HIV infection) should be excluded.

TROPICAL SPRUE

It is a malabsorption disorder seen in tropical areas and is manifested by chronic diarrhoea, steatorrhea, weight loss and nutritional deficiencies including those of both folate and cobalamin.

It is a diagnosis of exclusion as chronic diarrhea in a tropical environment is most often caused by infectious agents, including *G. lamblia*, *Yersinia enterocolitica*, *C. difficile*, *Cryptosporidium parvum*.

Tropical sprue should not be entertained as a possible diagnosis until the presence of cysts and trophozoites has been excluded in three stool samples.

Its occurrence is not evenly distributed in all tropical areas, it is found in specific locations, like southern India, Philippines.

Aetiology—The aetiology and pathogenesis of tropical sprue are uncertain. As tropical sprue responds to antibiotics the consensus is that it may be caused by one or more infectious agents.

Klebsiella pneumonia, *Enterobacter cloacae* and *E. coli* have been implicated in some studies of tropical

Figs. 26A and B: Contrast CT abdomen showing lymphadenopathy (A) coronal view venous phase; (B) axial view arterial phase

sprue, while other studies have favoured a role for a toxin produced by one or more of these bacteria.

Diagnosis—The diagnosis of tropical sprue is best based on an abnormal small-intestinal mucosal biopsy in an individual with chronic diarrhoea and evidence of mal-absorption who is either residing or has recently lived in a tropical country.

The small-intestinal biopsy in tropical sprue does not reveal pathognomonic features but resembles and can often be indistinguishable from, that seen in celiac disease.

The biopsy sample in tropical sprue has less villous architectural alteration and more mononuclear cell infiltrate in the lamina propria.

In contrast to those of celiac disease, the histologic features of tropical sprue manifest with a similar degree of severity throughout the small intestine and a gluten-free diet does not result in either clinical or histologic improvement in tropical sprue.

Treatment—Broad-spectrum antibiotics and folic acid are most often curative. Tetracycline should be used for up to 6 months and may be associated with improvement within 1–2 weeks. Folic acid alone induces hematologic remission as well as improvement in appetite, weight gain and some morphologic changes in small intestinal biopsy.

19. ABDOMINAL TUBERCULOSIS

Abdominal tuberculosis can affect the GI tract, peritoneum, lymphnodes of the small bowel mesentery (Figs. 26A and B), or solid viscera (liver, spleen, pancreas). The terminal ileum and ileocaecal region are the most common sites, possibly because of increased rate of fluid and electrolyte

absorption, minimal digestive activity and abundance of lymphoid tissue followed by the jejunum and colon. Multiple sites are common.

Clinical features of abdominal tuberculosis are very variable as listed in Table 30.

Signs: Vigorous peristaltic activity or distended bowel may be noted. Tenderness usually in right lower quadrant. Muscle guarding if peritoneum is involved. In presence of ileocaecal tuberculosis a tender fixed mass may be palpated in half the cases.

DIAGNOSIS

1. **Clinical**—Possibility of intestinal tuberculosis should be considered if – (i) Lung cavity with positive sputum. (ii) Abdominal symptoms appear in association with change of bowel habit. (iii) Temperature becomes irregular without change in lung lesion. (iv) Sudden reversal of pulmonary T.B. not explained by condition of lung lesion, or unsatisfactory clinical course in spite of adequate treatment.
2. **Radiology**—Suggestive features on barium meal examination – (i) Lack of barium retention in diseased segment of ileum and/or caecum (Stierlin sign). (ii) Persistent narrow stream of barium in small bowel (String sign). (iii) Areas of small bowel obstruction manifested by dilatation and delay in emptying in association with short segments of irregularity of bowel silhouette (Fig. 27) and mucosal markings. (iv) Single filling defect in caecum in hypertrophic tuberculosis. (v) Broad-based triangular appearance of terminal inch of ileum with base towards caecum (Fleischner sign).

Table 30: Clinical features of abdominal tuberculosis

Site of involvement	Type of lesion	Modes of presentation	Clinical features
Small intestine	Ulcerative	Chronic	Diarrhoea, malabsorption, lower GI bleeding, fever. Acute int. perforation, peritonitis.
		Acute on chronic	Acute on chronic int. obstruction
	Chronic	Subacute intestinal obstruction	
Ileocaecum and large intestine	Hypertrophic	Chronic	Mass, subacute int. obstruction
		Acute on chronic	Acute on chronic int. obstruction
Peritoneum	Ascites	Acute	Acute int. obstruction
		Chronic	Lower GI bleeding, fever
	Adhesive	Chronic	Pain, ascites, fever Subacute int. obst.
		Acute	Acute TB peritonitis
Liver	Diffuse hepatic involvement as in miliary TB. Single or multiple tuberculomas or abscesses.	Acute-on-chronic	Acute-on-chronic int. obstruction

**Fig. 27:** Colonic stricture due to tuberculosis**Fig. 28:** Ileocaecal TB

- Histology**—Demonstration of mycobacterium tuberculosis or histological evidence of tubercles with caseation necrosis tissues for histological examination can be obtained by - (a) Percutaneous fine-needle aspiration cytology (FNAC) from an abdominal mass, or ultra-sound guided or CT-guided FNAC from enlarged lymphnodes. (b) Colonoscopic biopsy from colonic and ileocaecal lesions (Fig. 28). (c) Laparoscopic biopsy of parietal peritoneum.

MANAGEMENT

- Diet—Bland, low in residue. Low fat diet if steatorrhoea.

- Anti-tuberculous therapy.
- Fat soluble vitamins, Vitamin C and calcium.
- Pancreatin 1–4 gm. after each meal if very poor absorption.
- Surgery: Indications—(a) Localised tuberculous involvement of hyperplastic type with marked diminution of lumen caliber. (b) Stenosis of bowel causing obstruction. (c) Perforation of tuberculous ulcer.

20. IRRITABLE BOWEL SYNDROME

IBS consists of a group of GI symptoms particularly associated with lower bowel in absence of demonstrable organic pathology.

CRITERIA FOR IRRITABLE BOWEL SYNDROME (ROME CRITERIA)

Recurrent abdominal pain or discomfort for at least 3 days per month in last 3 months (with symptoms onset at least 6 months prior to diagnosis) associated with two or more of the following:

1. Improvement after defecation
2. Onset associated with change in frequency of stool
3. Onset associated with change in form (appearance) of stool

Other symptoms that are not essential but support the diagnosis of IBS:

- Abnormal stool frequency (>3 bowel movements/day or <3 bowel movements/week)
- Abnormal stool form (lumpy/hard or loose/watery stools)
- Abnormal stool passage (straining, urgency or feeling of incomplete bowel movement)
- Passage of mucus
- Bloating or feeling of abdominal distension

CLINICAL TYPES

1. Chronic abdominal pain with constipation
2. Diarrhoea predominant IBS
3. Mixed IBS: Alternating diarrhoea and constipation

AETIOLOGY

1. **Pathophysiology**
 - (a) **Disturbance of GI motility**—In IBS, the fasted small intestine shows subtle differences in activity, particularly under conditions of stress and during sleep.
 - (b) **Sensory abnormalities (visceral hyperalgesia)**. IBS patients report discomfort at lower volume of gut distension. Such patients may suffer from 'visceral hypersensitivity' and the cause of the problem may be neural abnormality of the primary afferent nerves to the spinal cord, or of the intrinsic nerves of the colonic wall.
2. **Psychopathology**—Patients in whom continuous pain is the major symptom suffer more from depressive symptoms, whereas those with chronic unremitting symptoms tend to have subtle personality differences and low self-esteem. Marital difficulties and childhood physical abuse are reported more commonly in chronic IBS patients.

3. **Post-infective/post-inflammatory causes**—Onset of symptoms may follow an enteric infective episode (e.g. *Campylobacter*), and IBS-like symptoms are common in patients with coexistent inflammatory bowel disease.
4. **Abnormal regulatory physiology**—Patients with IBS have been reported to exhibit exaggerated GI responses, either as intrinsic reflexes (e.g. motility response to eating or infused cholecystokinin) or to exogenously infused drugs (e.g. cholinergics) and the stress-response mediator corticotrophin-releasing hormone (CRH).
5. **Diet**—Colonic fibre fermentation may be a source of perceived excess gas, and has led to suggestions of a role of abnormal colonic bacterial flora.

DIAGNOSIS

- Full blood count, ESR and sigmoidoscopy in patient under 40 with classical history of IBS and without significant disturbance or significant weight loss.
- Double-contrast barium enema or colonoscopy in patients over 40 with recent onset of symptoms to rule out malignancy.
- Rectal biopsy in patients with diarrhoea. Changes of inflammatory bowel disease or less common types of colitis may be found in a macroscopically normal rectum.
- In patients with chronic diarrhoea, further investigations to rule out coeliac disease, Crohn's disease and chronic GI infection e.g. giardiasis.

MANAGEMENT

1. **Explanation and reassurance**—Physiological explanation based on concept of 'spasm' of bowel. Reaction of the gut can be equated to reaction to emotion e.g. fast pulse and dry mouth to apprehension. Reassurance regarding absence of organic disease.
2. **Specific therapy**—According to the predominant complain of the patient.

Dietary Measures

Dietary fibre—With supplementation with bulking agents such as coarse wheat bran or ispaghula husk in gradually increasing amount.

Exclusion diets—Lactose-free diets may be tried in individuals with unexplained, chronic, painless diarrhoea.

Drug Therapy

Antispasmodics—Mebeverine 100 mg or Pinaverium bromide 50 mg, 30 minutes before food if symptoms following meals.

Antidiarrhoeal agents—Loperamide, codeine (long-term use may produce addiction) or diphenoxylate, if frequent loose stools.

Antidepressants—In patients with anxiety provoked symptoms.

Tegaserod—5 mg b.d. ½ hour before food if associated constipation predominant IBS.

Lubiprostone—Stimulates chloride channels in the apical membrane of intestinal epithelial cells. Chloride secretion induces passive movement of sodium and water into the bowel lumen and improves bowel function. Oral lubiprostone was effective in the treatment of patients with constipation-predominant IBS.

Linaclotide—It is a minimally absorbed 14-amino-acid peptide guanylate cyclase-C (GC-C) agonist that binds to and activates GC-C on the luminal surface of intestinal epithelium. Activation of GC-C results in generation of cyclic guanosine monophosphate (cGMP), which triggers secretion of fluid, sodium and bicarbonate. The analgesic action of linaclotide appears to be mediated by cGMP acting on afferent pain fibers innervating the GI tract. The drug has been approved for treatment of constipation in IBS-C patients. 290 µg given once daily, significantly improved abdominal pain, bloating and spontaneous bowel movement.

3. **Non-drug treatment**—If no response to conventional therapy. (a) Elimination diets when diarrhoea is predominant symptom in a well-motivated subject. (b) Relaxation techniques for stress management. (c) Specific biofeedback. (d) Psychotherapy. (e) Hypnotherapy.

21. DIVERTICULAR DISEASE

The term *Diverticulosis* simply describes the presence of diverticula. *Diverticulitis* is the clinical syndrome resulting from inflammation of a diverticulum.

Diverticular colitis—Mucosal changes are thought to be an idiosyncratic inflammatory response to diverticulitis.

AETIOLOGY

1. More common in older individuals. 2. Eating habits – Diverticulosis is less common in vegetarians than those who eat meat. Hence a diet poor in fibre is associated. 3. Factors that lead to constipation and colonic hypermotility or to a weak colonic wall may be involved.

PATHOGENESIS

Colonic diverticula are pulsion diverticula; they arise when the pressure within the colon is excessive and the wall is weakened as a result of ageing. The sigmoid colon

is the most common site for diverticulae formation. Occasionally the descending colon, less commonly the whole colon is involved. *Diverticulitis* occurs when a diverticulum becomes irritated by inspissated faecal material (faecolith).

COURSE OF THE DISEASE

1. **Uncomplicated diverticular disease**—No symptoms unless the wall changes are so severe as to cause obstruction.
2. **Rectal bleeding** is uncommon but tends to be sudden and profuse. Such bleeding usually occurs in simple diverticulosis rather than diverticulitis.
3. **Diverticulitis and pericolicitis** are usually associated with pain and tenderness in right iliac fossa that starts suddenly. Right-sided disease can mimic acute appendicitis. Patient may become extremely ill with peritonitis or Gram-negative septicaemia.
4. **Pericolic abscess** may occur in or outside the wall. Symptoms can be vague (e.g. anorexia, weakness). Abdominal and pelvic examination can reveal a tender mass.
5. **Fistulas**—An untreated pericolic abscess can erode into a neighbouring hollow organ, producing a fistula. Fistulas can cause new symptoms (e.g. pneumaturia and repeated urinary infections in case of colovesical fistula, malabsorption in colojejunal fistula). In women colovaginal fistulas are more common in women who have undergone hysterectomy.

INVESTIGATIONS

- **Barium enema.** Diverticulosis is readily detected. Barium enema and colonoscopy avoided in acute condition due to risk of perforation during procedure.
- **Abdominal CT** is also effective for diagnosis.
- **Colonoscopy** if chronic bleeding or insidious change in bowel habit, symptoms which may be caused by cancer of sigmoid colon which can be overlooked on barium enema in presence of diverticular disease. Colonoscopy should be performed after 6 weeks after attack of diverticular disease.

MANAGEMENT

1. **Symptomatic, uncomplicated diverticular disease**—Treatment same as irritable bowel syndrome. High fibre diet and/or bulking agents such as ispaghula and bran. If diarrhoea is the main symptom, antidiarrhoeal drugs. Musculotropic drug like mebeverine may relieve pain. Psychological support if anxiety or depression.

- Rectal bleeding**—Transfusion may be required in elderly patients. Occasionally embolization of bleeding vessel best performed at time of angiography. Endoscopic hemostasis by adrenaline injection.
- Diverticulitis and pericolicitis**—Hospitalization with rest and analgesics, nil by mouth and antibiotics against aerobic and anaerobic bacteria (e.g. cefuroxime and metronidazole).
- Pericolic abscess and fistulas**—CT and ultrasound imaging techniques allow abscesses to be drained percutaneously. Fistulas require surgery.

22. INFLAMMATORY BOWEL DISEASE

ULCERATIVE COLITIS (UC)

Ulcerative colitis is an inflammatory disorder of the colonic mucosa characterized by relapses and remissions. The rectal mucosa is always involved, occasionally by microscopic inflammation alone, and the disease extends proximally.

UC is classified into severity in two ways—According to extent of involvement or according to symptoms. If the disease is limited to only the rectum (proctitis), limited to rectum and sigmoid colon (proctosigmoiditis). Left sided UC involves descending colon, sigmoid colon and rectum. The term pancolitis suggests involvement of the whole colon or most of the colon. Sometimes ileum gets involved called as “Backwash ileitis”.

Potential etiological factors in UC are listed in Table 31.

Clinical Features

Presentation—Onset is usually gradual. Bloody diarrhoea is the hallmark of the disease, though proctitis may present with rectal bleeding and constipation. Urgency and

Table 32: Assessment of severity

Features	Mild	Moderate	Severe
Motions per day	< 4	4 to 6	> 6
Rectal bleeding	Little	Moderate	Large quantities
Fever	None	Mild	> 37.8°C on 2 of 4 days
Pulse rate	Normal	Intermediate	> 90 beats/min.
Hemoglobin	Normal	> 10.5 g/dL	< 10.5 g/dL
ESR	Normal	Slight rise	> 30 mm/hr.
Endoscopic appearance	Erythema, decreased vascular pattern, fine granularity	Marked erythema, coarse granularity, absent vascular markings, contact bleeding, no ulcerations	Spontaneous bleeding, ulcerations

crampy abdominal discomfort before defecation. Stool frequency is related to the severity of the disease. Assessment of the severity of disease is given in Table 32.

Systemic features and signs—Anorexia, weight loss. Anemia, fever, tachycardia, abdominal tenderness.

Extra-intestinal Manifestations

Ulcerative colitis has very varied systemic manifestations as given in Table 33.

Investigations

Sigmoidoscopy and rectal biopsy—The appearances can be graded as – (a) Mild: Hyperaemia and oedema. (b) Moderate: Granular mucosa with contact bleeding. (c) Severe: Ulceration, spontaneous bleeding.

Table 31: Potential etiological factors in UC

Factors	Evidence
<i>Genetic</i>	1:10 to 1:15
• Family frequency	70% of affected sib pairs suffer
• Concordance	
• HLA	Association with pancolitis
• Chromosomes 12, 6 and 2	Microsatellite markers
<i>Psychological</i>	Major stress can cause flareup or precipitation of symptoms
<i>Immunological</i>	
• 40kDA colonic protein	Tumor necrosis factor
• Cellular mechanisms	
• Cytokines	
• Neuroimmune	
<i>Environmental</i>	
• Sulphate-reducing bacteria	
• Smoking	Excess hydrogen sulphide
• Appendectomy	Protects—Ex-smokers at most risk
• Anti-inflammatory drugs	Protects
• Dietary factors	70% before UC
	Deficiency or excess of certain nutrients (l-arginine, gluten)

Table 33: Systemic manifestations of ulcerative colitis

Related to activity	
Common	Uncommon
Aphthous ulcers	Pyoderma gangrenosum
Erythema nodosum	Thromboembolism
Episcleritis	
Arthritis (large joints)	
Unrelated to activity	
Common	Uncommon
Sacroiliitis	Primary sclerosing cholangitis
Arthralgia (small joints)	Other liver disease
	Ankylosing spondylitis Sweet's syndrome

Fig. 29: Barium enema showing marked contraction and shortening of the colon (pipe stem appearance) due to long-standing ulcerative colitis

Fig. 30: Colonoscopy in active ulcerative colitis

Fig. 31: Descending colitis

Characteristic microscopic features are a chronic inflammatory infiltrate, glandular distortion, goblet cell depletion and crypt abscesses. The crypt architecture of the colon is distorted; crypts may be bifid and reduced in number, often with a gap between the crypt bases and the muscularis mucosae.

Some patients have basal plasma cells and multiple basal lymphoid aggregates.

Ileal changes in patients with backwash ileitis include villous atrophy and crypt regeneration with increased inflammation, increased neutrophil and mononuclear inflammation in the lamina propria and patchy cryptitis and crypt abscesses.

Plain abdominal radiography in only severe disease, to assess faecal distribution (the distal extent identifies the proximal extent of colitis in majority of patients), to exclude colonic dilatation (> 5.5 cm). It is also helpful in demonstrating proximal constipation in patients with very distal disease.

Colonoscopy vs barium enema—Typical barium enema features are as shown in Figure 29. Colonoscopy is always preferable in initial investigation of bloody diarrhoea, because it provides better mucosal definition and allows biopsies (Fig. 30). Colonoscopy however is dangerous in acute episode; flexible sigmoidoscopy after phosphate enema is then the procedure of choice.

CT abdomen can also define active colitis (Fig. 31) and its proximal extent.

Other investigations

Stool examination to exclude pathogens such as *E. histolytica*, *Clostridium difficile*, *E. coli*, *Campylobacter* spp. and *Shigella* spp.

Full blood count, ESR or C-reactive protein to evaluate severity.

Liver function investigation once in remission.

Differential Diagnosis

Infection—Other causes of bloody diarrhoea include *Clostridium difficile*, *E. coli*, *Campylobacter* spp. and *Shigella* spp. and *E. histolytica*. Cytomegalovirus should be considered in immunocompromised individuals.

Crohn's colitis—Diagnosis is achieved by considering history, endoscopic appearance, histology and contrast radiology. When features of both UC and Crohn's colitis are present, the term 'intermediate colitis' is best used.

Other Possibilities

Ischemic colitis—Usually sudden onset, rectum not affected.

Microscopic colitis—Causes watery, not bloody diarrhoea. Diagnosis is made by finding chronic inflammatory infiltrate (lymphocytic colitis).

Radiation colitis—History of pelvic or abdominal node irradiation with mucosal telangiectasia.

Toxic megacolon is defined as a severe attack of colitis with total or segmental dilatation of colon (diameter of transverse colon usually > 5–6 cm) recognised by plain X-rays. Megacolon is considered if 2 or more of the following criteria. 1. Pulse >100/min. 2. Temp. >101.5°F. 3. Leucocytosis >10,000/mm³. 4. Hypoalbuminemia <3 gm/dL.

Rectal mucosal prolapse (solitary rectal ulcer syndrome) is distinguished from proctitis by characteristic histology showing muscularis interdigitation between the crypts. Drug-induced NSAIDs may be identical to UC, but will not return once the drugs are withdrawn.

Management

Management of active UC is given in Table 34.

Refractory Disease

If initial response to corticosteroids and relapse with reduction of dose to 15 mg/day or within 6 weeks of stopping corticosteroids – Azathioprine 1.5–2.5 mg/kg/day. Monitoring full blood count every 4–6 weeks. If tolerated the drug is continued for 3–5 years to prevent relapse. Methotrexate if no response to azathioprine. Cyclosporine IV in severe UC refractory to steroids. Mycophenolate mofetil is effective in maintaining remission as also Infliximab.

Tofacitinib, an oral inhibitor of janus kinases 1, 3 is effective in moderate to severe UC in clinical trials.

Indications for Surgery

(a) Emergency surgery for severe disease, toxic dilatation of colon, perforation, severe hemorrhage. (b) Elective surgery: Acute disease that fails to respond to medical treatment, frequent relapses in spite of adequate treatment, chronic disease with permanently damaged bowels, strictures, total bowel involvement with activity extending over more than 10 years.

Colectomy with temporary ileostomy and ileoanal pouch construction is operation of choice.

CROHN'S DISEASE

A non-specific granulomatous inflammation involving sharply demarcated single or multiple areas of the intestine,

Table 34: Management of active UC

Drugs	Mild attack	Moderate attack	Severe attack
<i>Corticosteroids</i>			
Prednisolone oral	20 mg/d x 1 month	40 mg/d x 1 week	Hospitalize
	15 mg/d x 1 week	30 mg/d x 1 week	Hydrocortisone 400 mg iv/day
	10 mg/d x 1 week	Then as for	Rectal hydrocortisone.
	5 mg/d x 1 week	mild attack	Fluids IV
			Potassium supplements
Corticosteroid enema	Prednisolone phosphate 20 mg in saline od or bd or Hydrocortisone 100 mg od	As for mild attacks	Metronidazole 500 mg 6 hourly iv Thromboembolism prophylaxis Toxic dilatation – Treat medically for 12–24 hrs, if no improvement (pulse, stool frequency, diameter)– Colectomy
<i>5-ASA products</i>	Alternative to corticosteroids	Continue unchanged	
Sulphasalazine	2 g/day		
Or Olsalazine	1.2–2.4 g/day		
or	for 6 weeks		
Mesalazine enema	1 g in 100 mL saline		

and probably a non-specific pathological response to a variety of exciting agents.

It can affect any part of the GI tract, but most commonly affects the terminal ileum or the ileocaecal region.

Aetiology

Genetic factors: About 15–20% of patients with Crohn's disease have one or more family members (usually a first degree relative) with either Crohn's disease or ulcerative colitis. Mutations in the CARD15 (NOD2) gene on chromosome 16 have been found in about one-third of patients with Crohn's disease and are particularly associated with ileal disease. Genes within the HLA region (chromosome 6p) appear to influence colonic involvement and the presence of extraintestinal manifestations.

Smoking: Smokers are more likely to develop the disease than non-smokers. Also the disease has a more unfavourable course in smokers.

Table 35: Clinical features of Crohn's disease	
Disease site	Clinical features
Ileum	Abdominal pain
	Diarrhoea
	Obstructive symptoms
	Mass in right iliac fossa
	Acute ileitis (uncommon)
Colon	Rectal bleeding
	Perianal disease
	Extra intestinal manifestations
Rectum	Proctitis
Other sites	Mouth, stomach, duodenum affected (rarely)

Table 36: Extra-intestinal manifestations	
Related to disease activity	
•	Aphthous ulceration
•	Erythema nodosum
•	Pyoderma granulorum
•	Acute arthritis (large joint, transient)
•	Eye complications: Conjunctivitis, episcleritis, uveitis
Unrelated to disease activity	
•	Sacroiliitis (usually asymptomatic)
•	Ankylosing spondylitis

Infective organisms: *Mycobacterium paratuberculosis* has been found in tissue of a small number of patients with Crohn's disease.

Diet: High intake of refined sugar and low intake of fibre from fruits and vegetables have been reported in patients with Crohn's disease.

Immune mechanisms: There is evidence that the normal mechanisms for down-regulating mucosal immune response are impaired in patients with Crohn's disease.

Clinical Features

Clinical features of Crohn's disease depend on the site of disease as enumerated in Table 35. Table 36 lists the extra-intestinal manifestations of Crohn's disease.

Complications

- **Strictures**—More common in small intestine. May cause obstructive symptoms.
- **Fistulas**—may develop between loops of bowel adjacent to the bladder or vagina. Pneumaturia and recurrent urinary infections indicate fistula into the bladder. Passage of flatus or feculent vaginal discharge signifies a vaginal fistula.
- **Perianal disease**—Fissures, fistulas and abscesses. Fleshy skin tags with violaceous hue common.
- **Carcinoma of intestine**—may complicate long standing colonic disease.
- **Secondary amyloidosis** in long standing cases.

Investigations

1. **Stool examination** to exclude known pathogens.
2. **Sigmoidoscopy and rectal biopsy:** Patients with small bowel involvement may show histological evidence of rectal inflammation; this may show features of Crohn's disease (e.g. focal inflammation, granulomata).

Figs. 32A and B: (A) Small bowel enema in Crohn's disease of terminal ileum. The lumen is narrowed and there is fissure ulceration (arrows); (B) Combination of transmural thickening and spasm produces the classical 'string sign' in the terminal ileum

3. Imaging

- (a) Small bowel enema (enteroclysis) and an air-contrast barium enema—Crohn's disease often leads to separation of bowel loops, a normal (Fig. 32A) and ulcerated terminal ileum and in advanced cases the string sign (Fig. 32B).
- (b) Indium 111-labelled or 99 technetium-HMPAO-labelled leucocyte scans may also be helpful in demonstrating extent of inflammation if barium radiology is equivocal.
- (c) Ultrasonography may be helpful in patients with a palpable abdominal mass in order to differentiate an inflammatory mass from an abscess.
- (d) CT is often more useful and may show thickened loops of affected intestine.
- (e) MRI is the procedure of choice for investigating complex perianal disease.

Table 37: Differentiating features between ulcerative colitis and Crohn's disease

	<i>Ulcerative colitis</i>	<i>Crohn's disease</i>
<i>History</i>		
Smoking	Non-smokers	Smokers (more severe)
Family history	Occasionally	15–20%
<i>Clinical Features</i>		
Bloody diarrhoea	Common	Not so common
Abdominal lumps	Rare	Common
Perianal disease	Uncommon	Frequent
Signs of malabsorption	Never	Frequent
<i>Radiology</i>		
Rectal involvement	Invariable	Uncommon
Distribution	Continuous	Segmental
Mucosa	Fine ulceration	'Cobblestones'
	Double contour	'Rose-thorn' ulcers
<i>Histology</i>		
Distribution	Mucosal	Transmural
Cellular infiltrate	Neutrophils, plasma cells, eosinophils	Lymphocytes, plasma cells, macrophages
Glands	Destroyed	Preserved
	Crypt abscesses	Rare
Special features	None	Granulomas, Aphthous ulcer
		Histiocyte lined fissures
Colonoscopy/sigmoidoscopy	Loss of vascular pattern, contact bleeding, ulceration and spontaneous bleeding	Deep longitudinal ulcers, skip lesions
<i>Complications</i>		
Rectal involvement	Invariable	Uncommon
Strictures	Rare	Common
Fistulas	Very rare	May occur

- (f) Colonoscopy is useful for histological confirmation and for assessing extent of colonic involvement and for obtaining ileal biopsy specimens. Flexible sigmoidoscopy is safer because of higher risk of bowel perforation.

Table 37 enlists the differentiating features between ulcerative colitis and Crohn's disease.

Differential Diagnosis

Small intestinal disease—(a) *Tuberculosis*: Colonoscopy with multiple biopsy may be helpful and laparotomy may detect serosal tubercles. (b) *Microscopic colitis* is

characterised by chronic watery diarrhoea and histopathologically by typical microscopic abnormalities in an otherwise macroscopically normal colonic mucosa. Collagenous and lymphocytic colitis are the two common forms of microscopic colitis. (c) *Other conditions* include intestinal lymphoma, carcinoid, α -chain disease, actinomycosis, amyloidosis, Behcet's disease and carcinoma.

Management

1. **General measures**—Well-balanced diet with high fibre content. Low-fat, low-residue diet if steatorrhoea or strictures. Vitamin supplements. Rest in bed during acute phase with liquid diet. If anemia, iron by injection, or B₁₂ and folic acid if megaloblastic anaemia. Codeine sulphate, diphenoxylate or loperamide helps to reduce bowel looseness.

2. **Drug treatment**

Aminosalicylates—Sulphasalazine 1 g t.d.s. orally in active colonic disease. Mesalazine delayed release 400 mg t.d.s. for maintenance therapy.

Corticosteroids—are beneficial in active disease. (a) Local therapy—Hydrocortisone suppositories for disease of rectosigmoid colon, foam or liquid enema for more proximal disease od or bd \times 3–6 weeks. Prednisolone 0.25–0.75 mg/kg to maximum of 60 mg for 4 months. (b) Systemic treatment—Parenteral corticosteroids e.g. Hydrocortisone 100 mg. IV 8-hourly useful for inducing remission in severely ill patients with acute Crohn's colitis.

Metronidazole—400 mg t.d.s. if associated sepsis (e.g. in relation to fistulas or perianal disease or bacterial overgrowth of small intestine with resulting steatorrhoea).

Immunosuppressive agents—Azathioprine 2.5 mg/kg/day or 6-mercaptopurine 1.5 mg/kg/day may be used if other therapy has failed and surgical treatment is inappropriate. Regular blood count should be done to detect bone marrow suppression. Cyclosporine has rapid onset of action. IV injection at a dose of 2–4 mg/kg/day induces clinical improvement within a week. Prophylaxis against *Pneumocystis jiroveci* pneumonia is administered in all patients on the drug.

Immunotherapy—Infliximab (an IgG1 chimeric antibody to tumour necrosis factor). Single infusion of 5mg/kg i.v. Two-thirds of patients with chronic active disease resistant to corticosteroids and immunosuppression respond as also 50% with fistulas. Regular infusions every few months for maintenance. Side-effects are uncommon but include activation of latent tuberculosis, and appearance of antibodies to dsDNA with occasional manifestations of lupus-like syndrome.

Natalizumab is a recombinant humanized IgG4 antibody against α 4-integrin that has been shown to be effective in induction and maintenance of patients with CD. It has been approved since February 2008 for the treatment of patients with CD refractory or intolerant to anti-TNF therapy. Side effect is progressive multifocal leukoencephalopathy (PML). The most important risk factor for development of PML is exposure to the John Cunningham (JC) polyomavirus.

Vedolizumab, leukocyte trafficking inhibitor, monoclonal antibody directed against α 4 β 7 integrin, is indicated for patients who have had an inadequate response or lost response to or were intolerant of a TNF blocker or immunomodulator or had an inadequate response or were intolerant to or demonstrated dependence on glucocorticoids. It is an option for patients who are JC antibody positive since it does not cross the blood-brain barrier.

Ustekinumab, a fully human IgG 1 monoclonal antibody, blocks the biologic activity of IL-12 and IL-23, shows efficacy in moderate to severe CD in clinical trials.

Surgical Management

Indications:

- Intestinal obstruction
- Perforation
- Failure to respond to medical therapy.
- Complications such as fistulas and perianal disease.

Limited resections, stricturoplasty or end-to-end anastomosis as necessary. Split ileostomy to isolate colon in case of fistulas and perianal disease.

23. ISCHEMIC BOWEL DISEASE

ACUTE MESENTERIC ISCHEMIA

AMI is usually caused by superior mesenteric artery (SMA) embolization or thrombosis (Fig. 33), non-occlusive mesenteric ischemia or acute mesenteric venous thrombosis. Rare causes include vasculitis, fibromuscular dysplasia, dissection, trauma and rupture of a mesenteric aneurysm.

Emboli can originate from the heart or aorta. Most emboli lodge distal to origin of middle colic artery.

Thrombosis of SMA or coeliac axis occurs as a result of underlying mesenteric atherosclerotic stenosis progressing to occlusion, usually at the origin of the vessel.

Non-occlusive mesenteric ischemia develops in patients in a low cardiac output state, particularly in presence of digoxin or vasoconstrictors. Mesenteric

Fig. 33: Abdominal angiography showing celiac and superior mesenteric artery thrombus

vasoconstriction results in segmental vasospasm of secondary and tertiary branches of the SMA.

Mesenteric venous thrombosis may be secondary to infection, hypercoagulability states, cirrhosis, splenomegaly, malignancy, trauma or pancreatitis. Bowel oedema, impaired venous drainage and increased plasma viscosity reduce arterial inflow and may lead to bowel infarction.

Clinical Features and Diagnosis

Classically AMI presents with acute onset of abdominal pain disproportionate to the physical signs. Central abdominal pain. GI emptying may occur, with emesis and bloody diarrhoea.

Laboratory Findings

These include leucocytosis, acidosis, hyperkalemia and raised hematocrit, LDH, SGOT and creatine kinase occur later.

Imaging

CT angiography is sensitive for mesenteric occlusion. It also identifies non-vascular causes of acute abdominal pain. CT angiography with three dimensional reconstruction may show the vascular anatomy and pathology in sufficient detail for diagnosis and operative treatment.

Management

Acute SMA embolism—Balloon embolectomy, usually with patch angioplasty of the SMA. For chronic proximal occlusion or stenosis, bypass grafting. Resection of infarcted bowel after revascularization.

Acute SMA thrombosis—Replacement of a bypass graft to the SMA distal to the occlusive segment. Thrombolytic therapy is considered in acute thrombosis with no clinical signs of peritonitis.

Non-occlusive mesenteric ischemia—Any metabolic cause can be identified and corrected. The SMA is selectively catheterized and vasodilating agents such as papaverine given.

Mesenteric vein thrombosis—Fluid resuscitation and systemic anticoagulation. Thrombolysis in patients with no signs of peritonitis.

CHRONIC MESENTERIC ISCHEMIA

Clinical Features

Classical symptom is abdominal pain after eating (also termed 'mesenteric angina'). Diarrhoea secondary to malabsorption may occur. Patients become fearful of eating and thus lose weight. On physical examination an epigastric bruit may be heard. Signs of multifocal atherosclerosis are usually present.

Diagnosis

Lateral views on MDCT/MR aortography are the best means of demonstrating visceral occlusive lesions. Duplex scanning can document presence of stenosis in the visceral arteries.

Management

Mesenteric stenting—percutaneous angioplasty stent replacement in those with a suitable vascular anatomy offer long term relief from pain.

24. DRUG-INDUCED GASTROINTESTINAL DISORDERS

Drug effects on GI tract (Table 38) can be considered in four categories:

1. *Due to pharmacological mode of action*—Adverse drug reactions can occur as a predictable result of a drug's mode of action. For instance, anticholinergic agents (e.g. antidepressants) reduce oesophageal sphincter pressure resulting in reflux and heartburn, they also reduce colonic transit resulting in constipation.
2. *Impairment of GI defences*—example NSAIDs act principally by inhibiting prostaglandin synthesis.

Table 38: Categories of adverse effects of drugs on GI tract

	Problem	Causative drug
Oesophagus	Heart burn	Anticholinergic agents, tricyclic antidepressants, phenothiazines
	Oesophagitis, candida oesophagitis, strictures	Tetracycline, bisphosphonates Immunosuppressive drugs NSAIDs
		Pot chloride, quinidine (particularly slow-release preparations)
	Dyspepsia and gastroduodenal ulcers GI tract	NSAIDs, co-prescription of corticosteroids, warfarin, aspirin
Nausea and vomiting	Gut damage including ulceration	Locally irritant - Iron, NSAIDs, theophylline, and pharmacologically metronidazole
Diarrhoea	Disturb intestinal flora (e.g. <i>C. difficile</i>) Antagonising anti-peristaltic	Act via CNS: Levodopa, bromocriptine, opiates, digoxin, chemotherapeutic agents
	adrenergic stimulation	Cephalosporins, β -blockers
	Direct irritant action on colon	Bile acids
	Stimulation of intestinal	Misoprostol
	secretion and motility	Olsalazine
Constipation	Constipation induced abdominal pain	Antimuscarinic drugs: atropine, tricyclic antidepressants, opiates.
	Drug-induced mega colon from enteric neurotoxicity	Vincristine or possibly laxatives
	Bloating and occasionally impaction	Dietary fibres in excessive amounts
Colitis	Inflammation of the colon	Mefenamic acid, penicillamine, antibiotics, oral gold.
Malabsorption	Small intestinal disease Coeliac disease Folate deficiency	Colchicine, biguanides, laxatives, salicylates. Sulfasalazine and phenytoin cause folate malabsorption.

3. *Direct injury to GI tract*—example oesophageal damage by potassium preparation, gastroduodenal ulcer by cytotoxic drugs, and ulceration and colitis associated with oral gold.
4. *Changes in colonic bacterial flora.*

25. FACTITIOUS GASTROINTESTINAL SYMPTOMS AND MUNCHAUSEN

There are several syndromes that depend on lie. These may involve obvious secondary gain for example the malingerer who seeks compensation for disability. Alternatively, there may be no obvious motive, as in Munchausen's syndrome. The physician must be alert to complaints of abdominal pain, constipation, diarrhoea or vomiting when the tests are negative and the observed behaviour of the patient does not fit the complaint. The linking phenomena in such cases include elaborate, fantastic, deliberate fabrication of disease, often by someone with medical knowledge, and inexplicable, intractable and often hazardous compulsion to undergo treatment.

Munchausen syndrome is a type of factitious disease characterised by simulated disease, pathological lying (often elaborate and fantastic), and wandering from place to place and hospital to hospital.

TYPES OF MUNCHAUSEN SYNDROME

- Abdominal: Patients travel to various hospitals undergoing repeated operations, only to discharge themselves against advice (even with wounds still healing and iv drips in place).
- Bleeding: Characterised by bleeding symptoms: Anticoagulant subtype, anemia subtype, pretended bleeding subtype.
- Neurological: Patients present with unusual often convincing fits, spells, faints and anesthesia
- Miscellaneous: Pyrexia, dermatological, endocrine
- Munchausen syndrome-by-proxy: A form of child abuse in which a parent or carer feigns illness in a child.

MISCELLANEOUS

Oral Manifestations of Systemic Disease

Celiac disease occasionally produces oral ulceration, glossitis and/or angular stomatitis.

Allergic gingivostomatitis and cheilitis—Altered taste, burning or discomfort may occur as a result of food allergy to various foods, flavourings, preservatives and dental materials. In severe cases of food allergy, ulceration may occur.

Inflammatory bowel disease—Crohn's disease can manifest as tags, ulcers and/or mucosal granulomatosis leading to swelling or cobble-stoning. Ulcerative colitis may produce aphthae, chronic ulceration or pyostomatitis vegetans, which is characterized by deep fissuring and micropustules.

Behcet's syndrome is the association of orogenital ulceration with ocular disease.

Hematological disease—Hematinic deficiency may cause glossitis or ulceration. Leukemia and lymphoma may cause infections, ulcers, purpura or gingival swelling.

Genodermatoses with characteristic oral manifestations include - (a) Rendu-Osler-Weber disease with mucocutaneous telangiectasiae that are prone to spontaneous hemorrhage. (b) Cowen's syndrome characterized by circumoral and submucosal soft tissue nodules (trichilemmomas). (c) Peutz-Jeghers syndrome with mucocutaneous freckling and intestinal polyposis.

Skin manifestations of GI disease are listed in Table 39.

IMMUNODEFICIENCY AND THE GUT

Causes of Immune Deficiency

- Defects in production of secretory IgA
- Genetic defects
- Iatrogenic cellular immune deficiency (Total body irradiation or chemotherapy)
- HIV infection

Common Infections of the Intestines Associated with Immune Deficiency

- *Giardia lamblia*. Mainly acquired from water, but can occur in homosexual males as a result of sexual activity.
- Cryptosporidiosis is associated with chronic diarrhoea, wasting and death.
- Microsporidiosis with chronic diarrhoea and wasting

Table 39: Skin manifestations of GI disease

Condition	GI disorder
Erythema nodosum	Inflammatory bowel disease
Pyoderma gangrenosum	Inflammatory bowel disease
Purpura/petechiae	Bleeding disorders
Mucocutaneous pigmentation	Peutz-Jeghers syndrome
Acanthosis nigricans	GI malignancy

- Bacterial diarrhoea (Shigella, salmonella and campylobacter).
- Mycobacterium avium intracellulare. Diarrhoea is a late manifestation of HIV infection.
- Cytomegalovirus infection in patients with severe immune suppression causes bloody diarrhoea, sometimes associated with toxic dilatation and colonic perforation.
- CMV of oesophagus produces hemorrhagic oesophagitis.
- Ulcers of unknown aetiology similar to aphthous ulcers in appearance.

Gastroparesis means incomplete or partial paralysis of the stomach. It is a disorder of delayed gastric emptying in absence of mechanical obstruction. Causes-peptic ulcer disease, endocrine disorders, (thyroid, diabetes, parathyroid, collagen vascular disease), psychogenic causes.

Common Infections of the Oesophagus

- Oesophageal candidiasis causes pain on swallowing.

Hepatobiliary and Pancreatic Disease

1. INVESTIGATING AND IMAGING THE LIVER, BILIARY TRACT AND PANCREAS

INVESTIGATIVE MODALITIES FOR LIVER STRUCTURE AND FUNCTION

- Tests indicating some form of liver dysfunction but are generally nonspecific (e.g. biochemical liver function tests).
- Tests to assess liver function and the prognosis of disease (e.g. antipyrine clearance).

- Tests to detect structural abnormalities (CT scan and USG).
- Tests to determine underlying cause of liver disease (e.g. hepatic serology).

Blood Tests

1. Biochemical liver function tests

Biochemical liver function tests and their rationale and significance are given in Table 1.

Table 1: Biochemical liver function tests

Test	Normal values	Significance
Excretion		
Bilirubin		
Total	0.3–1 mg/dL	Cholestasis
Unconjugated	< 0.3 mg/dL	Hemolysis (congenital or acquired)
Urine bilirubin		Any bilirubin found in urine is conjugated bilirubin and indicates liver disease. Unconjugated bilirubin is highly bound to albumin and so not found in the urine.
Blood ammonia		Elevated in severe portal hypertension. Elevated levels correlate with outcome in severe hepatic failure.
Synthesis		
Serum albumin	3.5–5 g/dL	Low levels in a jaundiced patient suggest chronic liver disease.
Prothrombin time	12–15 sec	Prolonged in both biliary obstruction and parenchymal liver disease. > 5 seconds above control and not corrected by parenteral vitamin K administration. <i>Poor prognostic sign in acute viral hepatitis and other acute and chronic liver diseases.</i>
Tests reflecting cholestasis		
Serum alkaline phosphatase (AP)	30–120 IU/L	Intrahepatic or extrahepatic cholestasis. Early marker of liver metastases or abscess formation.
Serum gamma-glutamyl transpeptidase (GGT)	10–50 IU/L	May occur with focal hepatic lesions in absence of jaundice. In cholestasis, alkaline phosphatase (AP) is higher than GT, reverse in alcoholic liver disease and patients taking enzyme reducing agents. Used to identify patients with occult alcohol use.
Tests reflecting liver cell injury		
Serum aspartate aminotransferase (AST)	5–40 IU/L	Transaminases elevated in presence of liver cell injury. >1000 IU/L seen in (1) viral hepatitis, (2) ischemic liver injury, (3) toxin and drug induced injury.
Serum alanine aminotransferase (ALT)	5–35 IU/L	
AST:ALT ratio		<1 in chronic viral hepatitis and non-alcoholic steatohepatitis. >1 as cirrhosis develops

Table 2: Tumour markers in carcinoma of liver

Tumour marker	Significance
α -fetoprotein (AFP)	Hundred fold elevated in 80% in primary liver cell cancer and germ cell tumours. Elevated in only 50% hepatocellular carcinoma of patients. Modest elevation (up to 10 times normal), may be seen in active inflammation or regeneration, but progressively rising AFP of ominous significance. Lens culinaris agglutinin-reactive fraction of AFP (AFP-L3) assay is thought to be more specific.
des- γ -carboxy prothrombin (DCP)	A protein induced by vitamin K absence (P1VKA-2). Increased in as many as 80% of HCC patients. May also be elevated in patients with vitamin K deficiency. It is always elevated after warfarin use. It may also predict for portal vein invasion.
Carcinoembryonic antigen (CEA)	In follow-up of patients with treated colon cancer, in whom rising CEA levels may indicate presence of metastases in the liver.

Both AFP-L3 and DCP is US Food and Drug Administration (FDA) approved as serological assay in hepatocellular carcinoma.

2. **Hepatitis serology** is described in diagnosis of types of hepatitis virus infections.

3. Tumour markers

Tumour markers elevated in carcinoma of liver are given in Table 2.

4. Autoantibody and immunoglobulins characteristics of liver disease

Autoantibody and immunoglobulins characteristics of liver disease are listed in Table 3.

5. **Alcoholic aetiology** in a patient with liver disease is suggested by:

Parotid enlargement

Dupuytren's contracture

Increase in:

Gamma-glutamyl transpeptidase

Raised MCV

Decreased transferrin

Serum IgA

Aspartate aminotransferase alanine aminotransferase ratio

>2:1 Suggestive of alcoholic liver disease

>3:1 Highly Suggestive of alcoholic liver disease

Table 3: Autoantibody and immunoglobulins characteristics of liver disease

	Autoantibodies	Immunoglobulins
Primary biliary cirrhosis	High titre of antimitochondrial antibody in 95%	Raised IgM
Autoimmune chronic active hepatitis	Smooth muscle antibody in 70%, antinuclear factors in 60%	Raised IgG in all patients
Primary sclerosing cholangitis	Low antibody antimitochondrial antibody titre in 20%. Antinuclear cytoplasmic antibody (p-ANCA) in 30%.	

6. Other blood tests

Other blood tests useful in evaluation of liver disease are listed in Table 4.

Imaging Techniques

Plain abdominal radiography

- Gallstones
- Air in biliary tract
- Pancreatic calculi
- Calcified gallbladder (rarely)

Ultrasonography

- Presence of ascites
- Investigation of jaundice
- Hepatomegaly/Splenomegaly
- Detection of gallstones
- Focal liver disease (lesions > 1 cm)
- General parenchymal liver disease
- Excellent view of pancreas
- Assessment of patency of portal and hepatic veins
- Abdominal lymph node enlargement
- Intraoperative ultrasonography

Doppler USG

- For thrombosis of hepatic and portal veins
- Transient elastography and Magnetic resonance elastography.
- Transient elastography (TE), marketed as FibroScan, TE uses ultrasound waves to measure hepatic stiffness noninvasively.
- Accurate for identifying advanced fibrosis in patients with

Table 4: Other blood tests in evaluation of liver disease

Test	Significance	
Haematological		
Full blood count	Bleeding produces microcytic hypochromic anaemia	
	Alcohol causes macrocytosis, sometimes leucopenia, thrombocytopenia	
	Haemolysis occurs with acute liver failure	
Biochemical		
<i>a</i> -antitrypsin	Deficiency can cause cirrhosis	
Serum copper	Raised in Wilson's disease	
Ceruloplasmin	Decreased in Wilson's disease. May occasionally be normal in Wilson's causing chronic hepatitis. Raised in hepatic encephalopathy but no correlation with severity	
Serum iron and Serum ferritin	Raised in hemochromatosis	
Serum ammonia	Raised with serum globulin in most cases of chronic hepatitis	
Serum creatinine	Raised in hepatic failure and indicates impending onset of hepatorenal syndrome	
Amylase	Pancreatitis	Ca lung
	Ca pancreas	After ERCP
	Acute cholecystitis	Burns
	Mesenteric thrombosis and infarction	Ruptured tubal pregnancy
	Parotitis	Macroamylasemia
	Mumps	Acute ethanol ingestion
	Renal disease (end stage)	Diabetic ketoacidosis Post-op. abdominal surgery
Lipase	Same as amylase (except not in parotitis, mumps, macroamylasemia)	

1. chronic hepatitis C
2. primary biliary cirrhosis
3. haemochromatosis
4. non-alcoholic fatty liver disease and
5. recurrent chronic hepatitis after liver transplantation.

MRE

It has been found to be superior to TE for staging liver fibrosis but requires access to a magnetic resonance imaging scanner.

Transient elastography (TE) and magnetic resonance elastography (MRE) both have gained U.S. Food and Drug Administration approval for use in the management of patients with liver disease.

Oral cholecystography is best reserved for patients in whom ultrasonography is equivocal or is negative despite a strong clinical suspicion of gallbladder disease. It can be diagnostic of adenomyomatosis.₂

CT

Spiral CT

Scans can be obtained quickly and hence images at different phases of liver enhancement after bolus contrast injection is possible; e.g. one scan at 40 seconds after injection demonstrates the hepatic arterial phase optimally, and a second scan at 80 seconds shows the portal phase. This biphasic technique can detect and characterise liver abnormalities. With multi-slice CT much faster scans are possible.

CT arteriography (following placement of an arterial catheter in coeliac axis or superior mesenteric artery), a high contrast dose delivered to the liver leads to detection of more metastases because these enhance differentially compared to the background liver.

CT cholangiography (following infusion of iv cholangiographic contrast) can show the biliary tree in detail provided liver function is normal.

MRI—(a) Unenhanced MRI is comparable to enhanced spiral CT and better than ultrasonography in detection of liver lesions. (b) The technique can provide excellent non-invasive reconstructions of the bile ducts. (c) Contrast-enhanced MRI—'Life specific' agents e.g. iron oxide particles taken up by Kupffer cells, chelates of manganese taken up by hepatocytes. (d) MRI is a good 'one-stop' investigation for the liver, providing excellent anatomical detail and good lesion detection and characterization, and enabling assessment of the biliary tree, portal and hepatic arterial systems and related organs such as the pancreas and spleen. (e) Liver fat quantification—By comparing the signal intensity of hepatic fat by out-of phase (OP) and in-phase (IP) imaging. Signal loss of OP images indicates presence of fat, lack of signal loss suggests absence of fat.

Isotope scanning of the hepatobiliary system. Use of radionuclide in liver imaging has declined with availability of other imaging techniques. Uses include—

- Tc labelled RBCs to assess liver haemangioma.
- A combination of Tc-colloid and gadolinium-67 is used to differentiate hepatocellular carcinoma (increased vascular flow) from regenerative nodules of cirrhosis (diminished flow).
- 99mTc-iminodiacetic acid derivatives used to evaluate cystic duct patency. These agents have the advantage that they can be used at higher levels of bilirubin than iodinated cholecystographic media.

- Positron emission tomography (PET) by using labelled somatostatin analogues has the advantage of highlighting both primary and secondary tumors in a single scan.

Magnetic Resonance

Cholangiopancreatography (MRCP)

This technique involves manipulation of data by MRI. A heavily T₂ weighted sequence enhances visualization of the 'water-filled' bile ducts and pancreatic duct to produce high quality images of ductal anatomy and allows noninvasive visualization of bile and pancreatic ducts. It is superseding most diagnostic endoscopic cholangiopancreatography.

Angiography

Selective catheterization of coeliac axis and hepatic artery for detection of abnormal vasculature in hepatic tumors. Angiography does not detect GI bleeding at rates below 0.1 mL/min, but readily reveals underlying vascular abnormalities. In digital vascular imaging (DVI) contrast given IV or intra-arterially can be detected in the portal system using computerised subtraction analysis. Visualization of hepatic veins by venography is useful in diagnosis of Budd-Chiari syndrome.

Endoscopy

Endoscopic Ultrasonography

- Excellent views of pancreas, portal veins and biliary tree may be obtained.
- Intraoperative ultrasonography performed by direct application of a sterile probe onto the liver surface.
- Ultrasound contrast media are used to assess some liver tumors.

Endoscopic retrograde cholangiography (ERCP) is a procedure that combines the use of X-rays and/or endoscopy.

Indications

Biliary tree

- Obstructive jaundice (Stones, sclerosing cholangitis, focal liver parenchymal lesions).
- Postcholecystectomy syndrome
- To delineate intrahepatic biliary radicles
- Primary biliary cirrhosis

Pancreas

- Pancreatic carcinoma
- Chronic pancreatitis (Pre-operative)

Table 5: Indications for liver biopsy

Indications	Examples
Assessment of chronic liver disease	Severity of liver disease (e.g. whether cirrhosis is present) and assessing degree of disease activity (e.g. in chronic hepatitis) Determining cause of liver disease (e.g. stains for iron, hepatitis B and α -antitrypsin may establish aetiology of cirrhosis)
Investigation of acute hepatic dysfunction	Useful if diagnosis is in doubt (e.g. suspected drug reaction), or if course of severity of illness is unusual
Targeted biopsy for focal lesions	Focal lesions such as primary or secondary liver tumors
Investigation of systemic disease and PUO	To establish diagnosis in difficult cases (e.g. sarcoidosis, tuberculosis, amyloidosis, glycogen storage disease, lymphoma)
Assessment of liver transplantation	Liver histology is essential in potential transplant recipients. Serial biopsy of the grafted liver is an important means of detecting early rejection and other complications.

- Pancreatic lithiasis
- Pancreatic pseudocyst
- Pancreatic duct leaks

Percutaneous transhepatic cholangiography (PTC) is used to visualise intrahepatic and extrahepatic biliary tree.

Liver Biopsy

Indications for liver biopsy are listed in Table 5.

Contraindications

- Coagulopathy
- Patient inability to cooperate with the breathing manoeuvres needed for percutaneous biopsy (e.g. mental retardation, impaired consciousness, respiratory disease).
- Large ascites
- Suspected extrahepatic obstruction

Standard Percutaneous Biopsy

Preparation—Prothrombin time should not be > 3 seconds. Platelet count at least $80 \times 10^9/L$.

Administration of vitamin K and fresh frozen plasma if clotting parameters are borderline. Blood for grouping and cross-matching.

Biopsy site—Mid-axillary line just below upper limit of hepatic dullness. Local anaesthesia (2% lignocaine) is given from the skin down to the liver capsule. The biopsy is taken, with patient's breathing suspended in expiration,

Table 6: Complications of liver biopsy

Complication	Comment
Puncture of gallbladder or major bile ducts	Bile leakage causes immediate severe abdominal pain progressing to biliary peritonitis.
Haemobilia (bleeding into biliary tree)	May present with GI haemorrhage, colic and jaundice.
Cholangitis	May occur particularly with bile duct obstruction.
Puncture of viscera	Puncture of kidney or colon usually without sequelae. Pancreatic puncture may be serious.
Intrahepatic haemangiomas or arteriovenous fistulas	Heal spontaneously.

from the periphery of the right lobe of the liver. If a sample cannot be obtained or is inadequate after two attempts, the procedure should be repeated at a later date under ultrasound guidance.

Biopsy needles—These are of the aspiration type (Menghini) or cutting type (Tru-cut). The aspiration type is easier to perform, but has the disadvantage of potential sample fragmentation, particularly in cirrhosis. The external diameter of the needles is 1.6–2 mm.

Imaging—Taking a biopsy under imaging control is particularly helpful in locating a focal target lesion, but is also useful when the liver is small and difficult to localize by percussion.

Complications

Complications of liver biopsy are given in Table 6.

Alternative procedures—These are indicated if coagulopathy cannot readily be corrected and the risk of bleeding is greater.

Plugged biopsy—It is similar to standard biopsy, but an absorbable gelatine sponge is injected into the tract in the liver after the biopsy is withdrawn. The technique requires the patient to hold the breath a few seconds longer.

Transjugular liver biopsy—It is preferred in patients with significant coagulopathy because the sample is taken from within the liver via a catheter in the hepatic vein. A special tru-cut needle is inserted through a catheter placed in the hepatic vein via the jugular vein and a sample taken from within the liver. The advantages are the facility for multiple biopsies and simultaneous pressure measurements and venography. Also in patients with small livers.

Laparoscopic biopsy—is of particular value for target biopsy of focal lesion such as primary or secondary liver tumors.

2. VIRAL HEPATITIS

The term viral hepatitis refers to infections of the liver caused by five well-characterised hepatotropic viruses, which are designated hepatitis A, B, C, D and E. Infections with other viruses such as Epstein-Barr (EB) virus, cytomegalo virus (CMV) and herpes simplex virus (HSV), but the liver is not the primary site for replication and cellular damage.

Acute viral hepatitis may be asymptomatic, marked only by an increase in aminotransferase levels, or symptomatic with or without jaundice or subfulminant or fulminant depending on the causative agent. Though the natural history of acute hepatitis can vary according to the etiological agent, it can be divided as follows depending on clinical features and laboratory findings:

- Prodromal period**
 - Bilirubinuria appears earlier than a rise in serum bilirubin.
 - Serological viral markers help in arriving at a diagnosis.
 - Urobilinogen and total bilirubin rise occurs before clinical jaundice.
 - Liver enzymes AST and ALT are > 500 units
 - Leucopaenia may be observed with onset of fever.
- Acute icteric stage**
 - Bilirubin rises, plateaus and then gradually decreases.
 - Serum AST and ALT rise and fall rapidly and reach normal range in 2 to 5 weeks.
 - ESR is raised initially and falls during convalescence.
- Defervescent stage**
 - Diuresis occurs at onset of convalescence.
 - Bilirubinuria disappears, serum bilirubin is still increased.
 - Urine urobilinogen increases.
 - S. bilirubin becomes normal after 3 to 6 weeks.

HEPATITIS A

Transmission

The main route of transmission is faeco-oral, occasionally, HAV is transmitted by blood products or through illicit use of injectable drugs.

Pathogenesis

HAV replication occurs predominantly in hepatocytes without cytopathic effect; large quantities of virus are secreted into biliary canaliculi. In addition to faecal shedding of the virus, there is sustained viraemia which persists from the earlier phase of HAV infection until onset of liver injury.

Liver injury is immune mediated by natural killer cells, virus-specific CD8+ cytotoxic T lymphocytes and nonspecific cells recruited at the site of inflammation.

Clinical Features

Incubation period 2–6 weeks, related to the infecting dose. Prodromal symptoms consist of malaise, loss of appetite, nausea, vomiting and fever. Onset of dark urine is usually the first indication of disease, followed by jaundice and pale stools. Colour returns to the urine and stools after 2–3 weeks.

In most patients HAV infection is benign. Age is the most important determinant of the severity of hepatitis A as also presence of chronic liver disease.

Complications

Include: (a) Cholestatic hepatitis with itching and jaundice lasting up to 18 weeks. In such cases a short course of rapidly tapered corticosteroids may accelerate resolution. (b) Relapsing course with a second hepatitis flare 30–90 days later; this resolves without chronic sequelae.

Viral Hepatitis in Pregnancy

Viral hepatitis in pregnancy is an important cause of foetal wastage. Hepatitis E is one of the commonest causative organism of hepatitis during pregnancy. The presence of systemic inflammatory response syndrome (SIRS) is a significant factor increasing the rates of hepatitis as cause of maternal mortality. The increasing bilirubin, features of encephalopathy and appearance of coagulopathy are all important factors for increasing maternal mortality.

Diagnosis

Nonspecific Lab Tests

- Raised serum bilirubin (5 to 10 times normal) within few days and remains high up to 12 weeks.
- Serum AST and ALT levels remain high for 1 to 3 weeks
- Alkaline phosphatase level is only mildly elevated, though if it remains persistently high, it suggests hepatitis-associated cholestasis.

Specific Tests

- Hepatitis A specific IgM antibody can be detected at the onset of symptoms and at the first rise in serum ALT. It peaks within the first month and remains positive for 3–6 months.
- IgG anti HAV becomes positive at onset of illness and is detectable for many years. It is found in about 25% of

adult population indicating previous exposure to the virus.

- Nucleic acid based tests like PCR performed on stool have little role to play in clinical settings.

Management Supportive

Bed rest, fluid intake in form of fruit juices, sugar cane juice, avoidance of physical exertion and of alcohol. Patients at risk of complications should be monitored frequently.

Prophylaxis

Hepatitis A Vaccine

Dose primary course of 2 doses (1 mL each) one month apart. Booster Dose—One dose of 6–12 months after first dose for active immunization which provides long-lasting immunity. Apart from individuals at high risk, hepatitis A vaccination is recommended in patients with chronic hepatitis C.

Post-exposure Prophylaxis

For intimate contacts (household, sexual, institutional) of persons with hepatitis A.

Dose: Immunoglobulin 0.02 mL/kg is recommended as early after exposure as possible; it may be effective even when administered as late as 2 weeks after exposure.

HEPATITIS B

HBV infection is parenterally transmitted:

- In babies born to HBV infected mothers, after transfusion of blood and blood products.
- IV drug use
- Sexual contact
- HDV infection only in HBV-infected individuals.

Clinical Presentation of Hepatitis B

On exposure to Hepatitis B virus, the spectrum of clinical presentation depends on the immune status of the individual.

1. **Acute hepatitis B**—Appropriate immune response in majority of adults leads to acute hepatitis within 5 weeks to 5 months of exposure to infection but resolves within 6 months after the onset. No treatment is required as the body is able to clear the virus with the resolution of hepatitis, and clearance of virus markers and development of immunity.
2. **Acute and subacute liver failure** is a severe form of acute hepatitis that is complicated by liver failure. Paradoxically hepatitis B virus may be present in extremely

Table 7: Interpretations of various markers of Hepatitis B infection

Markers	Interpretation
HBsAg	Indicates presence of virus in the body
HBeAg	Active replication of the virus
HBe antibody	Indicates seroconversion and non replicative state
IgM anti-HBc	Indicates recent infection or acute flare of chronic infection. Low levels in chronic infection
IgG anti-HBc	Indicates remote past infection
HBs antibody	Indicates immunity against the infection either natural or following vaccine
HBV-DNA quantitative	Indicates viral load

Table 8: Hepatitis B serology and transaminases in clinical situation

Clinical situation	Viral markers	ALT/SGPT	Comment
Acute hepatitis B	HBsAg positive IgM anti-HBc +ve	>10 x ULN	No treatment required, spontaneous recovery
HBeAg +ve	HBsAg +ve/HBeAg +ve HBV-DNA >20,000 IU	↑	Treatment may be required
HBeAg -ve	HBsAg +ve/HBeAg -ve	↑	Treatment may be required
Chronic hepatitis B	HBV-DNA >20,000 IU		
Inactive	HBsAg +ve/HBeAg -ve	N	Treatment may not be required
Carrier	HBV-DNA low (<2000 IU)		
Resolved hepatitis B	HBsAg -ve	N	No treatment
Successful vaccination	HBs antibody +ve	-	Protection against infection

low quantity or be undetectable due to profound and inappropriate immune response. Antiviral therapy is indicated but liver transplant may be required if the condition does not stabilise.

- Chronic hepatitis B**—Persistence of Hepatitis B infection for more than 6 months is seen when the body has either inadequate or no response to HBV and is unable to clear the virus resulting in chronic inflammation of the liver of variable intensity. The entire clinical spectrum of HBV infection can be classified and interpreted on appropriate selection of tests:

Serology in Hepatitis B

Interpretation of various serological markers in hepatitis B is given in Table 7. Table 8 summarises clinical situations in hepatitis B infection and serological markers and transaminase levels.

Management of Chronic HBV Infection

Management of chronic HBV infection is as follows:

- Replication of the virus* must be checked. HBeAg positive and anti-HBe negative indicate a replicating virus.

- Evidence of accompanying liver disease:*

(a) Serum ALT/AST are the indicators for ongoing inflammation. Treatment is necessary, and effective where ALT and AST are elevated 2 × upper limit of normal.

(b) Assess extent of liver damage which already exists by clinical evidence of splenomegaly and ascites and biochemical evidence of low platelet count, prolonged prothrombin time, low albumin, high globulin and USG findings of nodular liver and collaterals.

- Treatment* of the patient should then be decided according to replicative status of the virus and accompanying liver injury. The goal of treatment would be to ensure loss of HBV DNA. This is usually indicated by normalization of ALT at end of therapy with conversion of HBeAg positivity to anti HBeAg positivity in antigen positive chronic hepatitis B.

Table 9 lists antiviral drugs used in chronic hepatitis B infection and Table 10 gives the factors that determine the choice drugs for treatment.

Table 11 depicts the treatment guidelines for chronic hepatitis B virus infection as per American Association for the Study of Liver Diseases (AASLD).

Table 9: Antiviral drug in chronic hepatitis B

Drugs	Pros	Cons
Entecavir	Most potent	High cost
	High genetic barrier for resistance < 1% Resistance at 6 years	Not recommended in pregnancy 22% resistance in Lam-R at 2 years
Tenofovir	Potent data in HIV/ HBV co-infection	Renal toxicity
	No resistance at 96 weeks	Long term data needed
Adefovir	Low cost effective in Lam-R	Inefficient hence 30% resistance at 4 years
		Renal toxicity in decompensated
Telbivudine	Potent Safe in Pregnancy	22% resistance at 2 years, 4% at 48 weeks even if HBV-DNA undetectable at 24 weeks
Lamivudine	Potent, low cost, safe in last trimester of pregnancy	Low genetic barrier for resistance 70% resistance of 5 years.
Combination Lam and Adefovir	Low cost/proven benefit in makes logical sense	Unproven role in native?

Table 11: AASLD guidelines for the treatment of chronic hepatitis B virus infection

<i>HBeAg Positive</i>	
Indication for treatment	HBV-DNA >20000 IU/mL and ALT >2 times upper normal limit
When to biopsy	HBV-DNA > 20000 IU/mL and ALT >1- 2 times upper normal limit especially if age >40 year or family history of HCC
Recommended drugs	PEG IFN, Entecavir, Tenofovir
<i>HBeAg Negative</i>	
Indication for treatment	HBV-DNA >20000 IU/mL and ALT >2 times upper normal limit
When to biopsy	HBV-DNA >2000 IU/mL and ALT >2 times upper normal limit
Recommended drugs	PEG IFN, Entecavir, Tenofovir
<i>Cirrhosis</i>	
Indication for treatment	Compensated: HBV-DNA >20000 IU/mL or HBV-DNA > 2000 IU/mL and ALT >2 times upper normal limit. Decompensated: any detectable HBV-DNA
Recommended drugs	Oral agents in case of decompensated patients

Table 10: Factors influencing choice of therapy

<i>Interferon</i>	<i>Oral antiviral</i>
• Peginterferon an option in a patient with	• Choice of oral agent dependent on
– Genotype A	– Potency: Highest with entecavir and tenofovir
– Low HBV-DNA	– Rate of resistance: lowest with entecavir and tenofovir
– High ALT	– Cost: lowest with lamivudine and adefovir; generic tenofovir
– No comorbidities	– Safety: good for all oral agents
– Desire for a fixed duration of therapy and avoidance of resistance	– Special circumstances, eg, pregnancy (telbivudine class B and lamivudine good safety experience)
	– HIV coinfection

Table 12: Recombinant hepatitis B vaccine

Age	<i>Recombivax-HB dose</i>	<i>Engerix-B dose</i>
<20 years	5 µg (0.5 mL)	10 µg (0.5 mL)
>20 years	10 µg (1 mL)	20 µg (1 mL)
<i>Haemodialysis patients</i>		
<20 years	5 µg (0.5 mL)	10 µg (0.5 mL)
>20 years	40 µg (4 mL)	40 µg (2 mL)

Pre-exposure Prophylaxis

It is indicated in:

1. Health workers
2. Haemodialysis patients and staff
3. Injection drug abusers
4. Haemophiliacs and Thalassemia patients who need frequent transfusions
5. Homosexuals
6. In patients with sexually transmitted disease
7. High risk behaviour, multiple sexual partners, commercial sexual worker

Hepatitis B immunization have been included in national immunization programme.

Dose: Recombinant vaccine is available depending on type dose as given in Table 12.

Schedule followed is at 0, 1 and 6 months usually 3 dosages but in case of Engerix-B dose schedule is 0, 1, 2 and 6 months for haemodialysis patients.

For haemodialysis patients, annual anti-HBs testing are recommended after vaccination; booster doses are recommended when anti-HBs levels fall to < 10 mIU/mL.

Post-exposure Prophylaxis for HBV

- Wash exposed area with soap and water
- Do anti HBs levels if prior vaccination
- Take HBIG 0.06 mL/kg (if not vaccinated)
- Take vaccine 1 mL + HBIG if Anti HBs levels < 10/or unvaccinated

HEPATITIS C

HCV is a small, enveloped RNA virus and a member of the Flaviviridae.

Individuals at Risk of HCV Infection

- Injecting drug users
- Health-care workers
- Individuals on haemodialysis
- High-risk sexual practices
- Unsafe injections or other parenteral exposure to blood
- Use of blood-contaminated implements for circumcision or surgery
- Acupuncture
- Tattooing, ear piercing/body piercing
- Mother-infant transmission can occur in mothers with high levels of viraemia (particularly HIV-HCV-co-infected mothers).

Acute Hepatitis C

Incubation period 6–12 weeks. Infection is clinically mild. Only 25% are icteric, but patients with jaundice are more likely to clear the virus.

Chronic Hepatitis C

Most cases are not preceded by clinically apparent icteric hepatitis. Serum aminotransferase levels remain abnormal after 12 months in 60–85% of patients with type C post-transfusion or sporadic hepatitis.

Cirrhosis develops within 10 years in about 10–20%, but remains indolent and is only slowly progressive after a prolonged period of time. Greater age at infection, concomitant alcohol intake, concurrent HBV or HIV infection or other illness may be important aggravating co-factors. Anti-HCV persists for years or even decades in chronic

HCV infection. HCV RNA usually persists in patients with abnormal serum aminotransferases and anti-HCV. Polymerase chain reaction (PCR) analysis is sensitive and specific for HCV RNA in blood and other tissues.

The infection causes systemic disease and may be associated with various complications, including a form of autoimmune cryoglobulinemia, porphyria cutanea tarda, lymphocytic sialadenitis and membranous glomerulonephritis. HCV infection is associated with non-Hodgkin lymphoma.

Diagnosis

Specific Markers for HCV Infection

1. *Antibodies to HCV* (anti-HCV)
 - Detection of antibodies to recombinant HCV polypeptides. Enzyme immunoassays (EIA) measures antibodies against two antigens NS4 and NS3
 - These assays can detect antibodies within 6 to 8 weeks of exposure
 - Average time for seroconversion is 2 to 3 weeks
2. Recombinant immunoassay (RIBA)
3. Hepatitis C virus RNA testing qualitative test
4. Hepatitis C virus RNA testing quantitative test
5. HCV genotyping is helpful in predicting response to therapy.

Treatment

Assessment for Treatment

- (a) *Evaluation of virological status in anti HCV positive individual*—Immune assays (EIA) to HCV are highly sensitive in immunocompetent patients. Genotyping may be done before starting treatment for further quantifying the amount of virus and the Genotype.

Patients who are immunocompromised or on dialysis may have false negative anti HCV test due to poor antibody response. HCV RNA is necessary to confirm presence of the virus. After exposure HCV-RNA becomes detectable in serum after 7 to 9 days. Followed by aminotransferase elevation and later (after 4–10 weeks) by presence of antibodies.

In event of Anti HCV test in a blood donor, confirmation of presence of virus is required by highly sensitive ELISA test.

- (b) *Assessment of liver dysfunction*—AST/ALT values if abnormal would suggest necroinflammation. Liver biopsy helps in assessment of severity of liver disease as the grade of inflammation and stage of fibrosis are not indicated by value of AST/ALT.

Table 13: Indications for treatment of hepatitis C

Should be treated	Treatment may be individualized	Treatment contraindicated
Chronic hepatitis C With Abnormal ALT With Liver biopsy showing significant inflammation and fibrosis With compensated liver disease	1. Acute hepatitis C not resolving within 3 months 2. Chronic Hepatitis C with normal ALT and AST but with significant inflammation and fibrosis on liver biopsy 3. Active substance abuse	Decompensated liver disease Post kidney transplant Associated: 1. Severe comorbid illness 2. Unconscious psychiatric illness 3. Autoimmune conditions 4. Pregnancy

(c) Specific issues in pretreatment evaluation

- Haematology: Estimation of WBC and platelet count and Hb.
- Estimation of thyroid function and ANA
- Psychiatric evaluation
- Testing for HBsAg and HIV coinfection
- Pregnancy - Interferon is contraindicated

Table 13 gives the indications for treatment of hepatitis C.

Combination therapy with conventional/pegylated interferon and Ribavirin is the standard treatment for chronic hepatitis C.

Other options are directly acting antiviral (DAA) agents, interferon-free combinations, which are found to have high cure rate and better compliance. These are Sofosbuvir, Ledipasvir, Simeprevir, Paritaprevir, Ombitasvir and Dasabuvir. But their high cost is main limitation for widespread use and availability in India.

Table 14 gives Indian National Association for Study of Liver.

Interferon

Dose of 3 million unit sc 3 times a week. Pegylated interferon dosage is weight based in Peg IFN2B (1–1.5 µg/kg) and standard dose of 180 mg in PegIFN2A.

Ribavirin

Treatment varies according to the Genotype. In Genotype I, Pegylated IFN is preferred and duration of therapy needs to be extended to 48 weeks with dose at 1000 mg/day if body weight < 75 kg and 1200 mg/day if >75 kg in Genotype II and III, response rates are much better and with Ribavirin at 800 mg/day with Pegylated IFN and duration of treatment 24 weeks.

Special Situations in Management of HCV Infection

1. Acute HCV infection is most often symptomatic. Treatment is indicated in persons exposed to Hepatitis C and those who have HCV-RNA positive 3 months after acute infection.

Table 14: INASL 2014 guidelines for hepatitis C management

For HCV Genotype 1, 4, 5, 6	
Interferon-eligible	Peg-IFN (2a or 2b) + weight-based Ribavirin 15 mg/kg for 48 weeks
Interferon-ineligible	Directly acting antivirals (DAA)
For HCV Genotype 2, 3	
First-line therapy	Directly acting antivirals (DAA) or Peg-IFN (2a or 2b) + weight-based Ribavirin 15 mg/kg for 24 weeks
Alternative regimen	Peg-IFN (2a or 2b) + weight-based Ribavirin 15 mg/kg for 24 weeks

2. Patients with CKD may get exposed to Hepatitis C during haemodialysis and develop hepatitis. They do not tolerate treatment well and have high chances of Ribavirin-induced haemolysis and anaemia. PEG IFN can be given in reduced doses. It is important to treat before a renal transplant to avoid possibility of rejection.
3. Patients with chronic Hepatitis C and normal SGOT, SGPT may be considered if liver biopsy shows significant fibrosis.
4. Treatment in HIV co-infection—Peg IFN and Ribavirin combination is preferred therapy. Use of erythropoietin and Granulocyte stimulating factors is advisable to avoid side effects.
5. Treatment of non-responders and relapses—Retreatment with longer duration and optimized dose of Ribavirin or changing the type of interferon may help.
6. Liver transplantation—Hepatitis C is one of the most common indication in decompensated liver disease. Monitoring postoperatively with serial liver biopsies is necessary and appropriate therapy can be given if HCV recurrence is associated with significant disease on histology of the new liver.

Post-exposure Prophylaxis

- No vaccine for C virus
- Check Anti HCV/SGPT for prior exposure
- HCV-RNA and not Anti-HCV test of choice within 12 weeks of exposure

Table 15: Viral hepatitis and their salient features

Disease	Incubation Period	Mode of Transmission	Family	Nucleic Acid	Salient Features	Mortality
Hepatitis A	2 to 6 weeks	Enteric	Picornaviridae	RNA	Acute and self-limiting, never causes liver disease	1% to 2%
Hepatitis B	4 to 24 weeks	Parenteral	Hepadnaviridae	DNA	Acute liver disease with chronic disease and risk of hepatic carcinoma	15–25% in chronically infected patient
Hepatitis C	2 to 26 weeks	Parenteral	Hepacivirus	RNA	Chronic liver disease (85%) with the risk of hepatic carcinoma (20%)	
Hepatitis D	3 to 7 weeks	Parenteral	Viroid deltaviridae	RNA	Depends on HBV for replication and expression	
Hepatitis E	4 to 6 weeks	Enteric	Hepeviridae	RNA	Water borne epidemics. Acute self-limiting hepatitis. No carrier state or chronic disease	90% mortality in fulminant cases, more often seen in pregnancy

- Spontaneous clearance likely if post exposure icteric illness
- Treatment for HCV required if HCV-RNA positive 1–3 months after exposure.

HEPATITIS D VIRUS INFECTION

- HDV virus infection should be considered in any individual who is HBsAg positive (super infection) or has evidence of recent HBV infection (coinfection). HDV is an RNA-deficient virus and hence requires presence of HBV infection.
- During HDV infection both IgM and IgG antibodies can be detected in serum in acute phase.
- HDV infection can also be detected using Reverse Transcription Polymerase chain reaction.
- Chronic HDV infection is more severe with higher mortality than other types of viral hepatitis. Cirrhosis occurs in 60 to 80% of patients with increased risk of hepatocellular carcinoma.

HEPATITIS E VIRUS

- The infection is often self-limited but may cause hepatitis of varying degree of severity. Fulminant HEV infection is often reported in pregnant women.
- Laboratory diagnosis: Identification of IgM antibodies to HEV from acute plasma serum samples (ELISA and Western block technologies). Antibodies detected are against the ORF (Open Reading Frames) 2 and ORF 3.
- Peak titres for IGM are observed during first 4 weeks while onset of infection. A rising titre of IgG antibodies is also diagnostic of infection.
- Molecular assays are used only for epidemiological studies.

Table 15 gives a brief overview of the different viruses implicated in the causation of hepatitis and their salient features.

Drug-induced hepatitis: (a) Direct toxic type related toxicity, short latent period, no extrahepatic manifestations. (b) Idiosyncratic type—most often dose related, variable latent period and presence of extrahepatic manifestations such as fever, rashes, arthralgia and eosinophilia.

Dengue fever hepatitis.

3. AUTOIMMUNE LIVER DISEASE

AUTOIMMUNE HEPATITIS

Autoimmune hepatitis is an unresolving inflammation of the liver of unknown cause that is characterized by:

- Hypergammaglobulinemia
- Auto-antibodies in the serum
- A history of other autoimmune disorders.

Clinical Features

Classic type 1 autoimmune hepatitis—May present insidiously with anorexia, nausea, malaise and fatigue. Most patients have palmar erythema and spider naevi. Some patients develop moon facies, buffalo hump, truncal obesity and abdominal striae (before corticosteroid treatment). Mild to moderate elevations of serum transaminases are common.

In some patients onset is relatively rapid resembling acute viral hepatitis with jaundice, multiple spider naevi, tender hepatomegaly and ascites. Laboratory findings indicate severe liver disease. It can end in liver failure.

Associated Conditions

- Keratoconjunctivitis sicca
- Renal tubular acidosis
- Peripheral neuropathy
- Autoimmune thyroiditis

- Grave's disease
- Ulcerative colitis
- Rheumatoid arthritis

Type 2 autoimmune hepatitis occurs most commonly in children. Presentation is usually acute or fulminant type, with rapid progression to severe liver disease and cirrhosis. It is associated with autoimmune thyroid disease, insulin-dependent diabetes mellitus and vitiligo.

Type 3 autoimmune hepatitis has clinical features similar to type 1 disease.

Diagnosis

Liver biopsy is the most important diagnostic test.

Indications for biopsy:

- Raised transaminases if relevant serum auto-antibody markers are detected (antinuclear-homogeneous pattern and smooth muscle antibodies in type 1, anti-liver-kidney microsomal antibodies in type 2, and antisoluble liver antigen in type 3).

Various autoantibodies depending on type:

Type 1 autoimmune hepatitis: Antinuclear antibody

Type 2 autoimmune hepatitis: Anti-LKM1 (liver kidney microsomes) antibody, Antinuclear antibody absent.

Type 3 autoimmune hepatitis: Antibody to soluble liver antigen.

Antinuclear antibody and Anti-LKM1 antibody absent.

- A florid acute presentation (resembling acute viral hepatitis) if there are no other diagnostic markers.
- Persistently elevated transaminases (above twice normal levels) of uncertain cause.

Other laboratory findings—Non-organ-specific autoantibodies are a cardinal feature of autoimmune hepatitis. Serological testing for anti-LKM1 and anti-SLA/LP is important, because these are subtypes that respond to treatment with immunosuppressive therapy.

Treatment

Prednisone initiated at dose of 60 mg/d.

This high dose is tapered successively over the course of a month down to a maintenance level of 20 mg/d.

An alternative approach is to begin with half the prednisone dose (30 mg/d) along with azathioprine (50 mg/d) then taper prednisone to 10 mg/d. It reduces chances of complications of long term steroid therapy.

PRIMARY BILIARY CIRRHOSIS

Primary biliary cirrhosis (PBC) is a chronic, progressive cholestatic disease of unknown aetiology that affects

mainly women. There is a strong association with anti-mitochondrial antibodies (AMA) and the disease is characterized by granulomatous cholangitis, which leads to progressive destruction of the small and middle-sized intrahepatic bile ducts, leading to fibrosis and cirrhosis.

Clinical Features and Course

Presymptomatic—In this stage, AMA are detectable in the serum but no symptoms and normal LFTs.

Asymptomatic—Circulating AMA and abnormal liver tests, but no characteristic symptoms of PBC. However 50% have established cirrhosis at time of diagnosis.

Symptomatic—Progressive jaundice, patient acquires bottle green colour

- Hepatosplenomegaly
- Finger clubbing
- Malabsorption—Vitamin A (night blindness), vitamin D (hepatic osteodystrophy), vitamin E (Dermatitis), vitamin K (Easybruising, ecchymosis).
- Hypercholesterolaemia—Xanthelasma around the eyes. Xanthomas over joints, tendons, handcreases, elbows and knees.
- CREST syndrome—Calcinosis (Raynaud's phenomenon, sclerodactyly, telangiectasia)

Decompensated patients present with symptoms or signs of liver decompensation (variceal hemorrhage, jaundice, ascites). Median time of death is 3–5 years.

Diseases Associated with PBC

Common (up to 80%)

Sicca syndrome

Less common (about 20%)

Thyroid disease

Arthralgia

Fibrosing alveolitis

Investigations

LFTs—Cholestatic pattern with elevated serum alkaline phosphatase and glutamyltransferase. Serum immunoglobulins, particularly IGM elevated.

Autoantibodies—AMA and nuclear pore protein (gp210) are specific to PBC.

Liver histology—Stages: 1. Granulomatous cholangitis. 2. Inflammation spreading beyond portal tracts, disappearing bile duct syndrome begins. 3. Scarring stage, adjacent portal tracts linked by fibrous septa. 4. Cirrhosis.

Management

No dietary restrictions unless indicated (e.g. sodium restriction for ascites).

Treatment of Symptoms

(a) *Pruritus*—Cholestyramine 4 g t.d.s. If not effective, colestipol. Alternative therapies include rifampicin 300mg/day, naltrexone 25 mg/day, plasmapheresis and a liver support device (e.g. MARS machine), and in severe cases liver transplantation. (b) *Bone disease*—Osteopenia is common and is treated with calcium and bisphosphonates or hormone replacement therapy. (c) *Malabsorption of fat soluble vitamins*—Replacement therapy with vitamins A, D, E and K.

Medical Treatment

Ursodeoxycholic acid (UDCA) 10–15 mg/kg/day in 2–4 divided doses. Reduction in serum alkaline phosphatase within 6 months is a useful predictor of clinical response. It improves both biochemical and histological profile of disease.

Liver transplantation—Indications: Symptomatic disease, intractable pruritus and other features suggesting end-stage liver disease.

SECONDARY BILIARY CIRRHOSIS

It results from prolonged obstruction to large biliary ducts by stones, bile duct strictures or sclerosing cholangitis.

Cl. Fs.: Recurring abdominal pain, fluctuating jaundice if stones, previous history of abdominal surgery in case of stricture.

Investigations: Hyperbilirubinemia, raised serum alkaline phosphatase. Ultrasound and CT scan abdomen, ERCP or MRCP.

Tr.: Relief of strictures by ERCP or surgery.

PRIMARY SCLEROSING CHOLANGITIS

Primary sclerosing cholangitis is a cholestatic liver disease caused by diffuse inflammation and fibrosis that can involve the entire biliary tree ultimately leading to biliary cirrhosis, portal hypertension and hepatic failure.

Aetiology

Cause is unknown but there is a close association with ulcerative colitis. Evidence suggests that it is an immunologically mediated disease, probably triggered in genetically susceptible individuals by acquired toxic or infectious agents, which may gain entry through the leaky diseased colon.

Clinical Features

Fatigue, intermittent jaundice, weight loss, right upper quadrant abdominal pain and pruritus. Hepatomegaly/

splenomegaly and jaundice are common findings. Over 50% patients have ulcerative colitis.

Laboratory Investigations

Serum biochemical tests usually indicate cholestasis. IgM concentrations are increased in about 50%. Sixty-five percent patients are positive for perinuclear antineutrophil antibody.

Diagnosis

Radiology—ERCP shows multiple irregular structuring and dilation. Magnetic resonance cholangiopancreatography is a non-invasive method of imaging the biliary tree.

Histology—Early features are periductal ‘onion-skin’ fibrosis and inflammation with portal oedema and bile ductal proliferation. Later fibrosis spreads leading to biliary cirrhosis.

Association with other diseases—UC, Crohn’s colitis, chronic pancreatitis, retroperitoneal fibrosis, Riedel’s thyroiditis, retro-orbital tumors, immunodeficiency states, Sjögren’s syndrome, angioimmunoplastic lymphadenopathy, histiocytosis X, autoimmune hemolytic anaemia.

Management

Treatment of cholestasis—Cholestyramine, dose increased until relief.

Management of complications—Broad spectrum antibiotics for acute attack. If obstruction to hepatic bile ducts, balloon dilatation at ERCP. Cholangiocarcinoma is most dreaded complication (Fig. 1).

Fig. 1: The ERCP images shows a dilated irregular common bile duct with multiple irregular filling defects. There is also a focal area of stricture involving the right main hepatic duct as well as narrowing and irregularity of the common hepatic duct

Specific treatment—UDCA 20–25 mg/kg daily. Combination therapy with immunosuppressive agents may be useful.

Orthotopic transplantation in young patients with advanced liver disease. Development of Cholangiocarcinoma is relative contraindication of liver transplantation.

4. METABOLIC LIVER DISEASE

NON-ALCOHOLIC STEATOHEPATITIS

Non-alcoholic Steatohepatitis (NASH) represents only a part of a wide spectrum of non-alcoholic fatty liver disease (NAFLD). Obesity, diabetes, hyperlipidaemia and female sex are important risk factors. NAFLD ranges from simple steatosis and steatohepatitis to advanced fibrosis and cirrhosis and primary liver cancer. Fibrosis is a dynamic process with continuous matrix deposition and matrix removal. Fibrosis to a large extent is produced by activated hepatic stellate cells (HSE). It is important to detect fibrosis in patients with NASH as patients with fibrosis (rather than with necroinflammation alone) may progress to cirrhosis. If NAFLD related cirrhosis develops annual incidence of primary liver cancer is 1%.

Pathophysiological Basis of Hepatic Steatosis

Table 16 gives the pathophysiological basis of hepatic steatosis.

Clinical Features and Diagnosis

Most patients with NASH have few symptoms and no signs of liver disease.

Table 16: Pathophysiological basis of hepatic steatosis

• Increased delivery of fatty acids to liver
– Obesity
– Starvation
• Increased synthesis of fatty acids in liver
– Excess carbohydrate
• Increased mitochondrial beta-oxidation of fatty acids
– Creatinine deficiency
– Mitochondrial dysfunction
• Decreased incorporation of triglycerides into functional VLDL
• Impaired lipoprotein synthesis
• Impaired cholesterol esterification
– Choline deficiency
– Protein malnutrition
• Insulin resistance
– Increased lipolysis
– Hyperinsulinaemia

Diagnosis of NAFLD relies on:

- Exclusion of other liver diseases by conventional tests.
- Demonstration of widespread fat in the liver by ultrasonography or liver fat quantification.
- Persistent cryptogenic elevation of ALT and glutamyltransferase.
- Transient elastography (FibroScan) measures liver stiffness used as surrogate marker of fibrosis.
- Keratins 8 and 18 (K8/18) are epithelial cytoskeletal proteins, released into the blood as hepatocytes die and studies suggest that serum levels of K8/18 differentiate individuals with NASH from those with simple steatosis or normal livers more reliably than do serum aminotransferase levels. K8/18 levels appear to parallel the severity of liver fibrosis.

Testing for K8/18 has not yet become standard clinical practice.

Management

Aims at reversal of causal factors namely weight reduction, lowering of serum lipids, exercise (improves insulin resistance) and medication to improve insulin resistance.

Fatty Liver

Fatty liver may be macrovesicular or microvesicular (Table 17).

Besides alcohol abuse, fatty liver is observed in obesity, DM (type 2), hypertriglyceridemia, HCV infection, Wilson's disease malnutrition total parenteral nutrition, jejunoileal bypass, rapid weight loss, drugs like corticosteroids, oestrogens, tamoxifen, amiodarone.

Table 17: Macrovesicular vs microvesicular fatty liver

	Macrovesicular	Microvesicular
Prevalence	Common	Uncommon
Nucleus	Large droplet pushes nucleus to one side	Small droplet with nucleus in centre
Causes	Alcohol, Obesity,	Fatty liver of pregnancy,
	Diabetes mellitus, Hypertriglyceridemia, Total parenteral nutrition,	Reye's syndrome, Valproic acid, Tetracycline,
	Malnutrition	Jejunoileal bypass
Computed tomography (CT)	Enlarged liver Diagnostic	May not be enlarged Not accurate
Mortality	Low	High

Table 18: Causes of iron overload

Primary iron overload	
• Hereditary haemochromatosis	
• Congenital aceruloplasminaemia	
• Congenital atransferrinaemia	
Secondary iron overload	
• Parenteral iron loading (blood transfusion, iron dextran infusions, chronic haemodialysis)	
• Iron-loading anaemia (thalassaemia, sideroblastic anaemia, pyruvate kinase deficiency)	
• Post-portacaval anastomosis	
• Prolonged oral iron therapy	
Complex iron overload	
• Juvenile hemochromatosis	
• Neonatal hemochromatosis	
• Alcoholic liver disease	
• Porphyria cutanea tarda	
• Bantu siderosis	

HAEMOCHROMATOSIS

Haemochromatosis is caused by increased iron load in body. Table 18 gives causes of increased iron load in body.

Clinical Features

Haemochromatosis is usually asymptomatic in early stages, but as iron deposition progresses, end-organ damage may lead varied features listed in Table 19.

Juvenile hemochromatosis presents in second decade and in contrast to HCC commonly presents with cardiac failure.

Investigations

- Primary test:* Serum ferritin >400 mg/L in men.
- Supportive test:* Iron saturation > 55%.
- Definitive test:* C282Y, H63D homozygosity.
- Liver biopsy* useful to confirm diagnosis, and measurement of dry-weight liver iron (>1.9 in 90%) (dry-weight liver iron- mcg/gm in homozygotes asymptomatic hemochromatosis 2000–4000 and in symptomatic hemochromatosis 6000–1800).
- LFTs* for assessing hepatic damage (but not presence of disease).

Management

Phlebotomy of 500 mL of blood (200–250 mg iron) once or twice per week until serum ferritin is <50 mg/L; this is

Table 19: Clinical features of haemochromatosis

• Skin pigmentation
• Liver failure
• Fibrosis leads to cirrhosis with risk of hepatocellular carcinoma
• Maturity onset diabetes mellitus
• Arthropathy (commonly affects MCPs, wrists and knees and may be complicated by chondrocalcinosis and pseudogout)
• Cardiac failure or cardiac dysrhythmias
• Anterior pituitary dysfunction (loss of libido may antedate other clinical manifestations)
• Testicular atrophy

maintained by phlebotomy every few months. Anaemia or cardiovascular compromise is managed by removing smaller volumes of blood or by increasing the interval between phlebotomies.

Iron chelating agent deferoxamine can be used. Disadvantage: (1) need to be used parenterally (2) amount of iron removed is 10–20 mg/day which is quite less compared to phlebotomy. Subcutaneous infusion using portable pump is effective method of administration.

Oral iron chelating agent deferasirox is under clinical trial for usage.

End-stage liver disease may be an indication for liver transplantation.

WILSON'S DISEASE

Wilson's disease is an inherited disorder of hepatic copper deposition caused by mutations in the gene *ATP7B* on chromosome 13; pattern of inheritance is autosomal recessive.

Pathophysiology

In Wilson's disease copper is not incorporated into ceruloplasmin within hepatocytes and is not excreted into bile. The level of ceruloplasmin is lower than normal, and because ceruloplasmin contains most of the copper in blood, serum copper levels are low. In addition because copper is not excreted from the liver via the bile, it accumulates in hepatocytes. When hepatocellular storage capacity is exceeded, free copper is liberated into the blood and deposited in various organs, notably the brain, eyes and kidneys. Rarely massive release of copper occurs, leading to acute liver failure, extensive intravascular haemolysis and renal dysfunction.

Table 20: Clinical features of Wilson's disease

Hepatic	
• Asymptomatic hepatomegaly	
• Persistently elevated AST, ALT	
• Fatty liver	
• Acute hepatitis resembling autoimmune hepatitis	
• Decompensated chronic liver disease	
• Fulminant hepatic failure	
Neurological	
• Movement disorders (tremors, poor coordination, loss of fine motor control, cramped handwriting, choreic/choreoathetoid movements with dystonia)	
• Rigid dystonia (mask-like facies, rigidity, gait disturbance, pseudobulbar symptoms such as dysarthria, drooling, difficulty in swallowing)	
Psychiatric	
• Depression	
• Neurotic behaviour	
• Aggressive/antisocial behaviour	
• Emotional lability	
• Impulsive behaviour	
• Poor memory and/or difficulty in abstract thinking	
Eyes	
• Kayser-Fleischer ring*	
Other organs	
• Pancreatitis	
• Arthropathy	
• Mild haemolysis, ± transient jaundice	
• Kidney (renal tubular damage)	
• Infertility or repeated spontaneous abortion	
• Hypoparathyroidism	

*A characteristic golden brown ring around the periphery of cornea due to deposition of copper in the Descemet's membrane of cornea. Visible at times to the naked eye its presence should be confirmed by slit-lamp examination. It tends to disappear with treatment.

Clinical Features

Spectrum of disease in childhood and early adolescence hepatic disease predominates, in late adolescence neuropsychiatric features predominate. See Table 20 for clinical features.

Diagnosis

- Primary test: Ceruloplasmin <10 mg/L.
- Supportive test: Urine/serum copper >80 mg/24 h.

Table 21: Treatment of Wilson's disease

Disease status	First Choice	Second choice
Initial hepatitis or cirrhosis without decompensation	Zinc	Trientine
Hepatic decompensation		
Mild	Trientine and Zinc	Penicillamine and Zinc
Moderate	Trientine and Zinc	Liver transplant
Severe	Trientine and Zinc	Liver transplant
Initial neurologic/psychiatric	Tetrathiomolybdate and Zinc	Zinc
Maintenance	Zinc	Trientine
Presymptomatic	Zinc	Trientine
Pediatric	Zinc	Trientine
Pregnant	Zinc	Trientine

- Definitive test: Liver biopsy with quantitative copper >200 µg/g dry weight.

Management

Treatment is life-long

- *Avoidance of alcohol and major sources of dietary copper*
- **Drugs**

D-penicillamine. About one-third of patients have to change to a different chelator because of side effects including skin disorders, protein-losing nephropathy, lupus-like systemic inflammatory conditions and bone marrow suppression.

Trientine is an alternative to penicillamine, it has fewer adverse effects.

Zinc 50 mg t.d.s. depletes total body copper stores by inducing enterocyte metallothionein, which binds copper avidly. Gastritis is occasionally a problem.

Vitamin E is a useful adjuvant therapy.

Treatment is summarised in Table 21.

The anticopper effects of trientine and penicillamine can be monitored by following 24-h "free" serum copper levels.

Liver transplantation is indicated in patients with fulminant hepatic failure or liver disease unresponsive to standard treatment.

ALPHA-1 ANTITRYPSIN DEFICIENCY

Alpha-1 antitrypsin is an enzyme α_1 globulin produced by the liver. It's an acute phase reaction and is released in

response to acute inflammation. Its deficiency is associated with liver disease and emphysema. There are multiple variants. The variant is expressed as an allele from both parents. Therefore, a person may have one or two forms of α -1 antitrypsin in the blood. One variant called Z, because of its unique electrophoretic mobility on gel, is the product of a single amino acid gene mutation from the wild type protein (m). The Z protein is difficult to excrete from the liver cell and causes local damage that may result in hepatitis and cirrhosis.

Clinical Features

- (a) In neonates α ₁-AT deficiency produces cholestatic jaundice.
- (b) In adults manifestations are
 - Chronic hepatitis
 - Cirrhosis
 - Hepatocellular carcinoma
 - Emphysema
 - Chronic bronchitis
 - Others - Colitis, pancreatitis, glomerulonephritis

Diagnosis

- (a) Serum protein electrophoresis - Absence of α ₁-globulin peak.
- (b) Low plasma α ₁-AT concentration (normal 150 gm/dL).
- (c) Liver biopsy - shows α ₁-AT containing globules in the liver.

Treatment

- (a) No smoking, alcohol.
- (b) In pts older than 18 years with airway obstruction, α ₁-AT derived from pooled human plasma given IV.
- (c) Transplantation of liver or lung.

5. HEPATIC ENCEPHALOPATHY

Hepatic encephalopathy is a reversible state of impaired cognitive function or altered consciousness. It may complicate acute or chronic liver disease. Two abnormalities hepatocellular failure and portosystemic shunting tend to be present in those in whom encephalopathy develops.

PATHOGENESIS

Hepatic encephalopathy arises as a result of a gut-derived neurotoxin that bypasses the liver to gain access to the CNS, crossing an abnormal blood-brain barrier. It appears

that ammonia and other substances trigger a cascade of events in the CNS, the combination of which produces hepatic encephalopathy.

Ammonia hypothesis—Ammonia might exert its effect on the glutamine-glutamate cycle. Glutamate is an important excitatory neurotransmitter; after reacting with post-synaptic receptors, it is converted within astrocytes to glutamine by glutamine synthetase. In hepatic encephalopathy, cerebral glutamate levels are decreased, glutamate re-uptake mechanisms are abnormal. Increased glutamine in astrocytes causes osmotic stress leading to cellular swelling.

γ -aminobutyric adrenergic benzodiazepine receptor hypothesis— γ -aminobutyric acid (GABA), benzodiazepine receptor antagonists and neurosteroid may trigger hyperpolarization and subsequent inhibitory effects. Ammonia has an enhancing effect on these stimuli.

Branched-chain amino acid/aromatic amine and false neurotransmitter theory—The branched-chain amino acid: aromatic amino ratio is altered in hepatic encephalopathy. Aromatic amines like tryptophan gain access to the brain and promote production of false neurotransmitters such as serotonin which affects consciousness and the sleep-wake pattern.

Other contributing substances are short-chain and long-chain fatty acids, and mercaptan acting as false neurotransmitters.

Altered glioneuronal communication as a result of low grade astrocyte swelling is one of the terminal events in pathogenesis of HE.

CLINICAL CLASSIFICATION

Although hepatic encephalopathy has a wide range of manifestations, it is important to differentiate between the two common types, which differ in prognosis, severity, pathophysiology and management. In acute liver failure, the shorter the interval between jaundice and encephalopathy, then it is more likely that cerebral oedema may be a major cause of death if fulminant hepatic failure is to occur.

CLINICAL FEATURES

- Altered consciousness (abnormal sleep pattern, drowsiness or coma)
- Monotonous speech
- Intellectual disturbances and behaviour changes
- Asterixis
- Feter hepaticus
- Decerebrate posturing

Table 22: Precipitating causes of hepatic encephalopathy

• Upper gastrointestinal bleeding
• Electrolyte imbalance (hypokalaemia, metabolic acidosis) Diuresis Vomiting Diarrhoea
• Infection
• Spontaneous bacterial peritonitis Urinary Chest
• Drugs Sedatives Alcohol withdrawal
• Constipation
• Ingestion of a large protein meal
• Paracentesis
• Acute liver injury
• Creation of portocaval shunts (e.g portosystemic surgery, transjugular intrahepatic portosystemic stent shunt)
• Kidney failure
• Trauma

Clinical Types

- In acute liver failure, the shorter the interval between jaundice and encephalopathy, cerebral oedema is likely to occur.
- Encephalopathy complicating cirrhosis and portosystemic shunt develops as a result of a specific precipitating cause or a deterioration of liver function which results in acute, subclinical or chronic encephalopathy but is almost never complicated by cerebral oedema.

PRECIPITATING CAUSES

Precipitating causes of hepatic encephalopathy are listed in Table 22.

Criteria for grading mental symptoms in hepatic encephalopathy is given in Table 23.

INVESTIGATIONS

Laboratory tests: Full blood count, urea, creatinine, sodium, potassium, calcium, glucose and liver function tests. Blood ammonia.

Abdominal paracentesis to exclude spontaneous bacterial peritonitis.

Ultrasonography to exclude thrombosed portal vein and hepatoma.

EEG: Classically shows bilateral, synchronous slowing of frequency from alpha to theta (4–7 Hz) or even to the

Table 23: Grading of hepatic encephalopathy

• Grade 0	No abnormality detected
• Grade 1	Trivial lack of awareness, euphoria, anxiety Reduced attention span Impaired performance in addition or subtraction Altered sleep rhythm
• Grade 2	Lethargy, apathy, disorientation for time and place Obvious personality change Inappropriate behaviour Dyspraxia and asterixis
• Grade 3	Somnolence to semi-stupor, but responsive to stimuli Confusion Gross disorientation Bizarre behaviour
• Grade 4	Coma

Table 24: Management principles of hepatic encephalopathy

Identification and correction of precipitant
Stop diuretics
Empty bowel of nitrogen content
Control bleeding
Protein-free diet
Drugs (see Table 25)
Reversal or reduction of artificially created shunt (particularly TIPS)
Liver transplantation

delta range (< 4 Hz), but these abnormalities are not specific for encephalopathy.

MANAGEMENT

Management principles of hepatic encephalopathy are given in Table 24.

MINIMAL HEPATIC ENCEPHALOPATHY

Minimal hepatic encephalopathy (MHE) is a condition in which patients with cirrhosis of liver that has normal mental and neurological states on standard clinical examination exhibit a number of neuropsychiatric and neurophysiological defects and may progress to HE.

Pathogenesis

Ammonia-induced alterations in cerebral blood flow and glucose metabolism have shown that there is a significant decrease of glucose utilization of various cortical regions that correlate with the patients cognitive functions.

Table 25: Drugs for the treatment of hepatic encephalopathy

Drug	Dose	Comments	Adverse-effects
<i>Ammonia hypothesis</i>			
<i>Disaccharides</i>			
Lactulose	15–30 mL po tds or qds. 300 mL enema plus water 700 mL or 20% lactulose (total 1 L) tds.	Aim for 2–3 stools/d. Enema if pt. comatose or has ileus, or it cannot be given. Reduces colonic-pH and accelerates GI transit.	Bloating, diarrhoea and dehydration if overdose
Lactitol	0.3–0.5 g/kg/d po 20% lactitol (total 1 L) enema bd or tds	As effective as lactulose	Bitter tastes, less side effects
<i>Antibiotics</i>			
Neomycin	2–4 g/d in divided doses	Maximum 48 hours Alters gut flora	Long-term use can cause nephrotoxicity and ototoxicity
Metronidazole	500–800 mg/d in divided doses	Metabolism impaired in liver disease	GI disturbance
Vancomycin	100 mg po bd	Safe in renal insufficiency	
Rifaximin	550 mg BD		Peripheral neuropathy
<i>Combined disaccharide and neomycin</i>			
Lactulose and neomycin		Additive anti-encephalopathic effect. Both reduce absorption of intestinally derived toxins.	Neomycin potentially nephrotoxic
Sodium benzoate	5 g po bd	Increases ammonia excretion	Nausea/vomiting, abdominal discomfort
Ornithine aspartate	20 g iv in 250 mL 5% fructose od	Increases ammonia excretion	Nausea, vomiting
<i>Gamma-aminobutyric acid / benzodiazepine receptor complex</i>			
Flumazenil	1–2 mg bolus iv	May be effective in benzodiazepine- induced hepatic encephalopathy	Flushing, nausea, vomiting, irritability
<i>False neurotransmitters / dopaminergic neurotransmission</i>			
Branched-chain amino acids	1–1.2g/kg/d po	Protein supplement in patients with protein intolerance No clear beneficial effect	
Bromocriptine	PO	No clear beneficial effect	
L-dopa	PO		
<i>Other agents</i>			
Zinc	600 mg/d po	Zinc is a component of urea cycle enzymes, and deficiency is common in cirrhosis	

Diagnosis

- Psychometric tests.
- Neurophysiological, e.g. EEG, evoked potentials, Critical Flicker Frequency (CFF) and MR spectroscopy.

Management

- Branched chain amino acids (BCAAs) may improve nitrogen metabolism, blood ammonia level and psychomotor tests.
- L-ornithine L-aspartate (OA) exerts its ammonia lowering action on kidneys, skeletal muscles, brain and also the liver.

- Lactulose lowers ammonia levels by alteration in gut flora, lowers colonic pH and decreases absorption of ammonia by non-ionic diffusion.

- Probiotics.

6. ACUTE LIVER FAILURE

Acute liver failure is defined as evidence of coagulation abnormality, usually an International Normalized Ratio (INR) ≥ 1.5 , and any degree of mental alteration (encephalopathy) in a patient without preexisting cirrhosis and with an illness of <26 weeks duration.

Table 26: Causes of acute liver failure

Viral hepatitis
Viral hepatitis A, B, D and E
Drugs and toxins
<i>Predictable</i>
Paracetamol
Mushrooms
Carbon tetrachloride
Zinc phosphide (rat killer)
Idiosyncratic
Anti-TB drugs (isoniazid, rifampicin)
Sulphonamides
NSAIDs (diclofenac)
Ketoconazole
Tricyclic antidepressants
Anti-epileptics (sodium valproate, carbamazepine, phenytoin)
Flutamide
Miscellaneous
Wilson's disease
Pregnancy-related syndromes
Budd-Chiari syndrome
Lymphoma
Sepsis
Hyperthermia
Hepatic ischaemia

CLASSIFICATION

- Hyperacute—Jaundice (Illness) for <7 days before onset of encephalopathy (e.g. paracetamol poisoning)
- Acute—Jaundice (Illness) for 8–28 days (7–21 days) before onset
- Subacute—Jaundice (Illness) for 4–12 weeks (21 days to 26 weeks) before onset

CAUSES

Table 26 enumerates causes of acute liver failure. Hepatitis B is the most common cause with or without hepatitis D. Hepatitis E is most lethal in pregnant women.

CLINICAL FEATURES

Encephalopathy—It is the usual presentation. Hypoglycaemia may impair consciousness before onset of encephalopathy.

Other signs of liver dysfunction—Flappy tremor and encephalopathy following acute liver failure ranges from mild drowsiness to complete unresponsiveness. Fetor is usually absent. Because of rapid onset, patients with hyperacute liver failure may not be overtly jaundiced.

Involvement of other systems

- CVS Hypertension (with cerebral oedema)
Hypotension
Tachyarrhythmias
Bradycardia
- Fever—Due to liver necrosis or infection
- Kidney failure—Early with paracetamol overdose, at later stage in other etiologies
- Respiratory failure—Mainly due to infection, fluid overload and adult respiratory distress syndrome, but aspiration and pulmonary hemorrhage may contribute.
- Coagulopathy—May manifest as bleeding from puncture sites and urinary and GI tracts.

INVESTIGATIONS

Tests for infection—Blood screened for acute hepatitis A and B by testing for anti-HAV IgM and anti-HBc IgM respectively. Also herpes simplex serology. HIV serology testing.

Toxicology screen, drug history, autoimmune markers (ANA and ASMA levels), ceruloplasmin level (if patient age is <40 years).

Ultrasonography and CT—For patency of hepatic veins, malignant infiltration and estimate of liver volume.

Prothrombin time and serum bilirubin, aminotransferase levels, serum albumin, serum creatinine, electrolyte levels.

MANAGEMENT

Drugs—(a) N-acetylcysteine is the only drug with a proven role. Its metabolism produces glutathione which detoxifies the toxic molecule. (b) Sucralfate to reduce bleeding from gastric erosions. (c) Vitamin K parenterally to patients who have been jaundiced for more than 2 weeks.

Inotropic support—Combination of noradrenalin or dopamine with N-acetylcysteine or prostacyclin.

Treatment of complications:

Table 27 summarises treatment of complications.

Liver transplantation—It has a survival rate of more than 60%. Auxiliary liver transplantation for a subgroup of patients who have the capacity to regain normal function in the native liver.

Other techniques—Extracorporeal circuits incorporating viable hepatocytes to offer artificial liver support. These devices aid recovery by acting as a bridge to transplantation, with or without a preliminary hepatectomy which often temporarily stabilises critically ill patients.

Table 27: Treatment of complications

Complication	Management
Intracranial hypertension and neurohypoxaemia	Intensive monitoring Minimize auditory and tactile stimuli
Subclinical seizures	Mannitol, barbiturates, inotropes, hyperoxygenation
Kidney failure	Continuous hemofiltration
Infection	Intensive treatment with systemic antimicrobials
Hypotension	Vasopressors with N-acetylcysteine or prostacyclin
Hypoglycaemia	Hourly blood glucose estimations
Respiratory failure	Early ventilatory support NO inhalation in severe cases
Coagulopathy	Treat clinical coagulopathy Platelet count to be watched
Pancreatitis	High index of suspicion required May contraindicate transplantation if severe
Malnutrition	Parenteral feeding
Electrolyte abnormalities	Tr. of sodium, potassium, phosphate, magnesium deficiency
Acid-base abnormalities	Metabolic alkalosis dominates (except in paracetamol poisoning)

7. JAUNDICE

It is a symptom complex characterized by increase of bile pigments in body fluids and tissues. Jaundice is perceptible only when the level of bilirubin and its conjugates exceeds 1.5 mg per 100 mL plasma. In its mildest form it is recognized by yellow discolouration of sclera. With deeper jaundice the skin and mucous membrane are also stained.

NORMAL BILIRUBIN METABOLISM (FIG. 2)

- Breakdown phase**—Haemoglobin breakdown occurs in the reticuloendothelial system forming the bile pigment bilirubin which is transported in the blood stream attached to albumin.
- Conjugation phase**—Unconjugated bilirubin is conjugated by the endoplasmic reticulum enzyme of the hepatocytes glucuronyl transferase, into bilirubin mono- and diglucuronide. These bilirubin conjugates are water soluble and transported into the bile via specific carriers on the hepatocyte membrane. Deep jaundice is always predominantly conjugated.

**Fig. 2: Normal bilirubin metabolism**

- Alimentary excretion phase**—The bilirubin is excreted through the bile canaliculi and so reaches the intestines, where it is converted into stercobilinogen, by bacterial action. A large part is reabsorbed from the intestine into portal blood and carried back to the liver and re-excreted into the bile (enterohepatic circulation of bile pigments). Stercobilinogen which is not absorbed is excreted in the stool.

TYPES OF JAUNDICE

Jaundice is best sub- divided into unconjugated and conjugated types. Deep jaundice is always predominantly conjugated.

Causes of Unconjugated Jaundice

- Increased bilirubin production results** from any form of haemolysis whether congenital, e.g. hereditary spherocytosis sometimes termed 'acholuric jaundice' to emphasize absence of bile in urine, or acquired (e.g. malaria).
- Impaired hepatic uptake of bilirubin:** Drugs are the main cause; they compete for protein binding or for the uptake receptor.
- Impairment of glucuronyl transferase:** The enzyme that converts bilirubin into a water-soluble glucuronide suitable for excretion into bile is immature in premature babies, and is congenitally absent (type I) or reduced in (type II) Crigler-Najjar syndrome. Isolated mild unconjugated jaundice in absence of liver enzyme abnormalities, almost always results from Gilbert's syndrome.

Table 28: Clinical classification and causes of jaundice**1. Hepatocellular jaundice****Acute:**

- Viral hepatitis
- Hepatic immaturity
- Drug hepatitis
- Alcoholic hepatitis
- Leptospirosis
- Infectious mononucleosis
- Yellow fever

Chronic:

- Cirrhosis
- Congenital hyperbilirubinaemias

2. Obstructive jaundice

Without mechanical obstruction:

Acute:

- Drugs, e.g. chlorpromazine
- Viral hepatitis with cholestasis
- Pregnancy (first 3 months)

Chronic:

- Primary biliary cirrhosis

With mechanical obstruction:

Intrahepatic:

- Intrahepatic neoplasms and reticulosis
- Congenital obliteration of bile ducts

Extrahepatic (Surgical jaundice):

- *Inside duct:* Gallstones, foreign body (broken T-tube), parasites (ascaris, hydatid).
- *In duct wall:* Congenital atresia, stricture, tumour of bile duct, sclerosing cholangitis
- *Outside duct:* Carcinoma head of pancreas or ampulla of Vater, metastasis in porta hepatitis, chronic pancreatitis.

3. Hemolytic jaundice**Causes of Conjugated Jaundice**

- In most cases of acquired liver disease, whether acute hepatitis or cirrhosis, jaundice is predominantly conjugated and accompanied by dark urine.
- In most cases cholestasis is the most common pattern of drug-induced jaundice. Common causes of extrahepatic cholestasis are bile duct stones and malignant bile duct obstruction (e.g. pancreatic cancer).

CLINICAL CLASSIFICATION

Three types but combinations can occur (Table 28).

Table 29: Differentiating features between types of jaundice

	<i>Hepatocellular</i>	<i>Obstructive</i>	<i>Hemolytic</i>
Colour of jaundice	Orange yellow	Greenish yellow	Lemon yellow
Depth of jaundice	Variable	Deep	Mild
Pruritus	Variable	Present	Absent
Bleeding tendency	Present	Present (late)	Absent
Bradycardia	Absent	Present	Absent
Anaemia	Absent	Absent	Present
Splenomegaly	Variable	Absent	Present
Palpable GB	No	May be present	No
Features of hepatocellular failure	Present (early)	Present (late)	Absent

Hemolytic jaundice—Results from increased destruction of RBCs or their precursors in the marrow, causing increased bilirubin production. A healthy liver can excrete a bilirubin level 6 times greater than normal before unconjugated bilirubin accumulates in the blood.

Increased destruction of RBCs or their precursors in the marrow, causing increased bilirubin production (See hemolytic anaemias). A healthy liver can excrete a bilirubin level 6 times greater than normal before unconjugated bilirubin accumulates in the blood.

Table 29 gives differentiating features between types of jaundice.

(a) Symptoms and signs:

- Anaemia - may vary from time to time developing rapidly with hemolytic crisis.
 - Jaundice usually mild and of a lemon yellow tint. No pruritus.
 - Pigmented gallstones may be associated with features of chronic cholecystitis.
 - Splenomegaly in chronic forms.
 - Ulcers or pigmentation from healed ulcers usually over the malleoli in some cases.
- Haematology**—Anaemia variable, anisocytosis, stippling, target cells. Reticulocytes increased. Leucocytosis common.
 - Stools**—Dark in colour due to increased stercobilinogen.
 - Urine**—Urobilinogen increased only during crisis. Haemoglobinuria if rapid blood destruction.
 - Serum biochemistry**—Serum unconjugated bilirubin raised (usually 1–3 mg/100 mL serum). Serum conjugated bilirubin slightly raised.

OTHER CAUSES OF JAUNDICE

1. **Portal cirrhosis**—(a) Jaundice usually slight and transient. (b) Liver enlarged, may be tender. (c) Long history of dyspeptic symptoms. (d) Hematemesis common.
2. **Amoebic abscess**—(a) History of amoebic dysentery may be obtained. (b) Liver enlarged and tender. Compression tenderness. (c) Jaundice slight. (d) Remittent fever. (e) Excessive sweating. (f) Rapid response to metronidazole or tinidazole.
3. **Acute alcoholic hepatitis**—History of heavy consumption of alcohol. Anorexia, weight loss, weakness and right upper abdominal pain. Jaundice. Liver enlarged and tender. Spleen may be palpable. Fever and mild anaemia.
4. **Drug-induced jaundice**—It can be in the form of acute hepatitis, cholestasis or steatosis.
5. **Autoimmune hepatitis**—It occurs typically in young women who present with jaundice of sudden onset and features of chronic liver disease. Other organs are involved and autoimmune phenomena are associated.
6. **Infectious mononucleosis**—(a) Jaundice between 5 to 14 days after onset of illness. Mild and transient. (b) Liver seldom palpable. (c) Pyrexia persisting in spite of subsidence of jaundice. (d) Late glandular enlargement. (e) Typical blood changes. (f) Positive Paul-Bunnell test.
7. **Malaria**- Jaundice with associated liver dysfunction can be seen in severe cases of *Plasmodium falciparum* malaria. The jaundice in these cases is due to a combination of indirect hyperbilirubinemia from hemolysis and both cholestatic and hepatocellular jaundice.

Investigation of a Case of Jaundice

History

Personal History:

Sex: More in males:

Ca pancreas
Liver cirrhosis
Hepatoma

Occupation:

Sexual association:

Family history

More in females:

Common duct stones
Primary biliary cirrhosis
Ca gallbladder
Exposure to alcohol
Infection in medical and paramedical
Diseases associated with male homosexuality
Familial tendency in congenital hyperbilirubinemia
Hemolytic jaundice
Gallstones
Family contacts with other jaundiced patients

Past history

- Hepatotoxic drugs
- Blood transfusion
- Renal dialysis
- Alcohol consumption
- Biliary surgery
- Sepsis: pneumonia or urinary tract infection

Duration of jaundice

< 1 month
1-2 months
> 2 months

Jaundice progression

Progressive
Fluctuating

Persistent mild jaundice of varying intensity

Viral hepatitis
Autoimmune hepatitis, Carcinoma
Chronic liver disease

Malignant obstruction
Stone in common bile duct
Carcinoma ampulla of Vater
Recurrent hemolytic episodes

Symptoms

- Anorexia and weight loss
- Abdominal pain
 - Colicky
 - Epigastric radiating through back
- Fever
- Chills and rigor
- Pruritus
- Backache
- Dry eyes/mouth
- *Colour of stool*
 - Clay coloured
 - Cholic and acholic alternately
 - Acholic persistent
 - Brown stools with deep jaundice
 - Tarry stools with jaundice
- *Colour of urine*
 - Dark
 - Hepatocellular jaundice

- Malignancy
- Cirrhosis
- Common duct stone
- Extrahepatic biliary obstruction
- Acute pancreatitis
- Ca pancreas
- Posterior penetrating duodenal ulcer
- Viral hepatitis
- Cirrhosis
- Acute cholecystitis
- Cholangitis
- Amoebic liver abscess
- Obstructive jaundice
- Intrahepatic cholestasis
- Pancreatic disease
- Sjögren's syndrome (associated with biliary cirrhosis)
- Acute viral hepatitis (for few days)
- Common duct stone
- Neoplasm
- Parenchymal jaundice
- Ca of ampulla of Vater
- Ca pancreas invading stomach or duodenum
- Cholestasis

General Physical Examination*Depth of jaundice*

- Orange-yellow
- Pale yellow tint
- Greenish-yellow

Signs of chronic liver disease

- Liver cell jaundice
- Hemolytic jaundice
- Obstructive jaundice
- Palmar erythema
- Clubbing
- White nails
- Gynecomastia
- Dupuytren's contracture

Skin changes

- Vascular spiders
- Greyish pigmentation
 - Trunk
 - Skin folds
- Acneform vesicular rash

- Hepatocellular jaundice
- Biliary cirrhosis
- Hemochromatosis
- Acute viral hepatitis
- Autoimmune hepatitis

Xanthoma	Long-standing cholestasis
Other rashes	Primary biliary cirrhosis (on elbows and palms)
Purpura	Drug reaction
Absent sexual hair	Manifestation of systemic disease possibly cirrhosis
Pigmented shins	Cirrhosis
Tumour deposits	Congenital spherocytosis
<i>Anaemia</i>	Malignancy
	Haemolysis
	Cirrhosis
	Malignancy
<i>Personality changes</i>	Hepatocellular jaundice
<i>Breath</i>	Faecal odour in liver failure
<i>Conjunctival suffusion</i>	Leptospirosis
<i>Peripheral oedema</i>	Portal hypertension
	Hypoproteinemia
<i>Features of alcoholism</i>	Parotid enlargement
	Dupuytren's contracture
	Gynecomastia
	Soft testes
	Fine tremors
<i>Chipmunk facies</i>	Hemolytic anaemia
Local Examination	
<i>Abdominal</i>	
Periumbilical veins	Cirrhosis
<i>Liver</i>	
• Size	Malignant deposits
Massive	Obstructive jaundice
Moderate	Hepatitis
	Cirrhosis
	Fatty infiltration
• Tenderness	Viral hepatitis
	Amoebic abscess
	Alcoholism
	Bacterial cholangitis
	Malignancy (rarely)
• Nodularity	Cirrhosis
	Hepatoma
	Hepatic syphilis
• Bruit	Primary hepatocellular tumour
	Alcoholic hepatitis
<i>Gallbladder</i>	
• Nontender palpable	Neoplastic obstruction of bile duct
• Firm or hard	Ca gallbladder

- Not palpable with cholestatic jaundice

Splenomegaly

Abdominal mass

Ascites

Lymphadenopathy

Xanthomata

Investigations

White cell count

- Leucopenia
- Leucocytosis
 - Eosinophilia
 - Atypical WBCs

Urine

- Urobilinogen
 - Absent
 - Excess
- Bilirubin
 - Absent
 - Excess

Faeces

- Occult blood

Viral markers

Liver function tests

- Hemolytic jaundice

- Liver cell jaundice

- Cholestasis

Shrunken GB with stone blocking common bile duct (Courvoisier's law)

Block in common bile duct above level of cystic duct

Hemolytic jaundice

Hepatitis acute or chronic

Cirrhosis

Protracted obstruction of common bile duct by stone or tumour

Malignancy

Cirrhosis

Peritoneal tumour implants

Portal obstruction due to tumour

Infectious mononucleosis

Lymphoma

Acute lymphoblastic leukaemia

Disseminated TB

Biliary obstruction

Biliary cirrhosis

Hepatocellular jaundice

Cholangitis, gallstones, carcinomatosis

Drug-induced jaundice

Infectious mononucleosis

Common bile duct obstruction

Hemolytic jaundice, liver cell disease

Hemolytic jaundice

Obstructive jaundice

Ampullary, pancreatic or alimentary tract Ca or portal hypertension

For viral hepatitis, cytomegalo and Epstein-Barr

Unconjugated hyperbilirubinaemia

No bilirubin in urine

Other LFTs usually normal

Elevated total and conjugated bilirubin

Raised serum transaminases

Reduced albumin in chronic jaundice

Raised serum alkaline phosphatase

Prolonged PT (corrected by vitamin K)

Indeterminate patterns

Fatty change
Cirrhosis
Hemochromatosis
Autoimmune hepatitis
Malignancy

Additional blood tests

For hemolytic jaundice

Hb and absolute values, reticulocyte count, blood film and immature cells, erythrocyte fragility, Coomb's test, bone marrow examination, transfused red cells survival studies

Immunological tests

(Refer)

Unusual cases of hepatitis

Infectious mononucleosis (Paul-Bunnell)

Toxoplasmosis (Toxoplasma dye test)

Cytomegalovirus (Cytomegalic complement fixation test)

Radiography

- CXR
- Plain X-ray abdomen
- Barium swallow
- Barium meal

May reveal metastasis

Gallstones

Oesophageal varices in cirrhosis

Widening of C loop of duodenum or displacement of duodenum by pancreatic tumour (inverted 3 sign)

Liver imaging

Ultrasonography

Dilated bile ducts seen as irregular tortuous tubes with poor wall echoes

Obstructive jaundice (too many tubes sign)

Common hepatic duct > 4 mm diameter or common bile duct

Differentiation of 'medical' from 'surgical' jaundice

> 7 mm diameter

Denotes obstruction

Intrahepatic bile ducts

High obstruction

dilated and GB and extrahepatic

biliary tree collapsed

CT scan

Gallbladder

Gallstones

Malignant obstruction

Arterial

Pancreatic tumors

Liver metastasis

Invasion of vessels, tumour vessels and vascular displacement

Venous

Occluded hepatic veins

Portal vein imaging

Fig. 3: Abdominal CECT with pancreatic malignancy (long arrows) with metastasis in liver (arrow heads)

Fig. 4: Abdominal CECT showing multiple hypodense liver abscesses (arrows)

Liver biopsy

Characteristic histology in acute hepatitis, cirrhosis, changes due to obstruction of common bile duct, liver malignancy, drug-induced jaundice.

Endoscopy

Gastroscopy
Duodenoscopy and cannulation
Laparoscopy

Varices
Visualization of bile ducts and biliary tree
Tumour nodules on liver
Large GB with dark green liver due to extrahepatic biliary obstruction.
Hobnail liver in cirrhosis
Pale yellowish-green liver suggestive of hepatitis
If extrahepatic cause for cholestasis, or diagnosis is in doubt.

Laparotomy

8. CIRRHOSIS OF LIVER

The term cirrhosis is applied to chronic diffuse liver disease of varied aetiology, and characterised by hepatic cell necrosis, proliferation of connective tissue and nodular regeneration, or in other words abnormal reconstruction of lobular architecture, and disturbed hepatic circulation.

PATHOLOGICAL CLASSIFICATION

- Micronodular cirrhosis** (portal or alcoholic cirrhosis). Characterised by thick, regular bands of connective tissue, by regenerating small nodules of almost same size and involvement of every lobule of the organ.
- Micronodular coarse cirrhosis** (post-necrotic). Liver reduced in size. Nodules of regenerating liver cells of different sizes intersected by fibrous bands of varying thickness containing proliferating bile ducts.

- Mixed micronodular and macronodular**—following bile duct stricture and minimal liver cell failure and portal hypertension.

AETIOLOGY OF CIRRHOSIS

Various aetiologies of cirrhosis are listed in Table 30.

Clinical features of cirrhosis depend mainly on:

- Liver cell dysfunction
- Portal hypertension

Onset

- Vague* with anorexia, dyspepsia, weight loss, malaise and loss of libido.
- Dramatic* with jaundice, ascites or haematemesis.
- Asymptomatic* with hepatomegaly
- Miscellaneous*—Swelling of ankles, diarrhoea, low grade fever.

Table 30: Aetiologies of cirrhosis

• <i>Viral hepatitis B and C</i>
• <i>Alcohol</i>
• <i>Cryptogenic</i>
• <i>Metabolic:</i>
Hemochromatosis
Wilson's disease
α_1 -antitrypsin deficiency
Cystic fibrosis
Glycogen storage disease
Galactosaemia
• <i>Biliary obstruction</i>
Primary biliary cirrhosis
Sclerosing cholangitis
Secondary biliary cirrhosis
• <i>Venous outflow obstruction</i>
Budd-Chiari syndrome
Veno-occlusive disease
Congestive heart failure
• <i>Drugs</i>
Methotrexate
Methyldopa
Oxyphenisatin
Amiodarone
• <i>Indian childhood cirrhosis</i>

Hepatic

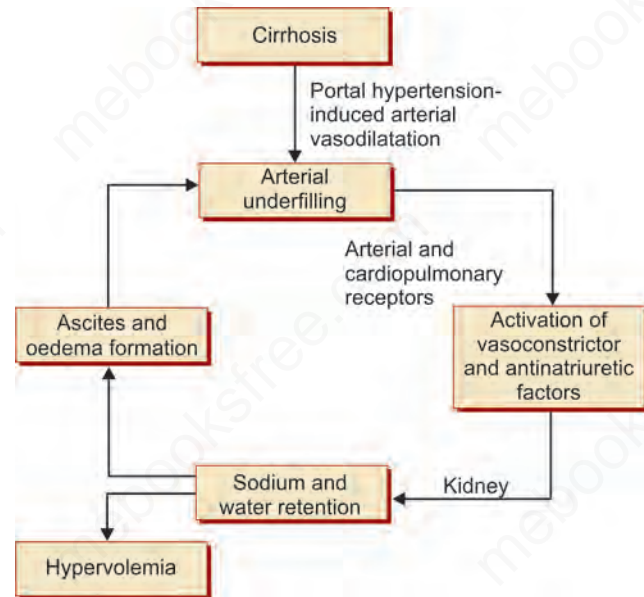

- **Hepatomegaly**—Liver may be palpable, non-tender, shrinks as disease advances.
- **Jaundice**—Uncommon, when present it may be due to hepatocellular failure or intrahepatic cholestasis.
- **Ascites**

Signs of ascites correlated to fluid quantity

CT scan - 80 mL
Ultrasound - 100 mL
Penfield methods - 120 mL
Puddle sign - 150 mL
Shifting dullness - 1-1.5 litres
Horse-shoe shaped dullness - 2-3 litres
Fluid thrill - > 3 litres

PATHOGENESIS OF ASCITES IN CIRRHOSIS (FIG. 5)

1. **Renal**—Liver failure leads to decrease in renal blood flow which then results in reduction of GFR and resorption of salt and water by renal tubules, thus salt and water retention.
2. **Secondary hyperaldosteronism**—Increased levels of renin which stimulates the angiotensin renal system

**Fig. 5:** Ascites formation in cirrhosis

which then causes secondary hyperaldosteronism causing salt and water retention.

3. **Vasopressin**—Vasopressin cannot be metabolised by liver, hence kidney water output is reduced.
4. **Increased capillary hydrostatic pressure** due to portal hypertension causing localization of fluid within peritoneal cavity.
5. **Reduced plasma osmotic pressure** due to hypoalbuminuria which once again causes extravasation of fluid, ascites and oedema.
6. **Hepatic lymph** oozes out from the surface of cirrhotic liver, this with portal hypertension adds to development of ascites.

SPONTANEOUS BACTERIAL PERITONITIS (SBP)

Spontaneous bacterial peritonitis is characterized by spontaneous infection of ascitic fluid without any intra-abdominal surgically treatable cause and is a severe complication of ascitic. In adults it occurs frequently in association with cirrhosis of liver, other causes are metastatic malignant diseases, chronic active hepatitis, congestive heart failure, acute viral hepatitis, SLE, lymphedema and in patients with no underlying cause.

The pathogenesis of SBP is bacterial translocation from the gut to mesenteric lymph nodes leading to bacteremia and seeding of ascitic fluid. This is facilitated by a diseased liver and altered portal circulation.

Table 31: Causes of abdominal pain in cirrhosis

TB peritonitis
Spontaneous bacterial peritonitis
Peptic ulcer
Chronic cholecystitis (pigment gallstones)
Portal vein thrombosis
Pancreatitis (with alcoholic cirrhosis)
Hepatoma
Zieve's syndrome (alcoholic) (Acute haemolysis, Acute alcoholic hepatitis, Hyperlipidaemia)

Causes of rapid development of ascites:

1. Decompensating event - GI bleeding or sepsis.
2. Sudden exacerbation of necroinflammatory activity in liver, e.g. seroconversion in a chronic hepatitis B carrier with a 'hepatitis flare'.
3. Alcohol abuse.

CLINICAL FEATURES**Gastrointestinal**

- *Haematemesis*—Due to rupture of oesophageal varices
- *Peptic ulcer*
- *Parotid enlargement*
- *Pancreatitis*
- *Chronic cholecystitis*
- *Portal vein thrombosis*
- *Abdominal pain in cirrhosis* (Table 31)

Endocrine

Male—Gynecomastia, testicular atrophy, feminisation, reduced body hair, impotence.

Female—**Lowered libido and usually atrophy of the breasts.**

Haematological

- *Purpura*
- *Anaemia* may be caused by—(i) bleeding, (ii) impaired conversion of folic acid into folinic acid, (iii) impaired metabolism of vitamin B12, (iv) haemolysis and (v) malnutrition.

Dermatological and Musculoskeletal

- *Arterial spiders* (Spider naevi)
- *Palmar erythema* (Liver palms)

- *Alopecia*—Loss of pubic, axillary and facial hair; women may rarely develop masculine distribution of body hair.
- *Nails*—White due to opacity of nail bed. Muehrcke's bands—white transverse bands across the nails if hypoalbuminemia. Clubbing may occur.
- *Paper money skin*—Often associated with arterial spiders and in a similar distribution are numerous small vessels scattered in the skin.
- *Dupuytren's contracture.*
- *Muscle atrophy.*
- *Erythema nodosum.*

Circulatory

- *Hyperdynamic circulation* due to increased blood volume, associated anaemia, A-V shunting within the lungs and excessive vasodilator material due to failure of detoxification by the damaged liver.
- *Clubbing*
- *Cyanosis*

Neurological

- *Porto-systemic encephalopathy*
- *Peripheral neuropathy*

HEPATORENAL SYNDROME

(Functional renal failure)—This azotaemia syndrome is renal failure with normal kidney function in a patient with chronic liver disease. It is due to reduction in effective circulatory volume and renal blood flow and usually affects patients of alcoholic cirrhosis. The kidney is normal histologically and functions normally if transplanted.

Two types are seen

- a. Type 1 HRS: Progressive impairment in renal function with rapidity in 1–2 weeks.
- b. Type 2 HRS: There is slow deterioration in renal function over 6 months with better outcome than type 1 HRS.

One-third of patients with chronic liver disease have mild hypoxaemia.

Clinical Features

- Ascites common
- Hyponatraemia
- Hepatic encephalopathy
- Lowered BP
- Pronounced oliguria

Fig. 6: Oesophageal varices after barium swallow.
Note: Ribbon-like lucent defects and irregular pattern

- Low renal sodium concentration (< 10 mmol/L)
- Urinary protein and casts minimal or absent.

Once kidney failure occurs due to any cause, with a high creatinine level in presence of cirrhosis, mortality is almost 100%. There is no effective treatment except liver transplantation. Haemofiltration or dialysis do not affect the outcome.

HEPATOPULMONARY SYNDROME (HPS)

HPS is defined as a clinical triad of advanced liver disease, arterial deoxygenation and intrapulmonary vascular dilatation. It is a rare complication of liver disease of varies etiology and has poor prognosis. The major clinical manifestations of HPS are cyanosis, clubbing and platypnoea. Arterial hypoxemia and orthodeoxia are specifically present. Hypoxaemia in hepatopulmonary syndrome results from right to left intrapulmonary shunts through dilatation in pulmonary vessels.

Respiratory

- May be cyanosis due to reduced pulmonary O₂ saturation due to intrapulmonary shunting through tiny AV fistulae.
- Reduced diffusing capacity due to ventilation-perfusion mismatch.
- Reduced transfer factor.
- Further reduction in pulmonary function due to raised diaphragm (ascites, hepatomegaly) and pleural effusion.

Miscellaneous

- *Fever*—Low grade common due to bacteraemia, or continuing hepatic cell necrosis, or infected ascites, or rarely due to development of hepatoma.
- *Hydrothorax*—may occur in right pleural cavity.

INVESTIGATIONS IN CIRRHOSIS

1. **Blood**—(a) Anaemia—Normocytic, normochromic; may be hypochromic if gastric haemorrhage. Occasionally macrocytic. (b) Low white cell count or reduced platelets due to hypersplenism. (c) Raised ESR from abnormal serum protein. (d) Mitochondrial antibodies in biliary cirrhosis.
2. **Liver function tests**—may be normal in patients with compensated cirrhosis. Usually slight increase in aminotransferase, and immunoglobulin levels and fall in serum albumin. Prothrombin time prolonged and not shortened by vitamin K.
3. **Radiology:**
 - *Barium swallow*—Oesophageal (Fig. 6) and gastric varices.
4. **Imaging:**
 - *Ultrasound*—(i) In cirrhosis may cause a 'bright liver' (also in fatty infiltration and chronic hepatitis), and nodules may be seen. (ii) In portal hypertension a large congested spleen is seen with dilatation of splenic and portal veins. (iii) Can also detect very small amounts of ascites.
 - *CT scan*—In early cirrhosis, CT scan is unremarkable, though late in the disease the contour of the shrinking liver is irregular due to nodules, the caudate lobe is enlarged and ascites is invariable (Fig. 7).
 - *Trans-splenic portal venography*—is required if the portal vein needs imaging (prior to shunt), when ultrasound or CT scan have failed to show it or have given conflicting results. It can confirm suspected malignancy.
 - *Selective coeliac arteriography*—If splenic venography is not possible, selective catheterization of coeliac axis can be performed following percutaneous puncture of femoral artery. The arteriographic phase will show characteristic corkscrew appearance of intrahepatic arteries in cirrhosis.
5. **Histological:**
 - Liver biopsy shows typical changes.

Fig. 7: CT scan in a patient with liver cirrhosis.
Note: Ascitic fluid (A), small irregular liver (L) and spleen (S)

6. **Scopies:**

- Proctoscopy**—To visualise hemorrhoids.
- Endoscopy**—Endoscopic appearance of red areas (cherry red spots) and darkening of the mucosa over the varices suggests that rupture may be imminent.
- Laparoscopy**—To visualise nodular liver surface. Distended vessels in falciform ligament over the peritoneum may indicate portal hypertension.

7. **EEG**—In presence of neuropsychiatric changes.

COMPLICATIONS OF CIRRHOSIS

- Due to portal hypertension**— Haematemesis, thrombosis of portal vein.
- Due to liver cell dysfunction** — Portasystemic encephalopathy.
- Due to formation of regeneration nodules** — Hepatoma.
- Mechanical due to ascites** — Hernia — Umbilical, inguinal, femoral, hiatal or incisional.
- Due to infection:**
 - Spontaneous bacterial peritonitis**—occurs due to bacteraemia of ascitic fluid. It may be asymptomatic or give rise to symptoms of abdominal pain, fever, malaise or encephalopathy, or a non-specific feeling of being unwell. There may be a pseudo-leus. Ascitic fluid—Neutrophil count > 250 mm³, usually pure culture of one organism.

Table 32: Differentiating features between postnecrotic and alcoholic cirrhosis of liver

	Postnecrotic cirrhosis	Alcoholic cirrhosis
Sex	More common in females	More common in males
Age	Any age	Usually middle age
Previous hepatitis	Frequent	Rare
Liver	Small or normal	Large
Spleen	Usually palpable	Not palpable in about 75%
Ascites	++	+
Haematemesis (Oesophageal varices)	Frequent	Uncommon
Hepatic coma	Common	Rare
Pyrexia	Rare	Common
Obesity	Rare	Common
Special features	Nil	Delirium tremens, peripheral neuritis, parotid enlargement, Dupuytren's contracture. Wasting of muscle mass. Increase in α -glutamyl transferase, MCV or serum IgA

- Secondary bacterial peritonitis**—is due to infection with aerobic and anaerobic bacteria and multiple organisms can be cultured from ascitic fluid.

- Tuberculous peritonitis.**

6. **Hypersplenism.**

7. **Chronic kidney failure**—An end-stage complication.

DIFFERENTIAL DIAGNOSIS

1. **Depending upon clinical presentation of:**

- Hepatomegaly
- Haematemesis
- Splenomegaly
- Jaundice
- Ascites
- Encephalopathy

2. **Two main types of cirrhosis**

Table 32 depicts differentiating features between post-necrotic and alcoholic cirrhosis of liver.

3. **Other rare types of cirrhosis**

- Primary biliary cirrhosis

Table 33: Differentiating features between postnecrotic and biliary cirrhosis of liver

	<i>Postnecrotic cirrhosis</i>	<i>Biliary cirrhosis</i>
Incidence	Common	Rare
Age	40–60	Any
Sex	Male	Female
Malnutrition	Frequent	Rare
Jaundice	Uncommon, mild	Always present, marked
Liver	May be small	Always markedly enlarged
Spleen	Enlarged	Slight enlargement
Ascites	Frequent	Rare and late
Xanthomas	Absent	May be seen
Alkaline phosphatase	Not raised	Raised
Serum cholesterol	Normal or diminished	Elevated
Mitochondrial antibodies	Absent	Antimitochondrial antibody (AMA) present
Autoimmune disorders	Nil	Present (RA, diabetes, thyroid disturbances, Sjögren's syndrome)

Table 33 depicts differentiating features between postnecrotic and biliary cirrhosis of liver.

(b) Hemochromatosis:

- Bronze skin pigmentation
- Liver failure
- Maturity onset diabetes mellitus
- Arthropathy (chondrocalcinosis)
- Cardiac failure
- Loss of libido, testicular atrophy, infertility
- Transferrin saturation > 62%
- High serum ferritin levels usual

(c) Wilson's disease- Cirrhosis with associated signs of:

- CNS manifestations: Dementia, dysarthria, involuntary movements.
- Kayser-Fleischer ring.
- Renal tubular dysfunction -Aminoaciduria and possibly glycosuria.

4. **Budd-Chiari syndrome**—This disorder is produced by obstruction of the venous drainage of the liver at any level from small hepatic veins to junction of IVC. The syndrome comprises triad of abdominal pain, ascites and hepatomegaly.

Aetiology: It can be due to lesions of large hepatic veins or to the central hepatic veins of individual lobules.

1. Obstruction of large hepatic veins—(a) Thrombosis e.g. in polycythaemia and prothrombotic conditions like factor V Leiden mutation, protein C and S deficiency, postpartum state rarely, after trauma and subphrenic abscess. (b) Neoplastic invasion particularly by a hypernephroma, and sometimes as part of thrombophlebitis complicating distant neoplasia.
2. Obstruction of small lobular veins due to toxins (veno-occlusive disease) and rarely drugs such as cytotoxic agents.
3. Presence of venous webs and valves.

Clinical Features:

1. **Fulminant form** presents with fulminant hepatic failure due to liver necrosis.
2. **Acute form** follows sudden venous occlusion (renal carcinoma, hepatoma, polycythaemia) with acute abdominal pain, vomiting, tender hepatomegaly, ascites and mild jaundice. If venous occlusion is total - delirium, hepatocellular failure and coma develop.
3. **Chronic form** more usual presentation. (a) Pain in abdomen, tender hepatomegaly and ascites. (b) Gradual development of portal hypertension and splenomegaly. (c) If IV obstruction—oedema feet, distended veins over abdomen flanks and back.

Diagnosis—(a) LFTs—Raised alkaline phosphatase and transaminases. (b) Ultrasound—Enlargement of caudal lobe, intra hepatic collaterals, echogenic areas due to occlusion of hepatic veins and ascites. (c) Doppler ultrasonography can detect abnormality of venous flow sufficient to establish the diagnosis. (d) Hepatovenography to detect extent of block and caval pressures.

Treatment—Anticoagulation is required and treatment of underlying pathology.

5. **Non-cirrhotic portal fibrosis (NCPF)**—It is intra-hepatic cause of portal hypertension with absence of hepatocellular damage and lack of nodular regeneration unlike cirrhosis. Possible etiological factors are - (a) Idiopathic portal hypertension. (b) Schistosomiasis. (c) Congenital hepatic fibrosis. (d) Chronic arsenic ingestion (from intake of deep tube-well water).

MANAGEMENT

Management is palliative.

- I. Rest in bed to maximise treatment of any reversible element of underlying liver disease and to improve renal perfusion.
- II. Correction of any etiological factor, e.g. abstinence from alcohol, prednisolone for chronic hepatitis, penicillamine for Wilson's disease, venesection and desferrioxamine for haemochromatosis, antiviral agents for viral hepatitis.
- III. Diet—Low salt. Total daily intake of 2000 calories with protein intake of 120 gm. if patient can tolerate it. Fats and carbohydrates in normal amounts. Vitamin B complex.
- IV. Drugs—(a) *Corticosteroids* - may help patient with active post-hepatitis cirrhosis. Prednisolone is continued in a small maintenance dose of 10 mg daily for many months. (b) *Immunosuppressive agents* - In case of troublesome side effects of corticosteroids. Azathioprine often of benefit in hepatitis, dose 50–75 mg daily.
- V. Symptomatic treatment:
 - (a) **Anaemia**—(a) Iron deficiency anaemia - Oral iron preparations or blood transfusion. (b) Macrocytic anaemia - Vitamin B₁₂ and folic acid. (c) In some patients haemodilution is the main cause since the red cell mass is normal or slightly increased. Here splenectomy is recommended since it results in decrease in plasma volume and consequent increase in haemoglobin concentration.
 - (b) **Restlessness**—All sedative drugs are potentially harmful but if patient becomes restless or noisy - Oxazepam or lorazepam
 - (c) **Ascites:**
 1. **Low sodium diet**—Sodium intake up to 500 mg daily. No salt in cooking. Milk restricted to 4 oz and dairy products minimum. Sodium-free protein preparations can be given. Patients with hepatic ascites often have secondary hyperaldosteronism and a potassium chloride supplement may be required. Not more than 1 litre fluid per day.
 2. **Diuretics:**

First 4 days—Bed rest. Weigh patient and measure urine output daily, plasma urea, electrolytes and creatinine on alternate days. Give Pot. chloride 100 mEq daily.

After 4 days—If weight loss > 1 kg in presence of oedema or > 0.5 kg in absence of oedema, give Spironolactone 100–200 mg/day. Reduce dose of Pot. chloride by half.

After one week—If weight loss < 1 kg in 3 days, increase dose of Spironolactone by 100 mg. If painful gynecomastia is a side effect substitute Amiloride 10 mg b.d. If still no response, add Frusemide 40 mg and increase by 20 mg increments upto maximum of 120 mg.

Note: Over-diuresis may result in dehydration, uraemia and hyponatraemia and may precipitate hepatic encephalopathy. Stop diuretic if pre-coma (flap), hyponatraemia or alkalosis, or weight loss > 0.5 kg/day. Do therapeutic paracentesis and give albumin infusion if necessary. (Refer).

REFRACTORY ASCITES

Criteria for Diagnosis:

- No diuretic response despite spironolactone 400 mg/day, and frusemide 120 mg/day.
- Electrolyte changes or hypovolaemia limiting use of effective dose of diuretic.
- Repeated and frequent paracentesis.
- Non-compliance drug therapy and low salt diet.
- Hypokalaemia and alkalosis which impair renal tubular sodium excretion.

Factors which may precipitate development of refractory ascites:

- Deterioration of liver function due to liver cell damage or development of primary carcinoma or internal malignancy.
 - SBP
 - Chylous ascites
 - Hepatic vein thrombosis
- Management* - Refer Ascites

9. ASCITES

CAUSES

Causes of ascites are listed in Table 34.

HISTORY

Personal history - Dietary habits and alcohol intake. Menstrual history in females.

Past history of tuberculosis or jaundice. History of haematemesis or piles.

Symptoms - Gain in weight, increase in girth of abdomen, abdominal discomfort and dyspnoea on exertion.

Table 34: Causes of ascites

1. Disease of peritoneum
Infections:
<ul style="list-style-type: none"> • Tuberculous peritonitis. • Spontaneous bacterial peritonitis. • Fungal – Candida, histoplasma. • Parasitic – Schistosoma, enterobius. • Viral – Acute severe hepatitis.
Neoplasms:
<ul style="list-style-type: none"> • Primary mesothelioma. • Secondary carcinomatosis, e.g. adenocarcinoma, sarcoma, teratoma, leukaemia, Hodgkin's disease, lymphocytic lymphoma, myeloid metaplasia.
Pseudomyxoma peritonei
Familial paroxysmal peritonitis
Miscellaneous
<ul style="list-style-type: none"> • Vasculitis – SLE and other collagen vascular diseases, allergic vasculitis (Henoch-Schonlein purpura). • Eosinophilic gastroenteritis. • Whipple's disease. • Granulomatous peritonitis – Sarcoidosis, Crohn's disease, starch peritonitis. • Peritoneal loose bodies. • Peritoneal encapsulation.
2. Portal hypertension
3. Congestive heart failure
4. Hypoalbuminemia
<ul style="list-style-type: none"> • Nephrosis • Malnutrition • Protein-losing enteropathy
5. Beriberi
6. Myxoedema
7. Ovarian disease:
<ul style="list-style-type: none"> • Meigs' syndrome • Struma ovarii • Ovarian overstimulation syndrome
8. Pancreatic ascites due to retroperitoneal leakage of pancreatic enzymes from a ruptured cyst or pancreatic duct.
9. Bile ascites
10. Chylous ascites
11. Epidemic dropsy

Mode of onset in relation to oedema of lower extremities or elsewhere. In cirrhosis the oedema always follows the ascites in contraindication to other forms of oedema which precede the ascites.

PHYSICAL EXAMINATION

(a) Signs

1. *General appearance*—'Spider man'—thin limbs with protuberant abdomen.

Table 35: Ascites in absence of peripheral oedema

• Cirrhosis
• Tuberculous peritonitis
• Constrictive pericarditis
• Restrictive cardiomyopathy
• Hepatic venous occlusion
• Intra-abdominal tumour

2. *Of free fluid in peritoneal cavity*—Generalised abdominal distension, bulging in the flanks, umbilicus transversely stretched or everted, central tympany and shifting dullness, fluid thrill.
3. *Of increased intra-abdominal pressure*—Abdominal wall hernias (umbilical or inguinal), divarication of recti, increased inferior vena cava pressure causing lower limb oedema (Table 35) and abdominal wall venous collaterals.
4. *Of causative condition*—e.g. (a) Portal hypertension—Splenohegaly, portal-systemic venous collaterals. (b) Chronic liver disease—Peripheral stigmata of chronic liver disease, or cholestasis, hepatic encephalopathy. (c) Evidence of tuberculosis elsewhere in tuberculous peritonitis.
5. *Rectal examination* for hemorrhoids, malignant lesion in pelvis or fluid in pouch of Douglas.

SPECIAL INVESTIGATIONS

Ascitic Fluid Analysis

Macroscopic Appearance

- *Clear*—usually occurs in congestive heart failure, hypoalbuminemia, cirrhosis, inferior vena cava obstruction, Budd-Chiari syndrome, Meigs' syndrome and vasculitis.
- *Turbid* is common in tuberculous peritonitis, peritoneal malignancy, bacterial peritonitis, pancreatic ascites, and myxoedema.
- *Haemorrhagic*—Traumatic tap, tuberculosis, acute haemorrhagic pancreatitis, mesenteric artery thrombosis, malignancy involving peritoneum or liver surface, benign hepatic adenoma or spontaneous bleeding from intra-abdominal portal-systemic collaterals.
- *Chylous (milky)*—Trauma to thoracic duct, filariasis, congenital. Tuberculosis, malignancy involving lymphatic system, or spontaneous; cirrhosis, nephrotic syndrome, protein-losing enteropathy, surgical or traumatic rupture of lymphatics which is not uncommon

Table 36: SAAG and causes of ascites

High gradient (>1.1 g/dL)		Low gradient (<1.1 g/dL)
Ascitic protein <2.5 gm/dL	Ascitic protein >2.5 gm/dL	
Cirrhosis	Alcoholic hepatitis	Peritoneal carcinomatosis
Late Budd-Chiari syndrome	Cardiac ascites	Tuberculous peritonitis
Massive liver metastasis	Early Budd-Chiari syndrome	Pancreatic ascites
	Portal vein thrombosis	Biliary ascites
	Veno-occlusive disease	Nephrotic syndrome
		Serositis of collagen vascular disease

after distal splenorenal shunt surgery. Lymphoma and other malignancies. Ether extraction of the fluid will lead to clearance of the turbidity.

- *Pseudochylous*—Turbid fluid due to leucocytes or tumour cells. Alkalinization of fluid will reduce turbidity.
- *Mucinous*—Pseudomyxoma peritonei or rarely colloid carcinoma of stomach or colon with peritoneal implants.

Cytology

- *Red cells*—If fluid is haemorrhagic.
- *White cells*—Polymorphs in peritoneal irritation caused by inflammation, infection or tumour. Lymphocytes and monocytes in tuberculosis. More than 250 neutrophils/mm³ suggestive of SBP. Eosinophils in enteritis and peritonitis.
- *Malignant cells*—in carcinomatosis.

Biochemistry

- *Protein content* seldom exceeds 1.5 g/dL. Higher values indicate infection, hepatic venous obstruction or malignancy. Low values (< 1.0 g/dL) indicate high risk of developing SBP.
- *Serum-ascites albumin gradient*
SAAG is more useful than total protein concentration of ascitic fluid (Table 36). The gradient is physiologically based on oncotic hydrostatic balance and is related directly to portal pressure. SAAG = Albumin (serum) - Albumin (ascites). Patients with gradients >1.1 gm/dL have portal hypertension, patients with gradient <1.1 gm/dL do not.
- *Glucose*—Glucose concentration is normal if fluid is not infected as in spontaneous bacterial peritonitis, but is usually < 3.0 mmol/L in secondary bacterial peritonitis. Values less than 60 mg/100 mL may suggest neoplastic effusion.

Fig. 8: CECT abdomen in bacterial peritonitis showing thickened enhancing peritoneum (arrow heads), ascites (thin white arrow) and intestines in fluid (thick black arrow)

- *Ascitic amylase* high in pancreatic ascites.
- *Triglycerides* elevated in chylous ascites.
- *Additional tests:*
 - (i) Adenosine deaminase if tuberculosis is suspected.
 - (ii) pH, lactate dehydrogenase if bacterial peritonitis is suspected.
 - (iii) High levels of interleukin-6 and tumour necrosis factor in cirrhotic ascites.
 - (iv) High levels of cytokines in aspirate fluid of patients with SBP and related complications such as impaired circulatory and renal function.
 - (v) Serum CA-125 and ascitic fluid cytology.

Additional Tests

1. SBP in patient with cirrhosis and ascites has high mortality. Positive bacterial culture of ascitic fluid is necessary for confirming diagnosis.
2. Investigations for suspected portal venous hypertension (*see* portal hypertension).
3. Ultrasonography can detect as little as 100 mL of abdominal fluid and may suggest the cause.
4. Liver biopsy of value in cirrhosis or malignancy of liver.
5. Liver function tests to confirm cirrhosis.
6. Liver scan for space occupying lesions of the liver.
7. Laparoscopy—Useful for (i) paracentesis, (ii) direct visualization of abdominal viscera, (iii) biopsy of liver.
8. Selective arteriography of the hepatic and splenic arteries with delayed films to visualise the portal vein may be helpful in ascites of obscure cause.
9. Needle Biopsy of peritoneum for diagnosis of tuberculous and malignant peritonitis.
10. CT scan (Fig. 8).
11. Laparotomy may be required in some cases.

Table 37: Ascitic fluid characteristics according to etiology

Aetiology	Protein (g/dL)	WBCs/mm ³	RBCs/mm ³	Other
Cirrhosis / portal hypertension	<2.5	300–500 (70% mononuclear)	Usually <1000	Serum-ascites albumin gradient >1.1 g/dL
Hepatocellular carcinoma	<2.5	300–500 (70% mononuclear)	Usually 1000 but may be >50,000	Cytology for neoplastic cells negative
Peritoneal carcinomatosis	>2.5	Variable (Mononuclear predom.)	Usually <1000 but may be >50,000	Neoplastic cells on cytology
Cardiogenic ascites	>2.5-3	300–500 (Mononuclear predom.)	<1000	Serum-ascites albumin gradient <1.1 g/dL
Pancreatic ascites	> 2.5	300–500 (Mononuclear predom.)	<1000	Very high amylase and lipase
TB peritonitis	>3 (may be <2.5 in cirrhotics)	>500 (Mononuclear predom.)	<1000	Elevated adenosine deaminase and lactic dehydrogenase
Spontaneous bacterial peritonitis	<2.5	>250 neutrophils	<1000	Normal glucose, pH, Lactic dehydrogenase
Bacterial peritonitis	>2.5 usually	>1000 neutrophils	Variable	Low glucose and pH Lactic dehydrogenase and amylase Bacteria on Gram stain

DIFFERENTIAL DIAGNOSIS

I. Differential diagnosis according to ascitic fluid characteristics

Differential diagnosis according to ascitic fluid characteristics is given in Table 37.

II. Other causes of abdominal distension –

- Pregnancy**—History of amenorrhoea. Percussion dullness central with tympany in flanks. Little change in note on change of posture. Foetal parts may be palpable.
- Excessive fat**—Abdomen usually enlarged out of proportion to rest of body and pendulous. No shifting dullness or fluid thrill. Symmetrical globular enlargement with accentuation of cutaneous folds.
- Tumours**—Abdominal dullness limited to area overlying growth. In ovarian tumours, distance between xiphisternum and umbilicus less than distance between umbilicus and symphysis. Vaginal examination diagnostic. Menstrual disturbances.
- Gaseous distension**—Tympanitic note if colonic distension, most marked in periphery. Prominence of epigastrium if undue distension of stomach.
- Distended bladder**—An over-distended bladder may be felt as a somewhat tender and rounded cystic mass above the symphysis pubis and extending upwards even up to the umbilicus.

- Abdominal proptosis**—Distension produced by contraction of diaphragm and exaggerated lumbar lordosis which is obvious on clinical examination. It is a psychiatric complaint.

III. Other causes of ascites:

(a) Ascites only or with oedema of feet:

- Cirrhosis of liver**
- Tuberculous peritonitis** (Table 38)
- Malignant ascites**—Symptoms and localising signs due to primary tumour. Liver may be enlarged and nodular. Peritoneal fluid may be haemorrhagic. High protein content, high serum-ascites albumin gradient (>1.1), high lactic acid dehydrogenase level, and high cholesterol values (>48 mg/dL). If necessary further confirmation by peritoneoscopy and peritoneal biopsy.
- Portal hypertension** (other than cirrhosis):
 - Obstruction to portal vein by enlarged glands—Presence of primary growth or enlarged lymph nodes elsewhere. Progressive jaundice.
 - Thrombosis of portal vein—Rapid development of ascites, hematemesis, melena and splenomegaly.
- Constrictive pericarditis:**
 - Presence of signs of congestive failure without signs of heart disease.

Table 38: Ascitic fluid in cirrhosis of liver vs TB peritonitis

	<i>Cirrhosis of liver</i>	<i>TB peritonitis</i>
Age	Usually middle age	Adolescent or young adults
Amount of fluid	Usually large	Small, moderate, or large
Liver	May not be palpable,	Not enlarged, if palpable firm and regular edge
Fever	Absent	Present
Tenderness of abdomen	Rare	Common
Other features	Emaciation, dyspepsia, evidences of collateral circulation, liver function impaired	Primary focus in the lungs may be found Lumps of matted omentum may be palpated
Ascitic fluid	Transudate	Exudate, predominantly lymphocytic
Laparotomy	Nodular liver surface	Peritoneum studded with small granulomas

- Impalpable apex beat.
 - Rise of jugular venous pressure on inspiration.
 - Hepatomegaly and ascites
 - 3rd heart sound (Pericardial knock sound).
 - Pulsus paradoxus.
 - Calcification of pericardium.
6. *Budd-Chiari syndrome* – Onset of:
- (a) Hepatic vein obstruction indicated by – pain, hepatic enlargement, vomiting and ascites. Liver large and tender. Failure of jugular veins to fill when liver is pressed. Condition suspected in presence of disorders of coagulation or malignant disease.
 - (b) Thrombosis of major venous channels such as portal vein will cause abdominal pain, ascites and bloody diarrhoea.
 - (c) Blockage of inferior vena cava may lead to albuminuria, prominent veins in the loin and rarely nephrotic syndrome.
- Ascitic fluid—High protein content.
 Ultrasound—Hepatic vein abnormalities, caudate lobe hypertrophy and compression of IVC.
7. *Spontaneous bacterial peritonitis (SBP)* Should be considered in –

- Patients with pre-existing ascites who develop fever or changing abdominal signs and symptoms.
 - Patient with a focus for bacteraemia such as indwelling catheters, cellulitis, or urinary, biliary or pulmonary infection.
 - Patients with decreased immunological competence, e.g. hypogammaglobulinemia.
 - Predictive indices for diagnosis include – Ascitic fluid polymorphonuclear count greater than 250/cm³, ascitic fluid pH <7.3.
 - GI hemorrhage.
 - Ascitic fluid cloudy with protein <1 g/dL, especially those with high bilirubin >2 mg/dL or low platelet count <98,000 cells/mm³.
 - Patients with hepatic encephalopathy.
 - May present as abrupt deterioration or hepatic encephalopathy in a patient with cirrhosis and ascites.
8. *Bacterial peritonitis* should be suspected when ascitic fluid analysis shows 2 or 3 of the following criteria: Total protein >1 gm/dL, glucose <50mg/dL, and LDH >225 IU/mL. Most of the ascitic fluid cultures in such cases are polymicrobial, whereas in SBP the infection is usually monomicrobial (commonly *E. coli*).
9. *Chylous ascites*—Due to obstruction of receptaculum chyli and thoracic duct by filariasis, neoplasms (intra-abdominal or thoracic), inflammations (mesenteric adenitis, tuberculosis, pancreatitis), traumatic rupture of thoracic duct, or idiopathic. Turbid fluid which separates into layers and contains lymphocytes.
10. *Pancreatic ascites*—Intermittent abdominal pain with rarely gross refractory ascites. Serum amylase elevated.
11. *Meigs' syndrome*—Triad of ascites, hydrothorax and fibroma of the ovary. The hydrothorax and ascites disappear when the ovarian tumour is removed.
12. *Pseudomyxoma peritonei*—Due to rupture of mucocoele of appendix or pseudomucinous cyst of ovary. Increasing abdominal girth, and occasional attacks of abdominal pain. Abdominal masses may be palpable; there is often a fluid thrill and sometimes shifting dullness. Disparity between amount of ascites and clinical state of patient. On paracentesis mucinous material often too sticky to be aspirated.

Table 39: Ascites in congestive heart failure vs nephrosis

<i>Congestive heart failure</i>	<i>Nephrosis</i>
Starts in feet	Starts as puffiness of face
Oedema maximum in evening	Oedema maximum in morning
Cyanosis	Pallor
Raised JVP	JVP normal
Heart always enlarged	Cardiac enlargement rare
Liver enlarged and tender	Liver not palpable.
	Oedema of abdominal wall common
Trace proteinuria	Massive proteinuria

13. *Bile ascites*—Extravasated bile may cause chronic peritoneal fluid accumulation. Abdominal distension after biliary tract surgery. Nausea, malaise, jaundice and acholic stools. Paracentesis yields bilious fluid.
14. *Hypothyroidism*—Impaired mentation often without other features of the disease. Yellow gelatinous fluid with proteins generally more than 4 gm per 100 mL. Ascites clears within 2–3 weeks after starting thyroxine.

b. **Ascites with generalized anasarca:**

1. *Congestive heart failure*
2. *Nephrosis* (Table 39)
3. *Anaemia and hypoproteinaemia:*
 - Gross anaemia.
 - Marked oedema of feet.
 - Ascites slight or moderate.
 - Spleen may be enlarged.
 - Serum proteins diminished, reversal of albumin globulin ratio.
4. *Beriberi:*
 - Symptoms of cardiac involvement.
 - Heart enlarged
 - Tachycardia
 - Tenderness of calf muscles and blunting of sensation.
 - Oedema firmer than that of nephrosis and does not involve scrotum.
 - Absent or sluggish deep reflexes.
 - Decreased urinary output of thiamine.
5. *Epidemic dropsy:*
 - Oedema of legs occurring in several members of the family, or several individuals in same locality.

Table 40: Indications for therapeutic paracentesis

- Marked abdominal discomfort.
- Cardiac or respiratory embarrassment (Tense ascites).
- Oliguria.
- Anorexia and dyspepsia.
- Following haematemesis in cirrhosis to reduce congestion.
- Patients refractory to full medical therapy.
- Danger of strangulation of secondary herniae.

- Marked tenderness over oedematous parts in most cases and severe burning of feet with paraesthesiae in majority.
- Preceding or accompanying gastro-intestinal symptoms.
- Diffuse blotchy erythema of skin
- Presence of cardiovascular symptoms.
- Glaucoma.
- Cutaneous nodules.
- Detection of argemone oil in cooking medium.

MANAGEMENT

Of the cause—Digitalis for cardiac failure, anti-tuberculous drugs for tuberculous peritonitis, pericardiolysis for constrictive pericarditis, Vitamin B₁ for beriberi.

Of ascites itself:

1. Bed rest improves renal perfusion.
2. Diet—Low sodium diet if fluid non-inflammatory. Restrict fluid to 1 litre/day.
3. Diuretics—Spironolactone 100 mg, if no response, add frusemide 40 mg. Increase doses stepwise to spironolactone 400 mg and frusemide 160 mg. Aim is to achieve weight loss of 300–500 g/day in ascitic patients with peripheral oedema.
4. Therapeutic paracentesis (Table 40)

Technique: Ask patient to empty his bladder and prop him up in bed. Paracentesis is usually performed in the right iliac fossa, avoiding inferior epigastric vessels, visible venous collaterals and scars of previous operations. The skin is cleansed and local anaesthetic infiltrated through to the peritoneum. To minimise chances of subsequent leakage of ascitic fluid, a thin bore needle (21–23 gauge) attached to a 20 mL syringe is used. The aspiration needle is inserted through the skin, which is then pulled sideways and the needle pushed through the abdominal wall, muscle and peritoneum. The fluid is drained slowly.

An abdominal binder or many-tailed bandage is placed round the abdomen and it is tightened as required. Paracentesis can also be performed with special needle with side holes, attached to low grade suction.

Complications and Management:

- (a) *Fainting*—Due to too rapid removal of fluid. Further removal should be stopped. If recovery is slow administer 500 mL 5% glucose IV. If marked fall in B.P. 200 mL 5% saline by infusion.
- (b) *Infection*—Acute peritonitis very rare but chronic infection may result from repeated paracentesis. If organism is cultured from sample of fluid give appropriate antibiotics.
- (c) *Perforation of viscus*—Rare. Usually gives rise to localised peritonitis treated with gentamicin and broad spectrum antibiotics.
- (d) *Acute liver failure*.
- (e) *Depletion of proteins*—Removal of 5 litres of ascitic fluid may involve loss of 50–100 gm. protein; can be avoided by giving simultaneous albumin infusion.

A total paracentesis can be carried out with concomitant infusion of 6–8 g of salt-poor albumin for every litre of ascitic fluid drained. 8 gm/litre of ascitic fluid removed to prevent post-paracentesis circulatory dysfunction (PICD) which is associated with increased risk of recurrence of ascites, greater diuretic requirements and shorter survival. No differences have been observed between albumin and other plasma expanders when < 5 litres are removed. Contraindicated in patients with grade C hepatic dysfunction, serum bilirubin > 10 gm/dL, prothrombin time < 40%, platelets < 40000, creatine or urine sodium < 10 mEq/24 hours.

5. Peritoneovenous shunt is as effective as paracentesis in control of refractory ascites but is reserved for patients who are not candidates for liver transplantation, TIPS placement or repeated large volume paracentesis.
6. TIPS is the only treatment aimed at relieving portal pressure and should be used in patients who respond poorly to paracentesis (compartmentalization of ascitic fluid, and those who need repeated taps often). In patients of cirrhosis, TIPS is associated with increased frequency of hepatic encephalopathy.

REFRACTORY (INTRACTABLE) ASCITES

Common causes: Portal hypertension, CHF, chronic kidney failure, tuberculosis and malignancies.

Tr. of refractory ascites in cirrhosis—(a) Removal of large amount of fluid (3–5 L) over 1–2 hours. Salt-free albumin 8 g/litre of ascitic fluid removed or Dextran. (b) LeVein shunt if infection, IVC thrombosis, pulmo-

Table 41: Causes of generalized portal hypertension

<i>Prehepatic</i>
Portal vein thrombosis
Splenic vein thrombosis
Extra-hepatic portal vein obstruction (Fig. 9)
Massive splenomegaly (Banti's syndrome)
<i>Intrahepatic</i>
Cirrhosis
Schistosomiasis

Congenital hepatic fibrosis
Granulomata
Metastatic malignant disease
<i>Posthepatic</i>
Budd-Chiari syndrome
Veno-occlusive disease
Constrictive pericarditis
Congestive heart failure
Inferior vena cava webs

nary oedema, bleeding from oesophageal varices, DIC.

(c) Side-to-side portocaval shunt. (d) Liver transplantation.

10. PORTAL HYPERTENSION

CAUSES

Causes of generalized portal hypertension, according to site of portal venous obstruction (Table 41 and Fig. 10).

MEASUREMENT OF PORTAL VENOUS PRESSURE

Wedged hepatic venous pressure (WHVP)—A cardiac catheter is passed to a hepatic vein under radiographic control until it 'wedges' in a hepatic venule and the pressure measured at that point. Normal 5–6 mm Hg.

Transhepatic—A 25-gauge needle is used under ultrasound guidance, the needle being replaced by catheter which is placed in the main portal vein.

COLLATERAL CIRCULATION

Abnormal communications (collateral channels, portosystemic anastomosis) develop between the portal vein and systemic veins. There are 4 main groups as given in Table 42.

Fig. 9: CECT abdomen venous phase showing extra-hepatic portal venous obstruction (EHPVO) with splenomegaly (black arrow), oesophageal varices (white arrow) and portal cavernoma (arrowhead)

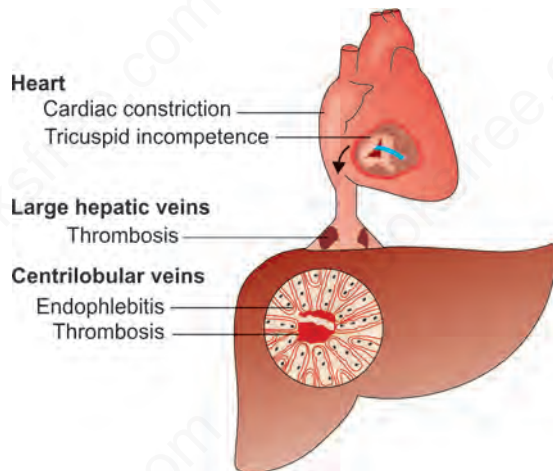

Fig. 10: Causes of increased venous pressure

HISTORY

Cirrhosis is the commonest cause hence relevant to it – hepatitis, alcohol. Hematemesis is the commonest presentation; melena without hematemesis may result from bleeding varices. Clotting disease and some drugs, e.g. oral contraceptives predispose to portal and hepatic venous thrombosis.

EXAMINATION

Abdominal wall veins are often prominent and rarely, they may form a caput medusae around the umbilicus.

Murmurs—A venous hum may be heard over the collaterals radiating occasionally to the precordium or over liver

Table 42: Portosystemic anastomosis

Site	Portal vessel	Caval vessel
I. Cardio-oesophageal Junction (Figs. 11 and 12)	Left gastric, posterior gastric, short gastric	Intercostal Diaphragmo-oesophageal Azygos minor
Lower end of rectum (Haemorrhoids)	Superior haemorrhoidal	Inferior haemorrhoidal + middle haemorrhoidal veins
II. Periumbilical or abdominal wall	Vein in falciform ligament	Para-umbilical veins
III. Site of contact of abdominal organs with retroperitoneal tissues	Hepatic vein Vein in ileorenal ligament	Diaphragmatic vein Omental vein Lumbar vein
IV. Retroperitoneal space	Portal vein	Left renal vein through blood entering directly from splenic vein via diaphragmatic, spermatic, left adrenal or gastric veins.

(Cruveilhier-Baumgarten syndrome). A thrill may be felt at the site of maximum intensity. An arterial systolic murmur suggests primary liver cancer or alcoholic hepatitis. The paraxiphoid umbilical veins indicate intrahepatic portal venous hypertension.

Spleen—Enlarges progressively, the edge is firm. Massive if presinusoidal portal obstruction, cirrhosis with hypersplenism, rarely tropical splenomegaly.

Liver—High pressures are more often associated with a small, fibrotic liver. A soft liver suggests extrahepatic portal venous obstruction, a firm liver cirrhosis.

Ascites—Portal hypertension raises capillary filtration pressure and increases quantity of ascitic fluid.

INVESTIGATIONS

Ultrasonography and Echo-Doppler ultrasonography should exclude an obvious space-occupying lesion and establish patency of the portal and hepatic veins.

Retrograde CO₂ portography – or splanchnic arteriography may be necessary to visualize the portal vein.

Portal venography demonstrates the site and often the cause of portal venous obstruction and is performed prior to surgery. A typical ‘spider web’ appearance on hepatic venography is diagnostic of Budd-Chiari syndrome.

Portal venous pressure measurements are seldom needed but can be used to confirm portal hypertension and differentiate sinusoidal from presinusoidal lesions.

Note: Minimal use or avoidance of radiological contrast (e.g. angiography) to minimize renal dysfunction.

Fig. 11: OGD scopy showing oesophageal varices

Fig. 12: OGD scopy showing gastric varices

COMPLICATIONS

Complications of portal hypertension are listed in Table 43.

MANAGEMENT

Major venous hepatic obstruction—(a) Thrombolytic therapy if seen soon after onset. (b) Side-to-side shunt between portal vein and IVC relieves hepatic engorgement and thus improves liver function. (c) Hepatic transplantation.

Variceal bleeding (Refer).

11. HEPATOMEGALY

CAUSES

Causes of hepatomegaly are enumerated in Table 44.

DIFFERENTIAL DIAGNOSIS OF HEPATOMEGALY

1. Hepatitis:

- (a) *Viral hepatitis*—Prodromal symptoms of gastrointestinal upset, abdominal discomfort, anorexia, malaise and fever followed by dark urine and jaundice. Enlarged tender liver with smooth edge. Spleen palpable.
- (b) *Amoebic abscess*—Moderate to huge enlargement of liver, pain in hepatic region and liver or intercostal tenderness. Moderate pyrexia, at times fever with rigors. Caecal tenderness may be found and history of diarrhoea with mucus and blood may be

Table 43: Complications of portal hypertension

• Variceal bleeding: In cirrhotics risk of bleeding is related to:
Size of varices
Presence of red signs at endoscopy (red weal marks)
Degree of liver dysfunction
• Ascites
• Congestive gastropathy
• Hypersplenism
• Hepatic encephalopathy
• Kidney failure

obtained. Spleen not palpable. Moderate leucocytosis. Diagnostic aspiration may show anchovy sauce pus if abscess and ultrasonography hypo-echoic area with ragged edges.

- (c) *Acute alcoholic hepatitis*—Commonly follows a period of heavy drinking. Right upper abdominal pain, anorexia, nausea and vomiting, and profound weakness. Jaundice common. Fever may occur. Liver usually enlarged and tender. Spider naevi may develop. Arterial bruit may be heard over the liver. Ascites develops rapidly.
- (d) *Autoimmune hepatitis*—High preponderance in young females. Clinical features - (i) Hepatic - Jaundice, spider naevi, enlarged spleen. (ii) Nonspecific - Pyrexia, malaise, lethargy, etc. (iii) Multisystem features - Rashes, arthritis, pleurisy, pericarditis, myocarditis, nephritis, etc. (iv) Liver biopsy is the most important diagnostic test. (v) Non-organ-specific autoantibodies are important in establishing the diagnosis.

Table 44: Causes of hepatomegaly

Infections
<i>Viral</i> – Viral hepatitis, yellow fever, infectious mononucleosis, Lassa fever
<i>Bacterial</i> – Typhoid, pneumonia, brucellosis, tuberculosis
<i>Protozoal</i> – Amoebiasis, malaria, kala azar
<i>Spirochaetal</i> – Weil's disease, syphilis, relapsing fever
<i>Parasitic</i> – Schistosomiasis, echinococcus, clonorchiasis
<i>Fungal</i> – Actinomycosis, histoplasmosis
Metabolic
Fatty liver
Amyloid
Glycogen storage disease
Congestive
(a) <i>General</i> – Congestive heart failure, tricuspid regurgitation, constrictive pericarditis
(b) <i>Local</i> – Portal hypertension (cirrhosis), hepatic vein thrombosis
Tumours
<i>Primary</i> : Benign and malignant hepatoma, benign and malignant cholangioma, fibroma, sarcoma, haemangioma
<i>Secondary</i> – Direct due to spread by contiguity, or embolic metastatic
Cysts
Hydatid
Polycystic
Biliary obstruction – Gallstones, strictures of bile ducts
Haematological
Leukaemias
Lymphoma
Myeloproliferative disorders
Storage disorders – Gaucher's disease, Niemann-Pick's disease, amyloidosis, glycogen storage disease, gargoylism, haemochromatosis
Myeloid metaplasia – Secondary carcinoma of bone, myelofibrosis, myelosclerosis, multiple myeloma, marble-bone disease
Genetic abnormalities – Sickle cell disease
Congenital – Riedel's lobe

- Portal cirrhosis—(i) Evidence of hepatocellular damage – Dyspeptic symptoms, vascular spiders, alopecia, palmar erythema. Palpable liver in about 75% of patients (ii) Evidence of portal hypertension – Palpable spleen, ascites in later stages, oesophageal varices, hemorrhoids.
- Congestive heart failure—Slight to huge enlargement of liver. Edge firm, smooth and tender on palpation.

Spleen may be palpable. Ascites in severe cases. Increased venous pressure and other signs of congestive failure. Pulsatile liver if tricuspid regurgitation.

- Malignant hepatic tumours:
 - Hepatocellular carcinoma*—Male predominance. About 80% in cirrhotic livers. In addition 80% are associated with markers of prior HBV infection, and also HCV.
Symptoms—Vague right upper quadrant pain, nausea, vomiting, jaundice. Signs –Hepatomegaly (nodularity, hard and may be tender) jaundice, ascites, cachexia, fever.
Diagnosis—Abnormal LFTs, and raised α -feto-protein.
Imaging—Ultrasonography and biphasic contrast enhanced CT detect lesions as small as 5 mm. CT following injection of iodised oil emulsion into hepatic artery can detect lesions that appear equivocal on plain scan (Fig. 13).
 - Uncommon tumors* include angiosarcomas, haemangioendotheliomas and mesenchymal tumors. Diagnosis is based on clinically palpable liver and ultrasonography or CT.
 - Metastatic tumors*—Liver is the most common site of metastatic disease after the lymph nodes. (a) Colorectal cancer. About 50% develop hepatic metastasis. Diagnosis on scanning. (b) Neuroendocrine tumors of pancreatic origin and carcinoma often metastasize to the liver.
- Malaria—Liver may be palpable in about half the cases. Spleen always palpable. Jaundice rare, transient. Fever with rigors. Demonstration of malarial parasites, and therapeutic response to antimalarial drugs.
- Alcoholic fatty liver—Liver enlarged, smooth, firm, non-tender. No enlargement of spleen. One may sometimes find hemolytic anaemia, jaundice and turbid serum due to hyperlipidaemia or marked cholestasis suggesting extrahepatic obstruction.
- Kalaazar—Some degree of liver enlargement always present. Progressive enlargement of spleen, long continued fever, loss of weight, anaemia, bleeding tendencies and increasing darkness of complexion. Demonstration of Leishman-Donovan bodies in sternal smear.
- Leukaemia—Smooth enlargement of liver, moderate in myeloid, gross in lymphoid leukaemia, massive splenomegaly, anaemia. Blood picture or at times needle biopsy of liver confirms diagnosis.

Fig. 13: CECT abdomen arterial phase showing enhancing large hepatocellular carcinoma (arrow heads)

9. Hodgkin's disease—Hepatosplenomegaly develops during course of the disease. Rubbery, non-tender lymph nodes usually in neck. Systemic symptoms like weight loss, night sweats, fever or pruritus. Raised ESR. Gland (or liver) biopsy reveals Sternberg-Reed binucleate giant cells.
10. PYOGENIC liver abscess or abscesses—Pain and tenderness localised in hepatic area, chills and fever. High leucocyte count. Location and number of abscess(es) determined by CT scan, sonography. Positive blood culture of pus or tissue aspirated from liver helpful in diagnosis and treatment.
11. Miliary tuberculosis—Tender liver edge. Pyrexia. Concomitant active tuberculosis elsewhere and other features of haematogenous dissemination.
12. Primary biliary cirrhosis (PBC)—Predominantly in females. Hepatomegaly and pruritus with or without jaundice. There may be pigmentation, xanthelasma, splenomegaly, ascites and bleeding varices. Elevated serum ALP and α -glutamyl transferase present in 95%.
13. Tropical splenomegaly syndrome (TSS)—Gross splenomegaly with moderate hepatomegaly in immune adults from areas of endemic malaria. Raised malarial antibody titres, high serum IgM level. Liver biopsy - Hepatic sinusoidal lymphocytosis. Absence of malarial parasites on peripheral smear.
14. Budd-chiari syndrome—(Hepatic venous obstruction) - Liver enlarged and tender. Failure of jugular veins to fill when liver is pressed. Ascites. Ascitic fluid of high protein content and may be blood stained.
15. Sickle cell disease—Moderate enlargement of liver with jaundice. Sickled red cells.
16. Hydatid cyst—Firm, smooth, non-tender liver. No jaundice, no splenic enlargement. History of contact with dogs. At times pyrexia of unknown origin following secondary pyogenic infection. Jaundice may occur due to pressure on bile ducts. Hydatid thrill may be elicited. Eosinophilia. Plain radiograph of abdomen - calcification in long-standing liver hydatids. Ultra-sound - Cysts with characteristic appearances of daughter cysts and scolices inside them.
17. Hemochromatosis—Hepatomegaly with predisposition to cirrhosis. Lethargy. Arthralgia with swelling of second and third metacarpal joints in early stages, late chondrocalcinosis of large and small joints. Skin pigmentation limited to shins and light-exposed areas. Elevated serum iron content. Measurement of chelatable iron excretion in urine after injection of desferrioxamine 10 mg/ kg body wt. - more than 2 mg of ferrioxamine excreted in 24 hours. Diagnostic histology on liver biopsy.
18. *Syphilis of the liver*—Firm, irregular enlargement. Stigmata of syphilis and positive serology. Therapeutic test in doubtful cases with iodides and penicillin will produce reduction of swelling and of local tenderness.
19. *Schistosomiasis*—Hepatomegaly with portal hypertension, splenomegaly, oesophageal varices and dependent oedema. Liver failure may lead to gynecomastia, scanty body hair and stunted growth. Diagnosis is established by remnants of lateral spinal eggs of *Schistosoma*, pigments, granulomas and portal fibrosis on liver biopsy.
20. *Clonorchiasis*—Due to infestation with *Clonorchis sinensis* (liver fluke). Advanced disease is characterised by hepatomegaly, ascites and oedema. Malignant change may lead to carcinoma of bile ducts or liver. Eosinophilia and raised alkaline phosphatase. Diagnosis confirmed by demonstration of eggs in faeces or in bile obtained by duodenal intubation.
21. *Amyloidosis*—Liver usually large, smooth, rubbery and nontender. Jaundice and ascites may occur. Generalised oedema common. Albuminuria and evidence of chronic sepsis or rheumatoid arthritis. Liver function tests normal. Aspiration liver biopsy, or kidney biopsy or rectal biopsy shows amyloid material.
22. *Myeloid metaplasia*—It can occur in conditions of bone marrow replacement or irritation. Liver enlarged with firm smooth edge. Massive spleen. Jaundice rare.

Liver function tests normal. Primitive leucocytes or red cells in the peripheral blood.

23. *Gaucher's disease*—Hepatosplenomegaly, pigmentation of exposed parts. Wedge-shaped thickening of conjunctivae at angles of eyes. Spontaneous bone fractures or bone pain with fever. X-rays of long bones like femur show expansion of lower end. Sternal marrow will show large pale Gaucher cells with fibrillary cytoplasm and eccentric hyperchromatic nuclei.

12. LIVER DISEASE IN PREGNANCY

LIVER DISEASE SPECIFIC TO PREGNANCY

1. *Liver dysfunction in hyperemesis gravidarum* is generally mild and resolves as the vomiting settles. IV dextrose 5% is useful.
2. *Cholestasis of pregnancy* usually presents as pruritus of extremities in last trimester of pregnancy but can be earlier. Jaundice is uncommon, ALT elevation is the routine test; serum bile acid elevation confirms the diagnosis when routine LFTs are normal. It is more common in multiple gestations and in women given progesterone supplements during pregnancy.

Treatment: Ursodeoxycholic acid, 10 mg/kg/day improves symptoms and biochemistry. Cholestasis and steatorrhoea may cause vitamin K deficiency and predispose to post-partum hemorrhage if prolonged prothrombin is not corrected before delivery. The foetus is at increased risk of premature labour, foetal distress and stillbirth, but elective delivery at 37–38 weeks avoids these in almost all cases.

3. *HELLP syndrome*. Features are nonspecific and are shared by overlapping syndromes such as hemolytic uraemic syndrome and thrombotic thrombocytopenic purpura. Defining features: (a) Haemolysis (microangiopathic). (b) Elevated ALT and AST (2 to 10 times upper limit of normal). (c) Low platelets $< 100,000 \times 10^9/L$. HELLP syndrome occurs in the setting of pre-eclampsia, with weight gain and oedema, hypertension and tenderness over the liver. Early delivery is helpful, though the condition may progress or develop *de novo* post-partum peaking at about 48 hours after delivery.
4. *Acute fatty liver of pregnancy* is most common in first and multiple pregnancies. Onset is confined to the third trimester, with vomiting, upper abdominal pain, anorexia and malaise. Early laboratory findings

include hyperuricemia and normoblasts on blood film. Later disseminated intra-vascular coagulation, leucocytosis, hypoglycemia and hyperammonemia develop and progress to fulminant liver failure.

5. *Ovarian hyperstimulation syndrome* is caused by fertility treatment. Ascites may require drainage, and correction of haemoconcentration is vital.
6. *Other liver diseases occurring during pregnancy*.

Gallstone formation is increased particularly in association with obstetric cholestasis.

Budd-Chiari syndrome may be seen when the heightened thrombotic tendency unmasks risk factors.

Hepatitis E has a high mortality in pregnancy.

13. DRUG-INDUCED LIVER DISEASE

Drug-induced liver disease may be immunologically mediated or caused by direct toxicity.

Manifestations of drug-induced liver disease can be varied as given in Table 45.

Peliosis hepatitis—Development of diffuse vascular lakes within the liver due to intake of androgens or oestrogens. The condition may predispose to acute hemorrhage within the liver or intraperitoneally. Another predisposing cause is vinyl chloride. Some cases occur spontaneously. The condition predisposes to angiosarcoma.

14. LIVER TRANSPLANTATION

Indications of liver transplant are listed in Table 46.

Table 47 lists contraindications for liver transplant.

COMPLICATIONS

Graft rejection is confirmed by liver biopsy. Acute rejection responds to high-dose corticosteroids. Chronic irreversible graft rejection typically develops during first year post-transplantation, and is associated with progressive jaundice. Histological features include degeneration of interlobular bile ducts (vanishing bile duct syndrome) and small artery occlusion by lipid-laden macrophages.

Opportunistic infection

- Fungal infection
- Cytomegalovirus (CMV) infection

Recurrent liver disease

- Viral hepatitis
- Primary biliary cirrhosis

Table 45: Manifestations of drug-induced liver disease

Abnormality	Causative drugs
• Acute hepatitis	Paracetamol, aspirin, isoniazid, halothane, penicillins, first-generation cephalosporins, allopurinol, cyclophosphamide, vincristine, furosemide, hydralazine, dantrolene, methylodopa, phenytoin, monoamine oxidases, co-amoxiclav
• Acute cholestasis	Chlorpromazine, gold, penicillamine, oral contraceptive pill, androgenic steroids, rifampicin, erythromycin, nitrofurantoin, azathioprine, cyclosporine, propylthiouracil, captopril
• Mixed hepatitis and cholestasis	Sulphonamides, penicillins, phenothiazines, tricyclic antidepressants chlorpropamide, diltiazem, diazepam, carbamazepine, colchicine, NSAIDs, carbimazole, flucloxacillin, co-amoxiclav
• Steatosis	
Microvesicular	Tetracycline, valproate, aspirin, zidovudine
Macrovesicular	Methotrexate, alcohol, glucocorticoids
• Steatohepatitis	Alcohol, amiodarone
• Chronic hepatitis	Isoniazid, nitrofurantoin, papaverine, dantrolene, methylodopa, hydralazine, co-amoxiclav
• Chronic cholestasis	Chlorpromazine, amitriptyline, phenobarbital, flucloxacillin
• Phospholipidosis	Amiodarone, perhexiline maleate
• Cirrhosis	Methotrexate, amiodarone, alcohol, methylodopa, vitamin A
• Granulomatous damage	Phenylbutazone, sulphonamides, phenytoin, diltiazem, tolbutamide, nitrofurantoin, aspirin, carbamazepine, procainamide, quinidine, penicillin, sulphonylureas, allopurinol, sulphasalazine
• Neoplasia	Anabolic steroids, oral contraceptive pill
• Vascular injury	Oral contraceptive pill, vitamin A, arsenic, azathioprine, dacarbazine, cyclophosphamide
• Biliary tract disease	Co-amoxiclav, dextropropoxyphene
• Gallstones	Clofibrate, octreotide, oral contraceptive pill
• Vanishing bile duct syndrome	Chlorpromazine

Table 46: Indications of liver transplant

Cirrhosis
<i>Acute liver failure</i>
• Paracetamol overdose
• Hepatitis B
• Hepatitis E
• Drugs is those used to treat TB
Primary biliary cirrhosis
• Serum bilirubin exceeds 100 mmol/l
• Refractory pruritus
Primary sclerosing cholangitis
• Increasing jaundice
• Recurrent symptomatic cholangitis
Chronic HCV infection
• Decline of liver synthetic function
• (Serum albumin < 28 g/L, prothrombin time > 6 seconds)
Alcoholic liver disease
• Liver failure persists despite abstinence
Hepatocellular carcinoma
<i>Rare causes</i>
• Hepatic venous obstruction pregnancy to cirrhosis
• Biliary atresia in babies
• Genetic disorders
• Wilson's disease
• Crigler-Najjar syndrome

Table 47: Contraindications for liver transplant

Absolute
Disseminated malignancy
Uncontrolled sepsis outside biliary tree
Severe cardiopulmonary disease
Chaotic behaviour (e.g. ongoing alcohol or sustained abuse)
Cholangiocarcinoma
Critical illness
Relative
Portal vein and/or mesenteric vein thrombosis
Advanced age (≥ 65)
Pulmonary hypertension (uncontrolled)
HIV infection

- Primary sclerosing cholangitis
- Autoimmune hepatitis
- Genetic hemochromatosis
- Alcoholic liver disease

Bile duct disorder stenosis, obstruction or leak Vascular compromise: (1) Portal vein obstruction (2) Hepatic artery thrombosis (3) Anastomotic leak with intraabdominal bleeding.

15. GALLSTONES

PATHOGENESIS

Physiochemical Factors

- Increased hepatic cholesterol secretion and chronic supersaturation of bile.
- Enhanced cholesterol crystal nucleation in gallbladder bile.

Motility Defects

- Gallbladder motility defects
- Gallbladder stasis
- Intestinal motility defects. Prolonged intestinal transit, longer migrating motor cycles and disrupted motilin release.

Risk Factors for Gallstones

These are listed in Table 48.

CLINICAL FEATURES OF GALLSTONES AND COMPLICATIONS

a. In the gallbladder

1. **No symptoms** (Silent gallstones)
2. **Biliary colic**—Due to contraction of gallbladder against a stone impacted in common bile duct. This gives rise to midline or right hypochondrial pain, at times associated with vomiting but generally without fever or systemic upset. Upper abdominal tenderness may be present.

3. Acute cholecystitis

Symptoms—(a) Pain - Type: *Distension pain* giving rise to a deep, central poorly localised pain. *Peritoneal pain* with overlying skin tenderness and muscle rigidity in right hypochondrium. *Referred pain* radiating to right scapular region. *Digestive tract pain* causing abdominal colic, nausea and flatulence without vomiting.

Table 48: Risk factors for gallstones

Cholesterol stones

Older age
Female sex
Obesity, metabolic syndrome, high calorie diet
GI motility disorders
Parenteral nutrition (reduces gallbladder motility)
Pregnancy and sex hormones
Drugs: Octreotide, Ceftriaxone
Diabetes mellitus, cystic fibrosis
Surgery (e.g. vagotomy, biliopancreatic bypass)

Pigment stones

Cirrhosis
Diseases of terminal ileum

Signs:

- (i) **General**—Include fever with often chills at onset, and tachycardia.
- (ii) **Local**—(a) Tenderness and muscle guarding in right upper quadrant. (b) Palpable mass - of globular shape below right costal margin and moving on inspiration may be felt. (c) Murphy's sign - Patient complains of pain on taking a deep breath while the examiner's hand is pressed below the right costal margin. (d) Abdominal distension - may occur and if marked simulates intestinal obstruction. (e) Boas sign - Area of hyperaesthesia over right subscapular region.

Investigations:

1. **Leucocyte count** raised with increased polymorphs.
2. **Radiograph**—Plain film of the abdomen may reveal radio-opaque gallstones or soft tissue mass in region of GB.
3. **Ultrasonography** is the most commonly used method of detecting stones (Fig. 14). Stones must be greater than 1–2 mm in diameter to be seen.

It is unable to distinguish between cholesterol and calcified stones.

4. **Oral cholecystography** identifies radiolucent stones. It is useful in determining gallbladder contraction and cystic duct patency, and identifying anatomical abnormalities of the gallbladder.

Fig. 14: Ultrasonography showing gallbladder stone (white arrow) with its acoustic shadow (black arrow)

Fig. 15: CT abdomen Showing large single gallstone (arrow) with thickened gallbladder (arrow heads)

5. *CT* is more sensitive in identifying gallstone calcification than plain radiology.

It is required in selection of patients for non-surgical therapy (Fig. 15).

6. *Other investigations* used in complicated gallstone disease include ERCP for common bile duct stones, LFTs for acute cholecystitis, serum amylase levels for acute pancreatitis.

Management:

1. *Diet*—Nothing by mouth for first 24 hours, or till nausea and vomiting have abated.
2. *Broad spectrum antibiotics*—Parenterally to prevent peritonitis, cholangitis and septicaemia.
3. *Special measures*—(a) Local heat to abdomen. (b) 5% glucose saline intravenously. (c) TPR 2 hourly. (d) Examine abdomen every 2 hours to follow changes in tenderness, rigidity, and character of any palpable mass. (e) Total and differential WBC count. (f) Gastric suction if persistent vomiting.
4. *Surgery*—Cholecystectomy within 2–3 days of the onset of symptoms shortens total hospital stay and avoids incidence of repeated attacks of waiting period of delayed ‘cold’ cholecystectomy.
5. *Chronic cholecystitis* may follow repeated attacks of biliary colic or present with abdominal distension or epigastric discomfort sometimes relieved by belching, nausea triggered by fatty food and a dull ache in right

hypochondrium, epigastrium and right subscapular region. There is localised tenderness in right hypochondrium and positive Murphy’s sign.

b. In bile ducts

1. **Biliary colic with transient jaundice**—Due to migration of small stones into the common bile duct and ejection through the papilla of Vater.
2. **Acute pancreatitis**—Due to probably reflux of bile into pancreatic duct through a common channel in ampulla of Vater.
3. **Obstructive jaundice**—From impaction of stone in common bile duct.
4. **Cholangitis:**
 - (a) **Pyogenic cholangitis**—Acute suppurative or non-suppurative inflammatory process in biliary system associated with biliary obstruction. Charcot’s triad of jaundice, upper abdominal pain and high fever with rigors. Added presence of bacteraemia and mental stupor constitute Reynold’s pentad.
 - (b) **Chronic recurrent cholangitis**—May occur in presence of incomplete bile duct strictures and result in secondary biliary cirrhosis and portal hypertension.

MANAGEMENT OF GALLSTONES

Surgical treatment—Laparoscopic or open cholecystectomy is the only radical procedure for symptomatic gallstones.

Non-surgical treatment

1. **Oral litholytic treatment**—Bile acids Chenodeoxycholic acid 10–12 mg/kg/day, and Ursodeoxycholic acid 10–12 mg/kg/day, alone or in combination (using one half of the dose of each) is suitable for radiolucent small stones (<10 mm in diameter). Pigment stones are not responsive to medical therapy. The whole dose should preferably be taken at bed time. Side effects – Chenodeoxycholic acid: diarrhoea and hypertransaminasemia. Ursodeoxycholic acid: gallstone calcification resulting in treatment failure.
2. **Contact dissolution treatment**—Percutaneous transhepatic gallbladder puncture followed by application of methyl-butyl ether (powerful cholesterol solvent) directly to the stones. Any number and size of stones can be treated. Complete dissolution is usually achieved within a few hours. Side effects – Post-puncture severe abdominal pain and nausea, erosive duodenitis and biliary peritonitis.
3. **Extracorporeal shockwave lithotripsy (ESWL)**—Fragments the stones using focussed sound waves; the fragments are subsequently dissolved by bile acid therapy. The procedure is suitable for patients with up to three stones of diameter 10–30 mm. Side effects – Biliary colic, haemobilia and pancreatitis.
Recurrent stones—are radiolucent and smaller, and can be redissolved with bile acids if detected early.

Table 49: Causes of acute pancreatitis

• Gallstones
• Alcohol
• Drugs: Tetracyclines, oestrogens, azathioprine, thiazides, valproic acid, corticosteroids, organophosphorus poisoning
• Infections: Viral hepatitis, mumps, toxoplasmosis, roundworms
• Iatrogenic: ERCP
• Metabolic conditions: Hypertriglyceridemia, kidney failure, post-kidney transplantation, hypercalcemia, acute fatty liver of pregnancy
• Trauma blunt and penetrating
• Hereditary
• Scorpion sting
• Idiopathic

- Vomiting
- Dehydration
- Epigastric tenderness
- Confusion (due to hypoxia)
- Jaundice (10–20%)
- Discoloration of flanks (Grey-Turner sign) and/or Discoloration of periumbilical area (Cullen's sign). Both these signs indicate severe necrotizing pancreatitis.

Diagnosis

- (a) Point-of-care urine Trypsinogen -2 test. Good sensitivity and specificity and can be used at the bed side.
- (b) In such cases CT should be performed to confirm the diagnosis.

Serum amylase and serum lipase elevated three fold or more. Serum amylase value tends to be normal in 3–7 days even in continuous presence of pancreatitis while serum lipase takes 7–14 days.

Management

Immediate treatment—Patient must be fitted with a face mask and given oxygen until there is no danger of organ failure. Simultaneously, fluid replacement with a mixture of crystalloid and colloid to restore circulating volume and maintain urine output. These measures help to limit or prevent organ failure.

Nutritional management: Enteral therapy is started after 2–3 days of admission. Enteral therapy is preferred over total parenteral nutrition as (1) Enteral feeding maintains gut barrier integrity, (2) Prevents bacterial translocation, (3) Less expensive and (4) Less complications.

16. PANCREATIC DISEASE**ACUTE PANCREATITIS**

Acute pancreatitis is characterized by sudden, severe abdominal pain and a varying degree of systemic upset.

Causes

Causes of acute pancreatitis are enumerated in Table 49.

Pathogenesis

Acute pancreatitis is caused by various insults to the pancreas leading to local injury, activation of pancreatic enzymes and in some cases, activation of the systemic inflammatory response syndrome (SIRS). This manifests as signs of organ failure or dysfunction and of sepsis. Local inflammatory changes in the pancreas, perhaps combined with systemic circulatory effects, lead to areas of necrosis of pancreatic tissue.

Clinical Features

- Pain – usually epigastric radiating to the back

Fig. 16: CT abdomen showing acute necrotising pancreatitis with large oedematous pancreas (arrows)

Further assessment—It can be undertaken once resuscitation has begun. (a) LFTs in first 24 hours indicate a likely biliary cause (raised transaminases or bilirubin). (b) Abdominal ultrasonography reveals any stones in GB. (c) CT may be helpful when there is doubt about the diagnosis, but it is preferable to wait 7–10 days after onset of symptoms for detection of pancreatic necrosis (Fig. 16).

Intervention can be in three forms:

- (a) *Treatment to remove the cause:* ERCP for gallstones within 48–72 hours of admission to hospital. Endoscopic sphincterotomy should be performed in all patients undergoing ERCP.
- (b) If secondary to alcohol consumption or medication (valproate, pentamidine, azathioprine, oestrogens, cytosine arabinoside, and possibly furosemide or corticosteroids) patient should avoid these agents in future.
 - *Preventive treatment:* Early enteral nutrition is safe and preferred to parenteral nutrition. Patients with mild pancreatitis can be allowed to drink freely from admission.
 - *Prophylactic antibiotics* in patients with predicted severe pancreatitis including evidence of pancreatic necrosis. There is no role of prophylactic antibiotics in necrotizing pancreatitis. If patient appears septic then broad spectrum antibiotic started till culture report awaits. In case of negative culture reports antibiotics should be stopped.
 - *Surgical treatment* may be necessary for complications such as pancreatic necrosis or pseudocyst.

Late Complications

Pseudocysts can cause abdominal pain, anorexia or gastric symptoms, can often be palpated, and are diagnosed by ultrasonography or CT.

Abscess presents like pseudocyst with additional symptoms of sepsis. Imaging, diagnostic aspiration and culture confirm the diagnosis.

Internal fistulas are uncommon but can cause pleural effusion and persisting ascites.

CHRONIC PANCREATITIS

Chronic pancreatitis is a progressive, irreversible inflammatory disease. The dominant symptom is usually upper abdominal pain, which can be incapacitating. As the disease progresses, exocrine insufficiency (manifested as weight loss and steatorrhoea) and/or endocrine insufficiency (diabetes mellitus) become more common.

Aetiology

1. *Chronic calcifying pancreatitis* (CCP)

Alcohol is the major cause, the risk related to duration of drinking and amount consumed. CCP is more likely to develop in individuals with a high-fat, high-protein diet. Most patients are men between ages of 40 and 50 years.

Idiopathic pancreatitis is equally common in men and women. There is bimodal age distribution. In contrast to alcoholic CCP, progression to diabetes and steatorrhoea is delayed.

Nutritional pancreatitis presents in childhood with equal sex distribution. Malnutrition and casava content of the diet have been implicated. Recurrent abdominal pain is the dominant symptom.

Hereditary pancreatitis is uncommon. Mutations in the cationic trypsinogen have been identified. It is an autosomal dominant condition that begins in childhood and is a significant risk factor for pancreatic cancer (Fig. 17).

Patients with hyperlipidaemia or hyperparathyroidism commonly present with acute pancreatitis, but some develop CCP.

2. *Chronic obstructive pancreatitis* is less common than CCP:

- Tumors of ampulla and pancreas (mostly malignant)
- Cystic lesions—Most inflammatory, few congenital or neoplastic.

Fig. 17: CT abdomen showing carcinoma of head of pancreas

- Pancreatic duct damage due to acute pancreatitis, resolution of cyst or pseudocyst, or trauma.
- Ampullary stenosis or associated diverticulum.
- Cholelithiasis usually causes acute pancreatitis but some patients have chronic disease.

Clinical Features: Presentation

- *Severe episodic upper abdominal pain*, that radiates to the back. It lasts for hours or days and may be relieved by bending forwards or vomiting. It is often precipitated by large meal or alcohol 12–36 hours previously. Some patients, particularly with idiopathic CCP, experience no pain.
- *Weight loss* with symptoms of pancreatic functional failure (steatorrhoea and diabetes mellitus).
- Some patients with *acute pancreatitis* are diagnosed incidentally at laparotomy or after finding of pancreatic calcification.
- *Complications of the disease* may be presenting feature e.g. epigastric mass from pseudocyst formation.
- *Obstructive jaundice* may result from common bile duct compression by inflamed head of pancreas.

Investigations

Imaging

Plain abdominal radiograph may show pancreatic calcification.

Ultrasonography shows changes in pancreatic size, shape, echotexture and calcification. Endoscopic ultrasonography allows detailed investigation of difficult cases (notably cystic or mass lesions), and demonstrates small calculi not seen by conventional ultrasound.

Fig. 18: CT scan showing multiple, discrete, small opacities, diagnostic of calcifying chronic pancreatitis

CT scan—It is initial modality of choice. It shows diffuse calcification, dilated ducts and atrophic pancreas. **CT** (Fig. 18) is less operator dependent and is not affected by bowel gas.

ERCP is the ‘gold standard’ investigation. Pancreatography demonstrates stenosis or disruption of pancreatic duct, variant duct anatomy and connections to cystic lesions. Cholangiography shows choledocholithiasis and ampullary or common bile duct stenosis.

Magnetic resonance cholangiopancreatography provides information about ductal and vascular structure and function. Uses include evaluation of tumors and cystic lesions, follow up of pseudocysts and stents, and when ERCP has failed to diagnose.

Biochemical investigations—There is no reliable biochemical test for chronic pancreatitis.

Serum enzymes amylase, isoamylase, trypsin and lipase levels may be elevated during an exacerbation, but are often normal. An abnormally low serum level is specific confirmation that steatorrhoea is of pancreatic origin.

Exocrine Function Test

- Secretion capacity: (i) Chymotrypsin or elastase in the stool. (ii) pancreozymin - secretin test has good specificity and sensitivity. The test requires intubation of the duodenum. After stimulation with pancreozymin and secretin, enzyme secretion and volume are measured. The test is positive if >50% of glandular tissue is destroyed.
- Digestive capacity: Tubeless pancreatic function test NBT-PTA test and pancreo lauryl test, which are based on the detection of degradation products released by

pancreatic specific enzymes after oral intake, and are resorbed from the intestine and excreted in urine.

Qualitative stool fat determination - In steatorrhoea fat content of stool >7g/24 hour.

(c) Endocrine function test: Oral glucose tolerance test is impaired.

Pancreatic biopsy. Percutaneous ultrasound-guided or CT - guided biopsy using automated device (biopsy gun) is safe and reliable technique to obtain a histological sample. It is used to determine the nature of pancreatic mass lesions, and in whom there is a strong suspicion of chronic pancreatitis if other investigations have not helped.

Management

Control of Pain

Nonsteroidal analgesics are preferred but most patients with severe pain require oral narcotic analgesics.

Abstinence from Alcohol

Steatorrhoea—Pancreatic enzyme supplements enteric coated. A few patients also require H₂ receptor antagonists or dietary fat restriction.

Diabetes—may be controlled using diet or oral hypoglycaemic agents. Patients who require insulin are prone to hypoglycaemic episodes.

Endoscopic therapy and ERCP—Patients are first screened by fluoroscopy and MRCP to assess the morphology of the duct and see the location, size and distribution of stones. Patients who are suitable for endotherapy are first subjected to intensive ESWL sessions for stone pulverization followed by ERCP and stone clearance.

Antioxidant therapy—Micronutrient supplementation with selenium, methionine and vitamins A, C and E, since evidence suggests that oxidative stress is an important factor in pathogenesis of pancreatitis, regardless of the aetiology.

Surgery—Suitability for surgical approach - Patients who have a complete distal pathology in the head, have an inflammatory head mass, those who have predominantly tail stones and those who have an atrophied gland with severe pain are most suitable for surgical intervention (Head coring, bypass or resection).

Chronic tropical pancreatitis is a juvenile form of pancreatitis affecting usually young males, and not related to intake of alcohol.

Abdominal pain - In epigastric area radiating to back and precipitated by large meal. Associated features parotid

gland enlargement, under nutrition, malabsorption and steatorrhoea due to pancreatic exocrine deficiency. Diabetes mellitus.

Tr. Same as chronic pancreatitis. Insulin for control of DM.

AUTOIMMUNE PANCREATITIS

It is disorder with autoimmune pathology and characteristic laboratory, histological and morphological features. It is associated with other disorders of presumed autoimmune etiology and this has been termed IgG4 systemic disease.

It has 2 types:

1. Type 1: Pancreas is involved as part of systemic IgG4 disease. On histopathology, there is lymphoplasmacytic infiltration with IgG4 positive cells.
2. Type 2: It is without IgG4 positive cells and systemic involvement

Clinical Features

Abdominal pain, weight loss, new onset diabetes, steatorrhoea.

Clinical features of associated systemic IgG4 diseases—Sjögren's syndrome, rheumatoid arthritis, cholangitis, Mikulicz's disease, sialadenitis, autoimmune thyroiditis, ulcerative colitis, tubulointerstitial nephritis.

Investigations

1. Alkaline phosphates elevated out of proportion to minimally elevated aminotransferase.
2. Elevated IgG4 levels.
3. Autoantibodies seen like ANA, rheumatoid factor.
4. CT scan reveals focal enlargement, diffuse enlargement and distinct enlargement of pancreatic head.
5. ERCP or MRCP reveal diffuse irregular narrowing of pancreatic duct.

Treatment

These patients respond well to systemic steroids. Prednisone is started at the dose of 40 mg/day for 2–4 weeks then as per patient response it is tapered 5 mg/week.

Response is monitored with clinical improvement, decrease in alkaline phosphatase level and IgG4 levels and serial changes in imaging.

Type 1 patients tend to relapse in those patients use of azathioprine has shown improvement. Other agents like rituximab, cyclophosphamide, cyclosporine have been successful in small group of patients.

The Respiratory System

1. INVESTIGATIONS OF RESPIRATORY DISEASE

Imaging in chest disease

CHEST RADIOGRAPHY

Radiographic Projections

Erect radiographs are preferred to supine radiographs because - (a) Lungs are more expanded, allowing easier assessment of pulmonary and mediastinal structure. (b) Air-fluid levels are detectable. (c) A gravitational gradient in vessel size from large at base to smaller at apex is present. A radiograph can be identified as erect if the gastric air bubble (though not always present) lies under the left hemidiaphragm.

Lateral views may be useful for - (a) Clarifying the nature of opacities seen on PA film. (b) Localizing lesions. (c) Detecting lesions lying behind heart or diaphragm. (d) In patients presenting with haemoptysis and a normal PA radiograph.

Alteration in Normal Anatomy

Lungs- Zones: For sake of convenience the lung fields are divided into upper (above anterior end of 2nd rib), middle (between anterior ends of 2nd and 4th ribs) and lower (below anterior end of 4th rib).

Observations - Both lung fields should be compared, they should be equally lucent at equivalent sites. Apices, costo-phrenic and cardio-phrenic angles should be clear. Vessels in upper zone are thinner than those of a similar generation in lower zones.

Reversed relationship is an important sign of raised pulmonary venous pressure or basal lung pathology e.g. pulmonary emboli or fibrosing alveolitis. The horizontal fissure is of hairline thickness and extends horizontally or slightly downwards from 1 cm below right hilar point (point at which superior pulmonary vein and pulmonary artery cross) to the chest wall. Displacement indicates a possible volume change in the right chest.

Diaphragm- Both the hemidiaphragms have a smooth curve, the right hemidiaphragm being higher by up to 3 cm, than the left. The curve is flattened in generalised emphysema. Elevation of the diaphragm can be unilateral or bilateral.

Chest wall- Ribs must be examined by scanning up and down. Main abnormalities include fracture, notching, evidence of surgery and change in structure such as sclerosis or destruction. Crowding of ribs seen in case of lung volume loss, e.g. fibrosis, post-tuberculosis sequelae and increased spacing between ribs seen in diseases like emphysema or compensatory inflation in response to lung volume loss on opposite side.

Mediastinum and heart- The mediastinum envelope is formed by borders of various structures, (enlargement of which causes local prominence of the appropriate segment).

Lung hila- Radiographically, the hila consist of vascular structures (arteries and veins). Each hilum should be approximately equal in size and of same density. **Hilar abnormalities** can be - (a) Change in size - usually enlargement of normal component e.g. enlargement of pulmonary artery in case of pulmonary hypertension. (b) Reorientation of normal components e.g. with collapse of a lobe. (c) Appearance of a mass e.g. lymphnode enlargement or carcinoma.

Digital chest radiography—Conventional requires exposure of a film to X-rays. In picture - achieving communication systems (PACS), pictures are taken using digital techniques that do not require formation of an image on a film. The information derived can be reimprinted onto a reusable photostimulable plate. The digital image generated can be printed onto film or stored in a computer system, from which it can be transmitted to wards and outpatients. The images can be manipulated, allowing magnification, measurement and contrast manipulation, and stored and recalled for comparison with earlier films.

Fig. 1: X-ray chest showing extensive homogeneous white shadowing in the mid and lower zones of right lung with air bronchogram

Fig. 2: CT thorax showing caseating enlarged mediastinal tubercular lymph nodes

Fig. 3: Pulmonary embolism

The chest radiograph in lung diseases. Basic patterns are:

- Air bronchogram
- Pulmonary collapse
- Pulmonary nodule/mass
- Multiple pulmonary nodules
- Ring shadows and cysts
- Line shadows
- Nodular, reticular honeycombing
- Increased transradiancy

Air bronchogram. The intrapulmonary airways distal to the proximal segmental bronchi are not normally visible on a chest radiograph. When the normally aerated pulmonary parenchyma is replaced by non-aerated tissue, the bronchi and bronchioles become visible as branching,

linear lucencies – the air bronchogram, this may occur because the alveoli are filled with fluid or cellular material or because the interstitium expands and compresses the alveolae. The most common causes are pneumonia and pulmonary oedema (Fig. 1).

CT scanning- Its important applications are – (a) Detection and characterization of mediastinal masses (Fig. 2). (b) Staging bronchial carcinoma, assessing spread particularly lymphnodes, and invasion of adjacent structures. (c) Locating and characterizing pleural disease, distinguishing between lung and pleural diseases, e.g. abscess and empyema, staging pleural mesothelioma and assessing chest wall invasion. (d) Assessing the doubtful hilum, distinguishing vessels and masses. (e) Metastatic nodule detection in the lung. (f) The 3-dimensional images obtained by multi detector CT scan (MDCT) can be reconstructed digitally and utilised to generate airways up to sixth or seventh generation, it is called as Virtual bronchoscopy. (g) CT pulmonary angiography, using contrast agent with MDCT, allows visualisation of pulmonary vasculature and helps in diagnosis of thromboembolic diseases upto segmental and subsegmental level. It has added advantage that simultaneous visualisation of pulmonary parenchyma to detect any contributory disease condition (Fig. 3).

High resolution CT (HRCT) scanning is more sensitive and specific in the diagnosis of parenchymal lung disease than conventional radiography. It can sometimes supplant biopsy e.g. in suspected cases of chronic fibrosing alveolitis, asbestosis and lymphangitis.

Ultrasound is useful for imaging pleural disease (both pleural fluid and pleural thickening) and outlining

diaphragmatic regions e.g. subphrenic abscess. It is also used for diagnostic and therapeutic pleural fluid aspiration especially in loculated effusions.

MRI has limited application in the chest. Its major applications include: (a) Imaging of aortic aneurysms. (b) Detection of tumour invasion of chest wall and mediastinum. (c) Distinguishing between tumour and consolidation or post-treatment fibrosis. (d) Assessing posterior mediastinal masses. (e) Distinguishing between nodes and vessels.

Bronchography - Radiography of the lungs after injection of an opaque medium in the bronchi may be indicated for - (a) Unexplained haemoptysis. (b) Bronchiectasis especially prior to surgery. (c) Broncho-pleural fistula. (d) Lung tumors. Contraindication - Recent episode of haemoptysis or severe chest infection.

Positron emission tomography (PET) scanning - It is used to identify malignant lesions of lung depending on uptake and metabolism radiolabelled glucose, [¹⁸F]-fluoro-2-deoxyglucose (FDG).

The drawback of test is limited anatomical definition which can be overcome by combining with CT scan. It allows superimposition of PET and CT images and helps in functional plus anatomical mapping.

PULMONARY FUNCTION TESTS

Indications for PFTs

See Table 1 for Indications for PFTs.

Limitations

1. Tests cannot reveal pulmonary disease unless the functions are sufficiently lower over an earlier testing.
2. Tests do not provide anatomical diagnosis but can help localise it to a section of airway or lung.
3. Tests fail to localise disease process except when lungs or lobes are tested separately.
4. Tests must be multiple since no single test can evaluate total abnormality at one time.

Tests for Airway Function—Spirometric Tests and Peak Expiratory Flow

Various tests that are done for airway function and their significance is given in Table 2.

Table 1: Indications for PFTs

• Initial and sequential evaluation of patient, with exertional or paroxysmal dyspnoea.
• Initial and sequential evaluation of a case of known respiratory disease.
• Differential diagnosis of lung disorders.
• Objective assessment of patients with chest problems, e.g. cough, dyspnoea, chest pain.
• Fitness for surgery, particularly on heart or lung.
• Monitoring response to therapy in drug evaluation, e.g. bronchodilators.
• Following course of general disease affecting lung function, e.g. myasthenia gravis, respiratory polio, polyneuritis, Parkinsonism.
• Degree of and disability assessment of occupational lung disease.
• Research purposes.

Table 2: Tests for airway function

Test	Definition	Normal values	Comments
PEF (Peak expiratory flow)	Fastest flow rate that can be sustained for 10 milliseconds at the start of a maximal expiration after full inspiration	300–700 L/minute	Reflects the calibre of airways Dependent on airway diameter and expiratory effort Inexpensive Most useful for monitoring changes in bronchial asthma
VC (Vital capacity)	Largest volume of air expired from full inspiration to full expiration, or inspired by the reverse process	Usual 3–6 L Decreases with age	Reduced in both restrictive and obstructive disorders Correlation with disability in chronic respiratory disorders
FVC (Forced vital capacity)	The largest volume of air that can be delivered by a forced maximal expiration after a full inspiration (TLC = Volume of air in lungs at full inspiration)	As for VC	As for VC
FEV1 (Forced expiratory volume in 1 second)	Volume expired in the first second of forced expiration after a full inspiration	>75–80% of normal VC	Useful indicator of severity of obstructive disease Correlated with maximal exercise capacity
FEV1/VC ratio	Ratio	>70% in males >75% in females Highest in young non-smokers	<70% diagnostic of airflow obstruction (except when VC is high) High (>85%) in lung fibrosis

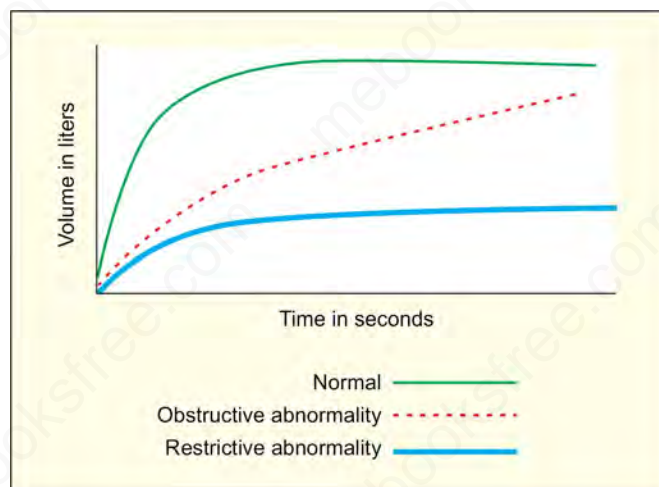

Fig. 4: Interpretation of spirometric data

Improvement (reversibility) of FEV₁ is defined as an improvement in FEV₁ by more than 15% and more than 0.3 litres after administration of salbutamol 200 µg or equivalent by inhalation.

Bronchial challenge studies—Patients with asthma characteristically react to small doses of pharmacological bronchoconstrictors, exhibiting transient decrease in FEV₁ and increase in airway resistance. Most commonly reported measurements are the dose of methacholine or histamine needed to provoke a 20% reduction of FEV₁.

Volume-time curve (Fig. 4) – The FEV₁ depends on good effort in healthy individuals, because the rate at which the lungs empty is determined by the elastic recoil of the lungs and the positive thoracic pressure applied round them by the expiratory muscles. In patients with pulmonary emphysema with reduced elastic recoil and very collapsible airway, FEV₁ is low even when the airways are patent.

Flow volume curves – The term refers to the tracing (a triangular shaped envelop) obtained when a maximal forced expiration is followed immediately by a forceful maximal inspiration (Fig. 5). It is the recording, during spirometry, of expiratory flow plotted against volume. In healthy individuals, the maximal expiratory flow rate decreases steadily throughout forced expiration; as the lungs empty, the airways diminish in size. This representation of maximal flow is useful demonstration of *Small airways disease* – Reduction of expiratory flow during middle of forced expiration, which may be present even when FEV₁ and FVC are normal.

In emphysema when tracheobronchial collapse occurs, peak flow is relatively well preserved but flow rates diminish early in expiration.

Fig. 5: Flow volume loop (obstruction in COPD - dotted lines)

In obstruction of the airways outside the thorax, (glottis, larynx or trachea) flow tends to be constant throughout the first part of expiration rather than decelerating; inspiratory flow is often even lower.

Flow volume loop is a graphic expression of flows of different lung volumes. It helps in identifying variable as well as fixed upper airway obstruction (UAO) at various levels. Patients presenting with obstructed main bronchus show 'biphasic flow volume loop' or 'two can effect' due to slow emptying and filling of the affected lung.

A plateau of the inspiratory and expiratory curves suggests large-airway obstruction in extrathoracic and intrathoracic locations, respectively.

Measurement of static lung by closed circuit helium dilution – Patient breathes from spirometer known volume containing about 10% helium 21% oxygen and nitrogen. Oxygen is added and carbon dioxide removed to maintain a constant volume of gas in the spirometer at the end of each breath. The concentration of helium is measured continuously; the patient rebreathes until the helium concentration remains constant as a result of equilibration with the gas in the lung.

Interpretation

- Restrictive (fibrosing alveolitis): FRC (functional residual capacity), RV and TLC are low, tidal volume often reduced.
 - Obstruction (chronic airflow obstruction) – TLC preserved because of increase in RV.
 - Airflow obstruction and lung fibrosis: Mixed.
- Assessment of reversibility with aerosolized bronchodilators. Significant reversibility is considered to be an increase

in FEV₁ of 200 ml and 12% after 15 minutes of bronchodilator therapy. Bronchial asthma shows good reversibility.

TESTS OF PULMONARY GAS EXCHANGE

The extent of CO gas transfer D_LCO depends on the pulmonary capillary blood volume and the matching between the distribution of ventilation and perfusion of the lungs.

Methods - In the single breath method the patient breathes out to RV, then inspires a gas mixture of helium and CO in air, to TLC. This is held in the lungs for 10 seconds, then the patient slowly exhales. An initial volume of 750 mL (equivalent to the dead space) is discarded, then a sample of expired gas is collected and analysed for alveolar concentrations of helium and carbon monoxide.

The size and integrity of the gas exchanging surface may be assessed using the carbon monoxide transfer factor D_LCO, which is usually measured during 10 seconds of breath holding after full inspiration from RV to TLC. Additional information can be obtained from the transfer coefficient D_LCO volume of air in the lungs during the breath-hold).

Interpretation

D_LCO depends on alveolar function, provided that:

- The airways are normal and allow the inhaled gas to reach the whole lung.
- The concentration of Hb in the blood is normal
- Thickness of the alveolar capillary barrier

D_LCO transfer coefficient is useful in following situations:

- In investigation of breathlessness. Low D_LCO strongly suggests disease at the alveolar level (e.g. interstitial lung disease, pulmonary vascular disease).
- In sarcoid and occupational lung diseases and in conditions characterized by widespread nodules on chest radiography, D_LCO and transfer coefficient reflect the severity of alveolar damage.
- In pleural and chest wall disease, a high transfer coefficient suggests there is no severe underlying lung disease, low values suggest associated alveolar destruction.

Note: Pulmonary plethora, recent pulmonary hemorrhage and polycythemia cause high (D_LCO) Isolated reduction in D_LCO with normal lung volumes in patients of dyspnoea is suggestive of pulmonary hypertension.

ARTERIAL BLOOD GAS ANALYSIS

Arterial blood gas analysis is useful for - (a) Detection of hypoxemia and hypercapnia. (b) Management of respiratory failure. (c) Care of the ventilated patient. (d) Detection of abnormalities of acid-base balance.

Method - Arterial samples can be taken from the radial artery. Whenever possible, blood sample must be taken while patient is breathing room air.

Arterial PCO₂ (PaCO₂) - Normal 40 mm Hg (about 5 kPa) ± 12%.

Arterial PO₂ (PaO₂) varies more widely (80-120 mm Hg, 10-16 kPa).

Interpretation

- Alveolar PaO₂ is high during hyperventilation and low in ventilatory failure.
- In healthy individuals, PaO₂ is 10-20 mm Hg less than PAO₂. Greater differences indicate ventilation/perfusion mismatch.
- The alveolar-arterial PO₂ difference may be calculated from the alveolar air equation:
PAO₂ = inspired PO₂ - PaCO₂ / R, where R is the ratio of carbon dioxide output to oxygen consumption.

Three rules of thumb follow from this:

- If PaO₂ + PaCO₂ < 120 mm Hg (16 kPa) when breathing air, pulmonary gas exchange must be abnormal.
- If PaO₂ + PaCO₂ > inspired PO₂, the patient must have recently breathed a greater concentration of oxygen.
- In normal lungs, PaO₂ (in mm Hg) ³ F% O₂ × 5 mm Hg and PaO₂ (in kPa) ³ F% O₂ × 0.75 kPa, where F% O₂ is the inspired concentration of oxygen.

Arterial oxygen saturation (SaO₂) may be monitored indirectly with an accuracy of ±2.5% using pulse oximetry. Haemoglobin is 95±2% saturated with oxygen at normal PaO₂. SaO₂ declines to 90% when PaO₂ is about 60 mm Hg (8 kPa), this is a clinically important cut-off point associated with the onset of a noticeable ventilatory stimulus and impairment of cerebral and tissue function in non-acclimatised individuals.

Patients with diseases that cause ventilation perfusion mismatch or shunt physiology have an increased gradient between alveolar gas and arterial blood oxygen tension (A-a) DO₂ at rest.

Arterial blood gas testing also allows the measurement of arterial PCO₂. Hypercarbia can accompany severe airway obstruction (e.g. COPD) or progressive restrictive physiology, as in patients with neuromuscular weakness.

Presentations Suggestive of Respiratory Muscle Weakness

Clinical Constellations

- Unexplained dyspnoea (particularly if combined with orthopnoea or dyspnoea in water)

Table 3: Causes of respiratory muscle weakness**Nerve***Acute*

Guillain-Barré syndrome
Organophosphate poisoning
Poliomyelitis

Chronic

Motor neuron disease
Neuralgic amyotrophy (idiopathic and familial)
Trauma (e.g. iatrogenic, road traffic accident)
Hereditary sensorimotor neuropathy
Toxins (e.g. lead)
Drugs (e.g. vincristine)
Porphyria, diabetes mellitus
Lymphomatous/malignant infiltration

Neuromuscular junction*Acute*

Botulism
Envenoming, shellfish poison
Drugs with neuromuscular blocking effects
(as main effect or side effect)

Chronic

Myasthenia gravis
Lambert-Eaton syndrome

Muscle*Acute*

Biochemical disturbance (e.g. hypokalemia)
Periodic paralysis

Chronic

Muscular dystrophies
Myopathy
Acid maltase deficiency
Hypothyroidism

- Chronic respiratory failure (likely to be accompanied by symptoms of nocturnal hypoventilation or hypercapnia)
- Difficulty weaning from mechanical ventilation in the absence of recognized cardiac or pulmonary cause (likely to have low oxygen requirement and low airway pressures, perhaps with difficulty triggering the ventilator)

Recognized Risk Factors

- Known neuromuscular disease (Table 3)
- Clinical features suggestive of neuralgic amyotrophy
- ICU stay of >1 week, particularly if sepsis, use of corticosteroids or neuromuscular blocking agents.
- Surgical/medical procedure known to carry risk to diaphragm or phrenic nerve.
- Marked electrolyte imbalance

Fig. 6: The effect of respiratory muscle weakness on lung volumes. (TLC= total lung capacity; TV = tidal volume; VC = vital capacity RV = residual volume)

Maintenance of oxygen/carbon dioxide haemostasis requires continuous Figure 3 into and out of the alveolus. In health, inspiration occurs when respiratory muscles contract to generate a sub-atmospheric pressure in the thorax, in contrast, expiration is passive at rest though it can be assisted by expiratory muscle contraction in absence of flow limitation.

A combination of one feature from list A and one from list B is particularly suggestive.

See Figure 6 for the effect of respiratory muscle weakness on lung volumes.

Orthopnoea is a classical symptom. In bilateral diaphragm paralysis, inwards (paradoxical) movement occurs in inspiration.

FIBRE-OPTIC BRONCHOSCOPY

The procedure is usually carried out under sedation and local anaesthesia.

Flexible bronchoscopy enables visual inspection of the airway down to the subsegment, and allows various samples to be easily obtained.

Indications of fibre-optic bronchoscopy are listed in Table 4.

Rigid bronchoscopy is now primarily used for interventional procedures such as removal of foreign bodies, tumour ablation and insertion of stents. It is also used in staging before surgical resection of tumour.

Table 4: Indications of fibre-optic bronchoscopy

Diagnostic
Investigation of symptoms
• Haemoptysis
• Persistent cough
• Recurrent infection
Suspected neoplasia
• Unexplained paralysis of vocal cords or hemidiaphragm
• Stridor
• Localized monophonic wheeze
• Suspicious sputum cytology
• Unexplained pleural effusion
Staging of lung cancer
• Mediastinal tissue diagnosis and staging
Infection
• Identification of organisms (e.g. suspected tuberculosis)
• Evaluate airways if recurrent or persistent infection
• Bronchiectasis/lobar collapse cause
Interstitial lung disease
• Bronchoalveolar lavage for differential cell count and histology
Therapeutic and palliative
• Clearance of mucus plugging
• Foreign body removal
• Palliation of neoplasm
• Endotracheal ablation of tumour and stenting

BRONCHOALVEOLAR LAVAGE (BAL)

Technique

A bronchoscope is wedged in a subsegmental bronchus (right middle lobe is the usual site) and sterile isotonic saline injected and aspirated to obtain lung fluid for examination of cells and fluid content.

Indications

- Diagnosis** – (a) Interstitial lung disease. (b) Atypical chest infections (especially in immunocompromised patients). (c) Post transplantation monitoring (diagnosis of infection). (d) Drug toxicity, e.g. amiodarone, bleomycin. (e) Histiocytosis. (f) Lipoid pneumonia. (g) Berylliosis (in vitro test diagnostic). (h) Malignancy (peripheral located tumours).
- Therapy** – (a) Alveolar proteinosis. (b) Asthma – especially in ventilated patients with segmental collapse. (c) Idiopathic pulmonary haemosiderosis. (d) Moni-

Table 5: Differential cell counts in diffuse interstitial lung disease on bronchoalveolar lavage

Lymphocytic excess	Neutrophil and/or eosinophil excess
15–40%	Neutrophils
Sarcoidosis Tuberculosis Berylliosis Drugs Organizing pneumonia HIV	4–15% Fibrosing alveolitis Cryptogenic fibrosing alveolitis Asbestosis Rheumatological disease
>50%	> 50%

	Adult respiratory distress syndrome
	<i>Eosinophils</i> >20%
	Pulmonary eosinophilia

toring effect of recombinant α_1 - antitrypsin therapy in patients with α_1 - antitrypsin deficiency.

Complications

(a) Pyrexia. (b) Bronchospasm. (c) Transient hypoxemia. Bronchoalveolar lavage. differential cell counts in diffuse interstitial lung disease. See Table 5.

LUNG BIOPSY

Many diagnostic procedures are available to sample any part of the lung and the choice of technique depends on the type and site of lesion.

Indications

- Investigation of diffuse lung disease, e.g. fibrosing alveolitis, sarcoidosis, alveolar cell carcinoma.
- Investigation of solitary pulmonary lesion.
- Investigation of possible infection in an immunocompromised patient.

Diagnostic Methods

- Transbronchial lung biopsy** – Under radiographic screening, the flexible biopsy forceps can be advanced to the edge of the lung. Complications: Pneumothorax, minor haemoptysis.
- Percutaneous fine-needle aspiration biopsy** – Disadvantage is the small size of tissue samples for cytological examination. Complications – Pneumothorax (higher incidence than transbronchial), minor haemoptysis, rarely air embolism.

3. *Percutaneous Tru-cut needle biopsy*– obtains larger samples for biopsy. Complications similar to other percutaneous techniques with higher incidence of pneumothorax, rarely haemothorax.
4. *Trephine needle biopsy*– Provides larger and less distorted tissue specimens. Complications similar as above but occasionally severe intrapulmonary hemorrhage.
5. *Open lung biopsy* is indicated in cases of chronic diffuse pulmonary shadowing when other less invasive techniques have been unsuccessful. Advantages – (a) It provides higher diagnostic yield. (b) It is more appropriate than transbronchial biopsy or FNAB for difficult cases e.g. pulmonary hypertension, high airway pressure hypoxia or coagulopathy. Complications – Pneumothorax, wound infection.

PULMONARY ANGIOGRAPHY

Indication – Establishing or excluding presence of pulmonary embolism. It is *contraindicated* in chronic pulmonary hypertension, severe cardiac decompensation or respiratory decompensation.

Observation – Presence of constant, intraluminal filling defect or sharp cut-off in vessels greater than 2.5 mm in diameter is diagnostic. Other abnormalities such as oligaemia, vessel pruning or loss of filling of small vessels are non-specific and may occur in pneumonia, atelectasis, bronchiectasis, primary pulmonary hypertension, emphysema.

2. COUGH AND EXPECTORATION

COUGH

Causes

1. *Infections* – (a) Acute – Laryngitis, tracheitis, bronchitis, bronchiolitis, pneumonia. Whooping cough. (b) Chronic – Pulmonary tuberculosis, chronic bronchitis, chronic laryngitis, bronchiectasis, lung abscess.
2. *Mechanical irritation* – (a) Inhalation of dust (pneumoconiosis), irritant gases, chemical fumes or pungent smells. Tobacco smoking. (b) Foreign body in larynx or bronchi. (c) Post-nasal drip in chronic sinusitis. (d) Gastro-oesophageal reflux. (e) Compression of air passages – (i) Extramural – Aortic aneurysm, pulmonary neoplasm, mediastinal masses, enlarged LA in mitral stenosis. (ii) Intramural – Bronchogenic carcinoma or adenoma, foreign bodies, bronchospasm (asthma), granulomatous endobronchial disease. (f) Pressure or tension on air passages – Pulmonary oedema, interstitial fibrosis, atelectasis, pericardial effusion, pneumothorax.
3. *Reflex* – From reflex irritation of vagus – (a) Wax in external ear or otitis media. (b) Distention of stomach or rarely of colon. (c) Subdiaphragmatic abscess or liver abscess.
4. *Thermal stimulus* – Inhalation of cold air especially in asthmatics and those with intercurrent infection.
5. *Habit cough* – When a patient has suffered from some prolonged illness in which cough has been a prominent feature, the cough may at times persist as a habit long after the cause has ceased to operate.
6. *Psychogenic cough* – may be a form of obsessional neurosis or co-ordinated tic.
7. *Iatrogenic* - ACE inhibitors, steroid aerosols.

Types of Cough

1. *Dry or unproductive* – Upper respiratory tract infection, early stage of pulmonary tuberculosis, bronchogenic carcinoma, smoker's cough, interstitial fibrosis, bronchial asthma, tropical eosinophilia, pulmonary infarction, etc. Psychogenic or habitual cough.
2. *Wet or productive* – Bronchiectasis, lung abscess, fungal infections.
3. *Paroxysmal* – Bronchial asthma, cardiac failure, whooping cough.
4. *With wheezing* – Bronchial asthma, tropical eosinophilia, chronic bronchitis.
5. *Barking* – Harsh, loud, 'seal-like' cough, paroxysmal or occasional, in hysteria (functional) disturbing to the hearer, but perhaps not to the patient himself or herself.
6. *Nocturnal* in asthma, pulmonary oedema, post-nasal drip in chronic sinusitis, reflux oesophagitis.
7. *Bovine* – (Brassy or gander, or leopard's growl) – due to laryngeal paralysis from involvement of recurrent laryngeal nerve e.g. in aortic aneurysm.
8. *Staccato* – In whooping cough there is paroxysmal cough ending in a whoop.
9. *Croupy* – Harsh, hoarse cough in laryngeal infection.
10. *Hacking* – Short, dry, irritable cough frequently repeated in congestive conditions of pharynx, upper air passages, and smoker's cough.

11. *Suppressed and painful* – In pleurisy cough is suppressed because chest pain is aggravated by coughing (and deep breathing).
12. *Toneless, whispering, aphonic cough* – in destructive lesions of vocal cords, e.g. tuberculous ulcer or neoplasm.
13. *Spluttering* in trache-oesophageal fistula.
14. *Cough related to exertion* – In early LV failure and mitral stenosis.
15. *Cough related to meals* – Suggests hiatal hernia, tracheo-oesophageal fistula, or oesophageal diverticula.
16. *Early morning cough* with expectoration in bronchiectasis and pulmonary TB.
17. *Nocturnal cough* – LV failure, bronchial asthma, chronic bronchitis, aspiration, post-nasal drip, GERD, oesophageal obstruction, ACE inhibitors.
18. *Recent worsening in case of chronic cough* is a common presenting symptom of bronchial carcinoma.

Complications

1. *Cough syncope* – Prolonged coughing can reduce venous return, impair cerebral blood flow, thus cerebral oxygenation and result in syncope.
2. *Rib fracture* – especially pathological, e.g. in multiple myeloma, osteoporosis and osteolytic metastasis.
3. *Spontaneous pneumothorax* from rupture of emphysematous bulla.
4. *Hernia* – at weak hernial sites.

Treatment

1. *Treatment of cause where possible.*
2. *Cough suppressants* – for dry cough. Diamorphine, methadone, codeine, or pholcodine in form of linctus. Dry cough in bronchial asthma responds to β -agonist inhalation.
3. *Expectorants* – Mucoytic drugs such as bromhexine, guaifenesin, acetylcysteine, carbocysteine reduce sputum viscosity and help expectoration.

Causes of recurrent, persistent cough

Table 6: Causes of recurrent, persistent cough

• Asthma
• Recurrent normal infections
• Prolonged infection (e.g. TB, whooping cough)
• Aspiration (gastro-oesophageal reflux)
• Habit, psychogenic
• Cigarette smoking (active/passive)
• Intrabronchial foreign body
• Suppurative lung disease
• Congenital abnormalities

See Table 6 for causes of recurrent, persistent cough.

EXPECTORATION

Naked Eye Examination

Quantity

1. *Scanty* – Small quantity of sticky secretion usually voided at end of asthmatic attack, in early stages of pneumonia and bronchitis.
2. *Moderate amount* – i.e. about 2 ounces daily in chronic chest complaints like bronchitis and tuberculosis, bronchiectasis, lung abscess.
3. *Large quantity* – Bronchiectasis, lung abscess, chronic bronchitis, cystic fibrosis. Sudden coughing up of large quantity in lung abscess, empyema or subphrenic abscess rupturing into bronchus.

Appearance

1. *Watery* – Due to pulmonary congestion or acute pulmonary oedema, alveolar cell carcinoma or ruptured hydatid cyst where fragments of daughter cysts may be detected.
2. *Mucoid* – Sticky sputum containing increased mucin in acute or chronic bronchitis, asthma, weakened bronchial musculature, pneumoconiosis, early stages of pulmonary TB and sometimes bronchogenic carcinoma.
3. *Mucopurulent* – The sputum is generally mucopurulent and almost all infections of bronchi and lungs give rise to this type of sputum. Such sputum may be nummular or coin like, the sputum when expectorated into fluid taking on the shape of flattened discs, such sputum indicates cavitation of any type. Mucopurulent sputum separates into three layers when collected in a conical glass.
4. *Purulent* – Indicates infection somewhere in the respiratory tract. Large quantities of purulent sputum in bronchiectasis, lung abscess, chronic foetid bronchitis, pulmonary tuberculosis and gangrene of lung.
5. *Colour of sputum* – (i) *Blackish* – due to inhalation of carbon in coal miners, copious black sputum (melanoptysis) may occur when there is breaking down of lung tissue. (ii) *Rusty (or khaki)* – due to altered blood mixed with tenacious sputum in lobar pneumonia. (iii) *Small yellow sulphur granules* – in actinomycosis of lungs. (iv) *Reddish colour* – indicates presence of blood, fresh or altered, depending on the interval between the haemoptysis and production of the specimen. (v) *Frothy pink sputum* – in pulmonary oedema. (vi) *Creamy yellow sputum* – of staphylococcus infection.

(vii) *Sticky brown-to-red sputum* – in *Klebsiella* (Friedlander's) infection. (viii) *"Currant jelly" sputum* – due to the presence in the sputum of blood tinged lung debris is likely to occur in influenza and bronchogenic carcinoma. (ix) *Dark brown purulent material* – like anchovy sauce in amoebic lung abscess and paragonimus (lung fluke) infection. (x) *Green colour* – (and musty odour) of sputum in pseudomonas infection. Purulent sputum if it has been stagnant as after overnight sleep, may be greenish owing to action of verdoperoxidase derived from neutrophils. (xi) *Blood oyster* – Fresh blood embedded within mucopurulent sputum in tuberculosis. (xii) *Rubbery brown plugs* – Allergic bronchopulmonary aspergillosis. (xiii) *Chalky white* and gummy consistency in pulmonary alveolar proteinosis.

Other Abnormalities

- Discrete discs* in a purulent sputum (nummular sputum) suggest cavitation.
- Dittrich's plugs* or small caseous masses, greyish yellow in colour and foul smelling in bronchiectasis.
- Mucus plugs* may be visible in asthma and the sputum may also appear yellow due to excess of eosinophils.
- Curschmann's spirals* (coalescence of granules from disintegrating eosinophils) in asthmatic sputum may be seen by naked eye.
- Fibrinous casts* of smaller bronchi may be expectorated in fibrinous bronchitis as grey, white or reddish yellow particles.
- Asbestos bodies* due to exposure to asbestos dust.
- Calcified bodies* occasionally coughed up in pulmonary alveolar microlithiasis.
- Hooklets* of hydatid disease if cyst ruptures into bronchus.

Odour:

A foul odour indicates infection with anaerobes, fusiform bacilli or spirilla and may occur in lung abscess, bronchiectasis, bronchial carcinoma, foetid bronchitis, gangrene lung.

Microscopic Examination

- Organised constituents:*
 - Fibrinous casts* – Casts of a small bronchus in fibrinous bronchitis, pneumonia during stage of resolution and diphtheritic affection of finer bronchi.
 - Bronchial spirals* – Resemble bronchial casts. Faint, translucent, elongated masses, with a delicate white fibre running longitudinally through centre of each spiral. Leucocytes, epithelial cells and Charcot-Leyden crystals entangled in the

spiral common in asthma. Sometimes in chronic bronchitis and pulmonary TB.

- Elastic tissue* – Single threads or small bundles indicate destructive process in lung, e.g. abscess of lung, cavitation, bronchiectasis.
- Eosinophils* – Presence of eosinophils suggests an allergic process, they are commonly found in asthma and pulmonary eosinophilia.
 - Animal parasites* – Paragonimus westermani, Entamoeba histolytica, filaria, tinea, echinococcus, ascariis, bilharzia.
 - Fungi* – Actinomycosis, aspergillosis.
 - Bacteria* – Tubercle bacillus, pneumococcus, C. diphtheria, H. influenzae, staphylococci and streptococci, etc.
 - Malignant cells* – May be found in bronchogenic carcinoma.
 - Foreign bodies* – Due to occupational dusts such as asbestos, silica, cotton flax, etc.

Culture and antibiotic Sensitivity Tests

Culture of fresh sputum is necessary for obtaining a microbial diagnosis of pneumonia, tuberculosis and fungal infections. Appropriate antibiotic sensitivity tests should be performed on all clinically significant isolates.

3. HAEMOPTYSIS

Coughing out of blood includes both blood-stained sputum and frank haemoptysis. Massive haemoptysis is defined as 600–800 mL of blood in 24 hours. See Table 7 for the causes of haemoptysis. Tables 8 and 9 list causes of massive and recurrent haemoptysis, respectively.

Table 10 gives differentiating features between haemoptysis and haematemesis.

INVESTIGATION OF HAEMOPTYSIS

History

(1) *Personal* – (a) Age – In childhood and adolescence: Pulmonary TB, M.S., bronchiectasis main causes. In adults: Pulmonary TB. After 40: TB, bronchial carcinoma, bronchiectasis. Idiopathic haemoptysis occurs almost solely in childhood. (b) Occupation: e.g. cotton mill workers. (2) *Symptoms* – (a) Amount of blood – Haemoptysis from pneumonia or infarct often merely consists of blood streaking of sputum. (b) Haemoptysis immediately preceded by cough indicates origin of bleeding at a level lower than the larynx. (c) Repeated severe haemoptysis without obvious deterioration in bronchiectasis. (d) Repeated haemoptysis over many years with perfect health in-between may suggest adenoma of bronchus. (e) Haemorrhages from other sites in bleeding disorders. (3) *Past history* – (a) Of fever,

Table 7: Causes of haemoptysis*Pulmonary causes***Infections**

- Tuberculosis
- Bronchiectasis
- Lung abscess
- Pneumonia
- Aspergilloma
- Parasites (hydatid, flukes)
- Actinomycosis
- Bronchial foreign body

Pulmonary infarction**Tumors**

- Bronchial carcinoma
- Bronchial adenoma

Pulmonary hemorrhage

- Idiopathic pulmonary haemosiderosis
- Goodpasture's syndrome
- Systemic lupus erythematosus
- Granulomatosis with polyangiitis
- Microscopic polyangiitis

Trauma

- Pulmonary contusion
- Needle biopsy
- Transbronchial biopsy

Vascular abnormality

- A-V malformation

Cardiovascular disease

- Pulmonary oedema
- Mitral stenosis
- Aortic aneurysm

Blood disorders

- Leukemias
- Haemophilia
- Anticoagulants

Idiopathic**Tables 9: Recurrent haemoptysis**

- Bronchiectasis, chronic bronchitis.
- Bronchial adenoma.
- Mitral stenosis, recurrent LV failure.
- Recurrent pulmonary embolism with infarction.
- Telangiectasia.

cough and expectoration in bronchiectasis. (b) Recent operation or phlebitis in pulmonary infarction. (c) Trauma to chest. (d) Tr. of squamous cell carcinoma of lung with Bevacizumab, a vascular endogenous growth factor inhibitor can result in massive haemoptysis. (4) *Family history* - of tuberculosis or bleeding disorder.

Physical Examination

(a) *Upper air passages* - for bleeding gums, epistaxis and superficial erosions of nasopharynx and mouth if small quantities of blood. Often the blood collects in larynx or

Tables 8: Massive haemoptysis

- Pulmonary TB (active or healed)
- Bronchiectasis
- Mycetoma
- Lung abscess
- Lung malignancy
- AV fistula

Table 10: Differentiation from hematemesis

Haemoptysis	Haematemesis
Symptoms and signs of pulmonary or cardiac disease	Symptoms of gastric or abdominal disease
Blood coughed up	Blood vomited
Blood bright red, frothy and mixed with sputum	Coffee ground, mixed with food particles
Relatively small amount	May be large amount
Reaction alkaline	Reaction acid
Sputum rusty next day	Stool tarry next day

trachea and is coughed out early morning. (b) *Heart and lungs* - Common causes of profuse haemoptysis are pulmonary tuberculosis, bronchiectasis, mitral stenosis and bronchogenic carcinoma. (c) *Lymph glands, and enlarged liver and spleen* - Splenomegaly, hepatomegaly, lymphadenopathy, hematomas, petechiae and signs of bleeding from other body areas are suggestive of a generalized haemorrhagic disease.

INVESTIGATIONS

1. *Sputum* - For tubercle bacilli and malignant cells. Rarely spirochetes, or ova of lung fluke.
2. *X-ray chest* - For diagnosis of pulmonary T.B., hilar mass suggestive of carcinoma, pneumonia or pulmonary infarct.
3. *Blood* - Red blood cell count and haemoglobin, bleeding, coagulation and prothrombin time. Measurement of plasma fibrinogen. Precipitating antibodies in *Aspergillus fumigatus*. Renal function tests and urinalysis is done in suspected patients with pulmonary-renal syndrome. If urinalysis shows red blood cells or casts testing of patient serum for antiglomerular basement membrane antibody, antineutrophil cytoplasmic antibody and antinuclear antibody should be considered.
4. *Examination of the larynx* - For evidence of ulceration.
5. *Bronchoscopy* - To exclude foreign body and malignant growth and for diagnosis of bronchiectasis.

Table 11: Mechanisms of lung infection

Mechanism	Examples
Aerosols inhalation	<i>Mycoplasma pneumoniae</i> <i>Chlamydoiphila psittaci</i> <i>Legionella pneumophila</i>
Aspiration of oropharyngeal secretions	<i>Streptococcus pneumoniae</i> <i>H. influenzae</i> <i>Anaerobes</i>
Haematological spread	<i>Staph. Aureus</i>
Reactivation of latent microorganisms	<i>M. tuberculosis</i> <i>Pneumocystis jiroveci</i>

- Bronchography** – To establish presence of localised bronchiectasis if sputum repeatedly negative and plain X-ray inconclusive.
- Needle aspiration biopsy** – If chest X-ray shows localised intrapulmonary lesion.
- Pulmonary angiography** – May show anomaly of vascular structure of lung, e.g. haemangioma, or distribution of aberrant vessels to pulmonary A-V fistula.
- CT scan** – Useful in diagnosis of pulmonary infarction, lung carcinoma, cavitory diseases like tuberculosis, bronchiectasis.
- Exploratory thoracotomy** – If investigations fail to reveal cause of bleeding and chest X-ray is normal, a diagnosis of idiopathic haemoptysis is justified. If X-ray lesion is present, exploratory thoracotomy is indicated.

MANAGEMENT

- Hospitalization** in ICU if massive haemoptysis. Sedation with diazepam or its equivalent. Pethidine or morphine is seldom necessary and a depression of the cough reflex is not desirable. Reassurance.
- Posture** – If site of bleeding is located, patient must be put in a semi-reclining dependent position (bleeding lung should be in dependent position)
- Fluids** – Colloids or crystalloids. **Blood transfusion** if profuse bleeding.
- Antitussives** – If cough exhausting or troublesome, small repeated doses of codeine or other cough suppressive.
- Antibiotics** – Useful in preventing secondary infection. Patients with active tuberculosis must be given anti-tuberculous drugs if not already in use.
- Balloon tamponade** for 24–48 h. If there is no bleeding on deflating the balloon and for 6–8 h subsequently, balloon can be removed.

- Selective embolization of bronchial arteries** – Supplying the affected area in case of severe haemoptysis in patients with nonresectable lung cancer.
- Thoracotomy and surgical resection** – Indications – (a) Severe haemoptysis with site of bleeding in lung segment or lobe. (b) If embolization is unsuccessful or cannot be performed. (c) Patient continues to be hemodynamically unstable, but has good pulmonary function.
- Laser therapy** as palliative measure for massive haemoptysis in case of non-resectable lung cancer.

4. INFLAMMATION OF THE BRONCHIAL TREE

RESPIRATORY DEFENCE MECHANISMS

A series of immune and non-immune mechanisms working differently and at different levels, keep normal lung a bacteria free zone. However, there are various ways by which various microorganism reach lungs (Table 11).

ACUTE BRONCHITIS

Acute infection of mucous membrane of trachea and bronchi produced by viruses, bacteria or external irritants.

Causes

Precipitating causes– (i) **Infection** – Either bacterial or viral, or descending infection from nasal sinuses or throat. (ii) **Complicating other diseases** – e.g. measles, whooping cough. (iii) **Physical and chemical irritants** – Inhaled dust, steam, gases like SO₂, ether. (iv) **Allergic bronchitis** – following inhalation of pollens or organic dusts.

Symptoms

- Toxaemic**– Malaise, fever, palpitation, sweating, etc.
- Irritative** – Cough with expectoration, at first scanty viscid sputum, later more copious and mucopurulent; substernal pain or raw sensation under the sternum.
- Obstructive** – Choked up feeling, paroxysms of dyspnoea particularly following spells of coughing relieved with expectoration.

Signs

In early stages few abnormal signs apart from occasional rhonchi. After 2 or 3 days diffuse, bilateral rhonchi, often with rales at the bases, prolonged expiration and an expiratory wheeze.

Treatment

Appropriate antibiotic therapy, e.g. amoxicillin, cephalosporin or clarithromycin. Bronchodilators in patients with chronic airflow limitation.

CHRONIC BRONCHITIS

A clinical disorder characterised by productive cough due to excessive mucus secretion in the bronchial tree not caused by local bronchopulmonary disease, on most of the days for at least 3 months of the year for at least two consecutive years. Chronic simple bronchitis is characterised by mucoid sputum production, chronic mucopurulent bronchitis by persistent or recurrent purulent sputum production in absence of bronchiectasis and chronic asthmatic bronchitis in patients who experience severe dyspnoea and wheezing during acute respiratory infections or following inhaled irritants.

Causes

1. *Infection* – (a) Result of acute bronchitis. (b) Infective focus in upper respiratory tract, the nasal sinuses or tonsils. (c) Infective focus in lungs, e.g. bronchiectasis, fibrosis, or tuberculosis.
2. *Smoking* – particularly of cigarettes.
3. *Air pollution* – due to industrial fumes and dust.
4. *General illness* – which favour infections, e.g. obesity, alcoholism, and chronic kidney disease.

Symptoms

1. *Cough* – Constant paroxysmal, worse in winter or on exposure to cold winds or sudden change of temperature.
2. *Expectoration* – Variable, may be little, thin and mucoid or thick or frothy, mucoid and sticky. May become mucopurulent during attacks of acute bronchitis in winter.
3. *Dyspnoea* – In advanced cases, breathing becomes quick and wheezing present even at rest.
4. *Fever* – Absent except in acute exacerbation.
5. *Haemoptysis* – Usually in the form of streaks of blood.

Signs

(a) *Build* – usually short and stocky. (b) *Cyanosis* – rarely with clubbing. (c) *Signs of airway obstruction* – Prolonged expiration, pursing of lips during expiration, contraction of expiratory muscles of respiration, fixation of scapulae by clamping the arms at the bedside, indrawing of supraclavicular fossae and intercostal spaces during inspiration, and jugular venous distension during expiration due to excessive swings of intrathoracic pressure. *Widespread wheezes* of variable pitch usually most marked in expiration. Crackles at lung bases in patients with excessive

bronchial secretions. Both wheezing and crackles may be altered in character by coughing.

Investigations

1. *Ventilatory indices* – Reduced PEF and VC.
2. *Chest radiography* may be normal. Infected episodes may produce patchy shadows of irregular distribution due to pneumonic consolidation and small linear fibrotic scarring may result.

Management: Principles

1. TO REMOVE THE CAUSE IF POSSIBLE – Air pollution, smoking. Elimination of aerosol sprays such as deodorants, insecticides and hair sprays. Other preventive measures include early vaccination against common influenza virus strains. Pneumococcal polysaccharide vaccine should be given only once because of danger of immunologic reactions following repeated vaccination.
2. TO PREVENT ACUTE EXACERBATIONS – By avoiding overheated rooms, damp and foggy places, stuffy clothing, overfeeding, smoking and too much alcohol. Long term treatment with tetracycline group of drugs often produces striking improvement in patients who have a purulent sputum.
3. TO TRY AND ARREST THE PROGRESS OF THE CHRONIC DISEASE BY:
 - a. *Increasing patient's power of resistance* – By giving to debilitated persons abundant butter, milk or cream, cheese and other fatty articles of diet. Weight reducing measures if obesity.
 - b. *Physical methods* – Regular exercises in fresh air and within limits of tolerance. Encouraging deep breathing and efficient clearance, coughing should follow a full inspiration. If economic condition permits, winter should be spent at warm resorts.
4. TO GIVE THE PATIENT AS MUCH COMFORT AS POSSIBLE – (a) *Antitussives* – such as linctus codeine if dry cough. (b) *Mucolytics* and inhalation of medicated steam. (c) *Expectorants* – (i) Ammonium salts, bromhexine or ambroxol in mixture form. (ii) Hot alkaline drink – compound sodium chloride mixture 15 ml sipped in a cup of hot water first thing in the morning. This should be followed after 15 minutes by a systematic attempt to cough the bronchi clear of accumulated secretions. (d) *Bronchodilators* – Orciprenaline sulphate or ipratropium bromide as aerosol, or Salbutamol 2–4 mg or Terbutaline 2.5–5 mg t.d.s. by mouth or 0.5% by inhaler, or theophylline orally. (e) *Antibiotics* – Clarithromycin or Co-amoxiclav for 7–14 days, a good index of response being clearing of infected sputum. Long-term chemotherapy is not indicated and

- External compression (e.g. tuberculous lymphnodes)

Following infections

- Tuberculosis
- Measles pneumonia
- Whooping cough
- Adenoviruses 3,7,21
- Mycoplasma pneumonia
- Pneumococcal pneumonia

Lung inflammation

- Gastric aspiration
- Inflammatory bowel disease
- Toxic gas inhalation (e.g. ammonia)
- IV heroin
- Rheumatoid arthritis
- Systemic vasculitis
- Riley-Day syndrome

Miscellaneous

- Diffuse pulmonary fibrosis
- Congenital cartilage deficiency
- α_1 -antitrypsin deficiency
- Yellow nail syndrome
- Primary lymphoedema
- Treated lymphoreticular malignancy
- Previous open heart surgery
- Congenital pulmonary sequestration
- Marfan's syndrome
- Ehlers-Danlos syndrome
- Post-irradiation

antibiotics should be started by the patient as soon as acute exacerbation occurs. (f) *Corticosteroids* – may be given during bad spells with an antibiotic control of co-existing infection, or if patient is severely disabled. (g) *Postural drainage* – In the patient who has a copious purulent sputum.

BRONCHIECTASIS

Bronchiectasis is a destructive lung disease characterized by chronic (permanent/irreversible) dilatation of the bronchi associated with persistent though variable inflammatory process in the lungs. These changes may involve any area but are predominantly found in the lung bases and can be divided into localized and diffuse forms. It may be associated with varied conditions listed in Table 12.

Pathology

The diagnostic feature of bronchiectasis is dilated bronchi. The Reid classification differentiates between pathological and radiological appearances of bronchiectasis.

Cylindrical bronchiectasis – Bronchial dilatation is mild and the bronchi retain their regular relatively straight outline.

Varicose bronchiectasis – Bronchial dilatation is greater and local constrictions are present, giving the airway an irregular appearance.

Saccular/cystic bronchiectasis is the most severe form and is characterized by large areas of distal 'grape-like' bronchial dilatation and loss of bronchial subdivision.

Atelectatic bronchiectasis is a localized form related to proximal bronchial distortion or occlusion.

Clinical Features*Symptoms – Clinical Types*

1. *Bronchitic* – Attacks of recurrent bronchitis, more common in winter. Clubbing of fingers diagnostic.
2. *Haemorrhagic* (bronchiectasis sicca) – Recurrent haemoptysis with good health in-between, or attacks of bronchitis.
3. *Suppurative* – Chronic cough, copious purulent expectoration, general toxæmia, clubbing of fingers varying from slight parrot beak curvature of finger nails to bulbous drum stick enlargement (pulmonary osteoarthropathy). During exacerbations, dyspnoea and wheezing occur in 75% of patients and pleuritic chest pain in 50%. Pleuritic chest pain is caused by distended peripheral airways and inflammation adjacent to the visceral pleura. Pyrexia is rare during exacerbations; if it is present, pneumonia should be excluded.

Fig. 7: X-ray chest showing streaky shadows and multiple cystic lesions with air fluid levels suggestive of bronchiectasis

Fig. 8: Bilateral cystic bronchiectasis

Fig. 9: High resolution CT scan of the lung showing dilated lower lobe bronchi with bronchial wall thickening and prominent adjacent pulmonary arteries

4. *With relatively rapid onset* – Symptoms developing with comparative suddenness, as a sequel to partial bronchial obstruction by a foreign body or after anaesthesia. In early stages paroxysmal cough with occasional offensive sputum which may be provoked by change of position. Later large amounts of foetid sputum.

Signs

Mostly limited to auscultation and depend on the size of the affected bronchi, patency of the airways and viscosity of secretions. There may be signs of (a) bronchitis, or (b) fibrosis, or (c) consolidation, or (d) collapse, or (e) of cavitation.

Early stages – Fine crackles or sticky rhonchi and slight alteration in character of breath sounds.

Late stages – Bronchial breathing, coarse crepts and perhaps signs of a cavity. Changing character of physical signs after a long bout of cough when air entry may become louder and bronchial in character or from day to day. Sharp metallic or “leathery” rales characteristic. Recurrent pneumonia in the same area of the lung is classically associated with bronchiectasis.

Investigations

1. SPUTUM – To exclude diagnosis of underlying pulmonary tuberculosis.
Culture and sensitivity of infecting organism as a guide to chemotherapy.
2. RADIOLOGY:
 - Sinus radiographs** – for chronic sinusitis.
 - Chest radiography** – for changes suggestive or associated with the diagnosis.
 - Collapse (segmental or lobar)
 - Crowding of pulmonary vessels, indicating area of damage or consolidation that may become infected.
 - ‘Tramline shadows’ suggesting bronchial wall oedema.
 - Cystic lesions suggesting saccular bronchiectasis (**Fig. 7**) and (**Fig. 8**).
 - Evidence of previous tuberculosis.
 - Evidence of previous heart surgery.
3. HRCT (Fig. 9) – High-resolution CT has replaced bronchography and is the preferred investigation. CT findings include the following:
 - The ‘signet ring’ sign (end-on dilated bronchi that are larger than the accompanying pulmonary artery) is seen in all form of bronchiectasis

Table 13: Complications of bronchiectasis

Pulmonary – recurrent pneumonia, lung abscess, haemoptysis
Pleural – pleurisy, pleural effusion or empyema
Corpulmonale
Cerebral abscess
Amyloidosis
Seronegative arthropathy

- Tramlines (non-tapering bronchi) are seen in cylindrical bronchiectasis
- Varicose bronchiectasis has a beaded (tree-in-bud) appearance
- ‘Cysts’ with air-fluid levels in dilated bronchi characteristic of cystic bronchiectasis

SPIRAL CT may aid diagnosis by reducing motion artefact and identifying subtle bronchiectatic changes.

4. SPECIAL INVESTIGATIONS: may indicate the cause of bronchiectasis in some patients.
 - *Immunoglobulins* – Most patients with bronchiectasis have raised plasma concentrations of immunoglobulins (especially IgA).
 - *Aspergillus precipitins* – Recurrent mucus plugging of major airways and development of proximal bronchiectasis occurs in allergic bronchopulmonary aspergillosis.
 - *Barium studies* – For gastrooesophageal reflux, since association of basal bronchiectasis is well recognised.
 - α_1 -antitrypsin deficiency is associated with premature pulmonary emphysema though rarely in association with bronchiectasis.
 - *Detection of cystic fibrosis* – By sweat test and/or genetic analysis.

Complications

Complications of bronchiectasis are listed in Table 13.

Differential diagnosis – See differential diagnosis of lung abscess.

Management

Medical

1. **Postural drainage**– Since bronchiectasis usually affects the lower lobes the prone position with the head tilted downwards is the most useful. Deep breathing or coughing, assisted by percussion of the affected part (clapping) helps to dislodge the secretions. It should be carried out at least twice daily for 15–20 minutes at a time. Expectoration is facilitated by cough mixtures, or better inhalation of nebulized bronchodilator isoproterenol followed by inhalation of nebulized

water or steam, followed by postural drainage. This should be done on arising in the morning since the patient with bronchiectasis tends to pool secretions during the night.

2. **Antibiotic therapy** – Antibiotics can delay progression in patients with cystic fibrosis. Antibiotics penetration into the bronchial mucosa and secretions is impaired and the dose needs to be higher and duration longer. *H. influenzae*, *H. parainfluenzae*, *Str. pneumonia* and *Moraxella catarrhalis* are the most common organisms in exacerbations, β -lactam antibiotics (e.g. amoxicillin 500 mg t.d.s. for 10–14 days) remain the first line therapy. Alternatives include quinolones and macrolides.

Chronic colonization with *Ps. aeruginosa* is common in severe disease. Choice of antibiotic is guided by sensitivities, but oral quinolones (e.g. ciprofloxacin 500 mg b.d. for 2 weeks) is the first time therapy. Development of resistance is common, and iv antibiotics e.g. ceftazidime 2 g t.d.s. for 14 days, gentamicin (in accordance with plasma levels), and piperacillin 4.5 g t.d.s. for 14 days, are required.

Nebulized antibiotics allow maximal concentrations of antibiotics in the airways with reduced systemic effects. Amoxicillin 500 mg b.d., gentamicin 80 mg b.d., and tobramycin solution for inhalation 300 mg b.d. can be used.

Acute exacerbations – Hospitalization in all severely ill patients, when chest pain limits coughing and sputum clearance (this increases risk of pneumonia) and iv antibiotics are required.

Prophylactic therapy – One guideline for therapy is when there are exacerbations every 2 months that prevent participation in normal activities of 2 weeks or more during the exacerbation. Continuous therapy is considered in patients who persistently expectorate purulent sputum. Aggressive treatment is warranted because persistent infection causes tissue destruction.

Bilateral lung transplantation has been used when respiratory failure develops despite optimal medical management.

3. **Intravenous immunoglobulin** replacement is thought to be effective in panhypogammaglobulinemia, but is given only to patients with established, widespread lung damage.
4. **α -antitrypsin replacement therapy** by inhaled route has the potential to neutralize damaging processes that are released as part of the airways inflammatory response.
5. **General supportive treatment** – (a) Adequate nutrition. (b) Eradication of chronic nocturnal post-nasal discharge and treatment of sinusitis. (c) Avoidance of smoking. (d) Adequate hydration.

Table 14: Indications for surgical resection

Table 16: Type of asthma

Symptoms of asthma	Severe persistent	Moderate persistent	Mild persistent	Intermittent (episodic)
Woken at night	>2 x / week	1-2 x /week	Rare	None
Bronchodilator (inhaled or oral)	>4 x /day	2-4 x /day	<2 x /day	With attacks
Seeks attention for acute symptoms	Monthly	2-3/month	Rarely	For attacks >80
PEF (% recent best)	<60	60-70	70-80	

Surgical

Indications for surgical resection are given in Table 14.

Primary Ciliary Dyskinesia

Generalized impairment of pulmonary defence occurs with immunoglobulin deficiency, primary ciliary disorders, or cystic fibrosis.

Primary cystic dyskinesia is inherited as an autosomal recessive disorder. Numerous defects are included under this subject, such as structural abnormalities of dynein arms, radial spokes and microtubules. The cilia become dyskinetic, with diminution in their coordinated propulsion, and impaired bacterial clearance. The clinical effects include recurrent, both upper and lower respiratory tract infections such as sinusitis, otitis media and bronchiectasis, left-right body asymmetry. Because normal sperm motility also depends upon proper ciliary function males are generally infertile.

Kartagener's syndrome is one of the subgroups of primary ciliary dysfunction in which there is bronchiectasis, sinusitis and situs inversus.

Young's syndrome is characterised by recurrent sinus and pulmonary infections and obstructive azospermia. The ultrastructure of the cilia does not show the defect that are characteristic of ciliary dyskinesia (e.g. lack of dynein

Table 15: Comparative features of extrinsic and intrinsic asthma

Extrinsic asthma	Intrinsic asthma
Young patient – child or teenager	Adult patient over 35 or more
History of eczema in childhood	No history of eczema in childhood
Family history of asthma, eczema or hay fever	Negative family history
Attacks related to specific antigens	Attacks related to infection, exercise, etc
Intermittent attacks	Often persistent asthma
Attacks are acute but usually self-limiting	Attacks more fulminant and severe
Not aspirin-sensitive, occasional polyps	Aspirin-sensitive, nasal polyps
Investigations	
Skin test with allergen extracts usually +ve	Skin test usually negative
Inhalation provocation test with allergens positive; negative or non-specific reactions to solvents	Normal or low IgE
IgE frequently raised	
Response to treatment	
Good response to beta-agonists and sodium cromoglycate	Poor response to beta-agonists, variable response to cromoglycate
Prognosis favourable	Prognosis poor

arms and transposition of microtubules) but show non-specific effects secondary to infection.

5. BRONCHIAL ASTHMA

Asthma is a syndrome of variable airflow obstruction. It is characterized pathologically by bronchial inflammation with prominent eosinophil infiltration, physiologically by bronchial hyper-reactivity, and clinically by variable cough, chest tightness and wheeze.

Atopy is the principal associate of asthma in individuals aged 5–30 years. It is a state of disordered immunity in which predominant T-helper lymphocyte type 2 (TH2) immune mechanisms drive production of IgE on exposure to common environmental antigens or allergens.

CLASSIFICATION

1. *Extrinsic asthma* – applies to those who produce excessive IgE in response to allergens (*atopic*).
2. *Intrinsic asthma* – refers to those cases in whom excessive IgE production cannot be demonstrated (*non-atopic*) (Table 15).
3. *Mixed forms*

Asthma is classified on basis of symptomatology as given in Table 16.

Table 17: Triggers of asthma

Night or early morning
Exercise (especially running)
Cold air, fog
Viral respiratory tract infection
Allergens (e.g. house dust, mite, cat fur)
Nonspecific irritants (e.g. cigarette smoke, perfumes, paints)
Drugs (e.g. β -blockers, aspirin, NSAIDs)
Emotion or stress
Occupational exposure

INDUCERS AND TRIGGERS OF ASTHMA

Inducers of asthma – After birth, several factors interact to result in the clinical manifestations of asthma. Factors called inducers actually ‘switch on’ the asthma following which symptoms may be present for weeks, months or years.

- Infections** – Recurrent bouts of significant airflow limitation in constitutionally small airways may result from viral infections. The syndrome often remits as the child gets older.
- Cigarette smoke** – If parents smoke during the first two years of their child’s life, the child is likely to develop asthma.
- Allergens** – The influence of both genetic and environmental factors is important and asthma is a complex response to a variety of stimuli, making it difficult to identify specific factors. (a) *Aero-allergens (inhalants)* – Such as house dust, mite allergens, tree pollens, feathers, paint, smoke, animal dander, moulds. (b) *Ingestants* – Milk, eggs, nuts, chocolates, fish, shell-fish, strawberries, etc.
- Induced by gastro-oesophageal reflux**
- Cough variant asthma. Cough predominant symptoms**

TRIGGERS OF ASTHMA

See Table 17 for triggers of asthma.

Asthmatic attack

- Premonitory symptoms** “asthmatic aura” – Sometimes sneezing, flatulence and drowsiness, or restlessness and irritability. Dry irritant cough may precede or accompany attacks of wheezy breathlessness.
- Paroxysm** – Usually sudden in middle of night. Sense of oppression in chest going into respiratory distress. Patient sits up and leans forward fighting for breath, or runs to window to relieve sense of suffocation. Anxiety, cyanosis, perspiration and cold extremities. Wheezing may be heard at a distance. On auscultation – inspi-

ration short and high pitched, expiration prolonged, plenty of wheeze. Crackles may be heard at the bases towards the end of an attack. However, in very severe airways obstruction airflow may be so reduced that the chest is almost silent. Tachycardia especially in children.

- Termination** – Spontaneously or as a result of therapy. As bronchial spasm gets less, patient is able to cough a little and may bring out viscid muco-fibrin.
- Duration of attack** – Varies from few minutes to several hours. Sometimes paroxysms are continuous – “status asthmaticus”.

Objective assessment – of variable airflow obstruction is essential for diagnosis of asthma and to determine its severity.

Home peak flow monitoring is the repeated measurement of peak flow, before and after inhaled β -agonist, at different times of day and night (if symptomatic).

Bronchodilator responsiveness is determined by measuring FEV₁ or peak flow before and after administration of bronchodilator. Diagnosis of asthma is confirmed if FEV₁ or peak flow improves > 15%.

Response to corticosteroid therapy – In some patients with relatively fixed airflow obstruction, improvement in lung function following a trial of oral or inhaled corticosteroid may be useful in confirming the diagnosis.

INVESTIGATIONS

- Chest radiograph** may be normal, or show signs of segmental or lobar collapse.
- Full blood count** – Eosinophilia.
- Sputum** – Eosinophils, Charcot-Leyden crystals and at times Curschmann’s spirals may appear purulent (due to eosinophilic leucocytes) in absence of infection).
- Skin tests** – may confirm allergens suggested by history.
- Lung function test** – Spirometry shows reduction in FEV₁, FEV₁/FVC ratio and peak expiratory flow (PEF). Reversibility, which is one of characteristic feature of asthma, is shown by >12% or 200 ml increase in FEV₁ 15 minutes after inhaled short acting β_2 agonist or 2–4 weeks trial of oral corticosteroids.
- Provocation (challenge) tests** – Exercise challenge tests useful in young adults and can be used to confirm diagnosis of asthma, since fall in FEV₁ or PEF occurs after 5–7 minutes of vigorous exercise in most patients with asthma.
- IgE and IgE specific test** – Elevation of total serum IgE supports diagnosis of atopy, and measurement of fractions of IgE specific to one allergen, radioallergosorbent test (RAST) can be useful in some patients in whom a specific allergy is suspected.

Table 18: Differences between COPD and asthma

	<i>COPD</i>	<i>Asthma</i>
<i>History</i>		
Age at onset	Usually in adulthood	Usually in childhood
Allergy or asthma in patient's family	No	Yes
Cough and sputum	Over many years	Often recent
Dyspnoea	Usually progressive	More often paroxysmal
Variable breathlessness	Slight	Much
Attacks of breathlessness at rest	Uncommon	Common
Cough at night	Wakes then coughs	Awakens coughing
<i>Investigations</i>		
Improvement in PEF after bronchodilator i.e. reversible obstruction	Little or none	Usually
Daily variations in PEF		
<i>Treatment</i>		
Effect of oral corticosteroids	Negligible	Improvement

DIFFERENTIAL DIAGNOSIS

- Other causes of paroxysmal dyspnoea** (Refer)
- Chronic obstructive pulmonary disease – Table 18 gives differences between COPD and asthma.
- Tropical eosinophilia
Table 19 gives differences between tropical eosinophilia and asthma.
- Obstruction in upper respiratory tract, trachea or primary bronchus** – Dyspnoea both inspiratory and expiratory usually associated with stridor. No generalized wheeze.

Table 19: Differences between tropical eosinophilia and asthma

	<i>Bronchial asthma</i>	<i>Tropical eosinophilia</i>
<i>History</i>		
Age	Usually starts before 3 years of age	Any age
Duration of symptoms	Long duration	Short duration
Cough and dyspnoea	Paroxysmal cough more than dyspnoea	Dyspnoea more than cough
Fever	Rare	Breathlessness particularly after bout of cough
Loss of weight	Seldom	Common
Auscultatory signs	Compatible with degree of cough and breathlessness	Fairly common
		Disproportion between cough and breathlessness and signs
<i>Investigations:</i>		
Blood	Normal WBC count. Eosinophils 8–15%	Leucocytosis, eosinophilia marked
Chest radiograph	Increased bronchial markings	Mottling may be seen
<i>Treatment</i>		
	No known cure	Diethylcarbamazine specific

- Allergic lung disease other than asthma** – Symptoms begin suddenly 3–6 hours after exposure to antigen with dyspnoea, cough and systemic reaction consisting of pyrexia, shivering and malaise. No evidence of airway obstruction. Some of the diseases causing allergic alveolitis are – Farmer's lung, bird breeder's lung, bagassosis, weaver's cough, etc. (Also see D.D. of pulmonary eosinophilia).
- Constrictive bronchiolitis** is characterised by a concentric obstruction of respiratory peribronchiolar or inflammatory exudates leading to total scarring obstruction. Chest X-ray may be normal but a CT of the lung shows circumscribed areas of mosaic pattern. The disease occurs in collagen vascular disease (e.g. Sjögren's syn.) but also following viral infections, inhalation of toxic gas, treatment with penicillamine and gold and after bone marrow transplantation.
- Cryptogenic organizing pneumonia** or idiopathic bronchiolitis obliterans (idiopathic BOOP) affecting both bronchioli and lung parenchyma. The bronchioles, alveolar ducts and eventually lung parenchyma are affected.

COMPLICATIONS

- Respiratory** – (a) From mucus plugs – (i) Atelectasis lobar or lobular. (ii) Bronchiectasis. (b) From cough – (i) Subcutaneous emphysema. (ii) Mediastinal emphysema. (iii) Spontaneous pneumothorax. (iv) Cystic degeneration of lungs. (v) Spontaneous rib fracture. (c) From infection – Recurrent bronchitis and pneumonia. (d) From uneven ventilation and pulmonary perfusion – Respiratory failure, and cor pulmonale.
- Cardiac:** (a) Dysrhythmias from hypoxia and stress of asthma, compounded by bronchodilator therapy with a β -agonist and theophylline. (b) Myocardial infarction rarely in acute severe asthma.

Table 20: Drugs used in asthma

Drug	Route of administration/Dose	Adverse effects and comments
A. Relievers (bronchodilators)		
β-agonists		
Short-acting (SABA)	Oral 2-4 mg	Skeletal muscle tremor
Salbutamol	Sustained release 4–8 mg	Hypokalemia
	Rotacaps 200 mg	Tachycardia
	Respirator sol. 5 mg/mL	Restlessness
	IV infusion	Hypoxemia
Terbutaline	Oral 2.5–5 mg	
	Inhalation 0.25 mg/metered dose	
	Nebulising sol. 10 mg/mL	
	Injection 0.5 mg/mL	
Long-acting (LABA)		
Inhaled Salmeterol	Inhaler 25 mg/metered dose	
	Rotacaps 50 mg	
Anticholinergics (Muscarin receptor antagonists)		
Ipratropium	Aerosol 20–40 mg (1–2 puffs) tds.	Safe and well tolerated Can be used as alternate or in addition To β-agonist in pts. with co-existing Chronic bronchitis
Xanthine derivatives		
Aminophylline	IV 250 mg infusion	Adverse effects likely to occur if plasma concentration >110 mmol/L
Theophylline	200–400 mg bd or 800 mg nocte	Vomiting, headache, cardiac arrhythmia, abdominal pain, diarrhoea, irritability and insomnia, seizures, hypokalaemia.
Doxofylline	400 mg bd	
B. Controllers (Anti-inflammatory)		
Chromones (Inhibit bronchoconstriction)		
Inhaled	5 mg metered dose aerosol	Bitter taste, throat irritation, cough Steroid-sparing effect
Disodium chromoglycate		
Oral (Nedocromil sodium)	1–2 mg bd	No bronchodilator action
Corticosteroids		
<i>Oral/parenteral</i>		
Prednisolone	5–60 mg/d po	First-line therapy for persistent disease. <i>Oral therapy:</i> Fluid retention, increased appetite, wt. gain, osteoporosis, capillary fragility, hypertension, peptic ulceration, diabetes, cataracts, and psychosis.
Methyl prednisolone	60–80 mg IV bolus q6h	
Hydrocortisone	2 mg/kg bolus q4h	
Deflazacort	6–30 mg bd po	<i>Inhaled:</i> (a) Local: Dysphonia, oropharyngeal candidiasis, cough. (b) Systemic: Adrenal suppression, growth suppression, bruising, osteoporosis, glaucoma, metabolic abnormalities (glucose, insulin, triglycerides), psychosis.
<i>Aerosol</i>		
Beclamethasone	200–400 µg bd	
Fluticasone	250–500 µg bd	
Budesonide	200–400 µg bd metered dose inhaler or dry powder	
Antileukotrienes (5-lipoxygenase inhibitor)		
Zafirlukast	20 mg bd	Mild liver dysfunction.
Zileuton	600 mg tds	Useful in asthma not controlled by inhaled corticosteroids
Montelukast	10 mg Hs	

3. *Hypokalemia*: Due to high-dose corticosteroids, high dose β -agonists, respiratory alkalosis of hypocapnia.
4. *Other complications*: (a) Nausea and vomiting from theophylline. (b) Acute myopathy due to high-dose i.v. steroids. This can lead to respiratory muscle weakness and, if patient is being ventilated, difficulty in weaning from the ventilator.

MANAGEMENT OF CHRONIC ASTHMA IN ADULTS

Drug Therapy

Drugs used in asthma are listed in Table 20.

Anti-IgE Omalizumab

It is a blocking antibody that neutralizes circulating IgE without binding to cell bound IgE. It reduces exacerbation in severe asthma but high cost is main limitation.

Step-wise approach

See Table 21 for the stepwise approach to asthma management.

Table 21: Stepwise approach to asthma management

Step 1: Mild intermittent asthma

Use of inhaled short-acting β -agonist as required for symptom relief is acceptable

If these are needed more than once daily, proceed to step 2, but first ensure that the patient is taking the treatment and has a good inhaler technique

Step 2: (Mild persistent) Regular preventer therapy

Add inhaled low dose corticosteroid (beclomethasone or equivalent) 200–400 $\mu\text{g}/\text{day}$ (usually 400 $\mu\text{g}/\text{day}$)

Step 3: (Moderate persistent) Add-on therapy

Add long-acting β_2 -agonist

Assess control of asthma by following means:

Good response to long-acting β_2 -agonist – continue

Benefit from long-acting β_2 -agonist but control remains

inadequate – continue and increase inhaled corticosteroid to 800 $\mu\text{g}/\text{day}$

No response to long-acting β_2 -agonist – stop, and increase inhaled corticosteroid to 800 $\mu\text{g}/\text{day}$. If control remains inadequate, try other therapies (e.g. leukotriene receptor antagonist, doxofylline)

Step 4: (Severe persistent) Persistent poor control

Consider trial of the following:

Increase inhaled corticosteroid to 2000 $\mu\text{g}/\text{day}$

Add a fourth drug (e.g. leukotriene receptor antagonist, theophylline, β_2 -agonist tablet)

Step 5: (Very severe persistent) Continuous or frequent use of oral corticosteroids

Use daily corticosteroid tablet at lowest dose providing adequate control

Maintain high dose inhaled corticosteroid 2000 $\mu\text{g}/\text{day}$

Consider other treatments to minimize use of corticosteroid tablets

- Avoidance of provoking factors when possible
- Patient involvement and education
- Selection of best inhaler device
- Treatment stepped up as necessary to achieve control
- Treatment stepped down if control of asthma is good

Note

- Patients should start treatment at the step most appropriate to the initial severity
- A rescue course of prednisolone may be needed at any time and at any step
- Prescribe a peak flow meter and monitor response to treatment.

Stepping Down

Review treatment every 3–6 hours, if control is achieved, stepwise reduction in treatment may be possible. Reduction may begin after a short period of time in patients in whom recently started at step 4 or 5 or included oral corticosteroid. In other patients with chronic asthma, a 3–6 month period of stability must occur before a slow, stepwise reduction is undertaken.

Status asthmaticus is the condition where severe persistent asthma does not respond to therapy.

Features of acute severe life-threatening asthma

See Table 22.

Table 22: Features of acute severe life-threatening asthma

Acute severe asthma

Any of the following:

- Peak expiratory flow 33–50% best or predicted
- Respiratory rate >25 breaths/minute
- Pulse rate >110/minute
- Cannot complete sentences in one breath

Life-threatening Asthma

Any one of the following in a patient with severe asthma

- Peak expiratory flow <33% best or predicted
- O_2 sat < 92%
- Poor respiratory effort
- Hypotension
- Exhaustion
- ‘Silent’ chest
- Cyanosis
- Bradycardia or other arrhythmia
- Confusion, altered consciousness or coma
- PaO_2 < 8 kPa
- Normal PaCO_2 (4.6–6.0 kPa)

Near-fatal asthma

- Raised PaCO₂ (>6kPa) and/or patient requires mechanical ventilation with raised inflation pressures

Arterial gas markers of a very severe attack

- Normal or high PaCO₂ (>5.0 kPa) 40 mm Hg
- PaO₂ < 8 kPa
- Low pH (< 7.36)

Management*Immediate*

- Oxygen- at high flow rates 6-8L/minute
- Salbutamol 5 mg or terbutaline 10 mg via oxygen-driven nebulizer
- Ipratropium bromide 0.5 mg via oxygen-driven nebulizer
- Prednisolone 30-60 mg p.o. or hydrocortisone 5 mg/kg i.v. or methyl prednisolone 16 mg i.v.
- Chest radiograph to exclude pneumothorax
- Aminophylline 250 mg i.v. over 20 minutes (avoid if patient on oral theophylline), or if required for more than 24 hours, serum concentration must be measured (range 10-20 mg/L)
- Salbutamol 0.25 mg i.v. or terbutaline 0.25 mg i.v. over 10 minutes.

Other treatments

- Rehydration, particularly when symptoms have been present for days before admission. Correction of plasma potassium may be required because β₂-agonists and corticosteroids can cause hypokalemia.
- Tracheal intubation is required in patients with cardiac arrest, apnoea or loss of consciousness. Following intubation, use of a benzodiazepine is indicated to ensure sedation, with neuromuscular blockade to improve pulmonary compliance and ventilation.
- Avoiding exposure to provoking factors
- No smoking
- Antibiotics - if fever or purulent sputum

Monitoring asthma control. Patients can be taught to recognise changes in the severity of acute asthma by identifying key symptoms and using objective measures of airflow obstruction such as peak flow rate.

Regular inhaled corticosteroids and intermittent β-agonists for long-term treatment; systemic corticosteroids, high dose inhaled β-agonists, oxygen therapy and medical review for acute severe exacerbations.

Integration of self-assessment and self-management with written guidelines for both long-term treatment of asthma and acute severe asthma.

6. CHRONIC OBSTRUCTIVE PULMONARY DISEASE (COPD)

COPD is defined by the Global Initiative for Obstructive Lung Disease (GOLD) as a disease characterized by airflow limitation that is not fully reversible. The airflow limitation is usually both progressive and associated with an abnormal inflammatory response of the lungs to noxious particles or gases.

RISK FACTORS FOR COPD

Table 23 enlists risk factors for the development of COPD.

Molecular Mechanisms in COPD

Two important and mutually non-exclusive mechanisms implicated are the presence of perpetual inflammation and oxidant-antioxidant imbalance leading to oxidative stress; unlike asthma the inflammatory cells in COPD do not respond to steroids. These inflammatory cells further release battery of inflammatory mediators like cytokines, chemokines and chemoattractants which perpetuate inflammation leading to an uncontrolled cascade. Proteolytic enzymes such as elastase, proteinase-3, cathepsin G and B and matrix metalloproteinases (MMP) released by neutrophils cause damage to elastic lung tissue.

A series of pathological changes have been attributed to oxidative stress such as oxidative inactivation of anti-proteases and surfactants, mucus hypersecretion, membrane lipid peroxidation, remodelling of extra cellular matrix and apoptosis, reduction in elastin collagen synthesis and fragmentation of skeletal proteins and steroid-unresponsiveness.

PATHOPHYSIOLOGY OF COPD

1. Elastin proteolysis results in reduction in elastic recoil pressure in the lungs. Also the damage to the elastin results in significant airway narrowing.
2. Fibrotic remodelling of airways results in fixed airway narrowing causing increased air resistance that does not fully revert with bronchodilators.
3. Histological feature such as emphysema which also reduces lung elastic recoil pressure which leads to reduced pressure for expiratory and physiological features such as decreased surface area of alveoli for gaseous exchange and ventilation-circulation (V/C) mismatch.
4. Lung hyperinflation or air trapping is hall mark of COPD and is the primary cause of dyspnoea, poor quality of life and disease prognosis. The barrel shaped chest in COPD is attributed to hyperinflation of the lungs.

Table 23: Risk factors for the development of COPD

1. Genes
2. Exposure to particles
– Tobacco smoke
– Indoor air pollution from heating and cooking with Biomass fuel in poorly ventilated homes (at least 25 years of exposure)
3. Occupational dusts
a. Coal mining, cement and textile mill manufacturing, automobile drivers and vehicular mechanics, chlorinated organic compounds, dyes, rubber products, grain dust and fungi in farmers, leather manufacturing, food products manufacturing, beauty care workers and welders in automotive industries.
b. Exposure to crystalline silica – Cement industry, brick manufacturing, pottery and ceramic work, silica, sand, iron and steel, gold mining and iron and steel founding.
4. Outdoor air pollution
– Reduced lung volumes
– Lung growth and development
– Previous tuberculosis
– Early childhood recurrent lower respiratory tract infections
– Poor nutrition
• Old age (physiological obstruction)
• Low socio-economic status

Systemic Inflammation in COPD

Markers of systemic inflammation such as ESR, CRP, TLC, neutrophils, ferritin and fibrinogen are increased. Consequences of systemic inflammation are – skeletal muscle wasting, cachexia, lung cancer, pulmonary hypertension, ischemic heart disease (endothelial dysfunction), CHF, osteoporosis, normocytic anemia, diabetes mellitus/metabolic syndrome.

DIAGNOSIS

- History of chronic progressive symptoms – cough and/or wheeze and/or breathlessness.
 - Reduction in FEV_1 , FEV_1/FVC with obstructive pattern.
- Emphysema** is a component of COPD characterised by abnormal permanent enlargement of the airspaces distal to the terminal bronchioles. It is caused by a combination of mechanical obstruction in the small airways from inflammation and later scarring, and loss of elastic recoil of the lungs which makes these airways more likely to collapse during expiration.

PATHOGENESIS

There is strong association between the prevalence of emphysema and the rare genetic disorder homozygous α_1 -antitrypsin deficiency; this genetic abnormality results from a complex configurational change in the α_1 -antitrypsin molecule that prevents release from the liver.

The pathogenesis of emphysema in non-deficient cigarette smokers is thought to involve increased elastase release into the lungs from neutrophils that migrate into the air spaces in smokers and a functional deficiency of α_1 -antitrypsin. This elastase can bind to and destroy elastin, damaging alveolar walls and leading to air space enlargement characteristic of emphysema.

A senile form of emphysema may be associated in part by degenerative vascular disease. The pathological process starts in the alveolar walls in which fenestrations or holes appear due to hypertrophy of mucosal glands and increased formation of goblet cells in the bronchi.

ANATOMICAL TYPES OF EMPHYSEMA

Centriacinar or centrilobular emphysema – The respiratory bronchioles, alveolar ducts and alveoli at the centre of the acini are destroyed. This type of emphysema tends to be more extensive in the upper lobes and apex of the lower lobes. Smokers are more prone (**Figs 10 and 11**).

Panacinar or panlobular emphysema – Here the entire acinus is destroyed. This is the predominant type of emphysema in α_1 -antitrypsin deficiency, though some smokers also develop this type of emphysema. The emphysema is more extensive in the lower lobes. Large emphysematous spaces can develop later and are termed ‘bullae’ when they exceed 1 cm in diameter (Fig. 12).

Paraseptal or periacinar emphysema

Involves the distal acinus.

Bronchiolitis – comprising infiltration of inflammatory cells, particularly macrophages, into bronchiolar wall is one of the earliest lesions in cigarette smokers. It can produce fibrosis of the small airways in patients with COPD.

Pulmonary hypertension – In advanced COPD with persistent hypoxemia, hypoxic vasoconstriction results in pulmonary hypertension. The oedema that usually develops in COPD patients with both hypoxemia and hypercapnia results from a complex series of events producing a reduction in renal blood flow, activation of the renin-angiotensin system, and salt and water retention.

Fig. 10: Chest X-ray showing hyperinflated lungs, the diaphragm is low-lying and flat. The heart is elongated. These are features of emphysematous chest

Fig. 11: Axial HRCT sections showing features of centriacinar emphysema

Fig. 12: Cross-sectional CT appearances of a patient with bullous emphysema. Note the relatively well-preserved lung structure in the left lung

ASSESSMENT OF SEVERITY OF COPD

GOLD criteria for assessment for severity of COPD is given in Table 24.

Blue bloater and pink puffer. These terms may reflect variation in ventilatory control. The hypersecretion of chronic bronchitis is associated with inspiratory drive in patients known as blue bloaters. Another group of patients with airways obstruction caused predominantly by emphysema retain their respiratory drive and are labelled pink puffers (Table 25).

Table 24: GOLD criteria for assessment for severity of COPD

GOLD stage	Severity	Spirometry
I	Mild	FEV ₁ /FVC 0.7 and FEV ₁ >80% predicted
II	Moderate	FEV ₁ /FVC 0.7 and FEV ₁ ≥50% and <80% predicted
III	Severe	FEV ₁ /FVC 0.7 and FEV ₁ ≥30% and <50% predicted
IV	Very severe	FEV ₁ /FVC 0.7 and FEV ₁ <30% predicted

MANAGEMENT OF COPD

1. **Smoking cessation** - arrests decline of lung function at all stages of disease severity.
2. **Antibiotics for treatment of bacterial exacerbations.**
3. **Drug therapy**
Drug therapy of COPD is given in Table 26.
4. **Domiciliary oxygen therapy** - Long term treatment with supplementary oxygen sufficient to raise PaO₂ to above 7.5 kPa improves survival in patients with persistent daytime hypoxemia, with or without hypercapnia.
5. **Pulmonary rehabilitation**- comprises a coordinated programme of non-pharmacological treatment and support including exercise training, smoking withdrawal attempts and improved nutrition.

Indications for Long-Term Oxygen Therapy and Pulmonary Rehabilitation

- PaO₂ <7.5 kPa when clinically stable (i.e. at least 4-5 weeks after an exacerbation)

Table 25: Differences between blue bloater and pink puffer

	Pink puffer (<i>Predominant emphysema</i>)	Blue bloater (<i>Predominant bronchitis</i>)
<i>Clinical features</i>		
Onset	Dyspnoea and cough	Cough without dyspnoea
Build	Thin	Obese
Sputum	Scanty	Profuse, mucopurulent
Dyspnoea	Intense with pursed lip breathing	Relatively mild dyspnoea
Cough	After dyspnoea starts	Before dyspnoea starts
Cardiac failure (Cor pulmonale)	Rarely develop oedema or overt heart failure	Often oedematous and easily lapse into CHF
Weight loss	Marked weight loss	No marked weight loss except terminally
Bronchial infections	Less frequent	More frequent
Episodes of resp. failure	Often terminal	Repeated
Pulmonary hypertension	None or mild	Moderate to severe
Course	Unrelenting downhill	Ambulatory
<i>Investigations:</i>		
Chest radiograph	Narrow cardiac shadow	Cardiac enlargement
Arterial PaCO ₂	Attenuated vessels	Increased bronchovascular markings
Elastic recoil	Emphysema, Bullous changes	Raised
Resistance	Normal	Normal
Diffusing capacity	Marked decrease	High
	Normal or slight increase	Normal or slight decrease
	Decreased	

Table 26: Drug therapy of COPD

<i>Drug</i>	<i>Advantages</i>	<i>Adverse effects</i>
β-agonists, long acting (LABA)		
Salbutamol (and terbutaline) Metered dose inhaler 200 µg as required upto 6 times/d Dry powder inhaler: 200 µg upto 6 times/d Nebulizer: 2.5–5 mg tds or qds (PO and IV not recommended) Salmeterol 50 µg bd Formeterol 12 µg bd	Rapid action Increase mucociliary clearance	Tremor Tachycardia Can worsen hypoxia Hypokalaemia
Anticholinergics Long-acting anticholinergics (LAMA) Ipratropium 40 mcg tds Tiotropium 8 mcg od	Extended action No tachyphylaxis Improves health status and reduces exacerbations	Same as above Expensive
As COPD severity increases to moderate type (FEVL < 80% predicted). Most patient will benefit with a combination of LABA + LAMA	M ₃ receptors	Dryness of mouth Contraindicated in narrow angle glaucoma
Methylxanthines Sustained release theophylline 175–300 mg bd po Doxofylline 200–400 mg bd or 800 mg at night	Oral route Anti-inflammatory effect	Slow onset of action Weak bronchodilator Drug interactions Arrhythmias and fits Nausea headache, Needs blood level measurements Candida infection Hoarseness Not indicated in milder disease or when no exacerbations
Inhaled corticosteroids Beclomethasone 200–400 µg bd by metered dose inhaler or dry powder inhaler Budesonide 200–400 µg bd by metered dose inhaler or dry powder inhaler Fluticasone 250–500 µg bd by metered dose inhaler or dry powder inhaler	May improve underlying disease Lower side-effects Reduces frequency of exacerbations in patients with moderately severe disease	
Mucolytics N acetyl cysteine (NAC) 600 mg bd	Reduce viscosity of sputum in the airways and help patient expectorate. Useful for recurrent exacerbations	

- $\text{PaCO}_2 > 5.0$ kPa when clinically stable (i.e. at least 4–5 weeks after an exacerbation)
 - Previous cor pulmonale (ankle oedema/ raised JVP and abnormal blood gases as above)
 - $\text{FEV}_1 < 1.5$ L and forced vital capacity > 2 L
 - For patients with resting hypoxemia (resting O_2 saturation $< 88\%$ or $< 90\%$ in patient with pulmonary hypertension or right heart failure) use of O_2 supplementation has demonstrated impact on mortality rate.
 - It is also useful in patients with exertional hypoxia and nocturnal hypoxia.
6. **Vaccine** – (a) *Influenza vaccine* given yearly 1–2 months prior to anticipated peak influenza season, because of new antigens and waning immunity from the previous year. (b) *Pneumococcal vaccine* to all COPD patients generally given only once, may be considered if last vaccination was given > 5 years previously.
7. **Surgery** – (a) *Bullectomy* for patients with large emphysematous bullae particularly if PaO_2 is normal and FEV_1 more than 1 litre. (b) *Lung volume reduction surgery* – Criteria include severe exercise limitation, $\text{FEV}_1 < 30\%$ predicted, dominant upper lobe emphysema on CT and normal arterial CO_2 tension. (c) Single-lung transplantation is relatively safe and effective. When marked sepsis is present, double - lung transplantation is necessary.

Management of Acute Exacerbation of COPD

Precipitating Factors

1. Infections: (lower resp. 50%)
Viral: Rhinovirus spp., influenza
Bacterial: Strep pneumonia
H. influenzae, M. catarrhalis
Enterobacteriaceae spp., Pseudomonas
2. Environment conditions: Sudden change in temperature and humidity, air pollution, exposure to tobacco smoke, noxious gases or irritant chemicals.
3. Host factors: Poor general health, poor nutritional status, immunocompromised pts., deficient compliance with therapy.

Symptoms

- Increased cough
- Increased breathlessness
- Fever
- Increase in cough volume and change in colour (yellow, green, blood stained)
- Chest pain

- Increased fatigue
- Increase in O_2 requirement (for pts. on long term O_2 therapy)

Investigations

- At home: Pulse oximetry
- In hospital: Chest radiograph, arterial blood gas tensions. ECG

Indications for hospitalization – 1. Unable to cope at home. 2. Severe breathlessness. 3. Cyanosis, worsening peripheral oedema, altered mental state, significant co-morbidity (heart disease, diabetes). $\text{SaO}_2 < 90$, arterial $\text{pH} < 7.35$, arterial $\text{PaO}_2 < 7$ kPa.

Management

Pharmacological Treatment

A. Bronchodilators –

- Salbutamol 100–200 mcg inhaler and /or
- Ipratropium 20, 40 mcg with spacer or nebulizer
- If pt. is hypercapnic or acidotic, compressed air nebuliser, not O_2 (to avoid worsening of hypercapnia)

B. Systemic corticosteroids

- Inhaled corticosteroids by MD or hand-held nebuliser
- Prednisolone 30 mg po for 7–14 days
- IV hydrocortisone 20 mg IV up to 14 days if pt. cannot tolerate oral intake

C. **Antibiotics.** If history of purulent sputum or change in colour, consistency, volume, signs of consolidation on chest radiograph or clinical features of pneumonia. In case of sputum culture, sensitivity to antibiotics to be checked.

If pseudomonas spp. and/or other Enterobacteriaceae combination therapy, e.g. Piperacillin/tazobactam (3.375 g q4h IV) or imipenem (500 mg q6h IV) or meropenem (1 g q8h IV) plus Amikacin 7.5 mg/kg q12h or (15 mg/kg q24h IV) or Levofloxacin (500 mg daily \times 10–14 days).

Theophylline IV should be used only as adjuvant if there is an inadequate response to nebulised bronchodilators. Care should be taken for the potential toxicity if pt. has been on oral theophylline.

Assisted Ventilation

1. *Non-invasive positive pressure ventilation* (NIPPV) which is a popular method of providing ventilation with a combination of continuous positive airway pressure (CPAP 4–8 cm H_2O) plus pressure support ventilation (PSV 10–15 cm H_2O). Indication for NTV - if after optimal medical therapy and oxygenation, hypercapnia, respiratory acidosis and/or excessive breathlessness persist.

Table 27: Summary of pharmacotherapy in stable COPD

<i>Mild COPD</i>	(a) LABA (Salmeterol alone) or LAMA (tiotropium) alone. (b) SABA (salbutamol or ipratropium + salbutamol) need-based only.
<i>Moderate COPD</i>	LABA + LAMA combination inhaler SABA need-based only.
<i>Severe COPD</i>	LABA + LAMA combination inhaler. Inhaled steroid +/- low dose theophylline.
<i>Very severe COPD</i>	LABA + LAMA combination inhaler. Inhaled steroid + low dose theophylline. Evaluate for home O ₂ therapy. NAC 600–1200 mg /day for frequent exacerbations.

2. **Mechanical ventilation** – Indications: NPPV failure – Worsening of arterial blood gases and or pH in 1–2 hr, lack of improvement in arterial blood gases and or pH after 4 hrs, life threatening hypoxemia, tachypnoea >35 breaths/min, impaired mental status.

Steroids– Inhaled steroids reduce frequency of exacerbations in patients with severe COPD. They should be used in patients with FEV₁ <50% of predicted (severe disease) and/or those with 2 or more exacerbations in a year. Side-effects like oral thrush and dysphonia can be reduced by rinsing after inhaler use or use of a spacer.

Dose: Fluticasone 200–500 mcg bd. Budesonide 200–400 mcg bd.

Antibiotics – Moxifloxacin every 6 weeks for a total of 6 courses has been shown to help reduce frequency of exacerbations.

See Table 27 for summary of pharmacotherapy in stable COPD.

Oxygen therapy has been shown to reduce mortality in COPD. The flow rate of O₂ should be sufficient to maintain patient's oxygen saturation above 88% at sea level and for at least 18 hours a day. Alternatively, O₂ can be given during exercise, sleep or strenuous activity whenever the need arises.

Criteria for long-term O₂ therapy: (i) PO₂ < 55 mm Hg, (ii) PO₂ 55–59 mm Hg with pulmonary hypertension, cor-pulmonale, polycythemia, oedema from right heart failure or impaired mental state, (iii) Desaturation during sleep, exercise and high altitude.

See Table 28 for complications of oxygen therapy.

7. CYSTIC FIBROSIS

Cystic fibrosis is a multisystem disorder characterised by recurrent lower respiratory tract infections, pancreatic insufficiency, high sweat chloride and male infertility.

Table 28: Complications of O₂ therapy

CO ₂ narcosis in patients with ventilatory failure when high concentrations of O ₂ is given.
Lung complications
Pulmonary oedema
Consolidation
ARDS
Lung fibrosis
Epilepsy (idiopathic)
In neonates and premature infants
Retrolental fibroplasia and blindness
Bronchopulmonary dysplasia

AETIOLOGY AND PATHOGENESIS

In cystic fibrosis, the airway epithelium shows a combination of defective chloride secretion and increased sodium absorption that leads to changes in the composition of the airway surface liquid, and predisposes the lung to chronic pulmonary infections and bronchiectasis.

The *gene* for cystic fibrosis is located on the long arm of chromosome 7 and encodes the cystic fibrosis transmembrane conductance regulator (CFTR), an amino acid protein found in various cell types, including lung epithelium, submucosal glands, pancreas, liver, sweat ducts and reproductive tract. This explains the multisystem nature of cystic fibrosis.

The high sweat sodium and chloride results from defective ion absorption along the sweat ducts which are impermeable to water.

Clinical presentation – differs between neonates and older children and young adults (Table 29).

DIAGNOSIS

- **Gene mutations** – All patients must be screened for known common cystic fibrosis gene mutations.
- **Sweat test** – Both chloride and sodium sweat concentrations are > 60 mmol/L, chloride more than sodium (Sweat is collected using pilocarpine directed to the sweat glands by iontophoresis). Elevated sweat chloride level is pathognomonic of cystic fibrosis and levels > 70 meq/L differentiates between cystic fibrosis and other lung diseases.
- The nasal PD measurement can document CFTR dysfunction if the sweat chloride test is normal or borderline and two CF mutations are not identified.

Table 29: Differences between neonates and older children and young adults

Neonates	Older children and young adults
Meconium ileus	Chronic sinusitis
Rectal prolapse	Bronchiectasis
Failure to thrive	Malabsorption
Recurrent bronchopulmonary infections	Meconium ileus
Steatorrhoea	Equivalent
	Male infertility
	Cirrhosis and portal
	Hypertension
	Osteoporosis

- **Assessment of exocrine pancreas** – Faecal elastase is a useful screening test for pancreatic damage. Levels are low.
- **Lung function** – deteriorates with disease progression by about 3% per year. The picture is typically obstructive.
- **Chest radiograph** – Accentuated bronchial markings, small ring shadows, nodular shadows and more extensive confluent consolidation are characteristic findings.
- **Guthrie test** – for neonatal diagnosis. A heel prick blood test for trypsin leaking from the pancreas into the blood. Immunoreactive trypsin levels are increased by 2–3 times.

MANAGEMENT

1. **Antibiotics** – oral or IV depending on the organism. It is necessary to clear lung of secretions for which chest percussion therapy and inhalation of hypertonic saline is advocated.
2. **Recombinant human DNase (rhDNase)** – Nebulised once daily to break up long strands of DNA released by degrading leucocytes making secretions viscous. Treatment also decreases frequency of respiratory exacerbations.
3. **Anti-inflammatory agents** – to control chronic inflammation in the lungs – corticosteroids and NSAIDs.
4. **Immunization** – Patients should be given usual childhood immunizations.
5. **Nutrition** – High-calorie oral supplementation with fat-soluble vitamins A, D and E.
6. **Pancreatic enzymes** – Distal intestinal obstruction syndrome often results from inadequate pancreatic supplementation.
7. **Treatment of liver disease** – oral ursodeoxycholic acid with or without taurine.
8. **Transplantation** – Sequential single-lung or heart-lung transplantation is an option in end-stage cystic fibrosis.

8. PNEUMONIA

Pneumonia is an accumulation of secretions and inflammatory cells in the alveolar spaces of the lungs caused by infection. The infecting organism, the inflammatory response and the disturbances of gas exchange caused by alveolar involvement are responsible for the clinical manifestations.

EPIDEMIOLOGICAL CLASSIFICATION

1. Community-acquired pneumonia (CAP).
2. Nosocomial or hospital acquired.
3. Aspiration pneumonia.
4. Ventilator associated pneumonias.
5. Pneumonia in immunocompromised patients.
6. Recurrent pneumonia.
7. Unusual pneumonias.

See Table 30 for the causes of pneumonia.

Based on the anatomical part of the lung parenchyma involved.

Lobar pneumonia occurs due to acute bacterial infection of a part of a lobe or complete lobe commonly Staph. pneumoniae, Staph. aureus, β Haemolytic streptococci are responsible (Figs 13, 14 and 15).

Bronchopneumonia. Acute bacterial infection of terminal bronchioles characterized by purulent exudation which extends into surrounding alveoli through endobronchial route resulting in patchy consolidation. It is usually seen in extremes of age and in association with chronic debilitatory conditions.

Interstitial pneumonia—Patchy inflammatory changes caused by viral or mycoplasma infection, mostly confined to the interstitial tissue of the lung without alveolar exudates. Commonly mycoplasma pneumoniae, respiratory syncytial virus, Influenza virus, adenoviruses, cytomegalovirus.

MICROBIAL AETIOLOGY

1. **Streptococcus pneumoniae** (Pneumococcus): accounts for most cases of pneumonia and also results in more severe pneumonias.
2. **Mycoplasma pneumoniae**— usually occurs in epidemics and in young adults. It may be associated with a persistent, non-productive cough, normal WBC, and bilateral patchy consolidation on CXR, which has led to the use of the term ‘atypical pneumonia’. Certain complications (e.g. hemolytic anemia, Stevens-Johnson syndrome, neurological problems such as Guillain-Barré syndrome) can occur.

Table 30: Causes of pneumonia

1. **Bacterial** – Streptococcus pneumoniae, Mycoplasma pneumoniae, Chlamydia pneumoniae, H. influenzae, Legionella spp. Also M. tuberculosis, anaerobes, Gram negative pathogens and Staph. aureus.
 2. **Primary atypical:**
 - a. **Viral** – Psittacosis-ornithosis group, respiratory syncytial virus, measles and influenza, cytomegalo-virus, adenoviruses, varicella, herpes zoster, lymphocytic choriomeningitis.
 - b. **Rickettsial** – Coxiella burnetti (Q fever).
 - c. **Mycoplasma** – Mycoplasma pneumoniae, Stevens - Johnson syndrome.
 3. **Protozoal** – Entamoeba histolytica.
 4. **Yeast and fungi** – Actinomycosis, aspergillosis, nocardiosis, histoplasmosis.
 5. **Chemical pneumonias:**
 - a. Aspiration of vomit.
 - b. Dysphagic pneumonia – pharyngeal diverticulum, achalasia cardia, hiatus hernia or oesophageal stricture.
 - c. Lipoid pneumonia – Kerosene, paraffin, petroleum.
 - d. Toxic gases and smokes.
 6. **Radiation pneumonia.**
3. **H. influenzae pneumonia**– occurs mainly in patients with underlying chest disease, (e.g. bronchiectasis, COPD).
 4. **Staph. aureus pneumonia** is associated in upto 50% of cases with prior influenza virus infection. Lung abscess and empyema common. CXR – Lobar consolidation with bulging of fissure suggesting the lobe is ‘stuffed’ with infected material.
 5. **Tuberculosis**– should be considered if the presenting history is long, cavitation is present or response to treatment is poor.
 6. **Legionella spp.**– uncommon cause of CAP (and nosocomial pneumonia). Air conditioning systems are the most important sources of infection. Inhalation of Legionella by a predisposed host, (usually a smoker with chronic lung disease) leads to clinical disease which may be a mild flu-like illness (Pontiac fever) or pneumonia.
 7. **Atypical pneumonia** refers to lower respiratory tract infections due to specific respiratory pathogens like Chlamydia psittaci (psittacosis), Francisella tularensis (tularemia), Coxiella burnetti (Q fever), Chlamydia pneumoniae, Mycoplasma pneumoniae or Legionella species.

- a. **Klebsiella pneumonia** is an important cause in some parts of the world of CAP, and the disease can be severe.
 - b. **Chlamydia psittaci** is an uncommon cause of CAP. It is usually acquired from birds such as parrots, and occasionally from sheep.
 - c. **C. pneumoniae** causes upper respiratory infection, but may be associated with CAP in some.
 - d. **Coxiella burnetti** is a rickettsial organism which causes Q fever that may take the form of pneumonia. It is usually acquired from sheep.
8. **Viral pneumonia** – (a) **Influenza viruses** are the most common viral cause of pneumonia in adults, both as primary infection and as precursor of secondary bacterial pneumonia. It has a high morbidity and mortality in elderly and in those with underlying disease. (b) **Other viruses** – Severe acute respiratory distress syndrome (SARS), Hantavirus, avian influenza and H1N1 influenza.
 9. **Other pathogens**– include melioidosis (Burkholderia pseudomallei), pneumonic plague, actinomycosis and systemic fungal infections (histoplasmosis, blastomycosis, coccidioidomycosis).

CLINICAL FEATURES

Symptoms: Onset often sudden although sometimes it follows a minor respiratory infection of a few days duration.

1. **General symptoms of infection** – Malaise, fever, rigors, and night sweats, vomiting; in the elderly confusion and disorientation.
2. **Pulmonary symptoms** – Dyspnoea, cough, and sputum which is often blood-stained or rusty and difficult to expectorate.
3. **Pleural symptoms** – Pain aggravated by cough, deep breath or movement, usually localised to site of inflammation.

SIGNS

1. **General** – Patient appears ill with tachycardia, rapid respiratory rate, high fever, flushed dry skin, herpes labialis, confusion, hypotension.
2. **Pulmonary** – (a) **Early signs** – Slight impairment of percussion note over the affected area, with weakness of breath sounds, or possibly harshness with prolonged expiration and fine crackles on deep inspiration or after cough. (b) **Signs of consolidation** – on second or

Table 31: Absence of physical signs in consolidation.

1. Deep seated pneumonia
2. Associated effusion or empyema
3. Bronchus not patent (bronchus and alveoli filled with exudate)
4. Hypostatic pneumonia at times
5. Shift of trachea

third day. (c) *Resolution* – Most signs disappear by end of second week but fine crackles and impairment of percussion note may be found longer.

At times there may not be typical signs of consolidation (Table 31). Occasionally pneumonia may be associated with jaundice (Table 32).

Table 33 lists the causes of recurrent pneumonia.

Etiological and Radiological features of pneumonia –

1. Alveolar or air space pneumonia – e.g. pneumococcal. Inflammatory exudate involves many contiguous alveoli. Segmental boundaries not preserved and bronchi remain patent. Hence nonsegmental consolidation with air bronchograms.
2. Interstitial pneumonia – e.g. mycoplasma and viral pneumonias. Inflammation mostly of interstitial septa. Hence reticular radiographic appearance.
3. Bronchopneumonia – Inflammation of terminal and respiratory bronchioles and surrounding alveoli. Hence segmental infiltrate without air bronchograms

INVESTIGATIONS

Routine Investigations

1. WBC Count – If raised points to bacterial infection.
2. Sputum gram stain and culture. Presence of > 25 WBC and 10 squamous epithelial cells per high power field suggest that the sputum is appropriate for examination. Specialised culture for *mycobacterium sp.*, *Legionella sp.*, may be valuable in appropriate clinical circumstances. Viral cultures are not useful in initial investigation of patients with CPP.

Laboratory Diagnosis

1. *Sputum microscopy and culture* are specific tests, but their sensitivity is very low due to (a) use of antibiotics prior to the test. (b) Inappropriate sample or no sputum. (c) Atypical or viral pathogens causing pneumonia may not grow on the commonly used media.
2. *Rapid diagnostic tests (RDTs):*

Table 32: Causes of jaundice in pneumonia.

1. Hemolysis in mycoplasma (viral) pneumonia
2. Hepatitis in pneumococcal. Also hemolytic
3. Hepatic metastasis in lung cancer
4. Septicaemia
5. Drug-induced
6. Legionella infection.

Table 33: Causes of recurrent pneumonia.

1. LOCAL BRONCHIAL OBSTRUCTION – (i) *Intraluminal*, e.g. foreign body. (ii) *Intramural*, e.g. adenoma, carcinoma, stenosis. (iii) *Extramural*, e.g. compression by lymph nodes
2. DIFFUSE BRONCHOPULMONARY DISEASE – Bronchiectasis, cystic fibrosis, chronic bronchitis, chronic sinusitis with post-nasal drip. Recurrent pulmonary infarcts
3. NON-RESPIRATORY DISEASE – (i) Recurrent aspiration, e.g. neuromuscular and oesophageal problems, alcoholics, epileptics. (ii) Immune deficiency states.

- Pneumococcal urine antigen detection test – Detects the capsular polysaccharide wall antigen common to all *S. pneumoniae* tests, with results available in 15 min. The test remains positive even after administration of antibiotics, but the sensitivity and specificity are less in children and in adults with nonbacteraemic pneumonia.
 - Legionella Urine antigen detection test: The test has high specificity and sensitivity, and rapidity (< 30 min) can be performed on patients who have taken prior antibiotic therapy. However it cannot identify Legionella infections caused by serogroups other than serogroup 1.
 - ELISA. Mycoplasma IgM ELISA assay is very useful in detecting mycoplasma pneumonia. In addition detection of cold agglutinins in blood also supports the diagnosis.
3. *Serological tests*
 - Indirect fluorescent assay detecting IgM antibodies against various atypical and viral pathogens which include Legionella pneumonia.
 - *Other investigations:* Important for assessment of severity are LFTs, urea and electrolytes, and oximetry/arterial blood gases.
- Patients with immunodeficiency are at risk of opportunistic pneumonias (Table 34).

Fig. 13: Lobar pneumonia of the right middle lobe

Table 34: Immunodeficiency and risk of opportunistic pneumonias.

Primary immunodeficiency	Secondary immunodeficiency
B cell deficiency (agammaglobulinaemia)	HIV infection (AIDS) Leukaemias and lymphomas
T cell deficiency (Di George syndrome)	Corticosteroid therapy Cytotoxic agents
T cell and B cell deficiency	(Particularly following organ transplantation and the treatment of haematological malignancies)
(Combined immunodeficiency)	Malnutrition, general debility, uraemia, liver failure, etc.

Table 35: Radiological features and the infecting organisms.

Pneumonia	CXR shadows	Occasional additional features	Likely organisms
Lobar	Homogenous most of lobe or Non-segmental (patchy but confined to one lobe)	Air bronchogram	Strep. pneumoniae
Bronchopneumonia	Nodular and linear opacities scattered and diffuse, when several nodules enlarge and coalesce.	Swelling or expansion of affected lobe may cavitate Mucus plugging, inflammatory narrowing can cause volume loss, pleural effusion	Klebsiella pneumoniae E. coli, pseudomonas Staph aureus Pneumococcus Anaerobes

FEATURES OF SEVERE PNEUMONIA

- Clinical:** (a) Mental confusion. (b) Respiratory rate >30 breaths/min. (c) Diastolic BP < 60 mm Hg. (d) New atrial fibrillation. (e) Multilobar involvement.
- Laboratory:** (a) Serum urea >7 mmol. (b) Serum albumin <35 g/L. (c) PaO₂ <8 kPa on air or oxygen. (d) WBC <4×10⁹/L or >20×10⁹/L. (e) Bacteraemia.

Radiological presentation can at times give a clue to the infecting organisms (Table 35).

Causes of Slow Resolution

- Elderly and debilitated patients.
- Infective complications – (i) Local intrathoracic – lung abscess, empyema. (ii) Metastatic – e.g. endocarditis, septic arthritis.
- Tuberculous pneumonia.
- Partial obstruction of bronchus.
- Decreased host resistance – Chronic alcoholism, cachexia, agranulocytosis, cardiac failure, immunoglobulin defects.
- Inappropriate chemotherapy.

- Superinfection due to organisms like Staph. aureus or E. coli or B. pyocyaneus.
- Confusion
- Urea >7 mmol/litre
- Respiratory rate ± 30 breaths per minute
- Blood pressure: systolic <90 mm Hg, diastolic <60 mm Hg.

DIFFERENTIAL DIAGNOSIS

- Pleural effusion** – Preliminary upper respiratory infection less likely in tuberculous effusion. Cough and sputum less obvious. Sputum not purulent. In early stages in pleural effusion there may be bronchial breathing. White cell count normal.
- Pulmonary infarction** – Sudden onset but no rapid rise of temperature or rigor as in pneumonia. Blood-stained sputum and presence of predisposing condition like obvious venous thrombosis or heart disease.
- Bronchiectasis** – Recurrent infection and persistently muco-purulent expectoration. Finger clubbing. Coarse basal crackles.

Fig. 14: X-ray chest showing right lower lobe pneumonia

Fig. 15: X-ray chest showing right upper lobe pneumonia

- d. *Atelectasis* – Detection of cause such as inhaled foreign body, or post-operative or following trauma. Displacement of mediastinum.
- e. *Lung cancer* – Patient may present with pneumonia affecting the ill-drained lung beyond the growth. Superimposed hilar shadows on X-ray may give clue to underlying pathology.
- f. *Exacerbation of asthma* – Patient known to have asthma, wheeze on examination.
- g. *Fibrosing alveolitis* – Long history of chronic cough that produces large amount of purulent sputum.
- (h) *Subdiaphragmatic conditions* – Subphrenic abscess or pancreatitis may present as lower lobe pneumonia.

MANAGEMENT

1. *Hospitalization* – If advanced age, signs of severe illness these can be remembered as the ‘CURB’ severity score.
2. *Fluids* – IV in those with severe illness or vomiting.
3. *Oxygen* – If initial blood gases indicate hypoxemia ($\text{PaO}_2 < 10 \text{ kPa}$). If oxygenation is inadequate continuous airways pressure may be sufficient to improve gas exchange, otherwise intubation and assisted ventilation.
4. *Antibiotics:*
 - A. For out-patients
 - a. For healthy and not received antibiotics in last 3 months
 - i. Macrolide – azithromycin 500 mg PO OD or clarithromycin 500 mg PO BID or

- ii. Doxycycline 100 mg PO BID
- b. Comorbidities or received antibiotics in last 3 months
 - i. Fluoroquinolones - Levofloxacin 750 mg/ Moxifloxacin 400 mg – PO qd or
 - ii. β lactam agents Amoxicillin + Clavulanic acid (2 gm bid)/Ceftriaxone 1–2 gm IV qd/Cefpodoxime 200 mg bid/Cefuroxime 500 mg bid + macrolide
- B. For inpatients
 - a. β lactam agents Inj. Amoxicillin + Clavulanic acid (2 gm bid)/Ceftriaxone 1–2 gm IV qd/Cefotaxime 1–2 gm IV + macrolide or fluoroquinolone IV
 - b. For specific organisms
 - i. *Pseudomonas*
 1. Antipseudomonal β lactam agents – Inj. Piperacillin and Tazobactam (4.5 gm q6h)/Inj. Cefipime (1–2 gm bid)/Inj. Imipenem (500 mg q6h)/Inj. Meropenem (1 gm tds) + Inj. Levofloxacin 750 mg qd
 2. Above Antipseudomonal β lactam agents + Aminoglycoside Inj. Amikacin (15 mg/kg qd) + Azithromycin
 - ii. MRSA
 3. Need to add Inj. Linezolid 600 mg IV q12hrly or Inj. Vancomycin 15 mg/kg q12hrly
 5. CURB uses 5 variables + confusion, Urea $>20 \text{ mg/dL}$, Respiratory rate $>30 \text{ min}$, Blood pressure (Systolic ≤ 90 or diastolic ≤ 60 , and age >65 years.

Failure of Treatment

Causes of failure of treatment are given in Table 36.

PREVENTION FOR CAP

Prevention is done mainly through vaccination.

Pneumococcal vaccines are available for prevention.

PPV 23 is pneumococcal polysaccharide vaccine and PCV13 is protein conjugated with capsular polysaccharide. Both are known to reduce overall incidence of pneumonia in children and adults.

PCV13 is recommended for elderly and younger immunocompromised patients.

Influenza vaccines are available both inactive, given intramuscularly, and live attenuated, given intranasally, for population who are at high risk for morbidity and mortality like extremes of ages, pregnancy, suffering from chronic lung diseases.

Stopping smoking is known to reduce risk of pneumococcal infection in patients of COPD.

NOSOCOMIAL PNEUMONIA

Pulmonary infection that develops 2 days or more after hospital admission.

Causes - Etiologic organisms include *Pseudomonas aeruginosa*, *Staph. aureus*, Gram-negative enterobacteria. Also *S. pneumoniae*, *Legionella*, viruses (respiratory syncytial virus, parainfluenza and influenza A).

Diagnosis - Examination of sputum with Gram staining. Specimens obtained at bronchoscopy with protected brush catheter or bronchoalveolar lavage. Presence of new and/or progressive pulmonary infiltrates (often in lower lobes, esp. rt. lower lobe) with new onset of fever, leucocytosis and purulent sputum is often considered as clinical evidence.

Management

Mild	Co-amoxiclav 500 mg tds.
Severe	Cefuroxime 750 mg i.v. q8h + Clarithromycin 250mg q8h

Table 36: Causes of failure of treatment

- Overwhelming infection.**
- Incorrect diagnosis** - *Common:* Pulmonary embolism, pulmonary oedema, bronchogenic carcinoma, fibrosing alveolitis. *Uncommon:* Pulmonary eosinophilia, extrinsic allergic alveolitis, cryptogenic organizing pneumonitis, pulmonary alveolar hemorrhage.
- Incorrect antibiotics** - (a) Pathogen resistant. (b) Antibiotic not reaching pathogen (e.g. poor absorption of oral antibiotic).
- Associated condition**— (a) Bronchial carcinoma. (b) Immunocompromised patient.
- Complications**— Empyema, lung abscess, metastatic abscess, secondary nosocomial infection, pulmonary embolus.
- Antibiotic hypersensitivity.

ASPIRATION PNEUMONIA – SEE LUNG ABSCESS PNEUMONIA IN THE IMMUNO-COMPROMISED HOST

Aetiology- Infection may be caused by almost any organism but bacterial infections with *Pseudomonas*, *Klebsiella*, *E. coli* and *S. aureus* are the most common. The four most opportunistic pathogens are pneumocystis, CMV, *Aspergillus fumigatus* and candida.

Diagnosis - (a) Invasive techniques - Percutaneous lung aspiration. (b) Bronchoscopy to obtain protected brush catheter specimens, bronchoalveolar lavage, transbronchial biopsies. (c) Chest radiograph - Other possible cause for acute lung shadowing in a patient receiving immunosuppressive therapy are - (i) Pulmonary oedema. (ii) Pulmonary hemorrhage from bleeding disorders or vasculitis. (iii) Underlying disease directly affecting the lung (e.g. tumour). (iv) Pulmonary reaction to radiotherapy or drug treatment - e.g. bleomycin or cytotoxic agents. (v) Infection. Focal radiologic shadows and mucopurulent sputum would suggest bacterial pathogens. Bilateral diffuse shadowing would be more typical of pneumocystis or cytomegalo (CMV) virus. Multiple discrete peripheral fluffy shadows perhaps with cavitation, may point to fungal or staphylococcal infection.

Management - (a) CMV - IV Ganciclovir. (b) *Aspergillus* - Amphotericin B. (c) *Candida* - Amphotericin B.

VENTILATOR-ASSOCIATED PNEUMONIA

Pneumonia is one of the common complications arising in patients on mechanical ventilation which leads to increase ICU stay, difficulty in weaning from mechanical ventilation and thus increasing medical cost as well as mortality and morbidity.

These patients are prone for infection by multi drug resistant (MDR) pathogens which includes (1) *Pseudomonas aeruginosa*, (2) MRSA, (3) *Acinetobacter* sp, (4) Enterobacteriaceae.

Following factors play role in pathogenesis for VAP:

- Colonization of oropharynx with pathogenic microbes which replace normal flora due to antibiotic selection pressure, cross infection from other patients or contaminated equipments and malnutrition.
- Aspiration of these pathogenic organisms from oropharynx.
- Compromised host defense mechanisms

Clinical Features

New-onset fever, increased respiratory secretions, tachypnoea, tachycardia, worsening oxygenation and increased minute ventilation.

Investigations

It shows leucocytosis, new or changing infiltrates on X-ray.

Culture of organism is main step in management of VAP which allows antibiotic sensitivity testing and helps to start specific treatment. Endotracheal aspirate is used for culture. More distal in respiratory tree diagnostic sampling done, more specific results are obtained.

Management

1. Hand washing: It is known to reduce significant cross infection and transmission of MDR pathogens from ICU.
2. Head elevation: Head end should be elevated to 45° to reduce aspiration.
3. Heavy sedation avoided.
4. Antibiotics: Choice of antibiotic should be guided by culture and sensitivity report. Till the time culture reports are available patient should be started on broad spectrum antibiotics which should include Antipseudomonal β lactam agents – Inj. Piperacillin and Tazobactam (4.5 gm q6h)/Inj. Cefipime (1–2 gm bid)/Inj. Imipenem (500 mg q6h)/Inj. Meropenem (1 gm tds) + Inj. Levofloxacin 750 mg qd or Aminoglycoside Inj. Amikacin (15 mg/kg qd) + Inj. Linezolid 600 mg IV q12hrly or Inj. Vancomycin 15 mg/kg q12hrly
5. Monitoring done with WBC counts, X-ray and O_2 requirement.

Unusual pneumonias – See Table 37 for Causes.

9. LUNG ABSCESS

Circumscribed suppurative inflammation of lung by pyogenic organisms leading to cavitation and necrosis.

CAUSES

1. *Aspiration abscess* – Aspiration of infected material – (a) From upper respiratory tract – Oral or pharyngeal sepsis, oesophageal obstruction, tracheo-oesophageal fistula, drowning. (b) Vomit. (c) Bronchiectasis. (d) Iatrogenic following use of intermittent positive pressure breathing therapy and nebulisers.
2. *Specific abscesses* – (a) Lobar pneumonia particularly Klebsiella, Staphylococcal or haemolytic streptococcal pneumonia. (b) Tuberculosis. (c) Fungal infection, e.g. actinomycosis.

Table 37: Causes of unusual pneumonias

<i>Bacterial</i>
• Acute TB
• Salmonella typhi and paratyphi
• Brucellosis
• Plague
• Tularemia
• Anthrax
<i>Viral</i>
• SARS
• Swine influenza (H ₁ N ₁)
• CMVS pneumonia
• Hantavirus pulmonary syndrome
<i>Spirochaetal</i>
• Leptospirosis
<i>Rickettsial</i>
• Typhus
<i>Protozoal, yeast and fungi</i>
• Coccidioidomycosis
• Actinomycosis
• Histoplasmosis

3. *Bronchial obstruction or stenosis* – Benign tumours, or inspissated bronchial mucus or foreign body, mucoviscidosis.
4. *Metastatic lung abscess* – Suppurative thromboembolism involving lung parenchyma – pulmonary embolism from pelvic thrombophlebitis or right sided endocarditis, or during septicaemia and pyemia.
5. *Malignancy* – Necrosis within a large solitary nodular malignant neoplasm.
6. *Infected cysts or bullae* – Congenital or acquired.
7. *Extension from neighbouring organs* – Diaphragm, e.g. amoebic infection, vertebral column.
8. *Other* – Wegener's granulomatosis, pneumoconiosis (silicosis, coal).

Symptoms – Groups:

1. *Mild general toxemia* – with slight fever. No symptoms referable to respiratory tract.
2. *Sudden onset* – with high fever, pleuritic chest pain, cough and later copious expectoration.
3. *Symptoms of subacute or chronic respiratory disease* – cough, foetid breath, expectoration and general toxemia. Haemoptysis may occur, or pain due to associated pleurisy.

Signs: Depend on situation and size of abscess and surrounding infiltration.

Fig. 16: Segmental involvement (a) in viral pneumonia. The consolidation lacks homogeneity

Fig. 17: X-ray chest showing a thick walled abscess cavity with air fluid level in left lower lobe

Fig. 18: CECT chest axial view showing right middle lobe atelectasis with lung abscess

Fig. 19: CECT chest coronal view showing right middle lobe atelectasis with lung abscess

1. *In early stages* – Pleural rub, local area of dullness and weak breath sounds or signs of consolidation.
2. *After evacuation of pus* – Signs of cavitation or signs of localized consolidation with amphoric or cavernous breath sounds and crackles of the resonating variety.
3. *Signs of effusion* – may overshadow those of the lung lesion.
4. *Clubbing of fingers.*
2. *Sputum* – Pus cells, organisms and necrotic lung tissue.
3. *Chest radiograph (Fig. 17)* – In acute phase dark shadow, later cavity with fluid level.
4. *Bronchoscopy* – to exclude foreign body or carcinoma.
5. *CT scan (Figs 18 and 19)*

INVESTIGATIONS

1. *Leucocyte count* – 20,000 to 30,000 cells per c.mm.

COMPLICATIONS

- Haemoptysis.
- Extension of inflammation to other parts of lung.
- Cerebral abscess.
- Rupture into pleural cavity.

Fig. 20: X-ray chest showing a well-defined with smooth outline, rounded soft tissue density lesion in the superior mediastinum paratracheal in position, extending into left lung apex

DIFFERENTIAL DIAGNOSIS

1. *Bronchiectasis* – History of cough influenced by posture and associated with copious sputum. Leathery crackles and variable physical signs. No elastic tissue in sputum. X-ray characteristic.
2. *Cavitated bronchial carcinoma* – Elderly patient. Pain in chest, cough and dyspnoea and other pressure symptoms. May be enlarged cervical or axillary lymph nodes. Cancer cells in sputum.
3. *Purulent bronchitis* – Long history. Widespread physical signs. No elastic tissue in sputum.
4. *Caseating tuberculosis* – Signs usually apical. Rapid wasting. Positive sputum.
5. *Interlobar empyema* – Signs generally more marked in axilla or near angle of scapula. Usually few signs. Diagnosis difficult without X-ray which will show an elliptical density in line of one of the fissures in lateral film; shadow with sharply outlined borders.
6. *Infected lung cyst* – Particularly bronchogenic (**Fig. 20**) and hydatid, difficult to differentiate unless previous X-ray shows uninfected cyst or cysts in other parts of the lung. Radiologically there is a clear-cut spherical shadow with little or no surrounding pneumonitis.
7. *Pulmonary infarction* – Postoperative or antecedent cardiovascular disease. Friction rub may be heard. Sputum may be blood stained. X-ray normal or wedge-shaped consolidation.
8. *Empyema with bronchopleural fistula* – Fistula can be demonstrated by injecting 2 mL of 1% methylene blue into the empyema and examining the sputum for the dye.
9. *Pulmonary haematoma* – History of chest trauma. Sputum not purulent and little cough. Spontaneous cure.
10. *Pulmonary mycoses* – Cough, expectoration which may be offensive, dyspnoea. Fever and night sweats. Diagnosis by identification of the fungus in the sputum.
11. *Infected pulmonary bulla with fluid level* – Patient not so ill. Air-fluid level in a cavity with a thin wall.
12. *Cavitated pneumoconiosis (Caplan's nodules)* – Occupational history. Evidence of pneumoconiosis in rest of the lungs.
13. *Cystic fibrosis (mucoviscidosis)* – Symptom complex of (a) pancreatic insufficiency, (b) chronic bronchopulmonary infection and (c) high sweat sodium. Picture similar to bronchiectasis but usually increased number of infectious flare-ups, more airway obstruction, earlier and more pulmonary insufficiency and poorer nutrition due, in part to exocrine pancreatic insufficiency, (d) atopy in majority. CXR – streaky or patchy shadows with or without cavitation.
14. *Wegener's granulomatosis* – Respiratory symptoms such as cough, haemoptysis, dyspnoea. Lesions bilateral and in lower lung fields. Cavitation with thin walls may be seen with sharply outlined borders.

MANAGEMENT

1. GENERAL – (a) Rest in bed. Ambulation as soon as signs of toxicity disappear. (b) High caloric, high protein diet with additional vitamins. (c) Transfusions as indicated. (d) Deep breathing exercises to encourage drainage.
2. MECHANICAL PROCEDURES – (a) *Postural drainage* – Percussion therapy or “clapping” over the site of the abscess with the patient in the postural drainage position is often effective in dislodging and expelling secretions from the cavity. (b) *Bronchoscopy* – Suction is applied to the orifices of the bronchi leading to segments presumed to be involved in the process in hope of initiating or promoting drainage. In addition any foreign material is removed and a careful search made for a tumour. (c) *Oxygen inhalations* – when sputum is foul because it checks the anaerobic organisms (d) Head elevation – patient bed should be inclined to 45° from horizontal plane in cases of altered mentation, on mechanical ventilatory support. (e) Minimal sedation used to avoid aspiration.
3. CHEMOTHERAPY – The most effective antibiotic is determined by culturing the sputum and testing the causative organism against the available drugs. Penicillin is the most useful antibiotic in the common forms of lung abscess. Amoxicillin 1 g. t.d.s. p.o. + Metronidazole 400 mg t.d.s. p.o. or Co-amoxiclav 500 mg t.d.s. or Clarithromycin 250–500 mg t.d.s.

Inj. Clindamycin 600 mg three times a day till fever disappears then switched to 300 mg four times a day orally or Inj. B lactam/ β lactamase inhibitor combination is used and as fever subsides switched to oral therapy.

4. BRONCHOSCOPY - may be needed to remove particulate matter or to exclude bronchial obstruction.
5. SURGICAL RESECTION - If at end of 3 weeks, there is no clinical and radiological improvement, segmental resection of lung, lobectomy or pneumonectomy. Also if localized malignancy or massive haemoptysis.

PROGNOSIS

Following factors indicate poor prognosis:

1. Age > 60 years
2. Sepsis at presentation
3. Abscess size > 6 cm
4. Aerobic growth on culture
5. Symptoms longer than 8 weeks

10. PULMONARY TUBERCULOSIS

RISK FACTORS

- *Close contact* with sputum-smear positive individual.
- *Environmental factors* that lower resistance - Malnutrition, poor and overcrowded housing, alcoholism and/ or drug addiction, heavy smoking, corticosteroid therapy.
- *Relation to other disease* - Not uncommon after influenza, whooping cough. More common with diabetes mellitus, cirrhosis of liver, pneumoconiosis, and following partial gastrectomy.
- *Immunosuppression* (including drugs and autoimmune deficiency syndrome).
- HIV infection/AIDS.
- Other risk factors - Kidney failure, diabetes, silicosis, family history, IV drug abuser.

Route of infection - In majority by inhalation of air-borne infected droplet nuclei derived from sputum of an adult with cavitory pulmonary tuberculosis.

CLINICAL TYPES

- I. **Primary pulmonary tuberculosis** - Primary tuberculosis refers to events following invasion by tubercle bacillus infection, being commonly caused by inhalation (rarely through skin or ingestion) of the bacilli into the lungs.

Primary complex- Inhaled bacilli are deposited in the alveoli where a subpleural inflammatory lesion occurs. When they reach the regional lymph nodes, these also become infected. (Ghon primary complex) The tubercu-

lin test becomes positive within 6 weeks of the infection. These two components of the primary complex may resolve without complications and sometimes result in local calcification (Fig. 21).

Progress - of primary complex may occur thus:

1. **Haematogenous dissemination**- about 3 months after primary infection. (a) Acute type - Miliary tuberculosis, TB meningitis. (b) Chronic type - with local manifestations in kidneys, bones, and joints.
2. **Progress of lung component**- most commonly in adolescents and young adults usually about 6 months after initial infection. The lung focus extends, cavitates and pleural involvement leads to pleural effusion.
3. **Progress of lymph node component**- It may cause pressure on trachea or main bronchi resulting in severe paroxysmal cough simulating whooping cough. There may also be dyspnoea, stridor or wheezing which may be mistaken for asthma.
4. **Bronchial involvement:**
 - a. *Partial bronchial* obstruction with valve action causing obstructive emphysema or
 - b. *Complete bronchial obstruction* may result in large areas of homogenous shadowing. Bronchial involvement commonly involves middle lobes and upper lobes. Aspiration of infected material causes pneumonia or collapse. Lesions may clear without sequelae but sometimes result in permanent collapse, bronchostenosis, bronchiectasis or obstructive emphysema.
 - c. *Middle lobe syndrome* - Compression of a bronchus by enlarged lymph nodes can cause pulmonary collapse. The large middle lobe bronchus is particularly vulnerable and the bronchiectasis may lead to recurrent middle lobe infection.

Fig. 21: Primary tuberculous infection. Calcified focus in the lung (a), calcification in the hilum (b)

Table 38: Differences between primary complex and reinfection

Reinfection	Primary complex
1. Absence of enlarged hilar lymph nodes.	1. Enlargement of hilar lymph nodes.
2. Usually subapical location.	2. Any part of lung.
3. Tendency to cavitation and progress.	3. Usually heals. Cavitation rare, thin walled.
4. Spread bronchogenic hence disease is localised to the lungs.	4. Spread by lymphatic route and haematogenous. Miliary spread common.
5. Healing of the lesion by fibrosis.	5. Healing of lesion mainly by calcification.

Table 38 gives differences between primary complex and reinfection.

MANAGEMENT – Rifampicin 12 mg/kg body weight (maximum 600 mg) and INH 5 mg/kg body weight in two divided doses. Streptomycin 50 mg/kg/day can be added in a severe case. If lesion is not resolving, bronchoscopy should be done and the bronchus sucked out as collapse may be associated with retained secretions.

II. Post-primary tuberculosis – Reactivation

1. As a progressive primary lesion.
2. As result of reactivation of dormant/primary lesion.
3. Haematogenous spread to the lungs

A. Acute pulmonary tuberculosis:

1. **Pneumonic tuberculosis**– affects usually upper lobe, rarely whole lung. Symptoms like acute lobar pneumonia, but irregular temperature, rapid breathing, sweats, signs of cavitation. Leucopenia and failure to respond to antibiotics.

Upper lobes are affected because TB bacillus is a strict aerobe and the upper lobes of the lungs have the highest alveolar oxygen tension.

2. **Bronchopneumonic tuberculosis**– Abrupt onset at times following influenza, or in children measles or whooping cough, or as a sequel of haemoptysis with aspiration of tuberculous matter into bronchi. Signs of diffuse bronchitis in early stage, later areas of consolidation especially at apex. Rapid wasting. X-ray shows scattered foci throughout lungs. May be rapidly fatal.
3. **Miliary tuberculosis** – Types
 - i. ACUTE MILIARY TB

CLINICAL FEATURES

- a. **Onset** – Gradual with vague ill-health, loss of weight and fever.
- b. **Fever** – irregular, wide variation between morning and evening.
- c. **Hepatosplenomegaly** – in 20–30% of cases.

- d. **Respiratory symptoms** – Dyspnoea and cyanosis out of proportion to signs in chest. Slight dry cough, scattered wheeze and occasional crepts.
- e. **CNS** – Headache common, often severe. Signs of meningeal irritation in early stages.
- f. **Cardio-vascular** – Tachycardia.
- g. **Skin** – Miliary lesions of skin rarely as macules, papules or purpuric lesions.
- h. **Fundus** – Choroid tubercles pathognomonic. Seen as single or multiple yellowish white spots which later become pigmented.

INVESTIGATIONS

Mantoux test – Positive in majority.

Chest radiograph – Scattered opacities throughout the lung fields – “snow storm appearance” (Fig. 22).

HRCT chest – (Figs 23 and 24).

Complications – 1. TB meningitis. 2. Pleural effusion or polyserositis. 3. Cervical lymphadenitis. 4. Hypokalaemia. 5. Blood dyscrasias – Anaemia with pancytopenia, at times leukaemoid reaction, purpura.

ii. CRYPTIC (OBSCURE) MILIARY TB

Occurs in elderly patients with prolonged low grade fever, hepatosplenomegaly may occur. Chest radiograph is usually normal, miliary mottling may appear months later. Tuberculin test is usually negative.

iii. ACUTE DISSEMINATED HAEMATOGENOUS TUBERCULOSIS:

- **Clinical features** – (i) Pyrexia of unknown origin lasting over few weeks, with sudden deterioration especially in immuno-compromised patients. (ii) Sputum absent or scanty. (iii) ARDS. (iv) Tachypnoea. (v) Development of dysfunction of multiple organs resembling sepsis.
- **CXR** – Miliary or scattered shadows.
- **Bronchoscopy** – AFB may be cultured from samples from bronchoalveolar lavage and caseating granulomas may be seen on histopathology of lesion obtained from transbronchial biopsy.
- **Liver cell dysfunction.**

B. Chronic pulmonary tuberculosis:

MODES OF PRESENTATION –

1. Symptom-free – Diagnosis on routine radiography.
2. Insidious – Malaise, undue fatigue, loss of weight, evening rise of temperature, and cough.
3. Persistent cough or “smoker’s cough”.
4. Unexplained loss of weight.
5. Pyrexia of unknown origin.

Fig. 22: X-ray chest showing miliary tuberculosis

Fig. 23: HRCT chest coronal view showing miliary tuberculosis

Fig. 24: HRCT chest axial view showing miliary tuberculosis

6. Catarrhal or influenzal – Repeated attacks of colds with run-down feeling, or failure to recover adequately from attack of influenza.
7. Haemoptysis – (a) May be due to pulmonary cavity. If a fairly large vessel is exposed within the cavity, small aneurysmal dilatations (Rasmussen’s aneurysms) can result along the course of such a vessel, a rupture of which would cause a large haemoptysis. (b) From endobronchial tuberculous granuloma. (c) As a sequel of pulmonary TB - (i) Persistence of open healed cavities in spite of therapy. (ii) Bronchiectasis of upper lobe. (iii) Secondary infection of a cavity (*Aspergillus fumigatus*). (iv) A broncholith (lymph node) extruded into a bronchus through blood vessels.

8. Non-resolving pneumonia.
9. Hoarseness of voice – due to laryngeal tuberculosis that occasionally complicates severe pulmonary infection.
10. Pleural – (a) Pleurisy dry or with effusion. (b) Spontaneous pneumothorax.
11. Traumatic – following injury to chest or “gassing”.
12. Following certain diseases – such as measles, whooping cough, especially if complicated by bronchopneumonia.
13. Senile – Slow onset, symptoms of bronchitis or emphysema.
14. Asthmatic – Usually young patient starts getting attacks of so called “bronchial asthma” for the first time.
15. Amenorrhoea or oligomenorrhoea – may be the presenting symptom in young women.
16. Lymph node enlargement – including hilar, mediastinal and cervical groups or generalised with splenomegaly.
17. Initial presentation of AIDS in HIV-positive patients. (Most TB in such cases is reactivation of past infection).

SYMPTOMS AND SIGNS OF RESPIRATORY TUBERCULOSIS

See Table 39 for symptoms and signs.

Signs

- Localised wheeze
- Apical crackles
- Non-resolving pneumonia

Table 39: Symptoms and signs of respiratory tuberculosis

Symptoms
Asymptomatic
Cough
Expectoration (mucoïd or purulent)
Haemoptysis
Fever and sweats
Malaise, fatigue
Chest wall pain
Dyspnoea due to extensive disease, pneumothorax or rapid development of pleural effusion.
Anorexia

Table 40: Complications

Pleural effusion
Empyema
Pneumothorax
Laryngitis
Enteritis as a result of swallowed sputum
Cor pulmonale from extensive disease and fibrosis
Adult respiratory distress syndrome
Mycetoma (<i>Aspergillus fumigatus</i>) in a healed open cavity

**Fig. 25:** Pulmonary tuberculosis – Lesion in left upper lobe with some shrinkage**Fig. 26:** X-ray chest showing a thick walled cavity

Complications

See Table 40 for complications.

Diagnosis

- Isolation of mycobacterium** – Repeated examination of sputum necessary. If sputum not available, laryngeal swabs, morning gastric lavage or specimens obtained by tracheobronchial suction are appropriate.
- Chest radiograph** – Common features:
 - Presence of opacities mainly in the upper zone, with a patchy or nodular appearance (Fig. 25).
 - Cavitation (Figs 26, 27 and 28).
 - Calcification
 - Dense nodular rounded or oval lesions (tuberculoma or bronchial cold abscess).

- CT of the thorax** – In miliary disease nodularity (Figs 29 and 30) may be better or sooner detected, and in TB with mediastinal lymphadenopathy.
- Haematological** – ESR usually increased. Haematological abnormalities in miliary disease.
- Tuberculin testing – Mantoux test:**

Strength: 10 T.U. (0.1 mL) = 0.0002 mg of P.P.D. equivalent to 1:1000 dilution of old tuberculin

Reading taken: After 48 hours of intradermal injection

See Table 41 for interpretation of Mantoux test.
- Bronchoscopy** – In patients with suspected TB but negative direct sputum specimens, fibreoptic bronchoscopic specimens for microscopy and culture (including transbronchial biopsy) may increase diagnostic yield.

Fig. 27: X-ray chest showing a thick walled cavity

Fig. 28: X-ray chest showing hydropneumothorax (Arrow in the air, white arrowhead over fluid and black arrowhead showing collapsed lung)

Fig. 29: Active pulm TB

Fig. 30: Cavitating TB left apical

Table 41: Interpretation of Mantoux test

<ul style="list-style-type: none"> • Negative reaction • Doubtful reaction • Positive reaction • False-positive reaction • False-negative reaction 	<ul style="list-style-type: none"> • Induration measuring <5 mm • Induration measuring 6–9 mm • Induration measuring >10 mm • Previous experience with atypical mycobacteria • Use of inactive PPD or improper deep injection into the skin, Viral infection • BCG vaccination, Miliary TB, Drugs • Steroids, Severe malnutrition, Neoplasms • Sarcoidosis, Immunosuppression.
---	--

7. **Biopsy** - Pleural biopsy is often helpful in diagnosis of pleural effusion.
8. **Thoracotomy** - TB is sometimes detected at thoracotomy for investigation of solid lesions.
9. **Other diagnostic techniques** - (a) *Serological* - Antigen detection by ELISA, competitive inhibition of the binding of monoclonal antibodies, immunoblotting techniques and agglutination-based tests. Antibodies have been detected in CSF, pleural fluid and bronchial washings. (b) *Polymerase chain reaction (PCR)* - For *M.tuberculosis*, the IS6110 DNA sequence is most commonly used. (c) *Restriction fragment link polymorphism* - variants of DNA restriction sites have been identified among

M. tuberculosis isolated by endonuclease restriction and electrophoresis.

Newer cultural techniques – BACTEC radiometric system. BACTEC MGIT – Non radiometric system (mycobacteria growth indicator tube). It contains a special broth with fluorescence quenching-based oxygen sensor embedded at the bottom of the tube. When inoculated with MTB, consumption of dissolved O₂ produces fluorescence with UV light.

PCR – Can help to identify type of mycobacterium within 2 hours.

Interferon – Gamma (INF-γ) assays – (a) Quantiferon (b) T spot – TB test.

ELISA test for detection of anti-TB antibodies (TB IgM, TB IgA, TB IgG) sensitivity and specificity are not good.

NAAT (Nucleic acid amplification test) – Not only helps in diagnosis but also in detecting resistance by identifying specific genes.

Drug - resistant tuberculosis

DOTS: Emergence of MDR TB

The WHO TB control strategy, directly DOTS, consists of 5 components including administration of standardised short course chemotherapy regimens with first-line drugs under direct observation, at least in the intensive treatment phase, regardless of patient drug susceptibility pattern.

Treatment strategies for drug resistance TB (WHO)

Anti TB drugs are divided into first and second-line drugs. First-line therapy may not be sufficient in settings with a high degree of resistance to anti-TB drugs. In order to promote the programmatic treatment of MDR-TB in low income and middle-income countries that have adopted the DOTS strategy, the WHO have been evolving the DOTS-Plus for MDR-TB programmes.

See Table 42 for the comparison of DOTS and DOTS-Plus strategies.

DIAGNOSIS

- Clinical:** (a) No visible clinical improvement in spite of regular and adequate chemotherapy for 3 months. (b) Presence of multiple or giant cavities. (c) Serial X-rays showing deterioration or no improvement after 3 months of therapy. (d) 'Fall and rise' phenomenon in which direct sputum smear examination initially shows a fall in number of bacteria followed by a gradual rise in count due to rise of resistant organisms.

Table 42: Comparison of DOTS and DOTS-Plus strategies

DOTS	DOTS-Plus
<ul style="list-style-type: none"> Political and administrative commitment Good-quality diagnosis by sputum microscopy Uninterrupted supply of first-line drugs for standardized treatment through outpatient therapy Directly observed treatment Systematic monitoring and accountability 	<ul style="list-style-type: none"> Sustained political and administrative commitment Accurate, timely diagnosis through quality-assured culture and drug susceptibility testing Uninterrupted supply of first and second-line drugs, utilizing the latter under strict supervision Directly observed treatment Standardized recording and reporting system that enable performance monitoring and evaluation of treatment outcome

- Laboratory:** (a) Sputum is positive by direct smear even after 5 months of adequate therapy. (b) Culture and sensitivity test of the bacilli by slide culture, use of egg enriched sheep blood media (FESBM), Bactec system of radiometric detection of mycobacterial growth, Luciferase Reporter Mycobacteriophage test (LRM test). (c) Gen box detects MR TB in 2 hours.

MANAGEMENT

Drugs used in primary chemotherapy are listed in Table 43 and regimes under DOTS in Table 44.

Prolongation of continuation phase

For 12 months for:

- CNS and TB meningitis
- Localized disease in intractable drug-resistant infection

Second-line antitubercular drugs

These are listed in Table 45.

Multidrug-resistant-TB management:

See Table 46 for the fundamental aspects of MDR-TB.

MDR-TB is defined as tuberculosis disease where bacilli are resistant to Isoniazid and Rifampicin, with or without resistant to other organism.

XDR-TB (Extensively drug resistant TB) is a subset of MDR-TB where bacilli, in addition to being resistant to Rifampicin and Isoniazid, are also resistant to fluoroquinolones and any one of the second line injectable drugs (Kanamycin, Capreomycin and Amikacin).

DST: Drug-sensitivity test; E: Ethambutol; FLD: First-line drug; FQ: Fluoroquinolone; H: Isoniazid; Km: Kanamycin; MDR: Multidrug-resistant; R: Rifampicin; SLD: Second-line drug, Z: Pyrazinamide

Table 43: Drugs for primary chemotherapy (First-line drugs)

Drug	Daily Dose (Adult)	Thrice Weekly Dose	Toxicity/Precautions
Rifampicin	>50 kg 600 mg <50 kg 450 mg.	(10 mg/kg) (10 mg/kg)	Urine coloured pinkish-orange. Hepatitis, rash.
Isoniazid	200–300 mg (In miliary TB 10 mg/kg)	(5 mg/kg) (10 mg/kg)	Fever and rash. Peripheral neuropathy, hepatitis. Pyridoxine 10 mg advised for patients at risk of peripheral neuropathy (diabetes, chronic renal failure, malnutrition).
Pyrazinamide	>50 kg 2 gm. (25 mg/kg max 2 gm) <50 kg 1.5 gm	(35 mg/kg, max 3 gm)	Arthralgia, hyperuricemia, photosensitivity. Biochemical evidence of hepatitis
Ethambutol	25 mg/kg in initial phase,	(30 mg/kg) 15 mg/kg in continuation phase	Optic neuritis. (Not to be given to young children, elderly and in renal failure).

Table 44: Under DOTs following treatment regimen are used

	Indication	Intensive Phase		Continuation phase	
		Drugs	Duration	Drugs	Duration
Category I	New sputum smear-positive New sputum smear-negative New extra-pulmonary tuberculosis	Isoniazid, Rifampicin, Pyrazinamide and Ethambutol	Thrice weekly for 2 months	Isoniazid and Rifampicin	Thrice weekly for 4 months
Category II	Sputum smear-positive relapse Sputum smear-positive failure Sputum smear-positive treatment after default	Isoniazid, Rifampicin, Pyrazinamide, Ethambutol and Streptomycin	Thrice weekly for 2 months followed by		
		Isoniazid, Rifampicin, Pyrazinamide and Ethambutol	For 1 month	Isoniazid, Rifampicin and Pyrazinamide	5 months

Table 45: Second-line antituberculous drugs.

Drug	Dose
Streptomycin	20-40 mg/kg/day od im
Kanamycin	15-30 mg/kg/day od im
Amikacin	15-22.5 mg/kg/day od im
Capreomycin	15-30 mg/kg/day od im
Ofloxacin	15-20 mg/kg/day bd orally
Levofloxacin	7.5-10 mg/kg/day od orally
Moxifloxacin	7.5-10 mg/kg/day orally
Ethionamide	15-20 mg/kg/day bd orally
Prothionamide	15-20 mg/kg/day bd orally
Cycloserine*	10-20 mg/kg/day od or bd orally
PAS*	150 mg/kg/day bd or tds orally

*Cycloserine and PAS are bacteriostatic others are bactericidal.

Table 46: Fundamental aspects of MDR-TB

Step	Considerations
1. Diagnose	Compile and compare information History of drugs: 1 month intake of a failed drug regimen could be a strong predictor of resistance DST: most reliable for R and H; also reliable for Km and FQ; less reliable for E and Z; very low reliability for group 4 drugs
2. Number of drugs	At least four effective drugs
3. Drugs selection	Use FLDs if they are still effective One injectable Use group 5 drugs until complete for effective drugs If necessary, use group 5 drugs to strengthen the regimen, or when no four effective drugs are reached with the previous groups
4. Length of the injectable	At least 4 months after smear or culture conversion; longer if there are no three effective drugs during continuation phase or are from group 5
5. Surgery	Consider only if: <ul style="list-style-type: none"> • Few effective drugs are available • Localized lesions • Sufficient respiratory reserve
6. Ideal regimen	Standardized: if there is no use of SLDs in the past Individualized: use of SLDs the past or contact of a MDR-TB patient who had use of them (treat with the effective regimen of the index case)

Treatment Regimen under RNTCP for MDR-TB and XDR-TB

For MDR-TB

Six drugs in intensive phase for 6–9 months: Kanamycin, Levofloxacin, Ethionamide, Cycloserine, Pyrazinamide and Ethambutol.

Four drugs in continuation phase for 18 months: Levofloxacin, Ethionamide, Cycloserine and Ethambutol

Reserve drug p-aminosalicylic acid.

For XDR-TB

Seven drugs in intensive phase for 6–12 months: Capreomycin, p-aminosalicylic acid, Moxifloxacin, high dose Isoniazid, Clofazimine, Linezolid, Amoxicillin and clavulanic acid.

Six drugs in continuation phase for 18 months: p-aminosalicylic acid, Moxifloxacin, high dose Isoniazid, Clofazimine, Linezolid, Amoxicillin and clavulanic acid.

Reserve drugs: Clarithromycin, Thiacetazone

1. Corticosteroids–

Indications for corticosteroids in tuberculosis are listed in Table 47.

2. Consider only if

- Few effective drugs are available
- Localized lesions
- Sufficient respiratory reserve

3. Surgery - Surgical resection of infected lobe if feasible.

4. Symptomatic treatment

- Cough – If irritative, linctus codeine. No smoking if associated catarrh or laryngitis.
- Haemoptysis (Refer).
- Laryngitis – Rest to the voice. If pain, anaesthetic powders, sprays or lozenges. Injection of alcohol into superior laryngeal nerve will give temporary relief.

Treatment in HIV-infected patients – HAART can be delayed if CD4 counts > 200 μ L until antituberculous therapy is completed. In those with CD4 count < 200 μ L, HAART should be started within 2 months of starting antituberculous therapy, to prevent a further AIDS-defining event.

Table 47: Indications for corticosteroids in tuberculosis

Tuberculous pneumonia
Miliary tuberculosis
Widespread infiltration
Pleural, pericardial or peritoneal effusion
Acutely ill patients
Segmental opacities in primary pulmonary tuberculosis of less than 3 months duration thereby significantly lowering incidence of bronchiectasis
Suppression of hypersensitivity reaction to anti-tuberculous drugs
Tuberculous meningitis
Large lymph nodes involving or compressing trachea or bronchi

TB immune reconstitution inflammatory syndrome (IRIS) is a relatively frequent complication in HIV-TB-coinfected patients after they start highly active antiretroviral therapy (HAART). There are two forms of TB IRIS: The 'paradoxical' type (clinical worsening of a patient on TB treatment) and the 'unmasking' type (undiagnosed TB becoming apparent after starting HAART). The pathogenesis appears to be IRIS following initiation of HAART is accompanied by an increase in immune responses to *Mycobacterium tuberculosis*. Diagnosis of IRIS include a low CD4 lymphocytic count, disseminated and a short interval between TB treatment and HAART initiation.

Drug resistance. Primary and acquired drug resistance is an increasing problem. A positive culture is the only means of determining drug susceptibilities. A history of prior treatment increases likelihood of drug resistance tenfold. Multi-drug resistant TB (MDR-TB) is defined as high resistance to rifampicin and isoniazid \pm other drugs (> 5%). Molecular probes for rifampicin resistance should be undertaken in patients in whom treatment has failed or who have been treated previously. Management of MDR-TB requires reserve drugs, and may last for up to 2 years. Non-MDR-TB resistant cases should be followed-up for one year after cessation of treatment, and MDR-TB indefinitely.

Chemoprophylaxis - Drug treatment is given to destroy or diminish bacterial populations and thus prevent clinical disease.

Primary chemoprophylaxis - (before evidence of infection) is required in children under age of 2 years who are close contacts of sputum smear-positive individuals. Isoniazid 5 mg/kg is given immediately and continued until serial tuberculin testing at a 6-8 week interval. If the initial or repeat test is positive, isoniazid for 6 months, or isoniazid 5 mg/kg and rifampicin 10 mg/kg for 3 months. If serial tuberculin tests are negative, isoniazid can be stopped and BCG vaccination performed, if not already given.

Secondary chemoprophylaxis - is to prevent progression to clinical disease in infected (tuberculin positive, but not following BCG), e.g. (a) Children under 5 years of age because of risk of miliary disease and meningitis. (b) Tuberculin-positive children and adults upto 35 years of age (who have not had BCG) in close contact with respiratory cases. (c) Recent tuberculin converters. (d) Patients on long-term corticosteroid or immunosuppressive drug therapy. Either Isoniazid 5-10 mg/kg (maximum 300 mg.)

for 6 months, or Rifampicin 10 mg/kg and Isoniazid 5-10 mg/kg for 3 months is advised. In HIV-positive patients with positive tuberculin test (who have not had BCG in the past), Isoniazid 5 mg/kg (upto 300 mg), should be continued indefinitely.

OPPORTUNISTIC MYCOBACTERIAL INFECTIONS

Common species: *M. kansasii*, *M. avium* intracellular, *M. malmoense* and *M. xenopi*.

Clinical features: More than 50% have pre-existing pulmonary disease, usually COPD and/or old pulmonary T.B. *M. kansasii*, is associated with occupational dust exposure and MAC with HIV/AIDS. Onset of symptoms is gradual with cough, sputum, haemoptysis, malaise, breathlessness, wt. loss. Radiological appearances are similar to those of the infiltrates and cavities of *M. tuberculosis* infection. Cavitation is seen in 60-80% of patients.

Diagnosis depends on culture and special means of identification (e.g. temperature range, oxygen preference, pigment production, hydrolysis of Tween 80, chromatography). DNA probes are available for MAC, *M. kansasii* and *M. gordonae*. Disease is diagnosed when cultures from two or more specimens taken more than 7 days apart are positive in a patient in whom chest radiography suggests mycobacterial infection.

Management - Rifampicin and ethambutol is the combination irrespective of results of *in vitro* sensitivity tests. There is synergism between these drugs and also between these drugs and streptomycin. In HIV/AIDS patients prophylactic clarithromycin protects against MAC, but such monotherapy risks development of resistance.

11. PULMONARY EOSINOPHILIA

A group of diseases in which the pulmonary pathology (commonly eosinophilic consolidation) manifests as fleeting shadowing on chest radiograph, is associated with raised blood eosinophil count in which more than 6% of the leucocytes are eosinophils ($>0.4 \times 10^9$ /litre) (Table 48). Lung infiltration with eosinophils, shown on lung biopsy or BAL, may occur with a normal eosinophil count. Conversely, a moderately raised eosinophil count may be a feature of several lung diseases with a non-eosinophilic pathology.

Table 48: Causes of eosinophilic lung diseases**Atopic allergy**

- Asthma
- Allergic bronchopulmonary aspergillosis

Pulmonary diseases with likely blood eosinophilia

- Sarcoidosis
- Tuberculosis
- Lung cancer
- Lymphoma, leukaemia
- Fibrosing alveolitis

Helminth infections

- Microfilaria
- Schistosoma spp.
- Ascaris lumbricoides
- Toxocara canis

Drugs

- Nitrofurantoin
- Tetracycline
- Sulphonamides
- Chlorpropamide
- Sodium aminosalicylate
- Imipramine
- Penicillins

Other ingestants

- Toxic oil syndrome
- (Distilled aniline, denatured rape-seed oil)
- Eosinophilic myalgia syndrome
- (Bacterial contaminant in L-tryptophan preparations)

Idiopathic

- Simple pulmonary eosinophilia (Loeffler's syndrome)
- Chronic eosinophilic pneumonia
- Acute eosinophilic pneumonia
- Allergic granulomatosis (Churg-Strauss syndrome).
- Idiopathic hypereosinophilic syndrome

TROPICAL PULMONARY EOSINOPHILIA (TPE)

A syndrome characterised chiefly by cough, paroxysms of dyspnoea, a raised white cell count with persistent and absolute eosinophilia, and often systemic manifestations such as fever, loss of weight and lassitude.

Causation

TPE has been considered to be hypersensitive reaction to filarial antigen because – (a) Microfilaria have been demonstrated in lung, liver and lymphnodes. (b) High filarial

antibody titres are found in patients and the titre decreases after cure. (c) Responds to antifilarial therapy.

Symptoms

ONSET– Slow and insidious with symptoms of asthmatic bronchitis. Rarely sudden onset with fever, headache and bodyache.

1. *Cough* – Most prominent symptom. In early stages dry, hacking. Later on paroxysmal and worse at night, especially early hours of morning. Sometimes no cough during day. Blood streaking of sputum not uncommon after paroxysm of cough. Rarely haemoptysis.
2. *Expiratory dyspnoea* – As paroxysms of cough become more frequent they are followed by wheezing and expiratory dyspnoea. Attacks simulating bronchial asthma may occur.
3. *Fever* – Common, 99 to 101°F. Usually continuous. Occasionally relapsing or intermittent. May rise to 104°F initially following treatment.
4. *Loss of weight* – Usually with onset of disease. Poor appetite and disinclination for evening meal in order to check cough at night.
5. *General weakness and exhaustion.*
6. *Pain in chest* – Common symptom in adults, usually substernal and dull aching.
7. *GI symptoms* – Attack of vomiting following paroxysm of cough common in children. Sometimes diarrhoea.
8. *Haemoptysis* – may occur in the hyperacute form of the disease.

Signs

1. *Ofasthmatic bronchitis* – With hyperresonance of chest, prolonged expiration and wheeze and crackles at bases.
2. *Sputum* – Scanty and viscid. Clumps of eosinophils.
3. *Spleen* – may be enlarged.
4. *Lymphadenopathy* – Often generalized.

Diagnosis

1. *White cell count* – 20,000–50,000/c.mm, eosinophils 20–90%. Absolute eosinophil count more than 2,500 per c.mm. Eosinophilic count is disproportionately elevated in chronic eosinophilic pneumonia.
2. *Filarial complement fixation test* – positive.
3. *Chest radiograph* – (a) Diffuse mottling of the lungs usually bilateral and symmetrical, coarser than miliary tuberculosis, or (b) prominent linear striations radiating from hilum, or (c) diffuse fan-shaped streakings, or (d) ground glass appearance or cotton wool appearance Figure 31.

Fig. 31: Diffusely distributed patches of density in pulmonary eosinophilia

4. *IgE* – (a) Total IgE and blood eosinophilic count are elevated proportionately in helminth infections. (b) Total IgE is disproportionately elevated in allergic bronchopulmonary mycoses.

Treatment: Diethylcarbamazine 50 mg qds. for one month. Three such courses can be repeated at monthly intervals to prevent relapse.

ALLERGIC BRONCHOPULMONARY ASPERGILLOSIS

APBA is the most common eosinophilic lung disease in temperate climates. Inhalation of spores of the microscopic fungus *Aspergillus fumigatus* by an allergic individual causes bronchial, peribronchial and/or alveolar eosinophilic pulmonary infiltrates. Fungal hyphae develop within the bronchial lumen mucus, leading to mucus plugging, bronchial wall thickening, fibrosis and bronchiectasis.

Eosinophilic pneumonia may cause infiltrates seen on chest radiography, and organizing exudate may cause bronchial obstruction and segmental/lobar collapse. Acute ABPA is clinically silent or causes fever, malaise, worsening asthma and plug expectoration. Criteria for diagnosis of ABPA is given in Table 49.

MANAGEMENT – *For acute ABPA:* Prednisolone 30 mg/day, until infiltrates have gone, dose tapered to zero over few weeks.

Recurrent disease: Persistent episodes may lead to – (a) Proximal bronchiectasis of saccular type. (B) Upper lobe fibrosis. Cavitation and mycetoma occur late. (c) Chronic fixed airway obstruction may occur as a conse-

Table 49: Criteria for diagnosis of ABPA

A. Main diagnostic criteria

- Asthma
- Chest radiograph change (infiltrates, segmental lobar collapse)
- Positive skin test/radioallergosorbent test for *A. fumigatus*
- IgG precipitating antibody to *A. fumigatus*
- Raised serum IgE (often >2000 IU/mL)
- Blood eosinophilia
- Proximal bronchiectasis

B. Other diagnostic features

- History of brownish plug in sputum
- Culture of *A. fumigatus* from sputum
- Elevated IgE (and IgG) class antibodies specific for *A. fumigatus*

quence of lung fibrosis. Treatment – Intermittent corticosteroids. Systemic antifungal drugs (e.g. itraconazole 220 mg or ketoconazole 200 mg daily) for 2 weeks may reduce requirement of a long-term corticosteroids.

Simple pulmonary eosinophilia (Loeffler's syndrome) comprises transient, bilateral, eosinophilic peripheral lung infiltrates, modest blood eosinophilia (<1500/ μ L) and few or no symptoms. In about 1/3 of patients there is no recognizable cause; infiltrates subside spontaneously in 2–4 weeks and do not require treatment.

Chronic eosinophilic pneumonia has an insidious onset with cough, fever, breathlessness and wt. loss. It is more common in women. One half of patients have asthma, and more than 80% peripheral eosinophilia (mean eosinophilic count 30% of total WBC count). Biopsy shows eosinophilic infiltration of the interstitium and alveoli with fibrosis. BAL shows gross eosinophilia (>60%), highly suggestive of the diagnosis. Two thirds of patients have high total serum IgE.

Chest radiograph (Fig. 32) – Peripheral patchy consolidation most common in upper and mid zone ('negative image of pulmonary oedema'). Cavitation and pleural effusion may occur and CT may show mediastinal lymphadenopathy. Lung function tests show restrictive disease. Respiratory failure may occur in severe cases.

Management – Prednisolone 30–40 mg/day produces immediate improvement, to be continued for at least 12 months.

Acute eosinophilic pneumonia is rare. It is an acute version of chronic eosinophilic pneumonia, comprising

Fig. 32: Eosinophilic pneumonia

a febrile illness of less than 5 days duration, hypoxemic respiratory failure, eosinophils on BAL. Chest radiograph does not show peripherally based infiltrates. Peripheral blood eosinophilic count is usually normal. No infectious agent has been shown to cause the disease.

Chronic eosinophilic pneumonia (Carrington's disease). CEP is a disease of unknown aetiology with accumulation of eosinophils in the lungs.

Cl Fs. - Gradual onset with cough, dyspnoea and wt. loss, X-ray chest - Bilateral peripheral shadows at times migratory. Eosinophils $> 1000 \text{ mm}^3$. BAL Eosinophils $> 40\%$ of other fluid cells. Treatment long-term steroids.

Eosinophilic granulomatosis with polyangiitis (EGPA) (earlier called Churg-Strauss syndrome) is a rare disease seen in patients with asthma. It comprises multiorgan, necrotizing small or medium vessel arteritis (Table 50).

Treatment - Corticosteroid with or without cyclophosphamide for at least one year.

Idiopathic hypereosinophilic syndrome is rare, and appears to be caused by fusion protein which produces persistently active tyrosine kinase. Eosinophil count is raised to more than 1500/mL for more than 6 months and eosinophils often constitute more than 30–70% of the total WBC count. The marrow exhibits eosinophilic infiltration. Pulmonary manifestations are cough, malaise, infiltrates and effusions. The heart and major arteries are affected, causing CHF, dysrhythmias, endomyocardial fibrosis and arterial thrombosis.

Treatment - Corticosteroids, cytotoxic drugs and interferon- α . Some patients may respond to imatinib mesylate (a tyrosine kinase inhibitor).

Table 50: Features of eosinophilic granulomatosis with polyangiitis

- Several years' asthma \pm other atopic disease
- Peripheral blood eosinophilia (usually $> 1.5 \times 10^9/\text{L}$)
- Pulmonary infiltrates usual
- High IgE
- High eosinophil levels on BAL
- Antineutrophil cytoplasm antibody positive in 50%
- Multisystem involvement due to vasculitis
- Upper respiratory tract (sinusitis, polyps)
- Skin (nodules, purpura) – 70%
- CNS (mononeuritis multiplex) – 65%
- GI tract (pain, bleeding, diarrhoea) – 60%
- CVS (pericarditis – 30%, CHF – 50%)
- Kidney impairment – 50%

HELMINTHIC PE

Ascaris lumbricoides. Simple pulmonary eosinophilia caused by an allergic reaction in the lung to the migrating larvae of *A. lumbricoides*. Migration occurs 10–16 days after egg ingestion, and the larvae lodge in pulmonary capillaries, a T cell-dependent eosinophilic reaction ensues. Cough and malaise may occur, but illness settles spontaneously over a few days or weeks.

Other parasites, notably *Wuchereria bancrofti*, *Brugia malayi* and other parasites (e.g. *A. duodenale*, *Strongyloides*, *Toxocara canis*) can cause a more severe illness sometimes termed 'tropical pulmonary eosinophilia'.

Drugs and toxins. Several drugs can cause pulmonary eosinophilia with or without cough and breathlessness. Most common are nitrofurantoin, sulphasalazine, NSAIDs, antibiotics (e.g. ampicillin, oxytetracycline) and antineoplastic drugs (e.g. bleomycin, methotrexate). Toxins have included contaminated L-tryptophan and rape seed oil contaminated with oleoalanide (marketed as olive oil).

12. LUNG CANCER

AETIOLOGY

Age - chiefly 40 to 55. *Sex* - More common in males.

Predisposing Factors

- Cigarette smoking - Risk of bronchogenic carcinoma varies directly with the number of cigarettes smoked. After stopping smoking, the risk declines rapidly and after 10 years approaches that of non-smokers.

Passive smokers (e.g. non-smokers living with a smoker) appear to have double the risk of developing lung cancer.

- Occupational exposure – to radioactive gases, asbestos, arsenic, nickel, chromates, metallic iron and iron oxides, coal gas manufacture.
- Atmospheric pollution – Urban malignancy twice that of rural areas.
- Lung disease – Risk of lung cancer is greatly increased in patients with cryptogenic fibrosing alveolitis. Also in alveolitis of systemic sclerosis and other types of active alveolitis.

CELL TYPES

Squamous cell carcinoma arises in large airways, grows relatively slowly, metastasizes less.

Adenocarcinoma is more commonly peripheral and is found more often in non-smokers. Bronchoalveolar cell carcinoma grows diffusely within a lobe using the alveolar walls like a trellis. This becomes coated with malignant cells, and it may mimic slowly progressive or non-resolving pneumonia.

Large cell and anaplastic carcinoma. Its behaviour is intermediate between squamous and small cell carcinoma.

Small cell carcinoma is highly malignant and rapidly growing. It typically arises as a relatively small central airway tumour that metastasizes early to thoracic nodes. Almost all patients have metastases at time of presentation.

SYMPTOMS

I. Non-specific – Weakness, loss of weight, tiredness, anorexia and fever.

II. Respiratory (local or primary) symptoms:

1. *Cough* – Affects majority of patients and is often associated with influenza-like illness or pneumonia distal to the obstruction caused by a tumour. Increasing persistence of cough is the most common symptom.
2. *Haemoptysis* – is usually mild and may be only occasional.
3. *Dyspnoea* – is usually associated with increased cough and sputum.
4. *Chest pain* – may be: (a) intermittent discomfort or pain on same side as lesion, usually worse at night, (b) pleural pain from local pneumonia or carcinomatous involvement of pleura, or (c) persistent, severe localized pain with radiation along distribution of intercostal nerve.

5. *Wheeze* – Some patients may notice a localized unilateral wheezing due to the tumour narrowing a main airway.

III. Metastatic symptoms:

A. INTRATHORACIC:

1. *Nerves* – (a) Phrenic nerve – hiccough, paresis of diaphragm. (b) Recurrent laryngeal nerve – Hoarseness or aphonia, bovine cough. (c) Cervical sympathetic – Horner's syndrome. (d) Vagus – Gastric symptoms. (e) Brachial plexus – Lower part involvement with pain around shoulder joint and in arm with sensory impairment along ulnar border of forearm and hand and development of muscular weakness and wasting. (f) Intercostal nerve – Severe pain along distribution of the nerve.
2. *Oesophagus* – Dysphagia.
3. *Vessels* – (a) Superior vena cava – Venous engorgement of head and neck. (b) Azygos vein – Dilatation of superficial veins on thorax. (c) Thoracic duct – Chylous effusion. (d) Axillary vessels – Loss of peripheral pulses and oedema of arm.
4. *Erosion of rib* – Local pain and bony tenderness.
5. *Invasion of heart and pericardium* – resulting in arrhythmias, or signs of pericardial effusion and CHF.

B. EXTRATHORACIC METASTASES:

1. Intracranial.
2. Bony metastasis predominantly in ribs, vertebrae, humeri and femora with pain as the presenting symptom.
3. Hepatic metastasis often silent.
4. Suprarenal metastasis seldom result in clinical Addison's disease.

IV. Symptoms due to non-metastatic extrapulmonary manifestations:

- *Endocrine and metabolic* – (a) Cushing's syndrome (ACTH) commonest, (b) Dilutional hyponatremia (SIADH), (c) Hypercalcemia (Osteolytic secondary to PTH), (d) Hypoglycemia (insulin), (e) Hyperthyroidism (TSH), (f) Gynaecomastia.
- *Skeletal* – Clubbing, hypertrophic pulmonary osteoarthropathy in which finger clubbing occurs with painful swelling of the wrists and often the ankles and periosteal new bone formation occurs on the tibia, fibula, radius and ulna.

Table 51: Differential diagnosis of lung Ca on radiography

Slowly resolving bacterial pneumonia
Lobar collapse from mucus impaction
Bronchial symptoms caused by a benign tumour
Peripheral mass or masses caused by metastasis from an abdominal primary (e.g. kidney carcinoma)
Pulmonary embolism
Endobronchial tuberculosis
Lymphoma
Pleural effusion from other malignancies (e.g. breast and ovary)
Lung abscess (cavitating tumour with necrosis can mimic lung abscess)
Diaphragmatic paralysis caused by phrenic nerve damage (e.g. thoracic trauma, neuralgic amyotrophy)

- *Skin* – Acanthosis nigricans, pruritus, eczematoid and bullous rashes.
- *Neurological* – (a) Encephalopathy with dementia, cerebellar damage or leucodystrophy. (b) Cerebellar degeneration syndrome. (c) Extra-pyramidal syndrome. (d) Myelopathy. (e) Neuropathy. (f) Myasthenic (Eaton-Lambert) syndrome is exclusive to small cell tumours and may precede detection of the tumour by between 6–12 months. (g) Motor neuron disease.
- *Renal* – Nephrotic syndrome.
- *Muscular* – Polymyositis, dermatomyositis.
- *Vascular* – Thrombophlebitis migrans, non-bacterial endocarditis.
- *Haematological* – Haemolytic anaemia, thrombocytopenia, red cell aplasia, eosinophilia.

Fig. 33: Collapse and consolidation of right upper lobe with some central transradiancy in area of necrosis

SIGNS

- Finger clubbing (80% of cases)
- Palpable supraclavicular nodes
- Mid-inspiratory crackles over a lobe, reduction in breath sounds over a lobe and signs of lobar collapse, which results from bronchial obstruction.
- Wheeze: Near-obstruction of a lobar or segmental airway may cause fixed, monophonic wheeze, near-obstruction of a main bronchus or trachea causes stridor.
- Pleural effusion, rib or back tenderness and SVC obstruction.

Pancoast tumour– A tumour at the apex of the lung may invade locally and produce Pancoast syndrome:

- Pain in the shoulder or upper anterior chest or between the scapulae, spreading to the arms once brachial plexus gets involved.
- Weakness and atrophy of muscles of hand
- Horner's syndrome
- Hoarseness

DIAGNOSIS

1. **Chest radiography**– Types of lesions (Table 51 for differential diagnosis):
 - Peripheral single mass. May be fairly well defined or more often irregular with 'pseudopodia' or 'sun ray' projections radiating from its surface (Fig. 33) or diffuse multinodular lesion or infiltrate (Fig. 34).
 - Collapse and/or consolidation of a lobe or segment with or without a hilar mass indistinguishable from simple pneumonia.

Fig. 34: Multiple pulmonary cannon ball metastases. A case of hepatocellular carcinoma. Other sources of such metastases may be malignant renal and adrenal tumours, malignant testicular tumours, or prostatic carcinoma

- Pleural effusion – because of direct pleural invasion by tumour or increase in lymphatic pressure by compression of draining lymphatics at the hilum.
- Hilar and/or mediastinal enlargement – due to lymph node spread from primary site.
- Elevation of hemidiaphragm
- Rib destruction due to direct invasion of chest wall or osteolytic lesions of the ribs from metastatic spread.
- Lung abscess – due to breakdown of tumour or infection of the lung beyond the malignant obstruction.

(For causes of multiple pulmonary nodules see Chapter 16).

2. **CT** – Thoracic CT including the upper abdomen is an essential investigation in all cases.

When possible CT should be undertaken before bronchoscopy because this is guided by the results. CT scan. Useful (i) for tumour size, (ii) for CT guided biopsy of suspected lesion. For nodules between 8 and 10mm, a biopsy may be attempted if the nodule is accessible. Use of CT fluoroscopy makes it easier to track the course of the biopsy cannula and needle, (iii) to assess response to treatment.

3. **Bronchoscopy** – Fibre-optic bronchoscopy has replaced sputum cytology as the usual method of cytological/histological support for the diagnosis.
4. **Sputum cytology** – Studies of sputum and bronchial washing for cancer cells.
5. **Needle biopsy** – Peripheral lung tumors are not visible at bronchoscopy and percutaneous fine needle biopsy is required for its diagnosis. Fine needle biopsy is also helpful for sampling supraclavicular or other nodes, skin deposits and possible liver or adrenal metastasis, and pleural biopsies in case of pleural effusion.

6. **CT Scan positron imaging tomography** – PET is more sensitive and more specific than CT for detection of metastases in intrathoracic lymphnodes and distant organs. It is particularly useful for examining enlarged mediastinal nodes. PET in combination with CT (CT-PET) is a definitive staging technique.
7. **Endoscopic oesophageal ultrasonography** – with needle aspiration is a non-invasive procedure for exploring especially the left side of the mediastinum.

MANAGEMENT

The most important factors which influence the choice of therapy are the histological cell type and the stage of the disease. Squamous cell carcinomas are relatively slow growing, tend to remain more localized and carry the best prognosis. On the other hand, small cell tumours disseminate early and widely and should be considered for multiple drug chemotherapy, with or without radiotherapy. Prognosis for adenocarcinomas and large cell carcinomas lies in between these two cell types (Figs 35 and 36).

1. **Surgery – Indications** – Factors in assessing suitability for surgery include – age of the patient, lung function, hilar and mediastinal node involvement, absence of extrathoracic disease and histological cell type. Surgery is most likely to be curative for non-small cell lung cancer. **Contraindications** – (a) Distant metastasis. (b) Mediastinal involvement – Vocal cord paralysis, vena cava obstruction, oesophageal involvement, positive scalene node biopsy, involvement of carina or trachea, blood stained pleural effusion. (c) Poor respiratory function. (d) Advanced age. (e) Most small cell carcinomas. (f) Extension to chest wall.

Fig. 35: Carcinoma of bronchus mediastinal window CT chest axial view

Fig. 36: Carcinoma of bronchus mediastinal window CT chest coronal view

2. **Radiotherapy** – Best indication is inoperability or operable tumour where resection is not carried out for other reasons (e.g. COPD, heart disease). Helpful palliative for distressing symptoms such as haemoptysis, cough and chest pain. Can temporarily relieve superior vena cava obstruction, or compression of oesophagus or major bronchus. Continuous hyperfractional accelerated radiotherapy (CHART) three times daily over 2 weeks improves chances of survival.
3. **Chemotherapy** – Is particularly useful for patients with wide-spread disease and no local symptoms (e.g. haemoptysis) requiring urgent palliative radiotherapy. Commonly used combinations include mitomycin-ifosfamide-cisplatin, mitomycin-vincristine-cisplatin, cisplatin-gemcitabine and cisplatin-vinorelbine. Three cycles are given.

PARANEOPLASTIC SYNDROME

(Notably Eaton-Lambert syndrome and pulmonary osteoarthropathy) improve when the primary tumour is removed. More commonly however specific treatment may be needed for – Hypercalcemia: Bisphosphonate and inappropriate antidiuretic hormone secretion (fluid restriction and demeclocycline).

13. PULMONARY OEDEMA

The term pulmonary oedema may be regarded as an increase in the fluid content of the extravascular tissues of the lung. Table 52 enlists the causes of pulmonary oedema.

CLINICAL FEATURES

1. Onset – Sudden.
2. Feeling of oppression in chest.
3. Acute and distressing dyspnoea.
4. Incessant short cough and copious frothy, sometimes blood tinged fluid from mouth and nose. Phenomena of “cough, cough, cough – spit, spit, spit”.
5. Sweats.
6. Feeble pulse.
7. Bubbling rales first at base, then over entire chest, Other physical signs relating to the cause of oedema e.g. septicaemia.
8. Fall of temperature.
9. Termination – may be fatal in few hours, the moist sounds increasing and becoming audible at a distance

Table 52: Causes of pulmonary oedema

Cardiogenic –	
• LV failure	
• Myocardial infarction	
• Mitral stenosis	
• Cardiac arrhythmias	
• LA myxoma	
• Hypertensive encephalopathy	
• Pulmonary infarction	
Non-cardiogenic –	
• Fluid overload (overhydration)	
• Neurogenic – Fracture skull, encephalitis, post-ictal state, increased intracranial pressure	
• Near-drowning	
• Shock	
• Infections – Endotoxins from gram-negative septicaemia, pneumonia and bronchopneumonia	
• Inhalation of noxious fumes and gases – Nitrogen dioxide, chlorine, hydrogen sulphide, sulphur dioxide, ammonia, phosgene, mustard gas, ozone, paraquat, polymer fumes, certain metallic salts	
• Inhalation of gastric acid (Mendelson's syndrome)	
• Rapid aspiration of large pleural effusion	
• High altitude pulmonary oedema	
• Uraemia	
• Trauma – Capillary damage causing ‘leaky lung’	
• Toxic	
a. Drug-induced: IV narcotic abuse particularly heroin, methadone, salicylates, propoxyphene. Cytotoxic drugs such as busulphan, bleomycin, cyclophosphamide. Nitrofurantoin.	
b. Poisoning – Alcohol, organophosphorus, barbiturates	
• Hypersensitive response – Blood transfusion (may also be due to fluid overload), angioedema, SLE, Goodpasture's syndrome	

(death rattle), or symptoms may persist for 12–24 hours and disappear.

X-ray – “Bats wing” appearance of confluent shadows extending from hilar region into midzones. A radiological feature of pulmonary oedema fluid is that it shifts with gravity into the bases when patient is upright or to dependent lung if patient is on his side.

MANAGEMENT

- (1) For treatment of acute left ventricular failure (Refer).
- (2) For oedema due to defective pulmonary drainage, e.g. chronic disease, coma, overdosage of drugs – (a) Maintenance of airway. (b) Tracheobronchial suction through catheter. (c) Bronchoscopy or tracheostomy and drainage.

(d) Administration of oxygen under pressure by mechanical assistance. (3) For circulatory overload – IV frusemide. (4) For high-altitude pulmonary oedema – Descent to lower altitude with supportive measures such as fluid replacement and ventilatory assistance. (5) Corticosteroids – in high doses for pneumonia, septicaemia and Mendelson's syndrome. (6) Treatment of specific cause if identified, e.g. emergency mitral valvotomy, control of systemic hypertension, treatment of septicaemia, etc.

14. PULMONARY THROMBOEMBOLISM

Pulmonary thromboembolism (PTE) is usually following venous thrombosis aedes due to various predisposing factors (Table 53).

CLINICAL FEATURES

- I. **Acute minor PE** – due to obstruction of small distal pulmonary arteries resulting in lung infarction. Symptoms if they occur are tachypnoea, pleuritic chest pain and haemoptysis. No signs, or tachycardia, pleural rub and pyrexia. *Management*– Analgesia, oxygen and Heparin 100 IU/kg as loading dose, followed by infusion of 1000–2000 IU/hr. Oral warfarin started simultaneously. When warfarin is started during active thrombosis, levels of protein C and protein S fall, creating a thrombogenic potential. Oral loading of warfarin should therefore be covered by simultaneous IV heparin for 4–5 days. Oral anticoagulation is given to achieve an international normalized ratio (INR) of 2.0–3.0 and is usually continued for 3–6 months.
- II. **Acute major PE** – follows significant obstruction to proximal pulmonary arteries.
 1. SOURCE OF CLOT – (a) *DVT* – of veins of calves or pelvis. (b) *Heart* – Myocardial infarction, mitral stenosis, infective endocarditis, isolated myocarditis.
 2. PRECIPITATING FACTORS – Straining at stool, out of bed or wheel chair, or paroxysm of cough.

Symptoms

1. *Circulatory collapse* – due to sudden reduction in cerebral and coronary blood flow from obstruction to RV outflow.
2. *Dyspnoea* – of sudden onset. Tachypnoea and hyper-ventilation. Asthmatic breathing if reflex bronchospasm.
3. *Chest pain* – (a) In precordium or retrosternal like angina or cardiac infarction. (b) Pain due to pleurisy may appear after few hours or days. Pain is usually worse on deep inspiration.

Table 53: Predisposing conditions for venous thrombosis

Common
• Major trauma
• Recent surgery
• Obesity and immobility
• Smoking
• Increasing age
• Oral contraceptive pill
• Malignant disease
Uncommon
• Hyperviscosity syndrome
• Nephrotic syndrome
• Underlying primary clotting abnormality e.g. defective fibrinolysis, elevated levels of antiphospholipid antibodies
• Congenital deficiencies of antithrombin III, protein C, protein S or plasminogen
• Factor V Leiden mutation

4. *Haemoptysis* – may occur.
5. *Syncope or death* – may occur when degree of pulmonary arterial obstruction is sudden and severe.

Signs

1. *Due to diminished cardiac output* – Sinus tachycardia. Hypotension, shock, impaired concentration, low urine output.
2. *Due to pulmonary hypertension and right ventricular failure* – Raised JVP, hepatic enlargement, diastolic gallop to left of midsternum. Pulmonic component of 2nd sound accentuated. Systolic murmur may appear in pulmonary area, it may have a scratchy quality suggesting pericardial friction rub. Systolic murmur may appear along left sternal border due to functional tricuspid regurgitation from right ventricular dilatation. Sometimes arrhythmias.
3. *Due to disturbance of pulmonary ventilation and perfusion* – Central cyanosis.
4. *Due to pulmonary infarction* – Usually after 12–24 hours. Fever, pleural rub, signs of consolidation. Effusion may develop, usually haemorrhagic.

INVESTIGATIONS

1. **ECG**– abnormal in about 25%. S₁, Q₃, T₃ pattern, RBBB, P pulmonale and right axis deviation.
2. **Chest radiography:**
 - a. Dilatation of major proximal artery (right descending pulmonary artery Palla's sign) and areas of pulmonary focal oligoemia if major arterial obstruction – (Westermark's sign).

- b. Wedge-shaped opacities in peripheral lung fields due to pulmonary infarction with or without small effusion may occur with minor PE - (Hampton's hump) (Fig. 37).
 - c. In chronic thromboembolic pulmonary hypertension, cardiothoracic ratio may be increased and may be evidence of RV dilatation. Patchy oligaemia and dilatation of main pulmonary arteries.
3. **Isotope radionuclide ventilation-perfusion (V/Q) lung scanning**- Normal perfusion scan rules out PE. When assessment of ventilation is made simultaneously, evidence of V/Q mismatch greatly increases likelihood of PE being the cause of reduced perfusion.
 4. **Pulmonary angiography**- is indicated when the index of clinical suspicion is moderate or high, and isotope scan is equivocal.
 5. **CT and MRI scanning**- can detect PE. Diagnostic criteria include constant intraluminal filling defects in several films and sharp cut off in vessels greater than 2.5 mm in diameter.

CT scan with intravenous contrast is investigation of choice as of now. Multi detector CT scan provides images better than conventional pulmonary angiography.

1. **D-dimer**- Increased levels in PE but not specific since elevated levels also occur postoperatively (for one week), in myocardial infarction, sepsis and other systemic illness.

It is used for screening of suspected patients of pulmonary embolism.

2. **Venography and impedance plethysmography**- for testing for DVT.
3. **2D-echocardiography**: it helps to rule out other conditions that mimic thromboembolism like pericardial tamponade, aortic dissection. In patients of PE, it shows hypokinesis of right ventricular free wall with normal movement of right ventricular apex - McConnell's sign.

MANAGEMENT

1. **Relief of pain and apprehension** - Analgesics
2. **Oxygen**- to relieve hypoxia.
3. **Thrombolysis**- Streptokinase loading dose of 250,000-600,000 IU is given over 30-minute period. Following this, a constant IV infusion of 1000,000 units/hour for upto 72 hours, or tPA 10 mg bolus, 50 mg over first hour, 20 mg over each hour for 2h. or Tenecteplase Thrombin time should be maintained at 1.5-2 times the control value. After a delay of 4 hours after stopping thrombolytic agent, heparin should be started.

Fig. 37: Infarction of the lateral segment of the right middle lobe (a)

(Recombinant tPA 100 mg is given as continuous peripheral infusion over 2 hour)

4. **Anticoagulants**- (a) *Heparin* - Loading dose of 10,000 units, followed by constant IV infusion at rate of about 1200 units/hour for 7-10 days. Dose is regulated by frequent measurement of APTT which should be maintained between at 1.5-2.5 times the normal. When higher doses are required of unfractionated heparin in those with DVT and FE, monitoring of plasma protein level is advisable. Low molecular weight heparins are less prone to binding than high molecular weight heparins, and therefore resistance is unlikely. Dose -2500 IU s.c. once daily. (b) *Warfarin* - 10 mg/day started after 7 days of IV heparin. Both drugs should be administered together for at least 4-5 days. Dose of Warfarin is adjusted to maintain PT at 1.5-2.5 times the normal value. The drug should be continued for 3 months. Persisting risk factors or a history of recurrent thromboembolism are indications for indefinite continuation of treatment.
5. **Antibiotics**- to prevent secondary infection.
6. **Vasopressor drugs, IV colloids**- for shock.
7. **Pulmonary embolectomy**-

Indications

- Patient with massive embolism who shows evidence of deterioration after initial improvement.
- Failure of conservative measures to help a seriously ill patient within one hour. Cardiopulmonary bypass has been advocated to support the severely decompensated patient while immediate thrombolytic therapy or embolectomy is instituted.

Acute massive pulmonary embolism can sometimes be successfully disrupted using a catheter inserted into the pulmonary artery. The clot may be partially fragmented and improve pulmonary blood flow, and the smaller fragments may then respond more rapidly to thrombolysis.

PREVENTION OF FURTHER EMBOLIZATION -

1. *General measures* - Elevation of legs in order to collapse the veins. Use of elastic stockings. Leg exercises in the form of pressing the feet against the foot of the bed several times a day.
2. *Anticoagulants*.
3. *Inferior vena cava interruption* - with percutaneous insertion of devices such as filters and umbrellas. Indications—(a) Embolization in patients receiving anticoagulants. (b) Anticoagulants are contraindicated. (c) Diseases predisposing to venous thrombosis and pulmonary embolism are prominent and persistent. (d) Septic embolism.

III. Chronic thromboembolic pulmonary hypertension (CTEPH) - is rare and is a result of chronically increasing pulmonary arterial obstruction, caused by unresolved or recurrent emboli, or thrombosis *in situ*. It usually presents with gradual onset of dyspnoea with or without history of venous thrombosis or pulmonary emboli. Exertional chest discomfort may occur and clinical signs are those of RV pressure overload.

Management - Domiciliary oxygen for symptomatic relief. CTEPH is the only type of pulmonary hypertension that can be successfully treated with conservative surgery that is pulmonary thromboemblectomy (PTE). Inserting an IVC filter prevents further pulmonary embolism.

15. FUNGAL INFECTIONS OF THE LUNG

PREDISPOSING CAUSES

Usually opportunist infection due to:

- States of general debility such as malnutrition, diabetes mellitus, cachexia of malignant disease, blood dyscrasias, and lymphomas.
- Local damage to respiratory tract due to previous inflammatory, neoplastic, allergic or vascular disease.
- Iatrogenic:
 - Antibiotics, especially broad spectrum such as tetracyclines.
 - Corticosteroids.
 - Cytotoxic and antileukaemic drugs.
 - Immunosuppressive drugs used, for example in transplant surgery.

CLASSIFICATION

1. *Diseases due to actinomycetes*

- a. **Actinomycosis** - Pulmonary variety usually results from inhalation of the organism, but the lungs may also be infected via blood stream or by spread through diaphragm via abdomen. It produces chronic suppurative and granulomatous disease of one or both lungs, usually lower lobes. Pleura may be involved with resultant empyema. Abscess and sinuses may form on chest wall. *X-ray* - Irregular areas of consolidation and erosion of ribs. Sputum shows sulphur granules and culture will grow typical colonies. *Treatment* - Benzyl penicillin 2 mega units 8-hourly for 6 weeks, followed by 600,000 units or twice daily together with oral penicillin for 6 weeks. If sensitivity tests demand, streptomycin, or tetracycline or sulphonamide may be added.
- b. **Nocardiosis** - caused by *Nocardia* asteroids. May develop in agricultural workers. Disease pattern resembles that of tuberculosis but it tends to be more acute, lung abscesses may form, and infection may involve the brain. *Treatment* - Same as actinomycosis, the organism also responds to sulphonamides.

2. *Diseases due to yeast and yeast-like fungi*

- a. **Moniliasis** - due to *Candida albicans*. A condition similar to thrush may occur in the bronchi resulting in irritating cough. Rarely moniliasis may invade the lung producing acute illness. Chest radiographs show ill-defined opacities in upper lobe, and occasionally septicaemia with endocarditis or meningitis results. *Management* - Removal of iatrogenic cause such as tetracycline. Pot. iodide by mouth. In severe infections Amphotericin-B.
- b. **Torulosis** - caused by *Cryptococcus neoformans*. If inhaled, it sets up a primary pulmonary lesion, usually minimal, but it may spread in the lung, producing a granulomatous consolidation resembling a tumour (toruloma), and may also cavitate. Lymphomas such as Hodgkin's disease often predispose to this condition. Diagnosis is by sputum mycology and by biopsy of bronchus or lung. *Treatment* - If a chronic lesion persists, surgical excision covered by fungicide therapy with Amphotericin-B or Hydroxystilbamidine.

3. *Diseases due to filamentous fungi*

- a. **Aspergillosis** - *Aspergillus fumigatus* is of chief importance, and agricultural workers are at special risk. The fungus may infect a lung previously

Fig. 38: Fungal ball in left upper lobe cavity

Fig. 39: Aspergilloma at right apex. The air space between the mycelial ball and the wall of the cavity is seen as a typical hypertranslucent crescent

Fig. 40: HRCT chest showing fungal ball in supine position

Fig. 41: HRCT chest of patient in Figure 40 in lateral decubitus showing change in position of fungal ball

damaged by a tuberculous cavity, unresolved pneumonia, pulmonary infarct or bronchiectasis. Three types of bronchopulmonary aspergillosis are known -

- i. **Allergic bronchopulmonary aspergillosis (ABPA)**—In individuals with atopic hypersensitivity, high titres of IgE antibody and precipitating IgG antibody to *Aspergillus fumigatus* results in episodes of intense, usually focal inflammation of medium-sized bronchi. See Table 49 for criteria for the diagnosis of ABPA.
- ii. **Aspergilloma (*Mycetoma*)** - Cavities from previous tuberculosis or sarcoid disease may become colonized by *A. fumigatus*. A ball-like fungal mass mixed with inflammatory debris

and blood forms in the cavity, which becomes lined with highly vascular granulation tissue (Fig. 38). Typical symptom is recurring mild episodes of haemoptysis, but severe bleeding can occur. The fungal ball may be difficult to see on a plain radiograph (Fig. 39) but can be easily visualized on CT scan, crescent of surrounding air within lung cavity. High titres of *Aspergillus* precipitins are usually present (Figs 40 and 41). Treatment - Lobectomy for patients with severe haemoptysis. Endoscopic percutaneous intracavitary instillation of amphotericin or ketoconazole can be useful for high-risk patients for pulmonary resection.

Fig. 42: X-ray chest showing gloved finger opacities and nodular infiltrates in both lung fields

iii. **Invasive aspergillosis**– In immuno-compromised individuals with severe neutropenia or T lymphocyte deficiency, invasive aspergillus infection of the lung parenchyma can produce an acute or subacute illness with fever and a local cavitary pneumonia or disseminated pneumonia. Diagnosis can be confirmed by demonstration of fungal hyphae in bronchoscopic or open lung samplings.

Voriconazole is preferred agent for invasive aspergillosis.

Stages of ABPA

Stage I - Acute: Patients are diagnosed with ABPA after meeting the diagnostic criteria mentioned above. Radiologically infiltrates in upper and lower lobes may be seen, good response to oral corticosteroids.

Stage II - Remission: Resolution of stage I findings for 6 months or longer when patients are off corticosteroids, chest X-ray may show complete resolution of infiltrates.

Stage III - Exacerbation: Relapse of symptoms, new infiltrates on chest radiograph, rising IgE levels.

Stage IV – End-stage: Patients whose diagnosis was missed in early stage and had received treatment for only asthma may progress to bronchiectasis, cavitary changes and fibrosis.

Criteria for ABPA Diagnosis in Cystic Fibrotic Patients

1. Clinical deterioration (coughing, wheezing, increased sputum production, exercise intolerance and decrease in pulmonary function).
2. Immediate hypersensitivity to *A. fumigatus* (positive skin test or IgE response).

3. Total serum IgE concentration >1000 ng/mL.
4. Precipitating antibodies to *A. fumigatus*.
5. Abnormal chest X-ray (infiltrate, mucus plugs or unexplained changes compared to previous chest X-ray). (**Fig. 42**).

TREATMENT

1. **Oral corticosteroids** - are the most effective treatment for acute phase of ABPA as they suppress the immunologic reaction and the inflammatory response. Dose: Prednisolone 0.5 mg/kg/day for 2 weeks, followed by progressive decrease in dose after 6–8 weeks. Treatments monitored by assessing symptoms are chest X-ray or CRST scan. Stage IV patients have severe asthma and in these cases, the minimal dose required to stabilise the patient must be identified.
2. **Antifungal agents** - Antifungal agent Itraconazole 200 mg/day for 16 weeks prevents disease progression in corticosteroid dependent ABPA patients without any toxic effect and can be used as an adjunctive therapy. Fiberoptic bronchoscopy may be necessary to remove the mucoid impaction responsible for atelectasis in rare cases.
3. **Bronchial hygiene** to improve airway clearance and inhaled bronchodilators to reduce bronchospasm. Pneumococcal vaccine and annual influenza vaccination should be included in management.
 - a. **Phycomycosis** (Mucormycosis) - Inhalation of the spore produces an acute pulmonary infection often associated with infarction which may take the form of acute pneumonitis with cavitation. *Treatment* - Amphotericin-B and surgical excision of any chronic localised lesion.
4. **Diseases due to dimorphic fungi:**
 - a. **Histoplasmosis** - caused by *Histoplasma capsulatum*. Primary lesions often calcify and produce hilar and miliary calcifications which are spherical and may show small air-space haloes. A secondary stage of more progressive disease produces fever, and emaciation with visceral involvement. It may mimic tuberculosis or produce tumour-like masses (Histoplasmoma). Enlarged lymph nodes may cause compressive symptoms due to involvement of vessels, airways or esophagus. Diagnosis depends upon positive culture. Serological tests show specific complement fixing antibody. *Treatment* - Amphotericin for several weeks.
 - b. **Coccidioidomycosis** - *Coccidioides immitis* is a soil fungus. Acute and chronic clinical forms of the disease mimic histoplasmosis and meningitis.

Diabetics and immunosuppressed patients suffer more progressive disease and need amphotericin therapy. Diagnosis is by culture of organisms or microscopy of tissue sections. *Treatment* – Amphotericin.

- c. **Blastomycosis** – due to *Blastomyces dermatitidis* causes granulomatous and suppurative lesions presenting as subacute or chronic pulmonary infection. Infection mimics pulmonary tuberculosis and is often accompanied by dissemination to skin of face and arms, causing nodules and plaques. Chest X-rays show massive areas of consolidation. Often fatal but may respond to Amphotericin-B or Hydroxystilbamidine.
- d. **Sporotrichosis** – caused by *Sporotrichum schenckii* occurs in farmers, nurserymen or woodmen. Usually affects skin first, and the disease may then spread to involve the lungs, or primary pulmonary infection which may become chronic. X-rays – Enlarged hilar shadows, miliary mottling and thin-walled cavities. Diagnosis by specific skin test and finding precipitating antibody in serum. *Treatment* – Potassium iodide. Other fungicides may be necessary.

16. AIRWAY PROBLEMS IN CHILDREN

CHRONIC UPPER AIRWAY OBSTRUCTION

1. **Laryngomalacia** is a relatively common condition presenting with variable inspiratory stridor in first few weeks of life. The immature laryngeal cartilages are soft, and supraglottic, collapse particularly of the arytenoids and epiglottis, occurs during inspiration. In most cases, the infant is noisy, but there is minimal respiratory distress. The stridor tends to settle during the first 2 years of life but may transiently worsen with intercurrent viral infections.
2. **Subglottic stenosis** may be congenital or acquired, the latter being an important cause of stridor in infants who were born preterm, as a consequence of scarring from intubation. There is often repeated history of ‘croup’ that may be slow to resolve. Children with moderate to severe stenosis have biphasic stridor. Treatment depends on severity of stenosis. Severe cases require tracheostomy and laryngotracheal reconstruction.
3. **Airway haemangiomas** are uncommon. They enlarge during first few months of life and present with stridor. The larynx is the common site and 50% of children have cutaneous haemangiomas. Tracheostomy is required until spontaneous involution of the haemangioma is complete (usually by age of 5 years).

4. **Vocal cord palsy** – Vocal cord palsies are uncommon and present with stridor. Tracheostomy is necessary for bilateral palsy. Damage to recurrent laryngeal is the most common cause of unilateral palsy.

ACUTE LOWER AIRWAY OBSTRUCTION

1. **Bronchiolitis:** Respiratory syncytial virus (RVS) is responsible for majority of cases. Classical features are tachypnoea, chest wall recession and hyperinflation, crepitations and wheeze are heard on auscultation. Diagnosis is confirmed by examination of nasolaryngeal aspirates for viral immunofluorescence. *Bronchiolitis obliterans* is rare complication of bronchiolitis resulting in fibrosis and permanent damage to lower airways. Prognosis is variable, some children develop progressive respiratory failure.
2. **Bronchial foreign body:** A bronchial foreign body must be considered in toddlers and young children presenting with acute wheeze of sudden onset. There may or may not be a recent history of choking. The foreign body may enter right or left main stem bronchus. Ball valve obstruction with over inflation. Distal impaction may result in lobar collapse.

CHRONIC LOWER AIRWAY OBSTRUCTION

1. **Bronchiectasis** is uncommon in children. Causes –
 - Cystic fibrosis
 - Primary ciliary dysplasia (including Kartagener’s syn.)
 - Immunodeficiency
 - Post-infectious adenovirus, *Bordetella*, undetected foreign body
 - Aspiration (e.g. H-type fistula, GER, swallowing incoordination (with neuromuscular problems)
 - Antitrypsin deficiency
 - Idiopathic
2. **Bronchopulmonary dysplasia** affects about 25% of all children before 28 weeks gestation. Initial respiratory failure associated with hyaline membrane disease, trauma from ventilation (volutrauma) and oxygen toxicity contributes to the airway and parenchymal lung damage. Intercurrent infections are common.
3. **Tracheomalacia** occurs almost exclusively in infants. The tracheal cartilages are soft and have a tendency to collapse. Symptoms vary from mild, with intermittent expiratory stridor, to severe, with episodes of apnoea and cyanosis termed ‘death spells’, that are usually associated with feeding. Ventral suspension of trachea by aortopexy in severe cases.

Table 54: Stages of sarcoidosis

Stage 0	Clear chest X-ray
Stage 1	Bilateral hilar/ mediastinal adenopathy
Stage 2	Bilateral hilar adenopathy and pulmonary infiltration
Stage 3	Bilateral infiltration without hilar adenopathy
Stage 4	Pulmonary fibrosis involving the upper lobes, traction bronchiectasis is common

17. PULMONARY SARCOIDOSIS

Sarcoidosis is a granulomatous inflammatory disorder of unknown cause. It principally affects young adults and has a variable presentation and course. Although sarcoidosis may affect any organ of the body, the mediastinal lymph nodes and lungs are affected in 90% of cases. See Table 54 for the stages of sarcoidosis.

AETIOLOGY

Genetic influences: There are reports of familial clustering in disparate ethnic groups, and evidence of a strong relationship between sarcoidosis and MHC class II alleles on chromosome 6. It is likely that genetic influences will be found that affect susceptibility to the disease, mode of presentation (acute or chronic) and responsiveness to corticosteroids.

PATHOLOGY AND PATHOGENESIS

Granulomas are the classical lesions and may be distributed in multiple organ systems including the lymph glands, lungs, liver and spleen. Analysis of BAL fluid in acute onset sarcoidosis shows intense concentration of activated CD4⁺ lymphocytes (helper cells) with release of inflammatory mediators (cytokines) and interferon- α . Why this immune-mediated response 'switches off' in some but persists and progresses to fibrosis in others remains unexplained.

CLINICAL FEATURES

- Onset** - Sarcoidosis may present acutely (Lofgren syn.), in subacute manner or insidiously. About half the patients are asymptomatic and sarcoidosis is commonly detected by chest radiograph.
- Symptoms** - Consist of unproductive cough and shortness of breath.
- Systemic manifestations** - (a) CNS - Neurosarcoidosis may manifest as paralysis of the nerves at the base of

Fig. 43: Enlarged hilar and paratracheal lymphnodes in sarcoidosis

the brain, spine and of peripheral nerves. (b) Liver - Enlargement with elevated liver enzymes. (c) Heart - Brady or tachycardia, dysrhythmias, cardiomyopathy. (d) Skin - macules, nodules and plaques on nose, cheeks, lips and ears. Erythema nodosum in Lofgren syn. (e) Uveo-parotid fever (Heerfordt syn.). Parotitis with facial nerve palsy and eye symptoms. (f) Joints - Main manifestation in Lofgren syn. (i) Arthralgia, often accompanied by erythema nodosum and an enlarged hilum. (ii) Intermittent monoarticular or polyarticular arthritis or persistent.

DIAGNOSIS

- Chest radiograph** - Bilateral hilar adenopathy (Fig. 43).
- CT scan** - Bilaterally enlarged hilar and mediastinal lymphnodes, thickening and nodules along the bronchovascular bundle, small nodules located in upper lobes and along the pleura, and interlobular septa.
- Tissue biopsy and histology** - Transbronchial lung biopsy in combination with biopsies of bronchial mucosa, reveals non-caseating granuloma even in patients with radiographic normal lung parenchyma. If no conclusive results, surgical biopsies by mediastinoscopy or thoracoscopy may be necessary.
- Non-invasive tests** - (a) *Bronchoalveolar lavage*. BAL fluid shows increase in T lymphocytes. (b) *Gallium scintigraphy* may show tracer accumulation in mediastinal lymph nodes along with an uptake in the parotid glands. (c) *Mantoux test* may be positive in chronic forms, but may be negative in active sarcoidosis. (d) *Angiotensin converting enzymes (ACE)* level is neither specific nor sensitive.

Fig. 44: HRCT of the lungs showing peribronchovascular nodules causing a 'beading' appearance with hilar lymphadenopathy

Table 55: Extra (-) pulmonary manifestations of sarcoidosis

• Skin	Erythema nodosum, lupus pernio, infiltrates, pruritus
• Eye	Uveitis, retinitis, glaucoma, sicca syndrome
• CNS	Bell's palsy, lymphocytic meningitis
• Liver/spleen	Raised enzymes, hepatosplenomegaly, portal hypertension
• CVS	Cardiomyopathy, heart block, arrhythmias, SVC obstruction
• Glands	Diffuse adenopathy - parotid, salivary, lachrymal
• Metabolic	Hypercalcemia, hypercalciuria, hypopituitary syndrome, hypo-thyroidism, tumour necrosis factor pyrexia syndrome
• Renal	Interstitial nephritis, nephrotic syndrome, nephrolithiasis
• Musculoskeletal	Cystic dactylitis, polyarthritis, myositis, nasal septum perforation.

TREATMENT

Stage I disease commonly resolves and does not need treatment unless presence of significant symptoms. Stage II and III disease with pulmonary and systemic involvement - (a) Prednisolone 20–40 mg/d × 4 wks followed by maintenance dose of 10 mg/d. (b) Immunosuppressant - Azathioprine or methotrexate as steroid sparing agents, if cannot be maintained on a low dose prednisolone. (c) Hydroxychloroquine for dermal, bone and joint involvement.

Lofgren's syndrome is an acute form of sarcoidosis characterized by erythema nodosum, bilateral hilar lymphadenopathy and polyarthralgia or polyarthritis.

Table 56: Causes of non-necrotizing pulmonary granulomas

Infections:

1. Bacterial

- M. Tuberculosis
- Non-tuberculous mycobacteria

2. Fungal

- Histoplasma
- Cryptococcus
- Blastomyces
- Pneumocystis
- Aspergillus
- Coccidioides

3. Miscellaneous

- Sarcoidosis
- Lymphoma
- Carcinoma
- Granulomatosis with polyangiitis
- Churg-Strauss syn.
- Brucellosis
- Crohn's disease
- Hypersensitive pneumonitis
- Berylliosis
- Talc granulomatosis
- Rheumatoid nodule
- Cat scratch disease
- Granulomatosis arteritides
- Hypogammaglobulinaemia.

HRCT of the lungs shows characteristic peribronchovascular nodules causing a 'beading' appearance with hilar lymphadenopathy (Fig. 44).

EXTRAPULMONARY SARCOIDOSIS

Table 55 lists the extra-pulmonary manifestations of sarcoidosis.

DIFFERENTIAL DIAGNOSIS

Causes of non-necrotizing pulmonary granulomas (Table 56) should be considered.

18. DIFFUSE PARENCHYMAL LUNG DISEASE

Diffuse parenchymal lung disease (DPLDs) represent a heterogenous group of principally inflammatory processes affecting the alveolar wall and often associated with exudates or transudates in the alveolar airspaces. Because

Fig. 45: X-ray chest suggestive of idiopathic pulmonary fibrosis

the disease affects the peripheral part of the lung, chest radiographs usually show widespread pulmonary shadows (Fig. 45). Causes are listed in Table 57.

DIAGNOSIS

History

Occupation and pastimes– Domestic and occupational exposures to dusts, and relation and exposure to birds such as pigeons.

Family and other history– Family history in cystic fibrosis. Some congenital conditions (e.g. neurofibromatosis) are associated with DPLD. Smokers are less likely to have sarcoidosis or allergic alveolitis and more likely to have Langerhans cell histiocytosis or Goodpasture's syndrome. A careful drug history is necessary. Risk factors for HIV and other forms of immunodeficiency should be sought.

Respiratory symptoms – (a) Breathlessness is not episodic unless caused by extrinsic allergen. (b) Wheeze is a feature in pulmonary eosinophilia associated with asthma, or occasionally with LVF. (c) Cough is not of diagnostic help. Large volumes of sputum (bronchorrhea) occur occasionally in bronchoalveolar carcinoma, and a long history of purulent sputum suggests bronchiectasis. (d) Hemoptysis is common in pulmonary hemorrhage and vasculitis, but seldom occurs in chronic DPLD.

Systemic symptoms: (a) Fever suggests infection, but also occurs in vasculitis, drug-induced lung disease and malignancy. (b) Weight loss if significant indicates malignancy or miliary TB. (c) Arthralgia or arthritis favour connective tissue disease or systemic vasculitis.

Table 57: Causes of diffuse parenchymal lung disease

Cause known:

- Organic dusts (extrinsic allergic alveolitis)
- Inorganic dusts (pneumoconiosis)
- Gases or fumes
- Drugs or radiation
- Infection.

Cause unknown:

- Cryptogenic fibrosing alveolitis
- Interstitial lung disease associated with rheumatoid disease (e.g. RA and systemic sclerosis)
- Granulomatous diseases (Sarcoidosis, Langerhans cells histiocytosis)
- Neoplasia (e.g. lymphoproliferative disease, metastases, and lymphangitis carcinomatosa)
- Vasculitis
- Inherited diseases (e.g. neurofibromatosis, tuberous sclerosis)
- Miscellaneous (amyloidosis, alveolar proteinosis).

Examination

(1) Clubbing is characteristic of FA and asbestosis, and seen occasionally in bronchiectasis. (2) Fine crackles (initially basal and inspiratory, later more widespread and expiratory as well) are hallmark of FA asbestosis. Crackles of bronchiectasis are coarser and occur in early inspiration; in extrinsic allergic alveolitis crackles often occur with a variety of squeaks.

Sarcoidosis reveals widespread radiographic shadowing but little abnormality on examination, whereas in FA patient may have a nearly normal chest radiograph, but profuse crackles.

Chest Radiography

Distribution of shadowing and size and shape of nodularity often give important diagnostic clues (Tables 58 and 59).

INVESTIGATIONS

Primary Investigations

Lung function tests – Most DPLDs cause restrictive defect with reduction in vital capacity, total lung capacity and carbon monoxide transfer factor.

Arterial blood gases – At rest both PaO₂ and PaCO₂ may be normal or reduced. Arterial desaturation on exercise may be early indication of DPLD.

Table 58: Diagnostic clues on chest radiography

	Basal	Mid-zone	Upper zone	All zones	Peripheral
Nodules/irregular shadows	CFA Asbestosis	Sarcoid	Chronic (fibrotic) sarcoid Silicosis	Miliary TB Coal worker's pneumoconiosis Metastases Tuberculosis EAA ARDS	
Confluent shadowing	Alveolar proteinosis	Pul. oedema <i>Pneumocystis jiroveci</i>			Pulmonary eosinophilia

Table 59: Causes of diffuse radiographic shadowing

	Acute	Chronic
<i>Infection</i>	Pneumonia (bacterial, viral, fungal)	Miliary TB
<i>Hemodynamic</i>	LVF, fluid overload	Chronic pulmonary venous hypertension
<i>ARDS</i>	Trauma, sepsis	
<i>Allergic</i>	Acute extrinsic allergic alveolitis	Chronic extrinsic allergic alveolitis (e.g. farmer's lung)
<i>Pneumoconiosis</i>		Asbestosis, silicosis
<i>Drugs, toxins</i>	Cytotoxics, inhalation of chlorine	Cytotoxics, amiodarone, radiotherapy
<i>Hemorrhage/vasculitis</i>	Wegener's granulomatosis, Goodpasture's syndrome	
<i>Malignancy</i>		Lymphangitis carcinomatosa (Fig. 46), bronchoalveolar cell carcinoma
<i>Suppurative lung disease</i>		Bronchiectasis
<i>Unknown cause</i>		Sarcoidosis, fibrosing alveolitis, ± connective tissue disease, cryptogenic organizing pneumonitis, other rare diffuse parenchymal lung diseases

Blood tests – (a) Raised eosinophil count in pulmonary eosinophilia. (b) High titre of rheumatoid or antinuclear factors can suggest connective tissue disease. (c) Positive anti-neutrophil cytoplasmic antibody in Wegener's granulomatosis and related Vasculitides. (d) Positive serum precipitins (e.g. to avian or farmer's lung antigens), which are strongly suggestive of EAA.

**Fig. 46:** HRCT chest showing lymphangitis carcinomatosa**FURTHER INVESTIGATIONS:**

High resolution CT (HRCT) can be useful in suspected cases of CFA (reticular sub-pleural changes), asbestosis (detection of early changes) and lymphangitis (beading of interlobular septa, polygonal lines).

Lung biopsy – (a) Transbronchial – Sarcoidosis, tuberculosis, berylliosis, EAA, lymphangitis carcinomatosa. (b) Open lung or thoracoscopic (VATS) – FA, rheumatological disease, other diffuse fibrosing lung disease, video-assisted pulmonary vasculitis, lymphangio-leiomyomatosis, Langerhans cell histiocytosis.

Bronchoalveolar lavage – to sample cells and non-cellular material from lower respiratory tract. Lipoproteinaceous material (in alveolar proteinosis). Intracellular X bodies (in histiocytosis X). Hemosiderin macrophages indicate pulmonary hemorrhage, asbestos bodies in asbestosis. Predominantly lymphocytic lavage suggests sarcoidosis or EAA.

Scanning – Technetium - DTP scanning is a sensitive marker of lung inflammation; it may help to predict progress in fibrosing alveolitis.

Fig. 47: HRCT chest showing interstitial lung disease UIP pattern

Fig. 48: HRCT chest showing interstitial lung disease UIP pattern honeycombing

Fig. 49: Axial HRCT showing fibrotic pattern of NSIP in a patient with scleroderma, note the dilated esophagus

Cardiopulmonary exercise testing – Hypoxia may not be present at rest and induced by exercise which helps to uncover underlying lung disease. 6-minute walk test can be used for same; drop in oxygen saturation can be seen depending on distance after which drop is seen and degree of reduction in saturation gives information about underlying disease condition.

SPECIFIC DIFFUSE PARENCHYMAL LUNG DISEASES

Idiopathic interstitial pneumonias. Fibrosing alveolitis is a clinical syndrome based on bilateral interstitial shad-

owing on chest radiograph with bilateral, basal inspiratory crackles and restrictive lung function, that occurs alone (termed 'CFA' or idiopathic pulmonary fibrosis (IPF) or with connective tissue disorders (e.g. RA, systemic sclerosis). However, within this broad clinical syndrome, seven different histological patterns have been recognized, in what are now termed the 'idiopathic interstitial pneumonias' (IIPs). The HRCT appearance and prognosis of these entities differ. Usual interstitial pneumonia (UIP) and nonspecific interstitial pneumonia (NSIP) are the most common.

- UIP is characterized by areas of fibrosis with fibroblastic foci alternating with areas of normal lung. It is seen in diseases like asbestosis, sarcoidosis, chronic eosinophilic pneumonia, radiation injury (Figs 47 and 48).
- In NSIP, inflammation and fibrosis are uniform across the biopsy, with ground glass shadowing and linear opacities on CT. NSIP often occurs with RA, progressive systemic sclerosis and other connective tissue and collagen vascular diseases and has a better prognosis than UIP (Fig. 49).

CRYPTOGENIC FIBROSING ALVEOLITIS (IDIOPATHIC PULMONARY FIBROSIS)

Aetiology—CFA is caused by several different agents on a background of individual genetic predisposition. Exposure to metal or wood dust may be responsible for some cases. Previous antidepressant use may also be important. There is an association with an interleukin-1 receptor antagonist polymorphism, and genetic variation in transforming growth factor B may influence disease progression. There is a strong association with cigarette smoking.

Table 60: Common ILDs

1. Hypersensitivity pneumonitis
2. Sarcoidosis
3. Cystic lung disease such as lymphogranulomatosis and histiocytosis X
4. Associated with collagen vascular disease and connective tissue disorders
5. Idiopathic pulmonary fibrosis which has subtypes, including cryptogenic organizing pneumonia
6. Drug - induced
7. Occupational, as in silicosis

Clinical features—Most patients present with breathlessness, cough and arthralgia; occasionally after routine chest radiography, and 5% are asymptomatic. Clubbing and late inspiratory, mainly basal crackles are found. Expiratory crackles, cyanosis and cor pulmonale occur late.

Investigations - (a) Lung function tests usually show a restrictive defect with reduced gas transfer. (b) Chest radiography - Reticular or reticulonodular shadowing, predominantly over lower zone but extending to other zones. Lung size is reduced and honey combing may develop. (c) HRCT UIP: Patchy, predominantly peripheral and basal reticular and honeycomb changes with irregular septal thickening. NSIP: Ground-glass shadowing and absence of honeycombing. (d) Biopsy in those with unusual clinical features, when HRCT is not typical, and in young patients who may become eligible for transplantation. VATS biopsy is the preferred technique.

Management - (a) Oral corticosteroids improve lung function in about 25% and symptoms in about 50%. (b) Immunosuppression - Azathioprine in combination with prednisolone. Cyclophosphamide has been used in cases of systemic sclerosis, vasculitis, rheumatoid arthritis with variable success.

Interstitial lung diseases (ILDs) form a heterogeneous group of disorders, characterised by predominant involvement of the interstitium. The alveolar spaces may also be concurrently involved. The common ILDs are listed in Table 60.

Diagnosis: HRCT of the lung allows extremely high-resolution image of the lung parenchyma. It is possible to pick up pathology in small structures such as the interlobular septae and secondary pulmonary nodules. HRCT of the lungs plays an integral role right from initial diagnosis, through characterization and finally monitoring of treatment in ILDs.

Table 61: Types of lung reaction

• Acute pulmonary oedema coming on within minutes or hours of exposure
• Acute tracheitis and bronchitis
• Destructive changes in lung parenchyma resulting ultimately in pulmonary emphysema and chronic airways obstruction
• Bronchial asthma
• Pulmonary fibrosis slowly progressing to cause restrictive disorder of lung function
• Malignant disease of lung or pleura after prolonged exposure

19. OCCUPATIONAL LUNG DISEASE

Occupational exposure to toxins and dusts produce various types of lung reactions (Table 61).

CLINICAL FEATURES

Depend on the Type of Inhalation

- A. **Acute tracheobronchial or lung irritation**— e.g. gases such as ammonia, chlorine, fluorine, bromine, sulphur dioxide or nitrogen oxide. Metallic fumes or some metallic dusts, e.g. cadmium, zinc, magnesium. Symptoms of tightness of chest, hoarseness of voice, cough and wheezing, acute pulmonary oedema. Rarely acute chemical pneumonia.
- B. **Pneumoconiosis**— Pulmonary disease resulting from inhalation of dust over sufficient length of time resulting in fibrosis of lung.
 1. **Due to inorganic dusts:**
 - i. **SILICOSIS** - caused by inhalation of free silica in quarrying and rock-drilling of quartz, flint and sandstone. Stages - (a) Bronchial with shortness of breath and exaggeration of linear markings on X-rays. (b) Nodular with discrete shadows in lung tending to coalesce seen in upper lobes (Fig. 50). Egg shell calcification of hilar nodes diagnostic. (c) Infective phase with fibrosis due to chronic tuberculous infection. Talc pneumoconiosis may be modified silicosis.
 - ii. **COAL WORKER'S PNEUMOCONIOSIS (Anthracosis)**—the (a) *Simple coal worker's pneumoconiosis* - diagnosed on basis of small rounded opacities fairly uniform in size. Not associated with any symptoms or impairment of lung function. (b) *Complicated coal worker's pneumoconiosis* is associated with progressive, predominantly upper lobe mass formation and fibrosis (progressive massive fibrosis, PMF). c) Caplan syndrome, first described in coal miners but subsequently in patients with silicosis, is the combination

Fig. 50: Silicosis with massive conglomerate densities and basal emphysema

Fig. 51: HRCT chest showing hypersensitivity pneumonitis with ill-defined nodules

Table 62 Classification of EAA

Disease	Source	Antigen
Farmer's lung	Mould hay	Thermoactinomyces vulgaris
Bird fancier's lung	Avian droppings (mostly pigeons)	Avian protein in faeces, feathers
Mushroom worker's lung	Mushroom compost	Mushroom spores
Malt worker's lung	Mould barley	Aspergillus species
Bagassosis	Sugar cane dust	Thermophilic fungi Actinomyces
Wood worker's lung	Wood dust	Wood dust
Isocyanate lung	Paints	Paints

of pneumoconiotic nodules and seropositive rheumatoid arthritis. Silica has immunoadjuvant properties and is often present in anthracitic coal dust.

- iii. **ASBESTOSIS** - Fibrosis of lung due to inhaled asbestos dust. Besides asbestosis, asbestos produces pleural plaques, carcinoma of lung, malignant mesothelioma of pleura, pericardium and peritoneum; pleural effusion, diffuse pleural thickening and skin corns. X-ray shows presence of fine irregular linear opacities at lung bases.
- iv. **PNEUMOCONIOSIS** - Due to metal inhalation - Iron (siderosis), beryllium (berylliosis), aluminium (aluminosis), tin (stannosis).

2. Due to organic dusts:

EXTRINSIC ALLERGIC ALVEOLITIS - is a diffuse alveolar, bronchiolar and interstitial disease that results from allergy to repairable environmental organic dusts. See Table 62 for the classification.

Symptoms - may be acute or chronic. (a) *Acute EAA* - Repeated episodes of an influenza-like illness with cough and shortness of breath, which begin from 1-10 hours after each exposure. Occasionally there is wheezing. Symptoms begin to subside within 12-24 hours. (b) *Chronic EAA* - is commonly seen with low but near-continuous exposure. There is slowly progressive loss of exercise tolerance due to breathlessness with or without accompanying cough. Main signs are inspiratory crackles and squeaks. Clubbing is rare.

OTHER AGENTS

Flock-worker's lung is an abnormal pulmonary response to inhaled nylon flock. During the flocking process, nylon-based fabric is cut finely to produce fabric used for upholstery.

Investigations - (a) Chest radiography - In acute EAA shows small (1-3 mm) nodules most common in lowest zones or diffuse infiltrates. In disease, upper and mid-zone fibrosis. (b) HRCT - patchy ground-glass shadowing and ill-defined nodules in acute EAA (Fig. 51). In chronic EAA fibrosis and irregular opacities. (c) Lung function tests - Restrictive lung function with reduced gas transfer. (d) Serum Precipitins: Assaying for precipitating IgG antibodies against specific antigens can be a useful adjunct in the diagnosis of HP.

Management: 1. *Preventive* - by controlling the dust at source. Symptomatic treatment, e.g. for exudative disease following exposure to gases or fumes - Rest and warmth, positive pressure oxygen with if necessary mechanical ventilatory assistance, correction of haemoconcentration in some cases, broad spectrum antibiotics if signs of infection, corticosteroids IV for few days followed by oral prednisolone, and sedatives in small doses to allay anxiety

or pain. 2. *Treatment of complications* – such as infections and cardiac failure.

20. LOBAR COLLAPSE OF THE LUNG

Collapse or atelectasis means airlessness or a loss of volume in the lung, lobe or segment from any cause. It may be obstructive due to occlusion of bronchus to the involved area, or may result from contraction due to chronic inflammation and fibrosis. In general usage the term *atelectasis* is confined to these two types of volume loss.

CAUSES

1. **Obstructive collapse** – (Resorption collapse) – occurs due to resorption of air distal to the bronchial obstruction and is of two types:
 - a. **Central obstructive collapse**– due to obstruction of major bronchus or collapse with bronchostenosis:
 - *Within lumen* – (a) Plugs of mucus from bronchial secretions, mucus impaction caused by *Aspergillus fumigatus*. (b) Inhalation of foreign bodies, blood or mucopurulent secretions from upper respiratory passages.
 - *Within the wall* – Adenoma or carcinoma of bronchus, stenosis.
 - *Outside the bronchus* – Aneurysm, enlarged glands, neoplasm, inflammatory mass or reticulosis.

CLINICAL FEATURES

Loss of hemithorax volume with reduced breath sounds and voice sounds, due to obstruction of bronchial lumen.

Fig. 52: Collapse of right lower lobe, preservation of outline of right heart border with elevated right hemidiaphragm

However in upper lobe collapse with shift of the trachea, the proximity of the collapsed upper lobe allows breath sounds and voice sounds to be conducted to the chest. Occasionally a monophonic or fixed wheeze is heard over the collapsed lung due to incomplete bronchial obstruction.

INVESTIGATIONS

Chest radiograph – (Figs 52 and 53)

- Displacement of the interlobar septa bounding the affected lobe; the degree of displacement varies with the extent of the collapse.
- Radiopacity of the affected lobe, reflecting the loss of aeration. In a collapsed lobe that still contains some air, the vascular markings may remain visible and the vessels may appear to lie close together.
- Secondary signs of lobar collapse – Unilateral elevation of the diaphragm, shift of mediastinal structures towards the side of affected lobe, ipsilateral decrease in size of thoracic cage, compensatory emphysema of the uninvolved lobes, and hilar displacement.

CT scan – The obstructed and collapsed lung shows increased density obliterating normal blood vessels and mucous filled bronchi. After contrast injection the mucous filled bronchi do not enhance the mucous bronchogram.

Bronchoscopy – is essential for management of collapse with major bronchial obstruction, for diagnosis and for therapy. Mucus impaction may require therapeutic bronchoscopy after chest physiotherapy has

Fig. 53: Unilateral homogenous opacity obliterating practically whole of one lung field, due to massive collapse with mediastinal shift to side of collapse. For other causes of unilateral homogenous shadow (increased density of a hemithorax)

been unsuccessful. The presence of an air bronchogram in the area of persistent atelectasis indicates that bronchoscopy is unlikely to help.

b. **Peripheral obstructive collapse** – is collapse with a patent bronchus. The site of obstruction is in more distal bronchi, beyond the fourth or fifth generation.

CAUSES – This type of collapse is commonly seen in resolving pneumonia, postoperative patients particularly following thoracic or upper abdominal surgery, critical care patients and asthmatic or eosinophilic lung conditions.

CLINICAL FEATURES – Signs of hemithoracic volume loss with percussion dullness, tubular bronchial breath sounds, positive whispering pectoriloquy, aegophony and bronchophony and crackles. The breath sounds and voice sounds are well conducted from the patent bronchus to the chest wall by the airless collapsed lung.

CHEST RADIOGRAPH – Signs of collapse with open bronchus sign on a penetrated film.

Right middle lobe (RML) syndrome (Brock's syndrome) – Isolated collapse of the right middle lobe is commonly due to non-specific lymphadenitis or malignant tumour. Radiologically the collapsed middle lobe causes obliteration of the right cardiac silhouette and is seen as a triangular paracardiac shadow on the lordotic film. CT scan and bronchoscopy can be used to identify the cause.

Contraction collapse (Fibrotic or cicatricial collapse) – It results from scarring of the lung, e.g. tuberculosis, silicosis, ankylosing spondylitis, sarcoidosis, hypersensitivity pneumonitis.

Adhesive collapse – Abnormality of surfactant system is the mechanism for collapse in conditions like ARDS and radiation injury.

2. **Compression atelectasis** (Relaxation collapse):

CAUSES – Pleural effusion, pneumothorax, large neoplasm or rarely cyst in substance of lung with valve-like communication with bronchus.

CLINICAL FEATURES – Since the central bronchus is often patent, the clinical signs are similar to those of peripheral obstructive collapse.

DIAGNOSIS – The collapsed lung is evident radiologically, however in case of effusion, the fluid and the lung are both opaque, hence the lung shadow is not evident. On CT scan the density of the collapsed lung is different from the effusion particularly after contrast injection. Another useful sign on CT scan is presence of air bronchogram in the collapsed lung upto several bronchial generations.

3. **Atelectasis due to surfactant deficiency or dysfunction** – (a) Small airway patency not maintained result-

ing in increased alveolar surface tension. (b) Can result from ARDS in preterm neonates and meconium aspiration and pneumonia.

Helical or round atelectasis (RA): is a localised form of collapse associated with pleural disease. Also called folded lung syndrome, shrinking pleuritis with atelectasis, it presents radiographically as a round, oval or angular mass. A diagnostic CT and radiographic sign is 'Comet tail' sign or 'vacuum cleaner effect' which is due to the bronchovascular bundle crowded together due to the collapsed lung and extending into the hilum.

Causes: RA is associated with asbestos exposure, parapneumonic effusions, CHF, Dressler's syndrome, pulmonary infarct and tuberculous effusions. No treatment is required.

Plate or disk atelectasis (Fleischner's syndrome): These are 2–5 cm long transverse lines several millimeters thick at the lung bases, associated with reduced diaphragmatic motion, and due to collapse of small pulmonary subdivisions. Distinction from infarction is difficult and the two may coexist.

21. SLEEP APNOEA SYNDROME

Obstructive sleep apnoea (OSA) is part of a spectrum of sleep-disordered breathing ranging from simple snoring to profound hypoventilation and respiratory failure at night. It is characterised by repeated episodes of partial or complete upper airway obstruction during sleep, commonly associated with hypoxia, and usually terminated by arousal from sleep, resulting in daytime symptoms such as sleepiness (OSA syndrome). Table 63 gives definitions in sleep-disordered breathing.

RISK FACTORS FOR OSA

Obesity – (a) Fat deposition around upper airway can cause airway narrowing and increased airway resistance. (b) Abdominal obesity can reduce lung volume, further reducing upper airway size.

Craniofacial/genetic factors – With narrowing of upper airways, e.g. micrognathia, retrognathia, high arch palate, macroglossia, Down's syndrome, Marfan's syndrome, adenotonsillar hypertrophy.

Gender – Higher incidence in men may be related to effects of androgens on upper airway neuromuscular properties or central fat deposition, alternatively progesterone may protect against OSA. (OSA syndrome is more prevalent in postmenopausal women).

Table 63: Definitions in sleep-disordered breathing

Apnoea	Complete cessation of airflow for at least 10 seconds
Hypopnoea	50% reduction in airflow for at least 10 seconds
Obstructive event	Continued respiratory effort despite reduced airflow
Central event	Absent respiratory effort with absent respiratory airflow
Hypoventilation	An abnormal rise in PaCO ₂ occurs during sleep, usually associated with oxygen desaturation, without specific respiratory events
Periodic respiration	Ventilation waxes and wanes (central apnoea to hyperventilation)
Apnoea-hypopnoea index (respiratory disturbance index)	Number of apnoeic and hypopnoeic episodes per hour of sleep >5 is usually considered abnormal (except in elderly)
Periodic breathing (Cheyne-Stokes respiration)	Ventilation waxes and wanes (central apnoea to hyperventilation) during sleep
Oxygen desaturation index	Number of episodes of discrete oxygen desaturation (usually >3%) per hour of sleep.

Reduced muscle tone – Alcohol reduces upper airway muscle tone, increasing the number of obstructive events at night. Similar effects occur with sedatives and some neurological conditions.

Nasal obstruction – can lead to increased negative upper airways pressure during inspiration predisposing to OSA.

CLINICAL FEATURES OF OSA

See Table 64 for the clinical features of OSA.

DIAGNOSIS

Polysomnography. This involves oximetry, direct recording of thoracic and abdominal muscles to assess breathing (apnoea and hypopnoea per hour), electro-oculography (EO) - eye movement and EEG to record patterns of sleep as usual. The apnoea-hypopnoea index is calculated by the average number of apnoea and hypopnoea per hour of sleep. Diagnosis of sleep apnoea is confirmed if AH1 ≥ 5 with mild OSA 5–15, moderate 16–30, severe >30 AH1.

CONSEQUENCES OF OSA

- **Impaired daytime functioning** (memory, sustained attention, vigilance)
- **Systemic hypertension**

Table 64: Clinical features of OSA

- Snoring
- Disturbed sleep
- Excessive daytime sleepiness
- Morning headaches
- Nocturia, enuresis
- Dry mouth/throat
- Reduced concentration
- Mood changes
- Reduced libido, impotence
- Nocturnal choking and gasping
- Nocturnal reflux
- Restless sleep, frequent awakening
- Mood changes (irritability, depression).

- **Cardiovascular disease**—OSA is associated with attenuation of the usual fall in BP at night ('non-dipping') which may be an independent risk factor for cardiovascular disease
- **Overlap syndrome** – A combination of COPD and OSA can lead to earlier development of hypercapnia, pulmonary hypertension and cor pulmonale.
- **Obesity-hypoventilation syndrome** – Day time respiratory failure with hypercapnia and hypoxia in absence of significant lung disease in some obese patients.

MANAGEMENT

General – (a) Weight loss of 10–30% significantly reduces severity of OSA. (b) Avoidance of alcohol and sedatives. (c) Relief of nasal obstruction with medical therapy.

Specific –

Nasal CRAP therapy – Positive pressure is applied to upper airway via a nasal mask, providing a 'pneumatic splint' to maintain upper airway patency, over the entire length of the collapsible airway. CRAP improves daytime sleepiness, neurocognitive performance, mood and quality of life.

Mandibular advancement devices – If CRAP is not tolerated or accepted, a removable oral appliance during the night is an option. This device is snapped into the dental arches and keeps the jaw in an advanced position thereby preventing collapse of upper airways.

Drugs – Tricyclic antidepressants reduce REM sleep time and can improve OSA in patients with REM - predominant disease.

Surgery – (a) Adenotonsillectomy can be curative in children and adolescents. (b) Uvulopalatopharyngoplasty – Successful result is seen in about 50%. (c) Complex maxillofacial surgery can be effective in majority of patients.

Central sleep apnoea – is less common. Patients snore less, are seldom obese, and complain of night time awakening. The central drive to breathing is abnormal. The syndrome occurs as a consequence of primary alveolar hypoventilation following bulbar polio or brainstem surgery.

22. RESPIRATORY FAILURE

Respiratory failure can be defined in two ways:

- Failure of oxygenation resulting in $\text{PaO}_2 < 8.0 \text{ kPa}$
- Failure of ventilation resulting in $\text{PaCO}_2 > 6.7 \text{ kPa}$ with accompanying acid-base changes

CAUSES OF RESPIRATORY FAILURE

Respiratory failure can occur due to varied etiology as given in Table 65.

CLINICAL FEATURES

Any combination of the features listed in Table 66 may be present.

Specific physical signs – depending on the cause (e.g. neurological signs if neuromuscular disease is suspected, chest wall deformities).

Interpretation of arterial blood gases

Hypoxemia – Normal PaO_2 declines with age from 13.3 kPa in childhood to about 9.3 kPa in the elderly due to deterioration in gas exchange efficiency as the lung ages. This results in increasing alveolar-arterial oxygen gradient ($\text{P}_{\text{A}}\text{O}_2 - \text{PaO}_2$). Calculation of $\text{P}_{\text{A}}\text{O}_2 - \text{PaO}_2$ allows hypoxemia caused by alveolar hypoventilation or altitude from other mechanisms (e.g. diffusion impairment, ventilation/perfusion mismatch, shunt). When hypoxemia is caused purely by alveolar hypoventilation $\text{P}_{\text{A}}\text{O}_2$ is decreased, and $\text{P}_{\text{A}}\text{CO}_2$ increased, and $\text{P}_{\text{A}}\text{O}_2 - \text{PaO}_2$ should be normal.

Acid-base balance – pH indicates whether there is tendency towards acidosis or alkalosis. In the acute setting of respiratory disturbance, every 0.13 kPa rise in PaCO_2 is associated with a 0.01 fall in pH.

MANAGEMENT

1. **Control of primary disease**– e.g. antibiotics for chronic bronchitis or fulminating pneumonia.
2. **Maintenance of patent airway**– Nasal catheter to remove secretions and stimulate expulsive coughing. If secretions cannot be cleared by simple means, tracheostomy or endotracheal tube.

Table 65: Causes of respiratory failure

Airway obstruction (Limits airflow and thus reduces airway ventilation)

Upper airway

- Obstructive sleep apnoea
- Trauma
- Angio-oedema
- Stevens - Johnson syndrome
- Inhaled foreign body
- Acute epiglottitis

Lower airway

- COPD
- Asthma
- Bronchiectasis
- Cystic fibrosis
- Bronchiolitis obliterans
- **Disorders of lung parenchyma**

Acute

- Acute respiratory distress syndrome
- Pneumonia
- Acute pulmonary oedema
- Acute pulmonary embolism
- Acute fibrosing alveolitis
- Severe ARDS

Chronic

- Chronic fibrosing alveolitis
- Pneumoconiosis
- Sarcoidosis
- **Disorders of respiratory muscle pump**

Neurological

- Brainstem disease
- Amyotrophic lateral sclerosis
- Over-sedation
- Post-poliomyelitis syndrome
- Guillain-Barré syndrome
- Central sleep apnoea
- Cervical cord trauma

Musculoskeletal

- Kyphoscoliosis
- Myasthenia gravis
- Muscular dystrophy
- Congenital myopathy
- Chest wall trauma

Table 66: Clinical features of respiratory failure**1. Due to hypoxemia**

- Restlessness
- Poor peripheral circulation
- Mental confusion
- Depressed level of consciousness
- Sweating
- Tachycardia
- Central cyanosis
- Cardiac arrhythmias

2. Due to hypercapnia

- Breathlessness
- Headache
- Warm extremities
- Bounding pulse
- Elevated BP
- Papilloedema occasionally
- Cardiac dysrhythmias (commonly multifocal atrial tachycardia)
- Muscle twitching
- Effects on CNS functions:
 - Asterixis
 - Hyporeflexia
 - Miosis
 - Confusion and coma
 - (CO₂ narcosis).

3. **Oxygen therapy**– The aim of oxygen therapy is to control hypoxemia without allowing CO₂ retention to threaten life from respiratory acidosis. This can be achieved by: (a) Low concentration of O₂ 1–2L/min. by nasal cannulae or calibrated Venturi mask and titrating PaO₂ to 8.0–9.3 kPa. (b) High flow systems increase effect of inspired oxygen concentration (FiO₂). (c) Continuous positive airway pressure can be added via a tight fitting face-mask to recruit collapsed alveoli and improve gas exchange. When oxygen systems fail to sustain adequate PaO₂ further intervention (intubation, mechanical ventilation) is needed.

Long-term supplemental oxygen therapy (LTOT) is required in chronic severe hypoxemia.

4. **Treatment of acidosis**– with IV sodabcarb. Acidosis corrects itself if adequate alveolar ventilation is maintained.
5. **Treatment of failure of ventilation by mechanical ventilatory assistance** –

NON-INVASIVE VENTILATION (NIV) is the provision of ventilatory support without instrumentation of the airway. It can be achieved with positive pressure administered through a well-fitting mask.

Table 67: Indications for ventilation

- Increasing respiratory rate
- Asynchronous respiratory pattern
- Altered mentation and conscious level
- Frequent oxygen desaturation despite increasing O₂ concentration
- Hypercapnia and respiratory acidosis
- Circulatory problems, including hypotension and atrial dysrhythmias

Criteria for NIV in Hypoxemic Respiratory Failure

- Dyspnoea
- Respiratory rate > 30 breaths per minute
- PaO₂ : FiO₂ < 200

Contraindications: NIV may not be appropriate in end-stage disease or in patients with several comorbidities. It is not used in patients having altered sensorium.

Monitoring: Continuous monitoring of oxygen saturation by pulse oximetry and regular assessment of arterial blood gas tensions and respiratory rate. Comparison of pH and respiratory rate immediately before NIV is started and at 4 hours is a useful measure of the success of NIV. When both improve success is very likely.

INVASIVE MECHANICAL VENTILATION – Mechanical ventilators provide a substitute for the respiratory muscle pump (Table 67).

Types of ventilators and principles of ventilation – Ventilators may be divided into – (a) Volume pre-set machines, in which rate and tidal volume are used to determine the minute volume delivered. Airway pressure is then a consequence of the set volume and total compliance of the system. The main advantage of this type of machine is guaranteed minute volumes despite changing lung mechanics (e.g. sudden onset of pulmonary oedema). (b) Pressure pre-set machines in which the volume of gas delivered in each machine-driven breath (tidal volume) is determined by the driving pressure of the gas and the compliance of the system in which gas is injected. This includes the chest, the chest wall and the machine / tubing interface. Pre-setting of the airway drive pressure prevents excessive airway pressures, but at the cost of unpredictable airway delivery.

Common terminologies used in mechanical ventilation are given in Table 68.

Tracheostomy and Weaning

Tracheostomy is usually performed between day 7 and day 14 in patients in whom prolonged ventilation is likely.

Table 68: Terminology in mechanical ventilation

Type	Explanation
Continuous positive airway pressure (CPAP)	Not a form of ventilation, because there is no inspiratory/expiratory cycle. Can be used only in spontaneously breathing patients
Positive end-expiratory pressure (PEEP)	Involves addition of an above-atmospheric pressure to the expiratory cycle of a ventilated breath. Fulfils same function as CPAP in spontaneously breathing patients
Controlled breath	A pre-set, machine-delivered breath that cannot be altered by the patient
Assisted breath	A machine-driven breath that is triggered by patient effort. Volume and duration of breath may also be under patient control
Synchronized, intermittent mandatory ventilation (SIMV)	A volume pre-set mode allowing spontaneous breathing between machine-triggered breaths. Aims to prevent simultaneous machine-initiated and patient-initiated breaths ('fighting the ventilator')
Pressure controlled ventilation (PCV)	A pressure pre-set mode of controlled ventilation; both inspiratory and expiratory pressures are pre-set
Pressure-support ventilation (PSV)	A patient-triggered form of ventilation. Following a patient-initiated breath, tidal volume is augmented by the machine-driven present pressure. Often used in conjunction with PCV to allow spontaneous breaths, and as a weaning mode.

Weaning – Daily trials of spontaneous breathing through a 'T-piece' circuit and gradual reduction of ventilatory assist using pressure-support ventilation has been shown superior to SIMV in weaning. Only awake, cooperative patients can be weaned, and daily cessation of sedation improves weaning and outcome in the critically ill.

23. ACUTE LUNG INJURY AND ACUTE RESPIRATORY DISTRESS SYNDROME

Adult respiratory distress syndrome (ARDS) is a common response to various pulmonary insults (Table 69); the generic term is acute lung injury (ALI), and the term ARDS is reserved for its more serious manifestations.

PATHOGENESIS

Lung injury may be a primary event (e.g. inhalation), secondary to systemic inflammatory stimuli, or a combination of both (e.g. infection). ALI tends to be one of the earliest manifestations of generalized inflammatory states, and ALI caused by primary lung injury may lead to a systemic inflammatory state, culminating in multiorgan dysfunction.

Mechanisms Involved

ARDS is characterized by diffuse alveolar epithelial and endothelial damage. It can be divided into three stages:

1. **Exudative phase** – In first few days, alveolar interstitium is infiltrated by inflammatory cells, and alveo-

lar spaces filled with proteinosis and haemorrhagic fluid.

2. **Proliferative phase** – The alveolar exudate resolves or undergoes organization over the next week or so.
3. **Fibrotic phase** – Fibrosis occurs after 3–4 weeks. Cyst formation and honeycomb changes occur particularly in dependant lung. Gradual reversal of fibrotic changes is usual in survivors.

CLINICAL FEATURES

Latent period – between time of initial insult and onset of respiratory symptoms 4–24 hours.

Symptoms

Dyspnoea – acute in onset or developing over several hours. Dry cough.

Cyanosis – may not be apparent, despite marked hypoxemia.

Tachypnoea – leads to hypocapnia, causing superficial vasoconstriction and a pale, waxy complexion. However patients with established ARDS due to sepsis may have hyperdynamic circulation due to increased basal metabolism with warm peripheries.

Signs

Initially normal but within 24 hours non-specific signs appear including widespread crackles and wheezes and diminished basal breath sounds.

With progression – (a) Sepsis. (b) Failure of other organs – Abnormal haematological indices (reduced

Table 69: Causes of ARDS**1. Respiratory** (Direct injury):

- Aspiration injury
 - Gastric juice
 - Chemicals
 - Smoke
 - Drowning
- Embolization
 - Amniotic fluid
 - Fat embolism
- Neurogenic pulmonary oedema.
- Drugs (e.g. heroin, aspirin, paraquat, heparin, protamine).
- Pulmonary contusion.
- Oxygen toxicity.
- Pneumonia (bacterial, viral, fungal or drug-induced e.g. bleomycin).
- Disseminate TB.
- Pulmonary vasculitis.
- Thoracic radiation.

2. Non-respiratory (Indirect injury):

- Severe sepsis
- Tropical conditions – Cerebral malaria, tetanus, salmonella infections, amoebiasis, acute gastroenteritis (gram -ve septicaemia), rabies.
- Poisoning (e.g. narcotic or organophosphorus compounds).
- Acute pancreatitis.
- Severe burns.
- Major extra-thoracic trauma.
- Post-cardiopulmonary bypass.
- Steven-Johnson syndrome.
- Disseminated intravascular coagulopathy.
- Miscellaneous – Eclampsia, hepatorenal failure, liver cell dysfunction, high altitude, seizures, multiple transfusions or massive hemorrhage, metastatic carcinoma.

platelet count, increased fibrinogen degradation products), shock, kidney failure, liver failure, ileus, CNS depression and metabolic derangements.

COURSE – ARDS tends to reach its maximal initial severity over the next 24–48 hours, and may be rapidly fatal if severe and untreated. Acute deterioration of stable or improving ARDS can be due to chest infection, pneumothorax or systemic complications such as septicemia, hypotension or DIC.

INVESTIGATIONS

1. **Chest radiograph** – Initially normal but within 24–48 hours diffuse ill-defined patchy shadowing of nonspe-

Figs 54A and B: Adult respiratory distress syndrome. (a) Early changes show bilateral infiltrates (b) Bilateral white-out

cific appearance is seen (Fig. 54A). The early changes of interstitial oedema rapidly become confluent (snowstorm or whiteout appearance) (Fig. 54B).

2. **Arterial blood gas analysis** – PaO₂ reduced and may be as low as 4–5 kPa despite FiO₂ of 0.4–0.6 (40–60%) or more.
3. **Tests for presence of other organ dysfunction** – Renal, hepatic, haematological parameters.
4. **Bacteriology** – Blood culture, culture of tracheal aspirate and culture of bronchoalveolar lavage in patients with nosocomial pneumonia.

COMPLICATIONS

1. **Early**– (a) Due to anaesthesia and muscle paralysis necessary for intubation. (b) Aspiration due to loss of protective laryngeal reflexes. (c) Reduction in cardiac

output due to decreased venous return as a result of initial positive pressure breaths. (d) Barotrauma and pneumothorax from positive intrapulmonary pressure.

2. **Later complications**– (a) Local trauma from endotracheal tube. (b) Damage to lungs and fibrosis – due to high O₂ concentration. (c) Barotrauma may occur when stiff lungs require high inflation pressures to achieve adequate ventilation or if emphysematous bullae are present. (d) Intrinsic positive end expiratory pressure (PEEP) – During lung deflation, relatively proximal.

MANAGEMENT

1. **Removal of underlying cause** – if possible, e.g. broad spectrum antibiotics for sepsis, drainage of infected fluid collections, removal of necrotic tissue.
2. **Support of the injured lung** – by restoration and maintenance of adequate tissue oxygen delivery. Most patients require ventilatory support. *Indications* – Severe respiratory failure, fatigue, tachypnoea, or evidence of circulatory inadequacy (e.g. lactic acidosis, poor tissue perfusion, hypotension).

The purpose of respiratory support is to achieve adequate arterial oxygenation without exacerbating the underlying lung injury. The usual aims are low respiratory rate (< 10–14/minute), low tidal volume (6–8 mL/kg), relatively high positive end-expiratory pressure (5–20 cm H₂O).

3. **Additional measures**
 - a. **Prone positioning** – is most effective in early exudative phase of lung injury when it allows recruitment of alveoli, improving ventilation/perfusion matching. There are also cardiovascular benefits.
 - b. **Inverse ratio ventilation** – In this method inspiratory time is increased so that it is longer than expiratory time. With decreased time to exhale, dynamic hyperinflation leads to increased end expiratory pressure which is similar to ventilator provided PEEP
 - c. **High-frequency ventilation (HFV)** – entails ventilating at extremely high respiratory rates (5–20 cycles per second) and low VTs (1–2 mL/kg).
 - d. Use of partial liquid ventilation (PLV) with perfluorocarbon (inert, high density liquid that easily solubilizes oxygen and carbon) has shown improvement in pulmonary function of ARDS patients with no survival benefit.
 - e. Lung-replacement therapy with extracorporeal membrane oxygenation (ECMO), which provides a clear survival benefit in neonatal respiratory distress syndrome, may also have utility in selected adult patients with ARDS.

- f. **Nitric oxide and nebulized prostacyclin** – Low concentrations (1–20 ppm) nitric oxide acts as a local vasodilator in the vicinity of ventilated alveoli reducing shunt. The same effect is achieved with nebulized prostacyclin.
- g. **Corticosteroids** – may be beneficial in ARDS caused by inflammation (e.g. acute pancreatitis) rather than sepsis. They may also hasten recovery and improve outcome in those with severe pulmonary fibrosis or persistent ARDS.
- h. **Reduction of lung water** – Excessive extravascular lung water may result from over-enthusiastic fluid replacement, or from severe pulmonary leak, reflecting the severity of inflammatory insult. Hence management includes attempts to keep the patient dry; this is reasonable in well-resuscitated patients with adequate circulation, but is inappropriate in septic patients with evidence of poor tissue perfusion, in whom inadequate fluid replacement increases risk of multiorgan dysfunction.

4. Prevention of complications

- a. **Multiorgan failure** – Common reasons are failure to treat the initiating insult and failure to re-establish adequate circulation. Restoration of adequate circulation requires colloids or crystalloid and combination of inotropes, vasopressors or vasodilators.

Note – The oedema in ARDS is an exudate rather than a transudate, and mortality is related more to multiorgan dysfunction rather than to hypoxia.

- b. **Nosocomial infections** – include ventilator-associated pneumonia and those from indwelling lines and catheters. Cultures should be taken if infection is suspected, (new pyrexia, rising WBC or C-reactive protein, deteriorating gas exchange or new shadows on chest radiography).
- c. **Pneumothorax** – is likely when excessive pressure or tidal volume is used, and in the late proliferative and fibrotic phase.
- d. **Supportive measures** – Patients who do not tolerate full enteral feeding may be partially enterally fed, with small hourly volumes of food supplemented by parenteral nutrition. Prophylaxis against 'stress' ulcer with H₂-antagonists and sucralfate.

24. SEVERE ACUTE RESPIRATORY SYNDROME (SARS)

SARS is an acute respiratory illness of infective aetiology associated with a coronavirus so-called because of complex projections on its surface known as peplomers giving it the appearance of a halo (corona = halo).

MODE OF TRANSMISSION

The virus is spread by close person-to-person contact and possibly by direct contact with infected body fluids. High concentrations of viral RNA have been demonstrated in sputum. Viral RNA has also been demonstrated in plasma in low concentrations during the course of illness and in faeces and urine during convalescence.

CLINICAL FEATURES

Incubation period is usually 2–7 days. SYMPTOMS – (a) The illness begins with fever (38°C) sometimes with chills and rigor. Other symptoms include headache, malaise and myalgias. (b) Lower respiratory phase starts after 3–7 days with onset of dry cough or dyspnoea that may be accompanied by or progress to hypoxemia. In 10–20% of cases the respiratory illness progresses to ARDS.

INVESTIGATIONS FOR A SUSPECT CASE OF SARS

1. *Chest radiograph* may be normal during the febrile period and throughout the course of illness. However in substantial number, the respiratory phase is characterized by early local infiltrates progressing to more generalized, patchy, interstitial infiltrates. In later stages there may be bilateral areas of opacification.
2. *Haematology* – WBC counts are generally normal or decreased. At the peak of respiratory illness about half the patients have leucopenia with relative lymphopenia and thrombocytopenia.
3. *Serological tests* – Demonstration of antibodies: (a) ELISA detects a mixture of IgG and IgM antibodies and is positive about 21 days after infection. (b) Immunofluorescence assay detects IgM antibodies after 10 days of illness.
4. *Molecular biological tests* – Polymerase Chain Reaction (PCR) can detect genetic material of SARS virus in clinical specimens such as blood, stool, respiratory secretions, urine or body tissue.
5. *Demonstration/Culture of SARS virus* – The coronavirus can be demonstrated in respiratory secretions, stool or urine by negative stain electron microscopy.

PROGNOSIS

The disease is usually associated with a worse prognosis if co-infection with other pathogens such as Chlamydia, paramyxovirus or hepatitis B is present.

MANAGEMENT

Antibacterial Treatment

- Levofloxacin 500 mg once daily intravenously or orally
- Or Clarithromycin 500 mg twice daily orally plus Co-amoxiclav 375 mg three times daily orally if patient <18 years or pregnant.

Ribavirin and Methylprednisolone

Add combination treatment with ribavirin and methylprednisolone with:

- Extensive or bilateral chest radiographic involvement
- Or persistent chest radiographic involvement and persistent high fever for 2 days
- Or oxygen saturation < 95% in room air.

Standard Corticosteroid Regimen for 21 days

Methylprednisolone 1 mg/kg every 8 h (3 mg/kg daily) intravenously for 5 days

Then methylprednisolone (1 mg/kg daily) intravenously for 5 days

Then prednisolone 0.5 mg/kg twice daily (1 mg/kg daily) orally for 5 days

Then prednisolone 0.25 mg/kg daily orally for 3 days
Then off.

Ribavirin Regimen for 10–14 days

Ribavirin 400 mg every 8 h (1200 mg daily) intravenously for at least 3 days (or until condition becomes stable)

Then ribavirin 1200 mg twice daily (2400 mg daily orally).

Pulsed Methylprednisolone

Give pulsed methylprednisolone if clinical condition, chest radiograph, or saturation worsens (at least two of these), and lymphopenia persists.

Give methylprednisolone 500 mg twice daily intravenously for 2 days, then back to standard corticosteroid regimen.

Ventilation – Consider non-invasive ventilation or mechanical ventilation if oxygen saturation < 96% while on > 6 L per min. oxygen or if patient complains of increasing shortness of breath.

25. SYSTEMIC DISEASES AND THE LUNGS

AUTOIMMUNE DISORDERS AND VASCULITIS

Rheumatoid Arthritis

Interstitial pneumonia – Clinical and radiological features identical to cryptogenic fibrosing alveolitis.

Pleural involvement – Rarely pleuritis and pleural effusions with high rheumatoid factor titre.

Airway involvement – Obliterative bronchiolitis. Inspiratory RHCT reveals a ‘mosaic pattern’ that is more prominent on full expiration because of gas trapping in the affected secondary pulmonary nodules.

Rheumatoid nodules – solitary or multiple, often a chance finding on chest radiography.

Infection – Bacterial low respiratory tract infection occasionally complicated by empyema.

Systemic Lupus Erythematosus

Interstitial disease – Alveolitis (rare), may be associated with diffuse alveolar hemorrhage

Pleural involvement – Pleurisy presenting symptom in about 10% and in 40–60% at some stage.

Pulmonary hypertension – though uncommon may result from pulmonary vasculitis, thrombosis and pulmonary artery vasoconstriction.

‘Shrinking lung’ – Rare syndrome with progressive reduction in VC and loss of lung volume on chest radiography.

Antiphospholipid syndrome – SLE patients may be at increased risk of venous and pulmonary thromboembolism.

Systemic Sclerosis

Interstitial disease – Pulmonary fibrosis. HRCT and histological features often those of nonspecific interstitial pneumonia.

Pulmonary hypertension due to pulmonary artery involvement.

Aspiration pneumonia due to involvement of oesophagus with altered contractility.

Myositis

Both polymyositis and dermatomyositis are characterized by respiratory muscle involvement and interstitial pulmonary fibrosis.

Sjögren’s Syndrome

Chronic bronchitis, mucus plugging, follicular bronchiolitis, lymphocytic interstitial pneumonitis, pleural effusions, pulmonary hypertension and lymphoma.

Ankylosing Spondylitis

Reduced respiratory excursion and restrictive ventilatory defect. Bilateral upper lobe fibrosis may develop and upper lobe cavitation, sometimes with aspergilliosis.

Behcet’s Syndrome

Pulmonary vascular involvement in about 5%. Presentation is usually with haemoptysis.

Relapsing Polychondritis

Progressive destruction of supportive cartilage in trachea and large airways can lead to large airway collapse during expiration. Patients present with breathlessness and wheeze that can mimic asthma.

RENAL DISEASE AND VASCULITIS (PULMONARY-RENAL SYNDROME)

Wegener’s Granulomatosis

Upper respiratory tract, lung and renal involvement and antinuclear cytoplasm antibodies (ANCA) against neutrophil enzyme proteinase. Lung involvement may be a presenting symptom in the form of cough, haemoptysis, breathlessness or pleuritic chest pain. Upper respiratory tract involvement results in subglottic stenosis and presents with exertional breathlessness and stridor. Chest radiography may show pulmonary infiltrates or nodules which often cavitate.

Microscopic Polyangiitis

Patients may have haemoptysis and alveolar hemorrhage, the main risk factor for death.

Churg-Strauss Syndrome

Is characterized by history of asthma, blood eosinophilia and vasculitis affecting two or more organs. Chest radiography commonly shows bilateral, patchy, non-segmental consolidation.

Henoch-Schonlein Purpura

Is rarely associated with alveolar hemorrhage.

Anti GBM Antibody Disease

Lung hemorrhage is a presenting feature particularly in smokers.

GENETIC DISORDERS

Marfan’s Syndrome

Emphysematous bullae leading to pneumothorax, and bilateral upper lobe pulmonary fibrosis.

Neurofibromatosis

Associated with progressive interstitial pulmonary fibrosis in 30% of adults; this may progress to respiratory failure. Large paraspinal neurofibroma may be associated with kyphoscoliosis and respiratory failure.

Tuberous Sclerosis

Female patients may develop pulmonary lymphangiomyomatosis with progressive destruction of the alveoli and oestrogen-dependent smooth muscle proliferation. Patients may present with progressive exertional dyspnoea or pneumothorax.

GI DISORDERS

Inflammatory Bowel Disease

Bronchiectasis and obliterative bronchiolitis rarely with UC and Crohn's disease, mostly in patients with pancolitis.

Cirrhosis

Refractory hypoxemia caused by multiple microscopic (and occasionally) macroscopic A-V shunts between small precapillary pulmonary arteries and veins. In severe portal hypertension anastomoses may develop between pulmonary and hepatic circulation.

Pancreatic Disorders

Acute pancreatitis is associated with acute pneumonia and lung injury that may develop into ARDS. Pleural effusion which is typically left-sided.

Disorders of Upper GI Tract

Gastro-oesophageal reflux is believed to be the underlying cause of chronic cough in one third of patients. Aspiration of large volumes may be seen in those with a pharyngeal pouch, oesophageal disease related to scleroderma, neuromuscular disease or alcoholism. All of these present with recurrent aspiration (usually lower lobe) pneumonia.

ENDOCRINOLOGICAL DISORDERS

Obesity

Is a common cause of reduced VC, small static lung volumes and reduced compliance. When excess fat lies in a truncal distribution, obesity is associated with OSA.

Acromegaly

Is associated with large lungs, trachea and bronchi. Macroglossia and enlargement of other soft tissues of upper airway can lead to OSA.

Thyroid Disease

Thyroid goitre can cause tracheal displacement and compression. Airway obstruction may be intrathoracic or extrathoracic, and may be associated with stridor, reduced PEF, characteristic abnormality of maximum inspiratory and expiratory flow-volume loop. Both hyperthyroidism and hypothyroidism may cause respiratory muscle dysfunction.

Diabetes Mellitus

Increased risk of lung infection including TB. Gross hyperventilation (Kussmaul's respiration) is a feature of diabetic ketoacidosis.

NEUROLOGICAL DISEASE

Guillain-Barré Syndrome

Progressive weakening of respiratory muscle pump can lead to type II respiratory failure.

Motor Neuron Disease

Oropharyngeal muscle involvement can cause dysfunctional swallowing and aspiration pneumonia. Progressive weakness of respiratory muscles leads to type II respiratory failure, a common mode of death.

HAEMATOLOGICAL DISORDERS

Pleural effusions in about 30% with lymphoma and may occur in leukaemia as a result of disease or opportunistic infection. About two-thirds of lymphoma patients have mediastinal or hilar lymphadenopathy, these compresses or invade larger airways, producing breathlessness and fixed wheeze. Great vein compression may produce SVC obstruction. The parenchyma may be involved at presentation in 10%, and in 30–40% parenchymal involvement occurs at some stage. Lymphoma may present as discrete masses that can coalesce or cavitate.

26. PLEURAL DISEASE

PNEUMOTHORAX

Pneumothorax is air in the pleural cavity. Air may enter the pleural cavity through the chest wall, mediastinum, or diaphragm, or from a puncture of the visceral pleura covering the lung. Primary spontaneous pneumothorax occurs in patients without clinical evidence of lung disease. Secondary spontaneous pneumothorax is related to parenchymal lung disease.

Causes

Spontaneous Pneumothorax

Primary spontaneous pneumothorax – Due to rupture of apical subpleural bleb (benign spontaneous pneumothorax). Most common in young men. Exclusively seen in smokers.

Secondary spontaneous pneumothorax –

- *Rupture of* – Subpleural TB focus (active lesion or local emphysematous area from old scarring). Emphysematous bullae. Congenital cysts and bullae. Honeycomb lung. Oesophageal rupture.
- *Infections* (other than TB) – Bacterial pneumonia, lung abscess, Pneumocystis jiroveci pneumonia, whooping cough, bronchiectasis.
- *Diffuse fibrosing pulmonary disease*: Sarcoidosis, Pneumoconiosis Interstitial fibrosis.
- *Asthma* – Chronic bronchitis and emphysema.
- *Cystic fibrosis*.
- *Neoplasms* – Bronchial or pleural.
- *Secondary to spontaneous mediastinal emphysema*.
- *Pulmonary infarction*.
- *Miscellaneous*: Rheumatoid lung disease, Histiocytosis X, tuberous sclerosis, Marfan's syndrome, Ehlers - Danlos syndrome, Endometriosis of pleura, pulmonary alveolar proteinosis, idiopathic pulmonary haemosiderosis.

Traumatic Pneumothorax

- a. *Penetrating trauma* – e.g. stab wounds, gunshot wounds, primarily by injuring the peripheral lung.
- b. *Blunt trauma* can lead to rib fracture and cause increased intrathoracic pressure and bronchial rupture manifested by 'fallen lung sign (ptotic lung sign)' hilum of lung is below expected level within chest cavity.

Pulmonary barotrauma – at high altitude of 3050 m or in scuba divers.

Chest aspiration, transbronchial biopsy, needle aspiration lung biopsy, intercostal nerve block, subclavian cannulation, positive pressure ventilation, transthoracic liver biopsy, surgical procedures at base of neck, chest compression injury (including external cardiac massage).

Iatrogenic pneumothorax – may be a complication of a transthoracic puncture or a puncture of the subclavian vein.

Mediastinal emphysema is due to passage of air from the lung to the mediastinum and may occur during coughing or an extreme Valsalva manoeuvre. It is suspected when subcutaneous emphysema occurs at the upper chest and the neck level.

Catamenial pneumothorax – Rare condition occurring in females of 25–30 years. Repeated attacks of spontaneous pneumothorax occur usually on right side in association with menstruation generally within 48 hrs before or after onset of menstruation.

Symptoms

Vary depending on – (a) amount of air in the pleural sac, (b) rapidity of its accumulation, (c) condition of the lungs.

1. *Insidious onset* – Vague discomfort in chest, later shortness of breath on exertion. In tuberculous spontaneous pneumothorax the onset is not always sudden as the condition commonly occurs in patients suffering from advanced pulmonary TB which has already cut down their normal activities. Patient may complain of more breathlessness or may have chest pain, or the pneumothorax may be latent and detected by routine chest examination.
2. *Sudden onset* – Feeling of something snapping in the chest, severe pain, shock, increasing shortness of breath. Blood streaked sputum, cyanosis, restlessness and collapse.
3. *If hydropneumothorax* – Splash of fluid in the chest when he jumps may be the first intimation to the patient.

Signs

'Hyper-resonance with silence'.

1. **CLOSED PNEUMOTHORAX** – The opening in the lung is very small and rapidly heals, thus allowing the lung to re-expand.

Inspection – (i) Diminished expansion on affected side. (ii) Bulging on the side of pneumothorax. (iii) Displacement of apex beat towards sound side.

Palpation – Trachea may be displaced.

Percussion – (i) Hyperresonance. (ii) If on the left side abolition of cardiac dullness. (iii) Right sided pneumothorax reduces upper level of liver dullness.

Auscultation – (i) VR absent. (ii) Breath sounds diminished or absent. Bronchial breath sounds described as metallic or amphoric may be heard. (iii) Crunching sound – In left-sided pneumothorax there may be 'crunch' over the heart if air is also present in mediastinum (Hamman's sign). (iv) Click – A shallow left pneumothorax may produce a sound synchronous with the heartbeat.

2. **OPEN PNEUMOTHORAX** – The opening remains patent and the pressure in the pleural space remains equal to that of the atmosphere. Signs same as above plus – (i) Cracked pot sound may be heard on percussion, (ii) on auscultation air can be heard passing to and fro through the opening, (iii) voice sounds and cough heard with metallic echo.

3. **TENSION PNEUMOTHORAX** – The opening is valvular and air can enter into the pleural space during inspiration but cannot escape during expiration so that a positive pressure occurs in the pleural cavity (Fig. 55). Tension

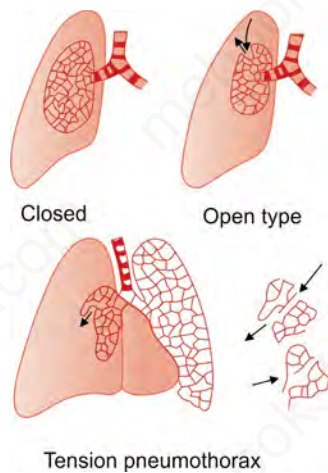

Fig. 55: Types of spontaneous pneumothorax. In closed pneumothorax the rupture gets sealed. In open type there is a bronchopleural fistula and the pleural pressure approximates atmospheric pressure. A check-valve mechanism leads to tension pneumothorax

Fig. 56: Right sided spontaneous pneumothorax with partial collapse of right lung. For other causes of unilateral hypertransradiancy

Fig. 57: X-ray chest shows left sided pneumothorax with underlying partial lung collapse of left lung, the trachea and mediastinum are pushed towards the right

pneumothorax may occur in clinical conditions such as ventilated patients, traumatic chest injuries, during cardiopulmonary resuscitation, patients undergoing hyperbaric O_2 treatment, blocked or displaced chest drains. Signs are: (a) Displacement of mediastinum. (b) Increasing cyanosis and dyspnoea. (c) Increasing rapidity of pulse. (d) Distended neck veins. (e) Widening of intercostal spaces. (f) Hyperresonant or tympanic note; note dull if intra-pleural tension very high. (g) Downward displacement of liver if right sided pneumothorax, and of diaphragm. (h) Positive coin test.

Table 70: Chest radiograph findings

Visceral pleural white line	Convexity towards hilum
Absence of lung markings	Distal or peripheral to the visceral pleural white line
Displacement of mediastinum	Towards opposite side
Deep sulcus sign	On frontal view, larger lateral costodiaphragmatic recess than on opposite side
Total/subtotal lung collapse	Diaphragm may be inverted on side with deep sulcus
Radiographic signs in upright position	This is passive or compressive atelectasis
	Sharp delineation of visceral pleura by dense pleural space
	Mediastinal shift to opposite side
	Air-fluid level in pleural space on erect chest radiograph
	White margin of visceral pleura separated from parietal pleura
	Usually seen in the apex of the lung
	Absence of vascular marking beyond visceral pleural margin
	May be accentuated by an expiratory film in which lung volume is reduced while amount of air in pneumothorax remains constant so that relative size of pneumothorax appears to increase
Radiographic signs in supine position (difficult to see)	Anteromedial pneumothorax (earliest location)
	Outline of medial diaphragm under cardiac silhouette
	Deep sulcus sign

Imaging Studies

Chest Radiograph: Radiographic findings are enumerated in Table 70.

2. **Chest CT scanning:** A CT scan is more sensitive than a chest radiograph in evaluation of small pneumotho-

rax and pneumomediastinum. It is the gold standard for diagnosing occult traumatic pneumothorax not apparent on supine chest radiograph (Figs 56 and 57).

3. **Ultrasonography:** Ultrasonic features include absence of lung sliding. M mode imaging demonstrates an alternating pattern of absent lung sliding with normal lung sliding. This occurs at the boundary of pneumothorax where during inspiration the lung is seen to slide transiently and during expiration the sliding is abolished. This phenomenon known as the 'lung point' is 100% specific for pneumothorax and can be used to determine the size of the pneumothorax.

Recurrent spontaneous pneumothorax

- Presence of emphysematous bullae or subpleural apical bleb
- Cystic fibrosis
- Lung cysts
- Honeycomb lung
- Rupture of bronchogenic or oesophageal carcinoma
- With lymphangioleiomyomatosis

Bilateral pneumothorax: Causes:

- Cystic fibrosis
- Bilateral rupture of apical blebs
- Congenital cysts
- Bilateral primary spontaneous pneumothorax (rare)

Differential Diagnosis

1. Of common types of pneumothorax-

Table 71 gives differences between benign and tuberculous pneumothorax.

2. Of causes of resonant note with diminished breath sounds-

Table 72 gives differences between large pulmonary cavity and pneumothorax.

Table 71: Differences between benign and tuberculous pneumothorax

Benign pneumothorax	Tuberculous pneumothorax
No family history of tuberculosis	Family history of tuberculosis may be obtained
Fever usually absent	Pyrexia common
No loss of weight	Weight loss common
No sweats	Night sweats frequent
Other lung normal	Other lung may show signs of tubercle
Fluid accumulation minimal or absent	Fair amount of fluid may accumulate
No adhesions	Adhesions frequently present

3. **Emphysematous bulla of large size** – Symptoms of chronic bronchitis. Transient crackles on auscultation. X-ray – Fine lines in shape of crescents and semicircles. The circumscribed lung is hyperilluminated and adjacent tissue condensed. No intrathoracic displacements.
4. **Pulmonary emphysema** – Compensatory or localized type. Breath sounds accentuated. Signs of disease in lung, e.g., collapse or massive effusion.
5. **Obstructive emphysema** or emphysema due to ball valve type of obstruction of main bronchus – Mediastinum may be displaced to sound side. X-ray – Lung markings extend to periphery. On screening contrast in transparency of two lungs easily seen at end of expiration.

Table 72: Differences between large pulmonary cavity and pneumothorax

Pneumothorax	Large pulmonary cavity
Acute onset	Insidious onset
Chest pain	No chest pain
Absence of movements of chest on affected side	Restriction of movements at apex only
Bulging of interspaces	Retraction of interspaces
VR diminished or absent	Increased VR
Breath sounds absent	Cavernous or amphoric breath sounds
Cracked pot sound rare	Cracked pot sound usual if cavity superficial
Succussion splash may be present	No succussion splash
Bell tympany constant	Bell tympany rare

Fig. 58: Eventration of the left dome of diaphragm which is thin and markedly elevated. Bowel loops are seen just below the left diaphragm herniating into left hemithorax. A fluid level is present the left side and mediastinum is shifted to the right side

6. **Congenital large cyst**– May be difficult to distinguish clinically from pneumothorax. X-ray – No evidence of collapsed lung at hilum. Delicate trabeculations may be seen.
7. **Eventration of diaphragm** (Fig. 58) – No symptoms or symptoms referable to gastrointestinal or circulatory system or lungs. Heightened inspiratory ascent of costal margin on affected side due to lack of opposition of paralysed diaphragm. X-ray –Diaphragm high in chest; paradoxical movement on fluoroscopy.
8. **Hernia of stomach or colon through diaphragm**– Same signs as eventration. Differentiated by barium meal. In herniation, level of radio opaque mass visible on a higher plane than that of the oesophageal opening, in eventration the two levels coincide.
9. **Subphrenic abscess**– History of abdominal illness or operation. Fever. Alternating zones of resonance and dullness from above downwards. Fluoroscopy – raised and immobile diaphragm.
10. **Distension of stomach**– May cause left half of diaphragm elevated well above the nipple. Symptoms of dyspepsia. Normal chest expansion, bulging in left upper abdominal quadrant. Gurgling may be heard.

Hydropneumothorax (Fig. 59) – *Causes:*

1. Rupture of subpleural tuberculous focus (commonest cause)
2. Rupture of subpleural lung abscess (pyopneumothorax)
3. Pulmonary infarction
4. Penetrating chest injury (haemopneumothorax). Iatrogenic: After cardiac surgery, aspiration of pleural fluid, secondary infection of pneumothorax following water-seal drainage.

Diagnostic signs:

1. Shifting dullness – The upper limit of dullness is horizontal and shifts when patient's position is altered.
2. Succussion splash (Hippocratic succussion).
3. Tinkling sound may be heard particularly after coughing.
4. Horizontal level of fluid on percussion

CHRONIC PNEUMOTHORAX – Pneumothorax persisting for more than 3 months. *Causes* – 1. Failure of collapse of lung due to adhesion. 2. Air leak through congenital cyst. 3. Generalized emphysema causing multiple leaks.

Management of Pneumothorax

Medical

1. **NO TREATMENT** – Only observation if small pneumothorax (occupying less than 20% of the hemithorax)

Fig. 59: Right-sided hydropneumothorax

rax) as the air usually gets absorbed within a few days. The exception is the patient with severe lung disease who cannot tolerate even a small pneumothorax and air has to be removed. Antituberculous therapy if evidence of tubercle.

2. SIMPLE ASPIRATION

Indications

- Significant dyspnoea
- Traumatic (minor)

Technique – Aspiration can be performed with a 16-gauge IV cannula attached to a 50 mL syringe and a three-way tap. An intercostal space is selected from chest radiographs and after sterilizing the skin over the intercostal space, it is anaesthetised with lignocaine down to parietal pleura. The cannula is then inserted through the intercostal space and pneumothorax aspirated into the syringe, and expelled via the three-way tap. As a precaution, a plastic tubing is attached to the exit arm of the three-way tap and its end placed in a bottle of sterile water. This will ensure that with each turn of the tap, air is being drawn from the pneumothorax.

Aspiration is discontinued when gentle suction yields no more air from the pneumothorax, suggesting that the lung has fully re-expanded, or earlier if patient shows signs of distress. If more than 2 litres of air are aspirated, a chest radiograph should be repeated to judge the volume of re-expansion. Absence of re-expansion suggests a bronchopleural fistula and intercostal tube drainage should be resorted to.

Disadvantage

Chances of subcutaneous emphysema.

3. INTERCOSTAL TUBE DRAINAGE

- A. **Tube drainage** – Initial use of small tubes (10–14 F) in most cases:

Indications

- Aspiration fails to resolve
- Tension pneumothorax
- Air space more than 50% of pneumothorax
- Traumatic (major)
- Ventilated (barotrauma)

Procedure

- a. *Site* – 2nd intercostal space in mid-clavicular line or sixth space in mid-axillary line. For women a basal drain is preferred to avoid an anterior chest scar. Chest radiographs should be used as a guide together with ultrasound if necessary.
- b. *Position of patient* – For apical drain, patient must lie flat, for a basal drain slightly rotated towards the opposite side with the arm slightly raised.
- c. *Local anaesthetic* – Upto 10 ml of 2% lignocaine to infiltrate skin, subcutaneous tissue, intercostal muscle and pleura.
- d. *Needle aspiration* – as site of insertion to confirm presence of fluid.
- e. *Skin incision* – just large enough for the cannula.
- f. *Introduction of intercostal drain* into pleural space. After insertion, the intercostal tube should be clamped immediately to avoid air entering pleural space.
- g. *Purse-string suture* around site of insertion and ends tied round the drain.
- h. *Connecting the tube to underwater seal bottle.*
- i. *Removal of clamp.*
- j. *Taping tube to chest wall* at a distance from point of insertion to prevent it being pulled out.

Care of the drain – Level of fluid in the tube connected to the under-water seal bottle should rise and fall with breathing. If fluid level stops swinging, it suggests blocking of the intercostal tube, of its falling out of the pleural cavity, or obstruction of the tube by the fully inflated lung (can be confirmed by chest X-ray). Constant bubbling of air through the underwater seal indicates bronchopleural fistula.

Removal of tube – When bubbling of air ceases, a chest X-ray should be taken. If the lung has re-expanded, the tube should be clamped for 12 hours, X-ray repeated, and if lung is still fully expanded, tube is removed. Failure of expansion of the lung after 7 days or persistence of air leak, indicates further intervention.

B. **Indwelling catheter drainage** – Indications same as for large-bore tube drainage.

C. **Chemical pleurodesis** – via an intercostal drain. Advantage over thoracic surgical procedures is that it is safer in patients with terminal disease (malignant effusion) or compromised lung function.

Requirements – Pleural surfaces to be in apposition, and is hence unsuccessful if the lung is not fully re-inflated, or if air or fluid continue to drain. Large, symptomatic and recurrent malignant effusions should be drained prior to pleurodesis.

Procedure – (i) Insert an intercostal drain. (ii) Connect the underwater bottle seal to wall suction at 10–20 cm H₂O. (iii) Continue until no more fluid can be removed. Stop suction and clamp the tube close to the chest wall. (iv) Inject sclerosant, e.g. talcum powder 10 g in 50 mL saline. Use of sclerosant is painful and analgesic such as dimorphine should be given i.m. 30 minutes before instillation and qds subsequently. (v) Leave the drain for 1–4 hours before removing the clamp. (vi) Dress the wound and repeat chest radiograph.

Surgical treatment

Indications – 1. Bilateral pneumothorax. 2. Haemopneumothorax. 3. Persistent leak due to bronchopleural fistula. 4. Air leak that persists for more than 1 week. 5. Recurrent pneumothorax. 6. Patients whose occupation poses special risks, e.g. pilots, seamen.

Procedures:

1. *Surgical closure of bronchopleural fistula.*
2. *Thoracoscopy/thoracotomy and cauterization* – of the breach in the pleura, or excision of the bulla and over-sewing of the defect.
3. *Pleurectomy* – Bullectomy and partial apical pleurectomy is surgical treatment of choice. Re-expansion of the lung then leads to obliteration of the pleural space.
4. *Decortication* – Stripping off of fibrin from affected visceral pleura.

Video-assisted thoracic surgery (VATS) is a technique that causes less operative pain, allows earlier discharge. However it is often unsuitable for a patient with chronic lung disease.

Other techniques

Indwelling small-bore catheter – is intermediate between simple aspiration and intercostal tube drainage methods. It allows the patient to remain mobile. A 24G catheter is connected to a flutter valve until the hole seals. This technique is useful in small air leaks, or to allow patients unsuitable for surgery to return home.

Table 73: Causes of pleurisy

1. *Infection* – Tuberculosis, pneumonia, bronchiectasis, lung abscess, infection with Coxsackie B virus (epidemic pleurodynia or Bornholm disease).
2. *Pulmonary infarction*.
3. *Bronchogenic carcinoma*.
4. *Injury to chest wall or disease of ribs*.
5. *Rheumatoid arthritis*.
6. *Systemic lupus erythematosus*.
7. *Uraemia*.
8. *Asbestos pleural disease*.
9. *Familial Mediterranean fever*.

Medical thoracoscopy – is intermediate between intercostal tube drainage and thoracic surgery. It is performed under sedation using a rigid instrument and allows – (a) Complete drainage of pleural fluid. (b) Pleurodesis with talc (more effective than chemical solutions). (c) Biopsy under direct vision of abnormal visceral and parietal pleura.

PLEURISY

See Table 73 for the causes of pleurisy. All pleural disorders with inflammatory exudation may start as fibrinous 'dry' pleurisy.

Symptoms

1. Pain in the side, sharp, stabbing or tearing, worse on coughing, deep respiration and pressure from outside. When the diaphragmatic pleura is affected the pain may be referred to the tip of the shoulder, or to upper abdomen from pleurisy affecting the lower lobes.
2. Rapid shallow breathing with unproductive cough.
3. Chilly sensations at onset and moderately intermittent fever.

Signs

1. Diminished movement on affected side.
2. Pleuritic rub – Crackling quality, heard during both inspiration and expiration, localised usually to a small area of chest wall, and often better heard on increasing the pressure of the stethoscope.

Management

1. Rest in bed.
2. Relief on pain with – (a) hot water bag, (b) splinting of chest with strapping, (c) analgesics and sedatives.
3. Relief of cough – Codeine preparations.
4. Specific treatment – according to cause of pleurisy.

PLEURAL EFFUSION

Pleural effusion is an accumulation of fluid in the pleural space as a result of excessive transudation or exudation from pleural surfaces. Pleural cavity normally contains less than 20 mL of fluid.

Mechanisms of Pleural Fluid Formation

- Increased pulmonary capillary pressure
- Decreased tissue oncotic pressure (e.g. hypoproteinemia)
- Decreased negative intrapleural pressure (e.g. atelectasis)
- Increased permeability of pleural membrane (e.g. pleurisy, malignancy)
- Obstruction of lymphatic flow (e.g. mediastinal nodal metastases)
- Transdiaphragmatic fluid flow from peritoneum (e.g. ascites from hepatic cirrhosis)

Causes

See Table 74 for the causes of pleural effusions.

Meigs' syndrome. Pleural fluid (hydrothorax) is associated with ascites due to an ovarian tumour (usually a benign fibroma), occasionally malignant disease. Resolution occurs if the tumors are removed. The same syndrome occurs with endometriosis. Small bilateral effusions are common with peritoneal dialysis, but occasionally the fluid collection is large, usually right sided and thus simulates Meigs' syndrome.

Symptoms

Onset – (i) Acute with attack of pleuritic pain or pyrexia of unknown origin, later with pain. (ii) Subacute. (iii) Insidious – with ill-defined health followed by dyspnoea.

1. Pain – in early stage due to dry pleurisy replaced by dull ache.
2. Dyspnoea – depends on rate of collection of fluid.
3. Cough usually dry.
4. Loss of weight.
5. Symptoms of toxæmia – Malaise, fever, anorexia.

Signs

About 500 mL of fluid is required to produce physical signs.

Inspection

1. With large effusion, orthopnoea or preference for lying on same side.
2. Diminished mobility of chest on one side.

Table 74: Causes of pleural effusions: Classification of pleural fluids.

Nature of fluid	Causes
<p>1. Serous</p> <p>a. Transudate (Hydrothorax) Pale yellow Sp. gr. 1008–1012 Proteins < 3 gm. Does not clot Cells – few endothelial or none Fluid LDH < 200 IU</p> <p>b. Exudate (Effusion) Yellow to brown Sp. gr. 1016 or more Proteins >3 gm. Clots spontaneously Pleural fluid protein : serum protein ratio >0.5 Pleural fluid LDH : serum LDH ratio >0.6 Pleural fluid LDH > two-thirds of upper limit of normal LDH</p> <p>2. Purulent effusion – Empyema <i>Character of pus:</i> Pneumococcus: Usually thick, greenish yellow with thick flakes of fibrin. Streptococcus: Thin, turbid and greenish in colour. May thicken later. Rheumatoid pleurisy: Turbid green fluid</p> <p>3. Haemorrhagic fluid <i>Blood-tinged exudate</i></p> <p><i>Frank blood</i></p> <p><i>Chocolate coloured fluid (degenerating RBCs)</i></p> <p>4. Opalescent fluid – (Chylous or milky) <i>Chylothorax</i> – Pure chyle. High triglyceride level (> 110 mg/dL). Chylomicrons found. Many large fat globules. <i>Chyliform</i> – Fat but not derived from thoracic duct but from degenerated cells. Globules smaller. <i>Pseudochylothorax (Cholesterol pleurisy)</i> – Cholesterol level > 200 mg/dL, cholesterol crystals seen on microscopy</p>	<p><i>Rare</i></p> <ul style="list-style-type: none"> • Constrictive pericarditis • Urinothorax • SVC obstruction • Ovarian hyperstimulation • Meigs' syndrome <p><i>Common</i></p> <ul style="list-style-type: none"> • LV failure • Liver cirrhosis • Hypoalbuminemia • Peritoneal dialysis <p><i>Less common</i></p> <ul style="list-style-type: none"> • Hypothyroidism • Nephrotic syndrome • Mitral stenosis • Pulmonary embolism <p><i>Rare</i></p> <ul style="list-style-type: none"> • Drugs (Amiodarone, metoprolol, bromocriptine, NFT, phenytoin, methotrexate) • Fungal infections • Yellow nail syndrome <p><i>Common</i></p> <ul style="list-style-type: none"> • Tuberculosis • Postpneumococcal • Malignancy <p><i>Less common</i></p> <ul style="list-style-type: none"> • Pulmonary infarction • Rheumatoid arthritis • Autoimmune diseases • Pancreatitis • Post-myocardial infarction syn. • Post-myocardial effusion • Benign asbestos effusion • Neoplastic implants on pleura. • Contusion of lung or chest wall. • Pulmonary infarction. • Tuberculosis. • Primary mesothelioma of pleura. • Rupture of pleural adhesions. • Anticoagulant therapy. • Haemophilia. • Acute aortic dissection. • Pleural endometriosis. • Pleuritis associated with amoebic liver abscess, benign pericarditis, or haemorrhagic pancreatitis. • Trauma to thorax • Haemorrhage from tumour implant. • Spontaneous haemopneumothorax. • Amoebic abscess of liver rupturing into pleural cavity. • Old cholesterol effusion. • Rupture of thoracic duct following trauma. • Malignant growth or mediastinal glands invading thoracic duct. • Tuberculosis. • Parasitic infection – Filariasis. • Thrombosis of left subclavian vein • Carcinoma or tuberculosis of lung or pleura. • Mediastinal radiotherapy • Sarcoidosis • Amyloidosis

Fig. 60: Massive pleural effusion right with trachea and mediastinum pushed to the right

Fig. 61: Pleural effusion in left pleural sac

3. Bulging of intercostal spaces on affected side if large effusion in a thin person.
4. Fullness of hypochondrium if large effusion.
5. Apex beat may be displaced to opposite side unless small, malignant (associated with compression collapse) or loculated effusion.
6. Sternomastoid sign (Trail's sign) - Sternomastoid muscle on side of mediastinal displacement may be prominent.

Shift of trachea to same side in effusion - associated with bronchial Ca:

If absorption collapse - Shift to same side due to negative intrapleural pressure.

If compression collapse - Shift to opposite side due to positive intrapleural pressure.

Causes of absence of mediastinal shift in pleural effusion:

1. Small effusion.
2. Encysted effusion.
3. Bilateral effusion.
4. Apical fibrosis on same side.
5. Associated lobar collapse.

Palpation

1. Immobility of chest.
2. Displacement of trachea to opposite side.
3. Diminished or absent TVF.

Percussion

1. Dull note (absolute dullness).
2. Increased resistance to percussion.
3. Dullness rising from the spine, highest in posterior axilla and falling again towards the sternum - Ellis's S shaped curve.

4. Skodaic resonance or boxy note just above the effusion.
5. Triangular area of dullness against the vertebral column at base of opposite lung (Grocco's triangle).
6. Obliteration of Traube's semilunar space if fluid on left side.

Auscultation

1. Diminished or absent breath sounds.
2. Bronchial breathing in early stages because lung is compressed but bronchi are patent.
3. Diminished or absent vocal resonance.
4. Aegophony and whispering pectoriloquy just above the upper level of fluid.
5. No foreign sounds with large collection of fluid. Crackles if small or moderate amount.
6. Crackles may be heard at the base of the opposite lung due to congestion.
7. Heart sounds (and apex beat) may be obscured in case of large effusion on left side.

Investigations

1. **Imaging**
 - a. **Chest radiograph** - Obliteration of costophrenic sinus on affected side with an opacity extending up the chest wall concave towards the lung on PA film in presence of about 200 ml. Smaller effusions (50 ml) can be detected if radiograph is taken with patient in lateral decubitus position. Views taken in this position are also useful when a subpulmonary collection of fluid mimics an elevated dome of the diaphragm (Figs 60 and 61).

Fig. 62: Encapsulated fluid in the minor fissure

Fig. 63: CT chest showing bilateral pleural effusion

Table 75: Pleural fluid appearance and suspected disease

Observation	Suspected disease
• Putrid odour	Anaerobic empyema
• Food particles	Oesophageal rupture
• Yellow-green	Rheumatoid pleurisy
• Ammonia smell	Urinothorax
• Milky	Chylothorax/pseudochylothorax
• Bilious	Biliary fistula
• Black	Aspergillus infection
• 'Anchovy sauce' fluid	Ruptured amoebic abscess

Fluid which is encysted by adhesions or is within one of the pulmonary fissures is not free to move under the influence of gravity and may cause a pseudotumour image (Fig. 62).

Phantom tumour or vanishing tumour of lung – is collection of effusion in transverse fissure of the lung in CHF which clears with diuretic therapy.

Ultrasonography is more accurate than plain chest radiography for estimating pleural fluid volume, and also aids thoracentesis when effusion is small or localized. It is also useful in demonstrating fibrinous loculation, and differentiates fluid and pleural thickening.

CT can detect pleural abnormalities more readily. It should be performed with contrast enhancement, with which benign and malignant pleural thickening can usually be differentiated (Fig. 63).

2. Examination of pleural fluid –

Pleural fluid observations (Table 75)

pH: Low pleural fluid pH usually defined as <7.2 , represents a substantial accumulation of hydrogen ions (nor-

mal pleural pH is about 7.6 because of accumulation of bicarbonate).

Disease causing pleural pH <7.2 – Empyema, parapneumonic effusion, collagen vascular disease (particularly RA), oesophageal rupture, tuberculosis, advanced malignant neoplasm.

Cytology. Malignant effusions can be diagnosed from a single pleural fluid cytology specimen in about 60%. Adenocarcinoma is diagnosed more often than mesothelioma.

Differential cell counts have a minor role in assessment of a pleural effusion. Pleural lymphocytosis is seen in tuberculous effusions and malignancy, and eosinophilic pleural effusion are often not benign. Coronary artery bypass grafting often causes left sided pleural effusions containing small lymphocytes.

Microbiological studies – on any exudate of possible inflammatory origin and should include Gram stain, aerobic and anaerobic cultures, and mycobacterial cultures.

Immunology – (i) *Rheumatoid factor* in rheumatoid effusion. (ii) *Antinuclear factor* in connective tissue diseases. (iii) *Complement level* may be low in rheumatoid or SLE effusions, but also in malignancy and infection.

Additional Biochemical Tests – in some clinical conditions

- Glucose concentration – <30 mg/100 mL is usual in rheumatoid effusions, but also found with malignant effusion.
- Amylase levels – High levels in effusion associated with pancreatitis. Occasionally in malignant effusions secondary to metastatic adenocarcinoma, and in pleural effusions caused by oesophageal perforation.
- Estimation of cholinesterase to differentiate pleural exudate from transudates. PF cholinesterase >2000 IU and PF/S cholinesterase ratio of >0.5 is taken as exudate and lower values as transudate.

Fig. 64: Abram's pleural biopsy punch

- Chylomicra or high triglyceride levels (more than 110 mg/dL) are diagnostic of chylous effusion. Lipoprotein electrophoresis should be performed in equivocal cases (triglyceride 50–110 mg/dL) to detect chylomicra.
 - Adenosine deaminase (ADA) high in empyema and TB.
 - Tuberculous effusion shows ADA level > 40 IU/L and Interferon- γ > 140 pg/mL.
3. **Percutaneous pleural biopsy** is of most value in diagnosis of granulomatous and malignant disease of the pleura. It should be performed in case of undiagnosed exudative effusions in whom cytology is non-diagnostic, and there is clinical suspicion of TB or malignancy. The Abram's pleural biopsy needle (Fig. 64) is most often used. At least four samples must be taken to optimize diagnostic accuracy, and these should be obtained from one site. Image-guided cutting needle pleural biopsy is more sensitive for diagnosis of pleural malignancy and should be the preferred biopsy method in patients with CT detectable pleural thickening.
 4. **Thoracoscopy** is used when less invasive techniques have failed. The sensitivity for malignancy is more than 90%. During the procedure, all the pleural fluid can be removed and pleurodesis performed.

Differential Diagnosis

I. Conditions above the Diaphragm:

1. Thickened pleura

- History of long standing.
- Interspaces depressed.
- Dullness over base.
- No change on change of posture.
- Diminished breath sounds.
- Chest radiograph – Shadow not so dense or uniform.
- Upper level not well defined, no displacement of heart.

2. Pleural effusion

- History acute, of few weeks.
- Interspaces bulging.
- Flat note at base with Skodaic resonance above level of fluid.
- Area of flat note changed by posture.
- Breath sounds often absent.

Table 76: Differences between pleural effusion and pneumonia.

<i>Pneumonia</i>	<i>Pleural effusion</i>
Onset acute	Onset rarely acute
Rusty sputum	Dry cough
Impaired note	Flat note
No displacement of mediastinum	Mediastinum may be displaced
Outline of dullness irregular and limited	Upper level of dullness extends from sternum to spine
Bronchial breath sounds (absent if massive pneumonia)	Diminished or absent breath sounds
Crackles always present	Crackles rarely heard
Bronchophony over area of consolidation	Egophony at upper level of fluid
Leucocytosis marked	Leucocytosis absent or moderate

Chest radiograph – Obliteration of costophrenic sinus.

Moderately large effusion causes a uniform dense opacity with curved upper level, the concavity facing upwards with the highest point in the axilla.

3. *Empyema* – Bulging of intercostal spaces, skin red and shiny with perhaps oedema of chest wall. Symptoms of sepsis. Leucocytosis.
4. *Hydrothorax* – Usually bilateral, if unilateral on right side. No pain in chest and no history of acute pleurisy. No fever. Evidence of cardiac, hepatic or kidney disease. Transudate.
5. *Lobar pneumonia*

Table 76 gives differences between pleural effusion and pneumonia.

6. *Fibrosis of lung* – Retraction of intercostal spaces, heart or trachea shifted to side of lesion. VR diminished. No stony dullness. Non-homogeneous opacity on X-ray.
7. *Massive collapse of lung* – Mediastinum drawn to same side. VR increased. Evidence of cause of collapse, e.g., mediastinal growth, etc. X-ray – Homogenous opacity.
8. *Bronchial carcinoma* – When extending to periphery gives similar signs or may be associated with pleural effusion. Haemoptysis, presence of pressure symptoms, progressive emaciation and cachexia. X-ray – shadow of growth or collapse of segment, lobe or lung.
9. *Large pericardial effusion* – Heart not displaced to right, area of dullness most marked in axillary region, normal pulmonary resonance at back. Heart sounds muffled or not heard.
10. *Mesothelioma of pleura* – Large mass of solid tissue obliterating pleural space. Associated with pleural effusion which is haemorrhagic, shows large endothelial cells and requires repeated tapping.

Fig. 65: Left-sided calcified pleural

Fig. 66: CT chest shows bilateral crowding of ribs. Left lung shows two areas of consolidation abutting the chest wall. The anterior consolidation shows air bronchogram, there is bilateral armor or sheet like pleural calcification. There is crowding of ribs suspected and diagnosed based on history and imaging studies. Unilateral pleural calcification is likely to be the result of previous empyema, hemothorax or pleurisy

11. *Cardiac enlargement* – No dullness at base of lung, marked pulsation in epigastrium, apex beat in axilla. Evidence of cause, e.g. aortic regurgitation, etc.
12. *Hydatid cyst of lung* – If large, signs of effusion usually at base with sometimes displacement of mediastinum. Cough and progressive dyspnoea common. X-ray shows shadow with well-defined margins. Eosinophilia common.

II. Conditions below the Diaphragm

13. *Subphrenic abscess* – History of appendicitis, abdominal operation or biliary infection. Broad zone of hyperresonance just above the dull area. Fever with rigors, some pain in upper abdomen and rigidity in epigastrium.
14. *Liver abscess* – may push the diaphragm and lower border of pleura up and give signs of effusion. History suggestive of liver disease. No moveable dullness. Compression tenderness present.

Complications

- Acute pulmonary tuberculosis or miliary tuberculosis.
 - Spread of disease to pericardium or peritoneum.
 - Pulmonary oedema.
 - Thrombosis of veins, e.g. superior or inferior vena cava or iliac or femoral veins.
 - Sudden death probably due to pulmonary embolism.
- Sequelae* – (1) Pulmonary tuberculosis within 5–6 years. (2) Permanent collapse of lung. (3) Pleural thickening and calcification (Figs 65 and 66), adhesions and bronchiectasis.

Management

- I. **General** – Rest in bed till fluid gets absorbed, nourishing diet, vitamins.

II. Chemotherapy

- a. *Tuberculous effusion* – Antituberculous therapy.
- b. *Malignant effusion* – After complete aspiration, injection of Tetracycline hydrochloride 500 mg in 20 ml saline into pleural cavity via intercostal drain followed by further 20 ml saline. Tube is then clamped for 6 hours during which patient should change position often so that the tetracycline is distributed around the pleural space. The tube is then unclamped and free drainage permitted. If treatment with tetracycline fails or there are difficulties with intercostal intubation, *C. parvum* may be used as an alternative. *C. parvum* 7 mg diluted in 20 ml saline is injected into the pleural cavity.

- III. **Management of the fluid itself** – Certain disadvantages may result from allowing the fluid to remain in the pleural cavity for any length of time – fibrin is deposited, the pleurae become thickened, re-expansion of the lung is hampered and the process may eventually lead to immobility of the thorax with loss of functional efficiency (frozen chest).

Therapeutic Thoracentesis

See Table 82.

PROCEDURE – *Position of patient* – The patient sits up against a back-rest or leans forward resting the arms on the top of a bed-table. *Site* – The skin is sterilized at the site of puncture which is usually the seventh or eighth intercostal

Table 77: Causes of acute pleural effusion

- Acute pancreatitis.
- Traumatic.
- Rupture of amoebic abscess into pleural cavity.
- Pulmonary infarction.
- Aortic dissection leak into pleural cavity.
- Oesophageal rupture.

Table 79: Bilateral pleural effusion

- Tuberculosis
- Infections: Viral, fungal
- Rheumatoid disease
- SLE
- Asbestosis
- Amoebiasis (Pleuropulmonary)
- Drug-induced
- Peritoneal dialysis.

Table 81: Predominant left sided fluid

- Acute pancreatitis
- Oesophageal rupture
- Dressler's syndrome

space in the mid-axillary line. Two percent lignocaine is used for local anaesthesia and it is injected right up to the parietal pleura. *Aspiration* - The aspiration needle is then introduced at right angles to the skin midway between two ribs and advanced into the chest till the penetration of the parietal pleura is indicated by a 'give in'. The needle is now attached to a 50 mL syringe with a two-way stop cork. As a rule not more than 1000 to 1500 mL of the fluid should be removed at one time. Aspiration should be discontinued if patient begins to cough or complains of tightness in the chest. After aspiration the needle is removed and the puncture wound sealed with collodion. If necessary aspiration may be repeated after 2 or 3 days.

Complications

1. *High negative intrapleural pressure* - The lung is unable to expand fully as indicated by increased pull on the syringe plunger. Patient feels tightness in the chest accompanied by coughing. This can be reduced by allowing some air to be sucked into the pleural space.
2. *Pleural shock* - due to vagal inhibition. The patient's head should be placed low and injection of adrenaline or dopamine given and oxygen started.
3. *Air embolism* - (a) If the aspiration needle tears the pleura and a superficial vein, air can be sucked into the pulmonary venous system through the needle itself or

Table 78: Diseases producing both transudate and exudate

- Amoebic liver abscess
- Systemic lupus erythematosus
- Hypothyroidism
- Congestive heart failure.

Table 80: Predominant right sided effusion

- Amoebic liver abscess
- Congestive heart failure
- Liver cirrhosis
- Meigs' syndrome

Table 82: Indications for aspiration of fluid

- Large effusion upto clavicle.
- Cardiac or respiratory embarrassment.
- Bilateral effusion.
- Acute pulmonary oedema.
- Secondary infection of effusion.
- Persistence of fever and constitutional symptoms.
- If effusion does not tend to get absorbed spontaneously even when anti-tuberculous treatment is being given.
- Fluid is haemorrhagic or has high content of protein.

adjacent lung alveoli. (b) Air may enter the coronary arteries causing cardiac arrest. (c) More often air goes to the cerebral arteries and produces transient neurological symptoms and signs. Emergency treatment is to tilt the patient's head down with his right side uppermost to discourage air from entering these vessels.

4. *Pulmonary oedema* - If the fluid is removed too quickly, oedema may develop in the re-expanded lung tissue. Treatment is reduction of intrapleural pressure by allowing some air to be sucked into the pleural space.
 5. *Circulatory collapse* - due to non-expansion of lung from pleural fibrosis causing high negative intrapleural pressure interfering with venous filling.
 6. *Rupture of intercostal vessel* - rare.
 7. *Pneumothorax or haemoptysis* - if lung is punctured.
 8. *Empyema* - due to introduction of infection into the pleural space.
- IV. **Corticosteroids**- can help to achieve a more rapid absorption of the fluid thus reducing the risk of pleural thickening with loss of respiratory function. Prednisolone 10 mg b.d. or t.d.s. later reduced to 5 mg together with chemotherapy. It should be given for at least 6 weeks after the fluid is absorbed to avoid recurrence. Indications - (a) Patients with large effusions who are acutely ill. (b) If aspiration presents practical difficulties, or if loculation of fluid has occurred.

Fig. 67: CECT chest showing empyema with split pleura sign

Fig. 68: CECT chest showing liver abscess tracking as empyema

- V. **Exercises**– to encourage expansion of the lower chest can be recommended quite early in the course of treatment.

EMPYEMA

Acute Empyema

Causes: See table classification of pleural fluids Table 77 to 81.

Symptoms

1. *Those of primary disease* – Imperfect recovery in pneumonic cases, or sudden increase in fever perhaps with rigors.
2. *Those due to mechanical effect* – Pleuritic chest pain in early stage, dyspnoea, cough and sputum.
3. *Those due to toxæmia*– Malaise, anorexia, sweats and loss of weight.

Signs

- a. Same as effusion with sometimes oedema of chest wall.
- b. Finger clubbing may develop within 2–3 weeks of the onset.

Investigations

Chest radiograph – Uniform opacity free in pleural space or localized by adhesions. Fluid level if bronchopleural fistula.

Leucocyte count – 15,000–20,000 per cmm.

Culture of fluid – for causative organism. Lack of bacterial growth suggests tuberculosis.

CT scan – (Figs 67 and 68)

Complications

1. **Bronchopleural fistula** – Expectoration of large volumes of purulent sputum which may be blood-stained. X-ray shows fluid levels.

2. *Empyema necessitans* – Untreated, an empyema may present as an abscess of the chest wall commonly in relation to costochondral junction of the rib.
3. *Pyopneumothorax* – Particularly empyema due to staphylococcal infection.

Management

Objectives of therapy – Control of infection, evacuation of pus, obliteration of pleural space, re-expansion of lung, and restoration of normal pulmonary function.

1. **Aspiration** – Pus is usually thin and should be aspirated with syringe every second or third day. Continuous drainage to a water seal may be necessary if fluid reaccumulates very rapidly.
2. **Antibiotics** – Penicillin 1 million units 6-hourly IM. Also intrapleurally 500,000 units at each aspiration in 5 to 10 mL of normal saline. If organism insensitive to penicillin other suitable broad spectrum antibiotic and metronidazole 400 mg t.d.s.
3. **Intercostal drainage** – if no definite improvement after about 10 days and in severely ill children. Indications for removal of drainage tube – (a) No fever suggesting control of infection. (b) Less than 100 mL fluid drainage in 24 hours. (c) Complete lung expansion. (d) Bronchopleural fistula if present, gets closed.
4. **Breathing exercises** – as soon as signs of general toxicity disappear.

Chronic Empyema

Empyema of more than 3 months duration is considered chronic.

Diagnostic criteria – (a) Demonstration of presence of bacteria in pleural space by culture and/or staining. (b) Culture negative pleural fluid with pH < 7 and glucose content < 40 mg/dL.

Causes

- *Ineffective drainage* – or failure to diagnose acute empyema.
- *Chronic infection* – Tuberculosis, lung abscess, bronchiectasis, actinomycosis.
- *Carcinoma lung* – with pleural involvement.
- *Bronchopleural fistula* – due to lung abscess, lung trauma or rupture of infected lung cysts.
- *Foreign body* – in pleural cavity, e.g. drainage tube, rib sequestrum.
- *Inadequate drainage of subphrenic abscess.*

Symptoms and Signs

Recurrent symptoms of chest pain and fever. Loss of weight and anaemia. Clubbing of fingers. Chest wall deformity from fibrosis. Chronic sinus tracts into the skin or lungs may develop. When bronchopleural fistula is present, air can be heard (or felt) blowing through a patent sinus during coughing.

Chest radiograph – Dense pleural opacity, crowding of ribs and elevation of diaphragm on affected side (Fig. 69).

Management

Intercostal drainage with instillation of appropriate antibiotics, streptokinase or rib resection and open drainage. When this fails, thoracotomy with excision of empyema sac, allowing the lung to re-expand and obliterate the dead space.

27. THERAPEUTIC AEROSOLS

Successful inhalation therapy depends not only on choosing the correct drug, but also in delivering the drug in adequate amounts to the airways by use of an appropriate delivery system.

INDICATIONS AND MEDICATIONS FOR INHALATION DELIVERY

Asthma and COPD

- Bronchodilatation – β -agonists, anticholinergics
- Prophylactic therapy – Corticosteroids, cromoglycate
- Emergency therapy for acute asthma and COPD
- Expectorant – Saline

Cystic fibrosis

- Prevention/treatment of infection – Inhaled antibiotics
- Reduction of sputum viscosity – DNase
- Secretion hydration – Amiloride
- Protease inhibition – α_1 -antitrypsin
- Gene therapy – via liposomes or viruses

Fig. 69: Encapsulated empyema

AIDS

- Prevention of *Pneumocystis jiroveci* pneumonia – Inhaled pentamidine
- Palliative care
Intractable cough – Lignocaine (probably)
- Treatment of hyperkalaemia

Nebulized salbutamol is as effective as i.v. insulin and glucose in reducing plasma potassium levels in uraemia

Immunization

- Measles vaccination – High rates of seroconversion in young infants vaccinated by inhalation route
- Treatment of croup
- Reduction of inflammation – Adrenaline and corticosteroids

Inhalational drug delivery in intensive care

- ARDS – Surfactant, prostacyclin, nitric oxide related vasodilators.
- Pulmonary hypertension – Nitroprusside, $MgSO_4$
- Bronchopulmonary dysplasia – Corticosteroids.

DEVICES FOR INHALING MEDICATIONS

Pressurised Metered Dose Inhalers (PMDIs) – are most widely used devices in treatment of airflow obstruction because of small size, convenience and low cost.

Chlorofluorocarbons – Free corticosteroid MDIs deliver a finer aerosol, with higher lung delivery and more peripheral deposition

Spacehaler – is a specially adapted MDI actuator that slows the emitted aerosol cloud, reducing oropharyngeal deposition of the drug and enhancing lung delivery.

Spacer devices – are used to improve therapy in specific group of patients, or to increase the proportion of delivered drug deposited in the lungs. Routine use of spacer devices with inhaled corticosteroids reduces the incidence of oral candidosis and dysphonia and decreases adrenal suppression.

Spacer devices may be divided into three broad types – (i) Simple ‘tube spacer’ extensions to the inhaler mouthpiece. (ii) Holding chambers, which generally have a one-way inhalation valve at the mouthpiece. (iii) ‘Reverse flow’ devices with the MDI being fired in a direction 180 degrees from the mouth, either into a collapsible bag, or into small volume from which outside air is entrained.

Dry powder inhalers (DPIs) – Rotahaler – The capsule containing the powder inhaler is inserted into the end of the device and broken up by twisting the mouthpiece. The powder falls into the body of the inhaler and the patient has to inhale through the mouthpiece to disperse the powder and to deliver the micronised drug particles to the lung.

Nebulizers – are useful for patients unable to use other devices, and for infants. Jet nebulizers are powered by compressed air (usually from an electrically operated compressor) by which compressed air passing through a constriction (venturi) undergoes a small reduction in pressure; this causes drug solution to be drawn up from a reservoir and fragmented into droplets in the gas stream. Nebulizers are a convenient way of delivering large doses of bronchodilators that may be required in treatment of acute severe asthma. Nebulizers have significant merit in terms of flexibility, i.e. a spray can be made of any drug substance and in virtually any dose.

28. DRUGS AND THE LUNGS

Undesired effects on the lungs from drugs can be:

1. **INDIRECT** – e.g. worsening of respiratory failure by sedative, haemoptysis from anticoagulants, or paralysis of respiratory muscles from muscle relaxants.
2. **DIRECT** – by toxic or immunological mechanisms –

A. Airways reactions:

a. **Drug-induced asthma** –

Effect predictable on pharmacological basis –
β-blockers

Cholinergic agents (pilocarpine, carbachol)

Cholinesterase inhibitors (pyridostigmine)

Unpredictable or idiosyncratic reactions – Oral: Analgesic and anti-inflammatory drugs. Parenteral: Penicillin, aminophylline, iron-dextran complex, hydrocortisone, N-acetylcysteine.

- b. **Drug-induced cough** – ACE inhibitors, due to increased concentration of kinins (Normally ACE catalyses the degradation of these peptides).

B. Alveolar reactions:

- a. **Noncardiogenic oedema or ARDS** – Opiates or salicylates overdose, hydrochlorothiazide, β-sympathomimetic agent, e.g. isoxuprine, naloxone, cytosine arabinoside.
- b. **Eosinophilic reaction**– Inflammatory exudative alveolitis with excess eosinophils in tissues and blood. Clinical picture varies from transient radiographic infiltrate to life-threatening illness with respiratory distress and hypoxemia. Often associated maculopapular rash. Common agents are sulphonamides, antibiotics like penicillin and tetracycline, neuroleptic agents, methotrexate and procarbazine.
- c. **Alveolitis and/or fibrosis** – Gradual onset of progressive shortness of breath, dry cough and sometimes fever. Chest X-ray shows non-specific interstitial or alveolar shadowing. Causes: Cytotoxic agents, e.g. bleomycin, busulphan. Other agents include oxygen, nitrofurantoin, amiodarone, tocainide.

C. Pleural reactions:

Pleural effusion or thickening. (i) *Drug-induced lupus syndrome* (procainamide and hydralazine in large doses). Amiodarone, Nitrofurantoin, Phenytoin, Methotrexate. Also at times Carbamazepine, Penicillamine, Cyclophosphamide. (ii) *Pleural reaction only* – Pleural fibrosis (often associated with retroperitoneal and mediastinal fibrosis) –Methysergide, methotrexate, bromocriptine, dantrolene.

29. RESPIRATORY PROBLEMS IN IMMUNOSUPPRESSED PATIENTS

Table 83 explains the infectious disorders, non infectious disorders and Iatrogenic diseases in Immunosuppressed Patients and Table 84 gives differential diagnosis of fever with pulmonary infiltration in an immunocompromised patient based on chest X-rays and onset of symptoms.

30. LUNG TRANSPLANTATION

INDICATIONS

Chronic Airflow Limitation

- COPD (often α₁-trypsin deficiency)
- Chronic asthma with fixed obstruction
- Bronchiolitis obliterans

Suppurative Lung Diseases

- Cystic fibrosis
- Bilateral bronchiectasis of other cause

Pulmonary Vascular Disease

- Primary pulmonary hypertension
- Eisenmenger's syndrome
- Thromboembolic pulmonary hypertension

Interstitial Lung Disease

- Cryptogenic fibrosing alveolitis

Uncommon Indications

- Severe chronic fibrotic sarcoid
- Severe chronic hypersensitivity pneumonitis
- Pulmonary lymphangiomyomatosis
- Histiocytosis X
- Re-transplantation
- Bronchoalveolar cell carcinoma

Table 83: Respiratory problems in immunosuppressed patients

Infectious Disorders	
Neutropenia	Gram-ve bacteria Staph. aureus Aspergillus and other mycelial fungi
Immunoglobulin deficiency	Strep. pneumoniae H.influenzae Mycoplasma
T lymphocyte deficiency	Bacterial infection as above Pneumocystis jiroveci and other fungi Mycobacterium Herpes viruses (CMV, varicella zoster) Nocardia asteroides Toxoplasma gondii
Non-infectious disorders	
<ul style="list-style-type: none"> • Pulmonary oedema • Pulmonary hemorrhage • Pulmonary embolism • Tumour (solid tumour, lymphoma/leukaemia, Kaposi's sarcoma) • Alveolar proteinosis 	
Iatrogenic	
<ul style="list-style-type: none"> • Drug (pneumonitis) • Radiation (pneumonitis) • WBC transfusion (leucoagglutinin reaction). 	

SELECTION OF ORGAN DONORS

- Brain death
- Exclusion of HIV-positive and hepatitis B antigen positive donors
- Adequate gas exchange ($\text{PaO}_2 > 300$ mm Hg at 100% FiO_2 and 5 cm H_2O positive end-expiratory pressure)
- Absence of significant pulmonary pathology on chest radiograph or bronchoscopy
- No significant active infection, or recent history of malignancy

TYPES OF LUNG TRANSPLANTATION

- Single lung Interstitial pulmonary fibrosis
- Double lung Suppurative conditions (e.g. cystic fibrosis)
Pulmonary vascular disease
Bilateral severe bullous emphysema
- Heart - lung Pulmonary hypertension with irreversible uncorrectable cardiac abnormality

COMPLICATIONS AFTER LUNG TRANSPLANTATION

- Hyperacute rejection Seconds to minutes
- Pulmonary oedema
- Bacterial lower respiratory tract infection 12-72 hours
Donor - acquired Hours to days
Recipient - acquired Days to years
- Airway complications Week to 1 month

Table 84: Differential diagnosis of fever with pulmonary infiltration

Chest X-ray	Acute onset	Subacute or chronic onset
1. Consolidation	Bacterial	Fungal
2. Interstitial infiltrate	Thromboembolic	Nocardial
3. Nodular infiltrates	Pulmonary haemorrhage	Tuberculous
	Pulmonary oedema	Viral
	Leucoagglutinin reaction	Viral
	(Acute lung injury following transfusion)	Pneumocystis jiroveci
	Bacterial	Radiation pneumonitis
	Pulmonary oedema	Drug - induced
		Tumour
		Fungal
		Nocardial
		Tuberculous
		Sarcoidosis

- | | |
|--|-----------------|
| • Acute rejection | Week to 2 years |
| • Opportunistic infections | Week to 4 years |
| • Chronic rejection (including bronchiolitis obliterans) | Week to 6 years |

Bronchopleural fistula: Causes

- | | |
|-------------------------|------------------------|
| • Lung abscess | Traumatic chest injury |
| • Cavity (Tuberculosis) | Post lung resection |
| • Necrotising pneumonia | Barotrauma |

31. MISCELLANEOUS

Yellow nail syndrome – Effusions associated with yellow discolouration of nails, lymphoedema and occasionally bronchiectasis and sinusitis. Lymphatic hypoplasia is the underlying disorder and the likely mechanism for the effusion.

Silhouette sign. The outline of many structures on the chest X-ray is visible because of an interface between opaque tissue (heart or diaphragm) and air in the lungs. If the lung adjacent to such structures also becomes opaque the 'silhouette' is lost. Thus collapse of the left lower lobe obscures the left hemidiaphragm and collapse of the lingula or right middle lobe obscures the left and right heart borders.

STEM CELLS AND LUNG DISEASES**Therapeutic Potential of Stem Cells**

1. ARDS (regeneration of extracellular matrix)
2. Emphysema (regeneration of alveoli and extracellular matrix)
3. Lung fibrosis (regeneration of extracellular matrix)
4. Cystic fibrosis (stem cells acting as genetic vectors)
5. Pulmonary arterial hypertension (Endothelial progenitor cells transduced with nitric oxide synthetase)
6. Lung cancer (targeting endogenous stem cells with potential for malignant transformation by identifying with specific surface markers).

The Cardiovascular System

1. INVESTIGATIONS IN CARDIOVASCULAR DISEASES

BLOOD

Full blood count, measurement of serum electrolytes and urea, uric acid, serum lipids, homocysteine. Thyroid function tests.

CHEST RADIOGRAPH

The structures to be observed are:

- The heart for size, chamber enlargement, valvular and other calcification.
- Lungs for pulmonary venous hypertension and pulmonary ossification.
- Mediastinum for aorta, superior vena cava, pulmonary arteries and veins.
- Thorax for depressed sternum and rib notching.

ELECTROCARDIOGRAM

The ECG is useful when:

- Patient has symptoms which suggest heart disease.
- Cardiac rhythm is irregular.
- In presence of cardiac enlargement.
- Heart murmurs are heard or heart failure is present.
- Exercise testing is useful in diagnosis of ischaemic heart disease.

HOLTER MONITORING

The equipment is a battery-powered recorder which samples ECG data comparable to data recorded by leads V1 and V5. These recorders allow for 24 hours continuous monitoring.

Clinical Uses

- To diagnose arrhythmias
- Assess antiarrhythmic therapy

- Assess pacemaker or implanted cardioverter defibrillator (ICD) function
- Detect ischaemia
- Monitor BP (using appropriate transducer)
- Determine prognosis

TREAD MILL TEST (TMT) ECG

Patients presenting for exercise testing may be divided roughly into subgroups:

- Those able to exercise maximally with an uninterpretable ECG.
- Those unable to exercise or can exercise only submaximally.
- Those with an uninterpretable ECG (due to LVH, LBBB, digitalis effect, etc.).

Indications

1. *Ischaemic heart disease:* (a) Diagnosis. (b) Risk stratification. (c) Assessment of suitability for and assessment of exercise training and rehabilitation. (d) Follow-up of patients with known CAD. (e) Screening asymptomatic men >40 years of age who are in specific professions (pilots, firemen, vocational drivers).
2. *Acute myocardial infarction:* Risk stratification and assessment of exercise tolerance.
3. *Coronary angioplasty or bypass grafting:* (a) Reassessment of recurring symptoms. (b) Routine evaluation pre- and post-intervention – (i) Early: 2–7 days after PTCA, 6 weeks after CABG. (ii) Late: 6 months after PTCA or CABG.
4. *Heart failure:* (a) Diagnosis of underlying cause (e.g. ischaemia). (b) Evaluation of symptoms in relation to exercise capacity. (c) Assessment of the need and timing of cardiac transplantation.
5. *Arrhythmias:* (a) Diagnosis in patients with exercise-related palpitations, dizziness or syncope. (b) Pacemaker selection in chronic A-V block.

Fig. 1: 2D echo apical 4 chamber view showing normal heart

Fig. 2: 2D echo parasternal short axis view showing normal heart

Criteria for Positive TMT

- *Mildly positive:* Horizontal ST depression of 1 to 5.5 mm and slowly rising junctional depression which remains depressed 1.5 mm more than 80 mins after the J point.
- *Moderately positive:* Horizontal ST depression of 1.5 to 2.5 mm, slowly rising ST depression which remains depressed more than 2.5 mm 80 mins after the J point and down sloping ST depression with J point depressed 1.2 mm.
- *Strongly positive:* Flat ST depression 2.5 mm or more, slowly rising ST depression at J point of 2 mm or more and horizontal sloping ST depression appearing in first stage of the exercise and remaining depressed for more than 8 mins into recovery.

ECHOCARDIOGRAPHY AND DOPPLER ULTRASOUND

The heart can be imaged with reflected ultrasound by the complimentary techniques of M-mode and cross-sectional echocardiography (CSE). Both techniques depend on high frequency sound which is transmitted to and then reflected from intracardiac structures. These echoes from the heart are then converted electronically into an image of the structures that reflected the sound waves.

Cross-sectional Echocardiography (CSE or 2D Echo)

Here multiple ultrasound beams, each produced by a single ultrasound crystal or by mechanically scanning the heart with a single crystal create a sector-shaped cross-section of the heart. Between 30 and 50 such cross-sections are built

up per minute and presented as a moving picture. Imaging planes such as parasternal, apical or subxiphoid are used to produce a complete picture of the heart. While 2D echocardiography does provide an accurate method for assessment of LV function, systolic 3D provides an accuracy in the assessment of LV volumes, and can be compared with gold standards such as cardiac MRI or radionuclide volumes (Figs. 1 to 3).

3D Echocardiography

(a) Assessment of ventricular function. 3D echo provides greater reproducibility, reliability and accuracy than 2D echocardiography in assessment of LV volumes and EF compared with cardiac MRI or radionuclide volumes. Global as well as regional wall motion can be displayed parametrically. (b) Congenital heart disease—3D echo is useful in assessment of congenital cardiac lesions. (c) LV dyssynchrony—3D echo can simultaneously integrate the clinical effects of radial, circumferential and longitudinal effects of all 17 myocardial segments on cardiac dyssynchrony.

Table 1 gives various modalities of echocardiography and their uses.

Transthoracic Echocardiography

Indications: See Table 2.

Transesophageal Echocardiography (TOE)

By mounting both imaging and Doppler transducers on a gastroscope, the heart can be interrogated from the oesophagus. Since there is little tissue between the heart and the transducer, high quality pictures can be obtained.

Fig. 3: 2D echo parasternal long axis view, normal heart, arrow shows aortic valve

Advantages – (a) Excellent access and superior imaging. (b) Valves closer to transducer, hence vegetations, prosthetic valve function more easily seen. (c) Clear vision of ascending and descending aorta.

Indications for Transesophageal echocardiography (with preparatory transthoracic study) are given in Table 3.

Stress Echocardiography

Stress echocardiography is used to predict presence of coronary disease, to stratify the risk of a coronary event and to detect hibernation. It is also used for assessment of functional reserve in patients with end-stage valve disease (Table 4).

Echocardiography in Suspected Heart Failure

Indications:

- Breathlessness or dependent oedema and clinical findings that suggest or cannot exclude heart disease
- Unexplained hypotension
- Exposure to cardiotoxic agents
- Known cardiomyopathy where there is a change in cardiac status

Echocardiography in Valve Disease

Indications for echocardiography in valvular heart disease are listed in Table 5.

Echocardiography for Screening

- Family history of genetically transmitted cardiovascular disease, e.g. Marfan syndrome, hypertrophic cardiomyopathy, dilated cardiomyopathy
- Potential donors for cardiac transplantation
- Baseline and re-evaluation of patients undergoing chemotherapy with cardiotoxic agents

Table 1: Modalities of echocardiography and their uses

Two-dimensional imaging	To describe anatomy and motion To measure cavity size and wall thickness To measure LV outflow tract diameter for calculation of stroke volume To estimate LV volumes and ejection fraction Planimetry of the orifice of mitral valve in mitral stenosis
M-mode	Measurement of cavity size and wall thickness Estimation of LV mass Timing of events within the heart In combination with colour flow mapping aids timing of a flow pattern
Continuous wave Doppler	Calculates the grade of stenotic valve lesions Estimates pulmonary artery pressure Semiquantitative assessment of the grade of valve regurgitation
Pulsed Doppler	Assesses diastolic LV function from recording at the mitral valve and in a pulmonary vein Estimates orifice area of aortic valve (in combination with 2D imaging and continuous wave Doppler) Calculates stroke volume and cardiac output Estimates shunt size
Colour flow mapping	Screens for abnormal flow, e.g. valve regurgitation or a shunt Semiquantitative estimate of grade of valve regurgitation
Doppler tissue	Detecting asynchrony of imaging contraction, e.g. early depolarization in Wolff-Parkinson-White syndrome or the origin of ventricular tachycardia Describing diastolic and systolic function including time intervals, regional function, long axis function and differences between endocardial and epicardial function. These can be used for diagnosis of coronary disease at rest or during dobutamine stress

CARDIAC CT

Demonstrates whether the coronary tree is normal or abnormal. Also, if the test is abnormal, it can tell the extent of abnormality which can range from minor disease (calcified, non-calcified plaques), to severe stenosis and occlusions.

Indications for Cardiac CT to rule out CAD—(a) Family H/o CAD (b) Atypical chest pain. (c) Preadult congenital heart disease or cardiac tumour surgery. (d) Pre-major surgery in adults over age of 50. (e) Smoking. (f) Equivocal ECGs, echocardiograms or after stress studies as routine check-up.

MAGNETIC RESONANCE IMAGING (MRI)

Is a powerful tool providing high-resolution images of the heart and great vessels without the use of ionising radiation or contrast agents.

Table 2: Indications for echocardiography

- *Congenital heart disease.*
- *Ischaemic heart disease*
 - (a) Diagnosis of acute chest pain.
 - (b) Stress echocardiography.
 - (c) Complications of MI.
 - (d) Detection of viable myocardium.
- *Heart failure*
 - (a) Diagnosis of mechanism, e.g. predominant systolic or diastolic dysfunction, dilated cardiomyopathy vs. restrictive heart muscle disease.
 - (b) Diagnosis of cause, e.g. IHD, unsuspected AS.
 - (c) Estimation of ventricular filling pressures.
 - (d) Assessment of global LV function and prognosis.
- *LV hypertrophy.*
- *Hypertrophic cardiomyopathy.*
- *Pericardial effusion and constriction.*
- *Valvular heart disease*
 - (a) Diagnosis and quantitation of valve stenosis or regurgitation.
 - (b) Mitral valve prolapse.
 - (c) Infective endocarditis.
 - (d) Monitoring function of prosthetic heart valves.
- *Suspected cardiogenic embolism or intracardiac thrombus (in conjunction with TOE).*
- *Suspected cardiac tumour, e.g. myxoma.*
- *Miscellaneous*
 - (a) Foetal echo when obstetric surveillance suggests a possible cardiac problem.
 - (b) Neonatal with cyanotic CHD.
 - (c) Older children: To exclude significant disease in patients with innocent systolic murmurs.
 - (d) Adult survivors of surgery for complex CHD developing problems.

Indications

- **Left ventricular structure and function:** Gradient echo sine imaging can provide multiple frames in a single slice with good contrast between myocardium and blood, and is accurate in measuring LV volumes. Wall thickening more accurately reflects extent of myocardial dysfunction in ischaemic heart disease than does wall motion. Using sine MRI, wall thickening can be quantified.
- **Valvular function:** Cine MRI can be used for identification and qualitative assessment of the severity of regurgitant or stenotic valvular lesions. Velocity encoded (VEC) MRI can be used to calculate velocity of blood flow through a given plane.

Table 3: Indications for transesophageal echocardiography

Suspected endocarditis

- In all cases of prosthetic valve endocarditis
- If transthoracic study is nondiagnostic
- Consider in all cases of native endocarditis

Cerebral infarction, TIA, peripheral embolism

- Patients aged <50 years with cerebral infarction
- Patients aged >50 years without evidence of cerebrovascular disease or other obvious cause, in whom the findings of echocardiography will change management (e.g. to start warfarin if a patent foramen ovale is found)

Prosthetic valve

- If patient is unwell, even if the transthoracic study is normal
- To improve quantification of MR
- Suspected endocarditis

Native valve disease

- To determine feasibility and safety of balloon mitral valvotomy
- To determine whether some cases of MR are repairable

Atrial septal defect

- To determine whether percutaneous closure is possible

Aorta

- To diagnose dissection, intramural hematoma
- To determine the size of the aorta if not clear transthoracically

Intraoperative

- To monitor left ventricular function
- To assess de-airing of the heart after cardiac surgery
- To assess the result of valve repair

Intensive care unit

- To assess loading, LV and RV function and valve function

- **Pericardial disease:** MRI allows differentiation of tissue characteristics. For example haemorrhagic, serous and chylous pericardial effusions can be differentiated based on their signal properties (T₁ or T₂-weighted sequences).

MRI is a sensitive measure of pericardial thickness in constrictive pericarditis.

- **Aortic disease:** MRI can provide evaluation of the aorta and its branch vessels. MRI is nearly 100% sensitive in diagnosis of aortic dissection. Gadolinium-DTPA enhanced three-dimensional MRI angiography helps in diagnosis of congenital aortic disease (Fig. 4), aortic aneurysms and dissection.
- **Congenital heart disease:** 3D displays allow measurement of LV volumes and mass and shunt calculations can be performed with phase velocity mapping of flow in ascending aorta and main pulmonary artery.
- **Cardiac masses:** Evaluation of intra and extra cardiac masses and intracardiac thrombi. Cine MRI for describing the attachment and motion of cardiac masses (Fig. 5).

Table 4: Indications of stress echocardiography

- Clinical uncertainty and normal or equivocal conventional exercise test
- Patient unable to exercise
- Resting ECG precluding electrical analysis (e.g. LBBB, LV hypertrophy with strain, digoxin)
- Risk stratification after acute MI
- Need to localize site of ischaemia
- To assess functional significance of a coronary stenosis in planning angioplasty or surgery
- To detect hibernating myocardium
- To grade aortic stenosis in presence of a low LV ejection fraction
- To determine if MR develops or worsens during strain

Fig. 4: A 3D Gd-DTPA - enhanced MR angiogram of a 3-year-old patient with a significant coarctation of the descending aorta just distal to the subclavian artery

- **Anomalous coronary arteries:** 2D MRI angiographic approaches to identify the course of anomalous coronary arteries.
- **Arrhythmogenic RV cardiomyopathy:** MR signs of this disorder include fatty infiltration of RV free wall, wall thinning, systolic dysfunction and cavity dilation.
- **Ischaemic heart disease**
- *Pharmacologic stress testing.* Dobutamine stress cine MRI shows improved sensitivity and specificity compared to dobutamine echocardiography.
- *Perfusion.* Gd-PTA based contrast agents can be infused to assess myocardial perfusion in myocardial ischaemia.
- *Contrast-enhanced infarct detection.* Using an imaging sequence, delayed hyper enhancement seen 5–15 minutes after contrast infusion delineates infarcted tissue.

Carotid intima-medial thickness (CMT) has a correlation with coronary risk factors. A high carotid IMT is a

Table 5: Indications of echocardiography in valve disease

- If patient is previously uninvestigated and symptomatic disease
- Murmur suggesting a moderate probability of organic disease
- Ejection systolic murmur filling most of systole or any pansystolic murmur
- Any diastolic murmur
- Abnormal second heart sound
- Wide pulse pressure and displaced apex beat or enlarged cardiac shadow
- Re-evaluation if there is LV dilation even if valve disease is mild or moderate
- Re-evaluation if symptoms change or with severe valve disease even with no symptoms
- Evidence of endocarditis
- Known significant valve disease and pregnancy
- For planning valve replacement, repair or valvotomy
- Routinely soon after valve surgery or if symptoms or signs suggest dysfunction

Fig. 5: Parasagittal 2-chamber long axis T1-weighted gradient echo cine image of a large left atrial myxoma (large round mass with low signal intensity) attached to the superior pole of the left atrium and prolapsing across the mitral valve

surrogate and reliable marker of higher risk of CAD. The carotid intima-medial thickness is measured by duplex screening of carotid arteries (use of Doppler to estimate blood flow characteristic in conjunction with B-mode ultrasound) is one of the most reliable markers for atherosclerotic vascular changes.

Myocardial viability – In patients who have already infarcted, it is necessary to know whether there is enough viable myocardium available, prior to attempting revascularization. If the myocardium is nonviable, there is no point doing a bypass or stenting the affected artery.

- **Cardiomyopathies** – (a) *In dilated cardiomyopathy*, cardiac MRI show global hypokinesia in absence of infarction and mid-myocardial fibrosis in a few cases. (b) *Hypertrophic cardiomyopathy* – Cardiac MRI is the most sensitive modality to assess the presence of apical HCM, which is often missed on echocardiography. In HOCM, it allows one to assess the extent of myocardial fibrosis and damage as well as the sub-aortic stenosis and flow impairment. (c) *Inflammatory and infiltrative cardiomyopathies* – In patients who have abnormal ectopics or who present with supraventricular or right ventricular tachycardias, it is important to know whether there is a structural cause for this. CMR is the most sensitive tool for diagnosing myocardial pathology. Sarcoidosis is the commonest inflammatory condition to affect the heart and presents with abnormal focal areas of enhancement in the RV and LV with wall motion abnormalities. Often mediastinal and hilar lymphadenopathy is seen in same study.

Cine magnetic resonance angiography (MRA): Shows graft patency well and its accuracy is similar to CT without the need for contrast agents. MRA using phase contrast techniques allows noninvasive measurement of flow in bypass grafts.

Contraindications for MRI – Cardiac pacemaker, ferromagnetic cerebral aneurysm clip, cochlear implant.

Magnetic resonance contrast agents for cardiac imaging: While MRI allows study of cardiac anatomy and contractile function in detail, tissue characterization of the pathophysiologic state of the myocardium may require special indicators or MRI contrast agents. These extracellular, blood pool and intracellular agents provide a wide range of indicator properties, e.g. myocardial extracellular space, blood pool, capillary permeability and membrane transport. Combined use of MRI and MRI contrast agents can thus provide a single diagnostic examination that fully and quantitatively assesses all indices of cardiac performance.

Nuclear magnetic resonance spectroscopy (NMR) – This is useful for evaluation of changes in metabolism with different disease states, as well as with therapeutic interventions:

- Metabolic evidence of ischaemia in patients with myocardial infarction and patients with known coronary disease.
- Patients with dilated and hypertrophic cardiomyopathies often have phosphodiester resonance.
- Changes suggestive of heart transplant rejection.

NUCLEAR CARDIOLOGY

It is the study of cardiac function, myocardial perfusion and blood flow, myocardial metabolism and myocardial damage with radio-pharmaceuticals. The complementary nature of the functional and physiologic informations with the anatomic and structural information obtained from cardiac catheterization procedures has led to widespread application of these techniques.

Techniques

1. Myocardial infarct imaging:

- a. **Technetium-99m labelled pyrophosphate** is an infarct-avid agent that serves as a marker for post-necrotic inflammation. **Disadvantages:** Scans do not become positive until 12–24 hours after infarction, and it requires significant amount of transmural necrosis before a diagnostic ‘hot spot’ is detected. **Uses**—Patients with LBBB or who are permanently paced (because changes of infarct are masked in these cases), or where enzyme tests are equivocal.
- b. **Indium-III labelled antimony:** Advantage over pyrophosphate imaging is that its delivery does not depend on residual flow to the infarct. Also useful for detecting necrosis due to rejection episodes in transplanted heart and imaging acute myocarditis.

2. Myocardial perfusion imaging:

- a. **Thallium-201 or Technetium-99m SESTAMIBI imaging** – TI 201 when injected IV provides information regarding relative regional myocardial perfusion. Hypoperfused areas appear as image defects. Areas of infarction on a cardiac image will appear as fixed defects in resting perfusion scans.

Stress thallium myocardial perfusion scanning: Patient is subjected to a symptom limited exercise on treadmill or bicycle ergometer. 2–3.5 mCi Thallium is injected iv at peak exercise and exercise is continued for further one minute. Patient is then transferred to the imaging table and images of the myocardium taken in multiple views.

In case of coronary artery stenosis, there is inhomogeneity of Thallium uptake with intense uptake in areas of myocardium supplied by normal arteries and relatively decreased uptake (perfusion defect) in areas supplied by stenosed arteries. Usually after about 4 hours, when the initial area of perfusion defect will show the same thallium concentration as the surrounding normal myocardium since thallium is washing in into ischaemic myocardium. Such a ‘reversible perfusion defect’ is the hallmark of ischaemic viable myocardium.

If the myocardium is infarcted, there will be no extraction of thallium in post-exercise images at 4 hours and then at 24 hours, the perfusion defect persists and is called 'fixed', or persistent defect indicating myocardial infarction.

- b. **Positron Emission Tomography (PET)** – Radiopharmaceuticals can be used to label natural substrates of myocardial metabolism. The positron is a positively charged electron produced during decaying of a nucleus. After the positron reacts with neighbouring electron, a pair of electrons are emitted which move at a direction 180° apart. The principle of positron tomography is an array of imaging detectors positioned round the patient. Different positive emitters can be used to study blood flow, e.g. N-13 ammonia, glucose utilisation (F-18 deoxyglucose), and metabolism and myocardial oxygen consumption.

Uses of Myocardial Perfusion Imaging

See Table 6 for indications of myocardial perfusion imaging.

3. **Myocardial metabolism:** Single photon emission computed tomography (SPECT) imaging has superseded multiple view planar images. SPECT technique gives a three-dimensional view, and the exact site and size of the lesion can be more readily determined. Also, multivessel coronary disease can be clearly identified by separating the perfusion defects into separate vascular territories. 'Bull's-eye' imaging is a topographical representation of multiple sagittal sections of the myocardium stacked in two dimensions from the apical section in the centre to the larger basal segments in the outer ring; this technique gives a 'topographical' view of LV perfusion. SPECT SESTAMIBI imaging reduces the false-positive rate and improves specificity for detection of an individual coronary stenosis.

Myocardial perfusion scanning with exercise: Myocardial imaging may be used to assess infarct size, myocardial viability, detection of multivessel disease and prognosis.

Myocardial perfusion imaging with pharmacological 'stress': In patients unable to exercise, pharmacological 'stress' perfusion imaging is useful using SESTAMIBI or ^{99m}Tc-tetrofosmin.

Table 6: Indications of myocardial perfusion imaging

• Risk stratification in IHD.
• Management and follow-up after therapeutic interventions, e.g. coronary angioplasty or surgery
• Prognostic assessment
• Detection of myocardial viability in ischaemic LV dysfunction.

- a. Dipyridamole or adenosine is used to increase coronary blood flow. The 'differential' flow between the normal artery and stenotic artery produces a relative perfusion defect, which can be imaged by perfusion agents.
- b. *Dobutamine* is also used for evaluating CHD. Dobutamine infusion, 5–40 mg/kg/min, produces a significant increase in B.P. and heart rate, which may precipitate myocardial ischaemia in patients with CHD. Use of simultaneous two-dimensional echo-cardiography and ^{99m}Tc SESTAMIBI SPECT to assess myocardial perfusion during dobutamine stress has an extremely high sensitivity and specificity for detecting CHD.
4. **Ventricular function studies:** The procedure known as radionuclide angiocardigraphy (RNV) is used in the assessment of ventricular performance. Two methods are available:

- a. **Equilibrium multigated technique (MUGA)** involves labelling the blood pool with ^{99m}Tc tagged to the patient's own RBCs, and imaging the whole cardiac blood pool carried at equilibrium using the ECG to gate the cardiac cycle so that systole and diastole can be adequately resolved. The left anterior oblique view is obtained to provide separation between right and left ventricles.
- b. **First-pass method** measures right and left ventricular performance sequentially during the initial transit of a bolus of radiotracer through the right and left heart.

Clinical uses – MUGA and first-pass studies are useful for: (a) Detection of left ventricular aneurysms and the differentiation of aneurysms from diffusely hypokinetic ventricles as well as for general assessment of LV function. (b) Left and right ventricular ejection fractions can be measured accurately. (c) Cardiac volumes may also be produced from which ejection and relaxation indices can be derived.

CARDIAC CATHETERIZATION

It is an invasive procedure which can be performed for:

- *Measurement of* – (i) Intracardiac pressures. (ii) Intracardiac oxygen saturation. (iii) Cardiac output.
- *As part of:* (i) Angiography. (ii) Angioplasty. (iii) Valvuloplasty. (iv) Cardiac biopsy.

Indications

- *Valve disease:* Severity of AS or PS.
- *Heart muscle disease*—Both hypertrophic and dilated cardiomyopathy can be diagnosed by echo, and

cardiac catheterization can be only of benefit for the information provided by coronary angiography, or when cardiac biopsy is indicated.

- **Heart failure** – Right heart catheterization is very useful for monitoring response to treatment in acute heart failure.
- **Measurement of cardiac output** is of little value clinically but essential for measurement of pulmonary or systemic vascular resistance in management of shock or as part of the work-up for cardiac transplantation.
- **Congenital disease** – Catheterization is usually reserved for complex cases. A balloon catheter can be used to create an atrial septal defect in transposition of great vessels in which intracardiac shunt can preserve life.
- **Cardiac biopsy** – in patient with suspected cardiomyopathy.

Intracardiac Pressures

Pressures within the cardiovascular system rise and fall. The changes are converted into wave forms either by moving a recording paper under a stylus or by sweeping a spot across an oscilloscope (Table 7).

Techniques – (a) Pressure in right chambers of heart and pulmonary artery are obtained by advancing a catheter through a vein (antecubital or femoral). This can be performed under fluoroscopic control or a catheter with an inflatable balloon near its tip can be carried by blood flow through the right chambers of the heart (Swan-Ganz technique) and the position of the catheter identified from the pressure wave form. (b) Pressures in aorta and LV are measured by passing a catheter against the blood flow through femoral or brachial artery. (c) Pulmonary capillary wedge (PCW) pressure – If an end hole catheter

passed through a vein is wedged into a small pulmonary artery, or if a balloon catheter is ‘floated’ as far as possible, and the balloon inflated, the PA pressure will no longer be recorded and the pressure measured will be that of the pulmonary vein and left atrium. This is the ‘indirect left atrial’ or ‘pulmonary wedge pressure’.

Complications

- Damage to arteries and veins with possible thromboembolism.
- Production of arrhythmia.
- Introduction of infection.

Coronary Angiography (CAG)

Coronary angiography is visualization by X-ray of contrast material injected into arteries, veins or heart chambers to define anatomy, disease or direction of blood flow. Basically, there are 3 types of angiography currently available – (1) Conventional film-screen angiography. (2) Intravenous digital subtraction angiography. (3) Intra-arterial digital subtraction angiography.

Coronary cine-angiography – is performed by arterial catheterization under local anaesthesia, usually by percutaneous puncture of femoral or radial artery. A catheter is introduced and guided under radiological control to the left ventricle and left and right coronary arteries in turn. Contrast medium is injected while video and cine images of the recordings are made.

Percutaneous Coronary Angioscopy

Conventional angiography though able to diagnose presence of intra-coronary stenosis, cannot provide information regarding the lesion morphology and intraluminal pathology. PCA provides an accurate three-dimensional view of coronary artery lumen. The chief utility of angioscopy has been in assessing the results of coronary interventions like balloon angioplasty, atherectomies and stenting. The limitations of this procedure are that it cannot see forward beyond tight stenosis or total occlusions and can only gauge surface morphology, being blind to subsurface pathology and plaque composition.

Table 7: Normal range of pressure within heart and great vessels

Location	Pressure (mm Hg)
Right atrium	
‘a’	7
‘v’	5
Mean	6
Right ventricle	30/5
Pulmonary capillary	30/15
wedge	
‘a’	7
‘v’	14
Mean	12
Left ventricle	150/12
Aorta	150/90

DIGITAL SUBTRACTION ANGIOGRAPHY (DSA)

DSA is a form of angiography where with the help of a computer, a clear image of the blood vessel (without bone overlap) can be obtained.

Table 8: Indications for DSA in cardiovascular cases

- To screen young hypertensives for renovascular cause.
- Occlusive disease of aorta and peripheral vessels.
- Pulsatile masses to rule out aneurysm.
- In the paediatric age group as safe alternative to angiography.
- Post-operative evaluation, e.g. graft patency.
- Follow-up after angioplasty.

IV DSA

Principle – The image acquisition system in DSA consists of a specially designed X-ray image intensifier and television video chain coupled to an image processor, where images are recorded, manipulated and displayed on a cathode ray tube. Images are converted into a digital format. Images obtained before the appearance of contrast material are subtracted from the images obtained after arrival of contrast material in the vessels, so that the resultant image is that of an isolated contrast contained arterial structure. The image is then electrically contrast enhanced to display the final image to its best advantage.

Technique – An antecubital vein is punctured with an 18 gauge needle. A guide wire is then threaded into SVC through the needle. The needle is withdrawn and a 5F high flow digital catheter is introduced over the guide wire and placed into the right atrium. The patient is asked not to breathe for 20–30 seconds during acquisition of the images. The transit time for the contrast material to reach the arterial vessel in question ranges from 4 to 30 seconds. Total dose of contrast material is 150–200 mL.

Indications for DSA in cardiovascular cases (see Table 8).

Advantages

- Simple and safe method and out-patient procedure.
- Avoids arterial puncture complications.

Limitations

1. Patient should be co-operative and have reasonable cardiac output.
2. Less spatial resolution.
3. Not suitable for patients with renal failure because of high volume of contrast.

2. PULSE

IMPORTANCE OF CLINICAL EXAMINATION

1. **Rate:** No absolute normal. Varies in different individuals and in same individual under different circumstances.

Table 9: Abnormalities of rate and rhythm of pulse

Causes of bradycardia

Regular rhythm

1. Sinus bradycardia
2. Complete heart block
3. Partial A-V block with fixed ratio of 2:1 or more
4. S-A block with ratio of 2:1 or more
5. Junctional rhythm (Nodal rhythm)

Irregular rhythm

1. Sinus bradycardia with sinus arrhythmia
2. Partial heart block with irregularly dropped beats
3. S-A block with irregularly dropped beats
4. Atrial fibrillation
5. A-V dissociation (slow type)

Causes of tachycardia

Regular rhythm

- Sinus tachycardia
- Paroxysmal tachycardia
- Atrial flutter

Irregular rhythm

- Atrial fibrillation
- Sinus tachycardia with ectopic beats
- Atrial flutter with varying block
- Paroxysmal atrial tachycardia with block

Causes of irregular rhythm with normal heart rate:

- Multiple ectopics
- Slow atrial fibrillation
- Sinus arrhythmia

In the adult male at rest during waking stage, rate varies between 60 and 80 per minute and in adult female from 70 to 90 per minute. The pulse is slower during sleep. *Bradycardia* is pulse rate less than 60 per minute. *Tachycardia* is pulse rate more than 100 per minute.

Pulse apex deficit – The pulse rate corresponds to heart rate except in the presence of premature contractions or atrial fibrillation, where some of the beats are not transmitted to the radial pulse so that the heart rate exceeds the pulse rate.

2. **Rhythm** – Normal pulse is regular in rhythm. For bedside diagnosis it is important to observe whether the rhythm is regular or irregular and whether the rate is unusually rapid or slow or normal (Table 9).
3. **Volume** – Corresponds to amplitude of the movement or lift of the vessel wall during the passage of the

Table 10: Causes of abnormal pulse volume**Pulse of large volume:** In high cardiac output states—*Physiological:*

- After exercise
- Pregnancy
- Warm humid environment.

Pathological:

- Anaemia
- Fever
- Thyrotoxicosis
- Cor pulmonale
- Cirrhosis of liver
- Systemic A-V fistula
- Systemic hypertension
- Beriberi heart disease
- Paget's disease
- Obesity
- Polycythaemia vera
- Idiopathic hyperkinetic heart syndrome
- Kidney disease: Acute nephritis, or chronic kidney insufficiency
- Carcinoid syndrome
- Polyostotic fibrous dysplasia.

Pulse of small volume (Hypokinetic or weak pulse):*Decreased cardiac output*

- CHF, acute myocardial infarction, states of shock, cardiac tamponade, constrictive pericarditis, myocarditis, cardiomyopathy.

Peripheral vasoconstriction

- Shock, hypovolaemia.

Mechanical obstruction

- Mitral stenosis, aortic stenosis, HOCM, coarctation of aorta.

pulse wave. The volume depends on cardiac output (Table 10).

4. **Force** – Corresponds to systolic blood pressure. Press the radial artery against the underlying bone with the more proximal of the two palpating fingers till the pulse wave is no longer felt with the distal finger. More the pressure required to obliterate the pulse higher the systolic blood pressure.
5. **Rate of rise or ascent of pulse** – Normal rate of rise of pulse signifies absence of significant obstruction of outflow at aortic valve. (i) *Rapidly rising pulse*—Light application of examining finger elicits a sharp tap or slap. Very rapid rate of rise with large pulse volume in aortic regurgitation, PDA, thyrotoxicosis. (ii) *Slowly rising pulse* – in aortic stenosis.

Table 11: Causes of unilateral or bilateral weakness of radial pulse

- Ectopic origin and aberrant course of the left subclavian artery
- Proximal compression
 - Aneurysm of aorta
 - Mediastinal growth
 - Cervical rib
 - Scalenus anterior syndrome
- Pulseless disease
- Peripheral embolism
- Coarctation of aorta
- In elderly
 - Dissection of the aorta
 - Aortitis
 - Trauma (including iatrogenic)
 - Embolism
 - Arteriosclerotic obstruction

6. **Tension** – Gives an idea of the diastolic pressure. When the tension is low, the artery is easily flattened and resumes its cylindrical shape without undue resistance. The pulse of low tension appears to collapse between the beats so that nothing is felt at this time. If the diastolic pressure is high, the artery is palpable both in systole and diastole.
7. **Condition of arterial walls** – In arteriosclerosis, the vessel is palpable and can be rolled between the fingers. The inelasticity of a rigid artery may cause a strong pulse to appear weak.
8. **Inequality of pulse** – It is essential to feel one of the larger pulses, such as the carotid or brachial, and the main peripheral pulses should also be felt for. Coarctation of aorta can give rise to discrepant pulses, and an absent or diminished left brachial pulse indicates that the obstruction is at or proximal to the left subclavian artery. Weakness of pulse at the wrist on one or other side may be due to various causes listed in Table 11.
9. **Radio-femoral lag** – In coarctation of aorta, the femoral pulse is delayed when compared to the radial and not synchronous as in normal subjects.
10. **Character or quality of pulse**
 - **Small weak pulse** – Often found in conditions with low stroke volume of left ventricle, narrow pulse pressure and increased peripheral resistance, e.g. left ventricular failure, diffuse myocardial disease, constrictive pericarditis, stenosis of mitral, pulmonary or tricuspid valve. A small, weak pulse at rapid rate (thready pulse) in states of shock.

Table 12: Causes of bounding or water-hammer pulse

• <i>Aortic run off into heart</i> – Aortic regurgitation, rupture of sinus of Valsalva into a cardiac chamber.
• <i>Aortic run off into pulmonary arteries</i> – PDA, aortopulmonary window.
• <i>Aortic run off into peripheral vessels</i>
• <i>Physiological</i> – Hot bath, alcohol, pregnancy.
• <i>High output states</i> – Anaemia, thyrotoxicosis, beriberi, anoxic cor pulmonale, liver cirrhosis.
• <i>Arteriovenous fistulae</i> – Vascular malformations, trauma, Paget's disease.
• <i>Extreme bradycardia</i> – A-V block.

- **Large bounding pulse (collapsing pulse)** – suggests a high pressure associated with an increased flow and is seen in hyperkinetic circulatory states. A very large, bounding pulse of the *water hammer or collapsing* variety is usually associated with an increased stroke volume of LV, a wide pulse pressure and a decrease in peripheral resistance. The pulse strikes the palpating finger with a rapid forceful jerk and quickly disappears. It is described as having a *water hammer quality* because of its sudden impact and a collapsing quality because it falls away so rapidly. The effect is accentuated if the pulse is examined with the patient's arm elevated because the radial artery is then in more direct line with the outflow stream from the aorta.

The collapsing pulse is caused by the artery suddenly emptying as some of the blood flows back from the aorta into the ventricle and may occur in any condition with a large pulse pressure and low diastolic pressure. It indicates a low filling resistance in the reservoir into which the left ventricle pumps its contents. Causes are listed in Table 12.

Twice beating pulse

Dicrotic pulse – The double beat is produced during diastole by an accentuated, palpable dicrotic wave and is likely to be present when peripheral resistance and diastolic pressure are low as in fevers. Aortic regurgitation, mild or moderate dilated cardiomyopathy, severe dehydration, LVF, cardiac tamponade, advanced CHF.

Anacrotic pulse – Rarely the anacrotic notch in severe aortic stenosis may be so marked that it is possible to feel the initial portion of the pulse wave and the main wave as separate waves. This is usually felt in the carotid artery. It may also occur in low output states.

Pulsus bisferiens – The first systolic peak of the pulse (percussion wave P) is followed by second late positive pulse wave (tidal wave T). Found in presence of:

- Combination of moderate AS and severe AR (If $P > T$, then AR more than AS, if $T > P$, AS more than AR).
- Severe hypertrophic obstructive cardiomyopathy.

Pulsus parvus et tardus – Small volume pulse (parvus) that rises slowly (tardus) to a late systolic peak due to mechanical obstruction to LV ejection in moderate to severe valvular aortic stenosis. It may be possible to palpate an anacrotic notch on the upstroke of the (carotid) pulse.

Pulsus alternans – A strong and weak beat occur alternately. It results probably from alternate rather than regular contraction of the muscle fibres of the left ventricle, those which respond to one stimulus failing to respond to the next. It may be found in association with left ventricular failure or toxic myocarditis and is a sign of ill omen. In apparently normal persons, pulsus alternans may occur during paroxysmal tachycardia or for several beats following a premature beat.

Jerky pulse – refers to a combination of a small volume pulse and collapsing pulse and is due to the rapid but short-lived ejection from the left ventricle. It is characteristic of hypertrophic cardiomyopathy, but it can also be found in severe mitral regurgitation (particularly when this develops rapidly), and in aortic regurgitation complicated by severe heart failure.

Pulsus bigeminus (coupling) – Recurrent grouping of the heart beats in pairs followed by a pause. *Causes:*

- Ectopic beats.
- Atrioventricular block, every third sinus impulse being blocked.
- Sinoatrial block with ventricular escape.
- Block in atrial flutter alternating between 2:1, 3:1 or 4:1.

Pulsus paradoxus – In normal persons the systolic blood pressure may decline 3–10 mm Hg during inspiration, so that pulsus paradoxus is exaggeration of a normal phenomenon. Although inspiration increases venous return to the right side of the heart, there is relative pooling of blood in pulmonary vasculature as a result of lung expansion and more negative intrathoracic pressure during the active phase of respiration. The net result is a decrease in return of blood to LA and LV and subsequent fall in LV output and decrease in arterial pressure. When the systolic blood pressure falls *more than 10 mm Hg* the pulse is referred to as pulsus paradoxus. The paradox in the pulse is that heart sounds are still audible at a time when no radial pulse is felt.

Causes

- *Limitation of inspiratory increase in blood flow to RV and pulmonary artery*, e.g. superior vena cava obstruction.
- *Greater than normal amount of inspiratory pooling of blood in pulmonary vasculature* causes the intrathoracic pressure to have wide excursions of pressure during inspiration, e.g. asthma, emphysema and airway obstruction.
- *Interference with venous return to either atrium during inspiration*, e.g. pericardial effusion, constrictive pericarditis and patients with severe congestive cardiac failure with markedly raised venous pressure.
- **Reverse pulsus paradoxus** indicates inspiratory rise in arterial BP seen in hypertrophic cardiomyopathy, intermittent positive pressure ventilation and AV dissociation.

3. CARDIAC ARRHYTHMIAS

Table 13 gives classification of arrhythmias according to the site of origin.

MECHANISMS

1. **Automaticity** - An abnormal pacemaker overrides the normal pacemaker function at the SA node.
2. **Re-entry** - Re-entry arrhythmias are circular movements of electrical depolarization within cardiac tissue. Re-entry requires the presence of two electrophysiologically different pathways around an insulated core (e.g. the AV valve annulus)
3. **Trigger activity** - is dependent on previous action potential when oscillations in the membrane depolarize the cell to threshold.

ANTI-ARRHYTHMIC DRUGS

Table 14 gives classification of anti-arrhythmic drugs and their actions.

DISTURBANCES OF IMPULSE FORMATION AND CONDUCTION

Sinus bradycardia: Sinus rhythm slower than 60 beats per minute (Table 15) (Fig. 6).

Sinus tachycardia: Sinus rhythm faster than 100 beats per minute (Table 16) (Fig. 7).

Sinus arrhythmia

Respiratory form - The heart rate increases on inspiration and slows at the height of inspiration and during expiration (Fig. 8). Phasic variation more than 10%. When the

Table 13: Classification of arrhythmias according to the site of origin

Sino-atrial node
• Sinus bradycardia
• Sinus tachycardia
• Sinus arrhythmia
• Sinus arrest or block
• Wandering pacemaker
• Sinus extrasystoles
Atria
• Premature atrial contractions
• Atrial tachycardia
• Atrial flutter and fibrillation
• Chaotic atrial rhythm (multifocal atrial tachycardia)
• Atrial standstill
Atrioventricular junction
• A-V junctional premature beats
• A-V junctional tachycardia
• A-V junctional rhythm
• Heart block
Ventricles
• Ventricular premature contractions
• Ventricular tachycardia
• Bundle branch block
• Ventricular flutter and fibrillation
• Ventricular standstill

breath is held the arrhythmia disappears. It is a normal phenomenon and depends on the respiratory variations in vagal tone inhibiting the SA node. This *phasic* type of sinus arrhythmia is common in children and athletes and is also seen in some old people. This variation in pulse rate is absent in patients with ASD.

Non-respiratory form - Phasic variation not related to respiration may occur with vagal stimulation of GI tract or digitalis toxicity.

Ventriculosinus arrhythmia - P-P intervals without intervening QRS complex longer than P-QRS-P intervals. May occur in CHB.

Sinoatrial block (Bradycardia-Tachycardia syndrome): Disorders of sinoatrial conduction and bradycardia-tachycardia syndrome are clearly linked due to the common substrate of conduction delay being the integral part of re-entry mechanisms.

Manifestations: Of sinus node dysfunction (sick sinus syndrome).

1. Persistent, severe and unexpected sinus bradycardia.
2. Sinus arrest with an escape or junctional rhythm. Sinus arrest is momentary failure of SA node to initiate an impulse.

Table 14: Classification of anti-arrhythmic drugs and their actions

Drug	Dosage	Indications	Toxic effects
Class I: Sodium block			
IA: Membrane stabilising agents			
Quinidine	200–400 mg q6h	Vent. arrhy. VPCs, VT	GI disturbances Cinchonism Widening of QRS
Procainamide	PO 250–1000 mg q3h IV 20 mg/min for 30–40 min	Junct. arrhy. Ectopics, tachy.	GI disturbances Hypotension after IV Lupus syndrome
Disopyramide	100–200 mg q6–8h	Supravent arrhy. APCs, PAT, AF, A flutter	Xerostomia Urinary retention Hypotension QRS prolonged
IB: Effect on vent. refractoriness			
Lidocaine	Bolus 75 mg, then 50 mg q5 min to total 225 mg	Ventricular arrhythmias	CNS: Lightheadedness, confusion, dizziness, tinnitus CVS: Bradycardia, hypotension
Mexiletine	200–400 mg q8h	Ventricular arrhythmias	GI: Nausea, vomiting CNS: Dizziness, lightheadedness, tremor
Phenytoin	250 mg in normal saline over 10 min, then 100 mg q5 min as needed	Digoxin toxicity arrhythmias	Nystagmus, ataxia, slurred speech, confusion, dizziness
IC: Effect on repolarization			
Flecainide	100–200 mg q12h	Sustained VT Symptomatic non-sustained VT Vent. ectopy	Prolonged PR, QRS. BBB Sinus node dysfunction Dizziness, visual disturbance Proarrhythmia
Encainide	20–50 mg q8h	Vent. arrhythmia	VT, V. Fib. Dizziness, blurred vision Rash. Proarrhythmia
Propafenone	150 mg q8h	Vent. arrhythmia Atrial arrhythmia (including WPW syn.)	Proarrhythmias Bronchospasm Dizziness
Class II: Beta-blockers			
Propranolol	PO: 20–80 mg q6h IV: 1–3 mg in NS (0.5–1 mg/min.)	SVTs PVCs AF and A flutter (Reduce vent. response)	} Bradycardia Bronchospasm Heart failure Hypotension
Esmolol	Bolus 500 µg/kg, then 50 µg/kg/ min for 4 min.	PVCs AF and A flutter (Reduce vent. response)	
Metoprolol	PO: 25–50 mg q12h	PVCs	
Class III: Prolongation of action potential and repolarization			
Sotalol	40 mg q6h	PVCs VT	Impaired peripheral circulation, bradycardia, hypotension
Amiodarone	PO: 800–1600 mg q6h Maint. 200–600 mg q6h IV: infusion with loading dose of 5 mg/kg over 20 mins, followed by infusion of 1 g/24 h for 48–72 h	PVCs VT, VF	Corneal microdeposits Thyroid abnormalities Photosensitivity Pul. fibrosis Bradycardia Proarrhythmia
Bretylum	Bolus 5–10 mg/kg, then 1–2 mg/ kg/min or repetitive bolus of 5–10 mg q6h	VT VF	Hypotension Increased arrhythmia
Class IVA: Calcium-channel blocking agents			

Contd...

Contd...

Drug	Dosage	Indications	Toxic effects
Verapamil	PO: 80 mg q6–8h IV: 5–10 mg over 2–3 min. Repeated after 15–30 min. if necessary	} SVT	Occasional hypotensive symptoms, headache
Diltiazem	PO: 30–60 mg q6–8h IV: 0.05–0.45 mg/kg over 2 min.		Minimal
IVB K ⁺ channel openers			
Adenosine	IV 0.05 mg/kg as bolus with 0.05 mg/kg increments at 2 mins intervals up to 0.25 mg/kg	Junctional tachycardias	Few side effects Transient marked slowing (sinus bradycardia or complete AV block)
Other drugs: Digitalis			
Digoxin	Loading: 1.25 mg over 24 h Maint. 0.25 mg/day	AF, Atrial flutter AT	GI: Anorexia, nausea, vomiting Blurred vision or chromatopsia Gynaecomastia Rhythm disturbances

Table 15: Causes of sinus bradycardia

Non-cardiac

- Athletes
- Normal during sleep and in elderly
- After viral infections
- Increased vagal tone (simple syncope)
- Increased intracranial pressure
- Drugs: Beta blockers, calcium antagonists, amiodarone, clonidine
- Hypothyroidism
- Hypothermia
- Cervical or mediastinal tumours
- Gram-ve sepsis
- Obstructive jaundice

Cardiac

- 2nd and 3rd degree heart block

Fig. 6: Sinus bradycardia. Rate 50 per minute

Causes - Acute MI, myocarditis, digitalis, type Ia antiarrhythmic drugs, fibrotic changes in SA node and atria.

When the SA node fails to initiate an impulse, one of the following may occur:

- SA node resumes - SA node takes over and a normal rhythm is restored. The P-P interval during the

Table 16: Causes of sinus tachycardia

Non-cardiac

- Infancy and childhood
- Emotional stress
- Anaemia or haemorrhage
- Fever
- Pregnancy
- Hypovolaemia
- Shock
- Drugs: Sympathomimetics, atropine group
- Alcoholism
- Carcinomatosis

Cardiac

- Myocardial ischaemia or infarction
- Myocarditis
- Untreated heart failure

Fig. 7: Sinus tachycardia. Rate 120 per minute

Fig. 8: Sinus arrhythmia. P-P interval shortens with inspiration and lengthens with expiration

Fig. 9: Sinus arrest. A pause during which a QRS complex is dropped

block is not an exact multiple of the normal P-P interval (Fig. 9).

- b. Escape beat – An ectopic focus in the atria, node or ventricle may take over or ‘escape’ from their usual control by a higher pacemaker in order to maintain the heartbeat. If the ventricular escape continues for two or more beats, it is designated idioventricular rhythm. *Treatment* – Permanent pacemaker if symptoms such as syncope.
3. Prolonged sinus arrest with failure of all subsidiary pacemakers resulting in total cardiac asystole.
4. Chronic atrial fibrillation with an unusually slow ventricular response not due to drug therapy.
5. Inability of the heart to resume sinus rhythm following electrocardioversion for atrial fibrillation or flutter.
6. Alternating bradyarrhythmias with tachyarrhythmias – Here sinus bradycardia (with or without sinus pauses) is associated with episodes of tachycardia. Occasionally, the sinus node may be very slow to restart after a paroxysm of tachycardia and there may be a period of sinus arrest. Drugs used to prevent tachycardia accentuate bradycardia and sinus pauses and may worsen the condition. Since these medications (beta-blockers, calcium antagonists) are used to treat the tachyarrhythmias, concomitant permanent pacing may be required.
7. Silent atrium – Occasionally, the atria fail to depolarise or to contract. P waves are absent from the ECG and cardiac rhythm is maintained by a lower centre, usually a junctional focus.

PREMATURE CONTRACTIONS (ECTOPIC BEATS)

Cardiac contractions which arise prematurely from a normal or abnormal pacemaker.

1. Premature Atrial Contractions (PACs)

Causes – Rheumatic heart disease notably mitral valve disease, congenital or acquired non-rheumatic MR, ischaemic heart disease, thyrotoxicosis, acute or chronic lung disease, ASD, thoracic surgery, alcohol, tobacco or caffeine excess, idiopathic.

Fig. 10: Atrial premature beats producing atrial bigeminy

ECG – Abnormal P wave configuration which is usually followed by a normal QRS (Fig. 10). The P-wave which may be hidden within the preceding T wave is usually upright but may be inverted or biphasic. PR interval more than 0.12 sec. No QRST complex following P wave if impulse reaches AV node when it is refractory (blocked atrial ectopic).

Clinical significance – (i) If associated with underlying heart disease they may herald other atrial arrhythmias. (ii) Occurring in mitral stenosis they presage onset of atrial fibrillation. (iii) Multifocal extrasystoles do not occur with a normal heart.

2. Junctional (Nodal)

Causes and significance – same as PACs.

ECG – Premature P wave followed by QRST complex or P wave buried in QRS complex or follows it. Full compensatory pause. PR interval less than 0.12 sec. (Fig. 11).

3. Premature Ventricular Contractions (PVCs)

Causes

- Idiopathic
- Organic heart disease – Ischaemic heart disease, hypertensive heart disease, myocarditis, any cause of ventricular hypertrophy such as cardiomyopathy, mitral valve prolapse.
- Drugs – Digitalis, quinidine, amphetamine, caffeine, thyroxine, adrenaline, nicotine.
- General – After major illness, or surgery, physical unfitness.

Grading of ventricular ectopy:

1. <30 uniform VPCs hour.
 - A. <1/min.
 - B. >1/min.
2. >30 uniform VPCs/hour
3. Multiform VPCs
4. A. Bigeminy

Fig. 11: Nodal ectopic beat. There is no P wave before the premature beat

B. Trigeminy

5. R-on-T phenomenon

ECG—QRS wide, and notched or slurred. T wave in opposite direction to QRS. P wave hidden in or follows QRS. Shape varies if multifocal. Fully compensatory (Fig. 12).

Clinical significance – (1) Idiopathic and may occur in health. May be caused by emotional upset, may occur during pregnancy. (2) Effect of exercise – (a) If abolished by exercise tachycardia they are usually considered benign. (b) If induced by exercise they may suggest presence of coronary insufficiency. (3) In acute MI, PVCs are a warning for more serious arrhythmias. In LBBB, PVCs may be the only ECG evidence of cardiac infarction. (4) A special subgroup of patients with mitral valve prolapse are at higher risk for serious ventricular arrhythmias. (5) Grading of ectopics – Complex and frequent ectopy is associated with increased risk of sudden death, while low grade ectopy has a benign prognosis.

- Interpolated extrasystole* – Occurrence of three beats in rapid succession in the time normally occupied by two and without a long pause. Common with ventricular ectopic beats.
- Fusion beats* – QRS complex intermediate in shape between a normal and aberrant QRS and preceded by a P wave.

Symptoms

- No symptoms in about 50%.
- Disagreeable sensation due to large beat or fear of heart stopping due to long pause.
- Pain and neurosis in hypersensitive subjects.
- Dizziness and faintness if premature beats numerous.

Signs

- Pulse* – Quick beat followed by pause, less than compensatory in atrial and nodal and equivalent to two

Fig. 12: Ventricular ectopic beats causing coupling or bigeminy

sinus cycles in ventricular premature beat ending in pulse more forceful than its predecessors. Early beat faintly palpable or impalpable at peripheral pulse (pulse deficit).

- Heart sounds* – (a) 1st sound – Generally accentuated in all ectopic beats since filling of the ventricles is interrupted and valves are still open. (b) 2nd sound—Normal splitting in atrial and nodal and wide splitting due to ventricular asynchrony. If ectopic beat is so premature that there is insufficient ejection of blood, no 2nd sound.
- Cannon waves* – In ventricular premature beat, cannon 'a' wave in jugular pulse coincides with or just follows 1st heart sound or carotid impulse in contrast with cannon wave in atrial premature beat which just precedes 1st sound or carotid impulse.

Treatment

- If no underlying organic heart disease* – (a) Reassurance regarding harmlessness of the condition. (b) Sedatives. (c) If persistent – Low-dose beta blocker.
- Removal of causative or aggravating factors* – Excessive intake of tea, coffee, alcohol, tobacco. Stress.
- Acute suppression* – e.g. acute MI (Refer). Digoxin fab for digitalis toxicity. Prophylactic IV lidocaine or procainamide may be used during thrombolysis or PTCA.
- Chronic cardiac disease* – Use of class Ia agents. Amiodarone if sustained arrhythmia that fails to respond to conventional agents.

NARROW COMPLEX TACHYCARDIAS ATRIAL FIBRILLATION

Causes of atrial fibrillation are listed in Table 17.

Clinical Classification

- Paroxysmal AF:**
 - Transient AF lasting less than 48 hours
 - Persistent: Episode of AF lasting more than 48 hrs 7 days.
- Permanent AF:** Sinus rhythm cannot be restored by pharmacological and non-pharmacological methods

Table 17: Causes of atrial fibrillation

I.	Paroxysmal and unrelated to underlying heart or other organ disease including 'lone' AF.
II.	Cardiac
	A. Valvular heart disease
	• Mitral stenosis
	• Mitral annular calcification
	• Mitral valve prolapse
	B. Nonvalvular heart disease
	• Ischaemic heart disease – Acute MI, Prinzmetal's angina, thrombolysis in acute MI, balloon deflation during PTCA.
	• Hypertensive heart disease.
	• Myocarditis
	• Cardiomyopathy particularly dilated and hypertrophic.
	• Pericarditis – Viral, postcardiotomy, postinfarction.
	• Atrial septal defect.
	• Post-operative – especially after thoracotomy or coronary artery bypass.
	• Pulmonary thromboembolism
	• Sick sinus syndrome
	• WPW syndrome
	• Atrial myxoma
III.	Systemic disorders
	• Hypoxia due to lung disease.
	• Infection acute (e.g. pneumonia) or chronic
	• Hyperthyroidism.
	• Cerebral vascular accident.
	• Electrolyte imbalance.
	• Hypotension and shock.
	• Drugs: Theophylline, amphetamines, adrenaline.
	• Alcohol, caffeine.
	Lone AF occurs more in males and is resistant both to drugs and electroversion.

Mechanisms

1. Re-entry is the primary mechanism
2. Multiple wavelets hypothesis – Grossly irregular wave fronts become fractionated into daughter wavelets, the more the wavelets, more likely for the arrhythmia to sustain.

Symptoms

- *Few or no symptoms* – If no underlying heart disease, or slow fibrillation.
- *Due to rapid heart rate* – Palpitation or thumping in chest.

- *Due to fall in cardiac output and systemic pressure* – (a) Anginal pain because of lowered coronary perfusion if coronary insufficiency. (b) Weakness, dyspnoea and cough due to heart failure. (c) Syncope or focal neurological symptoms such as hemiparesis, aphasia, etc. if cerebral artery narrowing.
- *Symptoms due to embolism* – if rheumatic mitral valve disease.

Signs

- *Irregularly irregular rhythm* – With ventricular rate usually between 100-200 beats per minute. Slower ventricular rate in old age, digitalis therapy or lone atrial fibrillation.
 - *Pulse apex deficit* – Pulse rate considerably less than apex rate because some systolic contractions are feeble.
 - *Heart sounds* – Variation in intensity of 1st sound. 2nd sound may not be heard if the ventricular contraction is too weak to open the semilunar valves.
 - *Murmurs* – Systolic murmurs preserved, louder following longer cycles and fainter after shorter cycles. No presystolic accentuation of diastolic rumble of mitral stenosis except when there is a short diastole.
 - *Neck vein pulsations* – Rarely rippling fibrillary waves. Usually no evidence of either atrial contraction or relaxation i.e. no 'a' waves or negative x descent.
- ECG** – (Figs. 13 to 15) (a) Absence of normal P waves. (b) Presence of fibrillary waves. (c) Amplitude of R wave varies from beat to beat.

Differential Diagnosis

See Table 25.

Management

1. Treatment of underlying Heart disease (if any), or the precipitating cause – e.g. control of ischaemic heart disease, antidigoxin antibodies for digitalis toxicity arrhythmia.

Paroxysmal AF

- i. **If no associated heart disease** – Rest, sedatives and digitalis for short paroxysms. For recurrent paroxysms control of ventricular rate with digitalis, beta blockers or calcium antagonists.
- ii. **If patient haemodynamically stable** – Class Ia antiarrhythmic drugs to convert to sinus rhythm. Quinidine is the most widely used 200–600 mg every 6 to 8 h. Careful monitoring of QT intervals for prolongation of QT interval and also serum drug levels during attempted chemical cardioversion. The class III agents sotalol and dofetilide can be administered to patients

Fig. 13: Atrial fibrillation with rapid rate

Fig. 14: Slow atrial fibrillation Digitalis effect

Fig. 15: 12-lead ECG showing atrial fibrillation

Fig. 16: ECG showing polymorphic ventricular tachycardia

with coronary artery disease or structural heart disease but have risk of inducing excessive QT prolongation and torsades des pointes (Fig. 16).

iii. **If haemodynamically unstable, significant AS or MS** - DC cardioversion to prevent or reverse pulmonary oedema.

Table 18: Drugs for conversion and maintenance of AF

Drug	Dosage	Comments
Quinidine		
Recent AF	1.5 g/d po	Proarrhythmia
Chronic AF	200–600 mg q6h po	
Procainamide	1.5 g/d po 10–15 mg/kg iv (loading), 2–4 mg/min iv	No significant side effects
Flecainide	100–200 mg q6h po	Contraindicated in severe LV dysfunction
Amiodarone	5 mg/kg iv over 20–30 mins, followed by infusion 1 g/24h for total 24–48 h 200 mg/d po maintenance	Severe bradycardia with iv dosing

Table 19: Cardioversion in atrial fibrillation

Indications
Recent onset AF
Prior peripheral embolism
Persistent AF after treatment of underlying cause
Rapid ventricular rate despite drugs
Persistent symptoms related to AF after medical treatment
Contraindications
Relative
AF > 1 year
Left atrial size > 50 mm
EF < 25%
Absolute
Digitalis toxicity
Underlying cause sick sinus syndrome

Sustained AF

- Patient HD unstable with heart rate 170–200/min.** – DC cardioversion with 50–100 J, increased if necessary to 200J.
- Patient HD stable** (and no emergency) – IV digoxin to slow ventricular rate. Dose 0.5 mg slowly over 5 min, then 0.25 mg q4h till ventricular rate < 100/min, or total dose of 1.5 mg is given. Patient may revert to sinus rhythm.

Drugs used for conversion and maintenance of AF are given in Table 18.

Conversion to sinus rhythm – Most of the following criteria should be met:

- AF has been present for < 1 year.
- LA size (echo) is < 45 mm.
- LV function (echo) is normal or nearly normal.
- Age < 75 years.
- No intracardiac thrombi (TOE).

Cardioversion

Indications and contraindications for cardioversion are given in Table 19.

Note: All patients with AF of more than two days duration should be placed on Warfarin for 3 weeks prior to conversion, and 4 weeks following cardioversion, until sinus rhythm has been established.

In AF both atria fibrillate hence right-sided embolization can occur from clot in RA.

Chronic AF

Drugs used to control ventricular rate are listed in Table 20.

Table 20: Control of ventricular rate

Drug	Loading dose	Maintenance dose
Digoxin	0.75–1 mg IV 0.75–1.5 mg po	0.125–0.25 mg/po
Esmolol	500 µg/kg/min IV	50–300 µg/min IV
Verapamil	5–10 mg IV	80 mg q6h po
Diltiazem	0.25 mg/kg IV	30–90 mg q8h po

Anticoagulation to prevent systemic and pulmonary embolization – *Indications:*

- Rheumatic mitral valve disease with recurrent, persistent or chronic AF.
- Dilated cardiomyopathy with recurrent, persistent or chronic AF.
- Elective cardioversion with mitral valve disease, prosthetic valves, dilated LA or previous events.
- Coronary or hypertensive heart disease and prior embolic episodes related to AF.

Contraindications – Prior bleeding events, uncontrolled hypertension, malignancy.

Catheter Ablation

Radiofrequency AV node ablation for drug resistant AF. The ejection fraction improves. Permanent pacing is required following ablation.

Surgical Treatment

Underlying principle is the hypothesis that critical mass of atrial tissue is required to sustain AF. The ‘corridor’ (MAZE) operation is designed to maintain sinus rhythm by isolating the sinus node by a small corridor connecting atrial tissue and AV node from remaining atrial tissue.

ATRIAL FLUTTER

Causes

Same as A. fibrillation, more often associated with heart disease than AF.

Diagnosis

1. *Pulse* - (a) Regular rate of about 150 per minute. (b) Abrupt drop in rate to half the previous rate due to shift from 2:1 to 4:1 block may occur.
2. *Jugular venous pulse* - Regular small rapid pulsations (flutter waves) may be seen.
3. *Heart sounds* - 1st heart sound may vary in intensity due to minor changes in P-R interval.
4. *Carotid sinus pressure* - Usually slows the ventricular rate to half. On release of pressure ventricular rate returns to previous level.
5. *ECG* - Saw-tooth (picket fence) appearance of atrial waves (Figs. 17 and 18) with ventricular response following every 2nd, 3rd (up to 8th) P wave.

Fig. 17: Atrial flutter with varying block

Differential Diagnosis

See Tables 24 and 25.

Management

Note: Any SVT at rate >150/min should be considered to be due to AFL unless proved otherwise.

Patient HD unstable (Low BP, restlessness, tachycardia, tachypnoea, acidosis) - (a) Cardioversion with 25-50 J or (b) Overdrive pacing of atria at frequency higher than flutter rate.

Patient HD stable: Reduce ventricular rate to 100/min - (a) Heart rate >140/min and no LV dysfunction - Verapamil 5 mg IV, repeat if necessary after 30 min. May convert to sinus rhythm. Danger of marked hypotension (treated with IV calcium).

Atrial flutter with LV dysfunction-IV digoxin 0.25-0.5 mg. Repeat after 2-4 h. Total in 24h 1-1.75 mg. If AF persists and reversion to sinus rhythm is desired: Quinidine 0.4 g q2h for 4-5 doses, then maintenance doses of 0.2 g q6h or Procainamide 500 mg q4h, then reduce to 500 mg q6h.

Note: Quinidine or procainamide should not be given till ventricular rate is slowed by verapamil or digoxin.

Fig. 18: 12-lead ECG showing atrial flutter with 2:1 block

Atrial pacing – may convert atrial flutter to sinus rhythm. Especially suited to patients who are a poor risk for anaesthesia used in giving DC shock such as elderly patients, those with acute myocardial infarction or advanced obstructive lung disease.

Prevention of Recurrence

Quinidine 200 mg qds. or sustained release tablets in a dose of 800–1200 mg/day, or slow release procainamide 500–750 mg po q6h may be given or added to propranolol with restoration of sinus rhythm. Amiodarone can be tried for refractory cardiac failure. After a 3-week loading period, sinus rhythm may be restored by electrical cardioversion and maintained by amiodarone 200 mg po daily.

PAROXYSMAL TACHYCARDIA

Presence of six or more successive ectopic beats.

Classification

- Supraventricular:
 - Atrial
 - A-V junctional (Nodal)
- Ventricular

PAROXYSMAL SUPRAVENTRICULAR TACHYCARDIA (PSVT)

Causes

- Idiopathic in majority.
- As for atrial ectopics – notably rheumatic and ischaemic heart disease.
- Digitalis intoxication.
- Pre-excitation (Wolff-Parkinson-White syndrome).
- Short PR interval with normal QRS complex (Lown-Ganong-Levine syndrome).

Symptoms

- Local** – Precordial discomfort or anginal pain. Disagreeable fluttering over precordium. Fullness in neck. Pounding of vessels in head, arms, abdomen and leg.
- Psychic and reflex nervous symptoms** – Anxiety, coldness, sweating, and dizziness. Abdominal distension, nausea and vomiting. Polyuria at end of attack.
- Cardiovascular** – If heart diseased or paroxysm prolonged – (a) Symptoms due to cerebral ischaemia – Syncope or Adams-Stokes syndrome. (b) Cardiac failure especially when there is underlying heart disease or in children.

Fig. 19: Paroxysmal atrial tachycardia

Signs

- Regular heart rate of 160–220/min.
- Changing intensity of S_1 in junctional tachycardia and atrial tachycardia with varying block.
- Vagal stimulation by carotid sinus pressure or Valsalva manoeuvre may cause sudden reduction in heart rate.

ECG – Three types of patterns:

- Rapid rate with normal ventricular complexes. Atrial activity is often difficult to identify but there is 1:1 A-V response (Fig. 19).
- A faster atrial rate with 2:1 response found in digitalis toxicity and acute ischaemia.
- 1:1 A-V response with aberrant A-V conduction resembling bundle branch block and simulating ventricular tachycardia.

PSVT DUE TO AV NODAL RE-ENTRY

A benign disorder and the most common form of PSVT. It is characterised by two functionally distinct pathways (slow and fast) within the AV node.

ECG – Retrograde P waves appear buried within QRS or appear immediately after (Figs. 20 and 21).

Differential Diagnosis

See Table 24.

Management

A. Of attack:

- Sedation and reassurance**
- Vagotonic manoeuvres** – (i) Carotid sinus massage, first on right, then on left side for 3 to 5 seconds at a time. Should not be done in patients with history of cerebrovascular insufficiency. (ii) Valsalva manoeuvre – Have the patient inhale deeply, hold his breath and then strain down hard when he counts slowly to 10. (iii) Drinking a glass of ice-cold water. (iv) Induction of gagging or vomiting by placing a finger in the oropharynx. (v) “Diving reflex” – While the breath is held the patient immerses his face into a basin of cold water.

3. **Drugs**

Drugs used in treatment of PSVT are given in Table 21.

4. **Cardioversion** - (a) If above measures unsuccessful, in presence of hemodynamic instability. (b) If medical therapy ineffective or poorly tolerated or when differentiation from ventricular tachycardia is difficult because of bundle branch block. Digitalis should be discontinued before cardioversion. Relative contraindications to DC shock include digitalis toxicity, hyperkalaemia, anaesthetic risks and frequently recurrent arrhythmia.

5. **Ablation of electrical pathway** - (AV node or accessory connections) by catheter or surgery.

6. **Pacing devices** - designed to interrupt paroxysms of tachycardia and restore sinus rhythm.

B. **Prevention of recurrence:**

1. **General measures** - Use of sedatives and avoiding excess fatigue, emotional tension, excess alcohol, smoking, and stopping use of sympathetic drugs if any.

Table 21: Drugs used in treatment of PSVT

Drugs	Dosage
Adenosine	6 mg as initial rapid IV bolus. If ineffective within 2 mins, further 12 mg bolus which may be repeated once.
Verapamil	5 mg IV over 5 mins. Can be repeated every 5 minutes until conversion occurs, or total dose reaches 20 mg.
Digoxin	0.5 mg over 10 mins. IV followed by additional 0.25 mg every 4 h to maximum of 1.5 mg in 24 h.
Esmolol	Loading infusion of 500 µg/kg/min. If no response within 5 mins, same dose to be repeated followed by maintenance infusion 500 µg/kg/min.
Diltiazem	0.25 mg/kg as bolus over 2 mins. If response inadequate second dose after 15 mins 0.35 mg/kg.

Fig. 20: Atrioventricular nodal re-entry tachycardia (AVNRT)

Fig. 21: 12-lead ECG atrioventricular nodal reentrant tachycardia (AVNRT)

2. **Drugs** - Verapamil 80 mg. t.d.s. or Digoxin 0.25 mg. once a day, or Quinidine 0.2 g. qds., or Propranolol 10-40 mg. qds.

II. **PSVT due to WPW syndrome** - In sinus rhythm, the presence of the accessory pathway results in pre-excitation of the ventricle which produces the delta wave and short PR interval on the ECG.

ECG - P wave seen in ST segment (Figs. 22 and 23).

W-P-W syndrome: It is associated with Ebstein's anomaly, HCM, and mitral valve prolapse. AF is the main risk of sudden death if conduction is 1:1 down in accessory pathway causing VF.

Treatment - Vagal manoeuvres. Verapamil, propranolol or Class I antiarrhythmic agents. Digoxin contraindicated.

III. **Ectopic atrial tachycardias** (Long RP tachycardia) - Characterised by abnormal P-wave vector, low P-wave amplitude and rapid rate (160-240/min). If associated with high-grade AV block (PAT with block) digitalis toxicity is likely.

ECG - P wave falls before QRS complex

Treatment - (a) Of precipitating factor, e.g. decompensated COPD, electrolyte imbalance, metabolic

abnormalities, hypoxia, thyrotoxicosis. (b) Antiarrhythmic agents effective if no reversible cause.

Multifocal atrial tachycardia (MAT) usually occurs in patients with severe pulmonary or heart disease in relation to acute respiratory insufficiency. Rate usually <150/min.

ECG - Three or more different configuration ectopic P waves (Fig. 24).

Treatment - of underlying cause. Verapamil or quinidine in maintenance doses.

Fig. 22: WPW syndrome

Fig. 23: 12-lead ECG in WPW (pre excitation) syndrome. Note short PR interval and delta waves (slurred initial portion of QRS complexes)

Fig. 24: ECG features of various SVTs

Wandering atrial Pacemaker: Here the rhythm of the heart is not controlled exclusively by the sinus node, but other foci in atrium (and occasionally AV junction) fire and conduct to the ventricles.

ECG – Different P wave configurations and different PR intervals.

Treatment – Permanent pacemaker if patient symptomatic. Later appropriate drugs for control of tachyarrhythmia.

Lown-Ganong-Levine Syndrome: Association of bouts of tachycardia with, between attacks, short PR interval but no delta wave and no prolonged QRS. PT is usually supraventricular but may be ventricular.

Supraventricular tachycardia with aberrant condition

SV conduction of SVT, either atrial or junctional results in broad QRS complexes. This may be caused by either left or right bundle branch block which may be permanent and present in sinus rhythm or may be rate-related and present only during tachycardia. An ECG may be of value with typical BBB pattern seen in SVT and more bizarre morphologies in VT.

BROAD COMPLEX TACHYCARDIA VENTRICULAR TACHYCARDIA (VT)

A series of 3 or more consecutive ventricular complexes.

Causes

These are listed in Table 22.

Diagnosis

See Table 24 of differential diagnosis of tachycardias.

ECG – Wide and bizarre QRS complexes usually at a rate of 160 or more (Fig. 25). P waves independent of QRS complexes at normal sinus rate but as a rule difficult to detect. The rhythm may be slightly irregular (Table 23). Carotid sinus massage has no effect.

Management

Any wide complex tachycardia should be treated as an emergency as if it is VT.

Table 22: Causes of ventricular tachycardia

• Ischaemic heart disease
– Chronic or variant angina
– Acute myocardial infarction
Following recovery from infarction particularly those complicated by development of ventricular aneurysm
• Most of the causes of ventricular ectopics.
• Idiopathic paroxysmal or intermittent variety rarely in youth.
• Drug toxicity
– Digitalis
– Quinidine
– Sympathomimetic drugs

1. **Non-sustained VT** — No treatment unless associated cardiac disease. Removal of potentially reversible causes if present, e.g. IHD, hypoxaemia, acidosis, electrolyte abnormalities (hyperkalaemia, hypocalcaemia, hypomagnesaemia), hyper-thyroidism, digitalis toxicity, intracardiac catheters.

2. **Sustained VT**

Patient HD unstable – DC cardioversion with 50 J. If ineffective 150 J, and if needed 250 J. After conversion to sinus rhythm Lidocaine infusion at rate of 2-4 mg/min.

Patient HD stable – Lidocaine bolus 1 mg/kg IV. Repeat after 10 min. if no reversal to sinus rhythm. After reversion prophylactic lidocaine drip at rate of 2-4 mg/min. If lidocaine fails – (ii) Mexiletine 100-150 mg IV at rate of 25 mg/min for 3 h, then maintenance infusion of 0.5 mg/min. (iii) If DC shock, lidocaine and mexiletine fail – correction of factors that potentiate the arrhythmia (hyperkalaemia, metabolic acidosis, hypoxia) if present and 20-40 mEq of potassium chloride in 5% dextrose infusion can be tried.

If no response to above regime and in presence of hypotension or fast pulse rate – Amiodarone IV bolus 300 mg followed by infusion of 1.2 g over 24 h, or Bretylium tosylate 5-10 mg/kg IV over 20 min. Repeat 100 mg every 10 min till total dose of 500 mg. Maintenance dose 100 mg q8h. In refractory cases not responding to antiarrhythmic drugs – Magnesium sulphate 2 g stat IV, followed by infusion containing 8 g of the drug.

If failure to convert by DC shock or antiarrhythmic drugs – Trial of programmed electrical stimulation of ventricles, or overdriving of ventricles through transvenous pacing catheter introduced into RV.

Fig. 25: 12-lead ECG showing ventricular tachycardia

Table 23: ECG features of ventricular tachycardia

- Abnormal wide complexes
- QRS > 0.12 second
- Extreme axis deviation
- Fusion or capture beats
- Chest lead concordance
- Right bundle branch block morphology with Rsr' in V1 or qS in V6

Prophylaxis (Long-term Treatment)

1. Management of underlying heart disease such as heart failure and maintenance of serum electrolytes within normal range.
2. Drugs - Amiodarone or Sotalol.
3. Radiofrequency catheter and surgical ablation-for some patients with stable monomorphic VT.
4. Automatic implantable cardioverter/defibrillator (AICD). *Indications*—
 - Survival of an episode of ventricular fibrillation or hypotensive VT in absence of acute MI.
 - Incomplete suppression of the arrhythmia by antiarrhythmic drugs, as determined by electrophysiologic testing, stress testing, or ambulatory ECG recording.
 - Patients with symptoms of syncope not documented by VT (or VF) during EP testing but who demonstrate inducible VT or VF during EP testing and do not respond to drugs.

Working - The AICD pulse generator is implanted subcutaneously in paraumbilical area. If a malignant tachyarrhythmia occurs, the AICD recognises it within 5–15 sec. and then delivers the shock. This results in termination of the arrhythmia in most cases.

Other Types of VT

NON-SUSTAINED VT - At least 6 consecutive impulses lasting up to 30 sec. Danger of sustained VT in patients with advanced IHD or cardiomyopathy. Treatment same as with other forms of PVCs.

REPETITIVE MONOPHASIC VT - A benign disturbance; paroxysms may be separated by only one sinus beat. Occasionally turn into sustained VT. No treatment unless associated structural heart disease.

TORSADES DE POINTES (Cardiac ballet or pre-fibrillary VT) - Polymorphic VT which occurs as a proarrhythmic response to Class IA or at times Class C antiarrhythmic agents. Also complete AV block, hyperkalaemia and tricyclic antidepressants, or as part of congenital prolonged QT syndrome, transient myocardial ischaemia, thrombolytic therapy or Prinzmetal's angina.

ECG - Characteristic variation in axis of QRS complexes causing an undulating or 'twisted' appearance (Fig. 26).

Treatment is of underlying cause. Overdrive atrial or ventricular pacing may be necessary.

Re-entry tachycardias Most cardiac arrhythmias are generated by a depolarization wave form which

Fig. 26: Torsades de pointes

repetitively circulates around an area of block to conduction. A common example is the AV re-entry tachycardia (AVRT) seen in WPW syndrome.

Intracardiac electrophysiology, Catheter Ablation and Implantable Cardioverter Defibrillators

Interventional therapies of catheter ablation and the implantable cardioverter defibrillator have been increasingly applied in the management of cardiac arrhythmias.

Catheter ablation represents a natural progression of EPS from a diagnostic procedure to therapy. Successful treatment of an arrhythmia by ablation depends on establishing the arrhythmia mechanism and localizing the arrhythmogenic area of myocardium (mapping). This area is then destroyed without damage to the surrounding tissue (ablation).

Table 26 lists complications and management of ablation.

Computer mapping systems allow complete mapping of the arrhythmia substrates. Alternative forms of energy development may be cooled. tip RF delivery, laser cryotherapy, ultrasound and microwave frequencies.

Indications and targets for ablation

See Table 27 for details of ablation in various types of arrhythmias.

Implantable defibrillators

An implantable cardiac defibrillator (ICD) automatically detects an arrhythmia and delivers either overdrive pacing therapy or a DC shock to terminate it. ICDs are implanted in a subpectoral pouch (Fig. 27).

HEART BLOCK

Types

1. Sino-atrial
2. Atrioventricular block at division of bundle of His.
3. AV block at level of bundle branches.

SINO-ATRIAL BLOCK

A condition in which the SA node initiates an impulse but there is a block to the exit of the impulse from the SA node to the atria.

Diagnosis

- Intermittent pulse, halving of cardiac rate or long pause depending on frequency of dropped beats.
- Abolished by exercise or atropine.
- ECG – Pause with complete absence of PQRST. P-P interval twice the dominant P-P interval (Fig. 29).

Table 24: Differential diagnosis of regular tachycardia

	<i>Sinus tachycardia</i>	<i>Supraventricular tachycardia</i>	<i>Ventricular tachycardia</i>	<i>Atrial flutter with 2:1 block</i>
Onset and termination	Gradual	Sudden	Sudden	May be sudden
Heart disease	Absent	Often absent	Usually present	Usually present
Heart rate	Rarely more than 160	160 or more	160 or more	Usually 150
Jugular venous pulse				
(a) Rate compared to ventricular rate	Same	Same	Difficult to distinguish	Ventricular rate half the rate of flutter waves
(b) Cannon waves	Absent	Regular cannon waves	Irregular cannon waves may be seen	Regular cannon waves may be observed
1st heart sound	Constant	Constant	Variable intensity	Constant
Carotid sinus	Gradual slowing with gradual return to previous rate on release of pressure	No change or abrupt reversion to normal	No change	Abrupt slowing for few beats only

Table 25: Differential diagnosis of irregular tachycardia

	<i>Multiple ectopic beats</i>	<i>Atrial fibrillation</i>	<i>Atrial flutter (with varying block)</i>	<i>Sinus arrhythmia (with tachycardia)</i>
Associated condition	Idiopathic, ischaemic heart disease, digitalis toxicity, etc.	Rheumatic heart disease, thyrotoxicosis, ischaemic, or hypertensive heart disease, or none	Same as in A. fibrillation	Normal heart Common in children
Rate at apex	Usually less than 120	More than 120	About 160	Less than 140
Effect of exercise	Disappear	Rhythm becomes more irregular	May become regular	Disappear
Pulse apex deficit	May be present	Marked	None	None
Heart sounds	Occasionally only 1st sound heard	Vary in intensity	Variation of 1st heart sound	Normal
Other features	Long pauses preceded by premature beats. Irregular cannon waves in jugular pulse	Pauses without preceding premature beats. More often permanent	Jugular pulse shows flutter waves. More often paroxysmal	Rhythm becomes regular if breath is held

Table 26: Complications of ablation

<i>Complication</i>	<i>Treatment</i>
Heart block	Permanent pacemaker
Tamponade	Percutaneous drainage and reversal of heparin
Hematoma and false aneurysm	May require surgical repair
Thromboembolism (effects usually transient)	Anticoagulation, aspirin

Management – (i) Treatment of cause – e.g. digitalis intoxication. (ii) Pacing for rare cases in which there is prolonged asystole and Stokes-Adams attacks.

ATRIOVENTRICULAR BLOCK

I. **First degree block – Prolonged PR interval.**

Causes – See Table 28.

Table 27: Indications and targets for ablation

<i>Arrhythmia</i>	<i>Substrate</i>	<i>Frequency</i>	<i>Region targeted</i>
Atrioventricular nodal reentry tachycardia	Two insertions to the compact atrioventricular node	About 70% of regular supraventricular tachycardias	Slow pathway (lower complication and higher success) or fast pathway (higher risk of atrioventricular block)
Accessory pathway	Anywhere around atrioventricular junction, 65% left free wall, 25% septal, 10% right free wall	10% of regular supraventricular tachycardias	The accessory pathway
Atrial flutter	Rotation around the right atrial free wall and between the tricuspid valve and the inferior vena cava isthmus in a clockwise (common) or anticlockwise direction	10% of regular supraventricular tachycardias	Tricuspid valve and inferior vena cava isthmus
Atrial fibrillation	Many re-entry circuits throughout both atria	4% of adult population	Curative: Still not determined Palliative: Atrioventricular node
Ventricular tachycardia	Re-entry around scar (usually left ventricle secondary to ischaemia)	84% of referrals	Diastolic potentials
	Bundle branch re-entry	6% of referrals	Right bundle
	Idiopathic (focus in right ventricular outflow tract in 70%)	10% of referrals	Right ventricular outflow tract

Fig. 27: A posteroanterior radiograph of the chest of a patient with a pectorally implanted defibrillator. The lead can be seen passing through the left subclavian vein to the right ventricular apex. Two defibrillation coils can be seen on the lead

Fig. 29: S-A block. A complete PQRST complex is omitted and the P-P interval is twice the normal length

Fig. 30: First degree heart block. P-R interval almost 0.4 second

Diagnosis

1. Pre-systolic triple rhythm – Atrial systole is so far removed from ventricular systole that it becomes audible.
2. S₁ diminished in intensity.
3. Definite interval between presystolic murmur and first sound at apex if mitral stenosis.

Fig. 28: Conducting system of the heart

Table 28: Causes of first degree heart block

Acute rheumatic fever
Inferior myocardial infarct
Myocarditis, e.g. diphtheritic
Degenerative myocardial disease
Drugs – Digitalis, β-blockers, calcium antagonists, emetine
Hyperkalaemia
Congenital heart disease (ASD)
Increased vagal tone (in normal individuals)

4. Prolongation of AV conduction may be judged if ‘a’ waves visible in the neck on one side and carotid pulsation palpated on other side.
5. Cannon waves in the neck if PR interval is so prolonged that P falls between QRS and T of the previous cycle.
ECG – PR interval more than 0.2 sec. (Figs. 30 and 31).
Treatment – No specific therapy is required.

II. **Second degree block (Partial heart block)**

Causes

- Acute rheumatic fever, diphtheria.
- Ischaemic heart disease.
- Digitalis toxicity
- Viral infections.

Types of Partial Heart Block

1. **Mobitz type I (Wenckebach phenomena)** – Gradual lengthening of PR interval until a P wave is not followed by a QRS complex, the cycle then starts again, (Figs. 32 and 33). As AV conduction worsens, less impulses are transmitted in each cycle and then Wenckebach period shortens. Ultimately 2:1 AV block may occur.
Recognised at bedside by – (a) Occurrence of dropped beat without preceding premature beat. (b) Intensity of 1st sound may be constantly faint or it may decrease in intensity over several beats.

Fig. 31: 12-lead ECG showing first degree AV block

In regular 2:1 or 3:1 block, it may be impossible to distinguish between a high or Mobitz type I block and a low or Mobitz type II block on standard ECG, but the site of lesion can be localised by His bundle electrogram.

Treatment - A stable arrhythmia which rarely requires permanent pacing.

2. Mobitz type II (Intermittent type)

- Regular rhythm with sudden pauses slightly less than two normal cycles.
- Small atrial waves may be seen in the jugular vein during these pauses.
- ECG - PR interval remains constant but QRS complexes are dropped out intermittently (Fig. 34).

3. Fixed type - Ventricles respond to every second (Figs. 35 and 36) third or fourth beat - 2:1, 3:1, 4:1, block, but the PR interval remains constant. When the conduction is 3:1 or 4:1 the block is termed high grade AV block.

Signs - Pulse slow and regular. Neck veins show pulsations of atrial origin at a rate of two, or three, or four times faster than the radial pulse rate.

Treatment - Since it may progress to complete heart block, permanent pacing indicated to prevent symptomatic episodes.

III. Third degree block (Complete heart block)

CAUSES: See Table 29.

Symptoms

- *Due to low cardiac output* - Lassitude, fatigue, light-headedness, and especially during exercise syncope. Symptoms of vertebrobasilar insufficiency and congestive heart failure may be precipitated.
- *Due to increased stroke volume* - Uncomfortable awareness of heart beat, or slow palpitation if block is intermittent.
- *Due to transient circulatory arrest* - Stokes-Adams attacks - Symptoms depend on duration of standstill of circulation: About 5 seconds - giddiness and faintness, about 10 seconds - convulsions. Convulsions and incontinence may suggest epilepsy, but in transient asystole pallor is often striking, patient flushes during recovery, and consciousness is regained very rapidly, though some permanent impairment of cerebral function may occur after long or repeated episodes.

Signs

- *Slow and regular heart rate* - at 30 to 50 beats per minute, which does not usually increase significantly with physical activity or exercise.
- *Raised JVP* - 'a' waves may be seen in the neck unrelated to ventricular beats.

Fig. 32: Wenckebach second degree AV block. Progressive lengthening of PR interval followed by dropped QRS. A junctional escape beat delays the start of the next sequence

Fig. 33: Mobitz type 1 2nd degree AV block. Serial prolongation of PR interval till one P wave is not followed by a QRS complex

Fig. 34: Mobitz type II AV block

Fig. 35: 2:1 AV block

- **Cannon waves** – Giant ‘a’ waves which are transmitted to the neck when the atrium contracts against a closed tricuspid valve.
- **Variation in intensity of 1st heart sound** – 1st sound is loudest when the interval between the preceding atrial beat and the ventricular beat is short, it is faintest when the interval is long. From time to time, there is a sharp accentuation of the 1st sound at the apex (cannon sound).
- **Wide pulse pressure** – due to increased systolic pressure and low diastolic pressure. This gives rise to water hammer pulse and capillary pulsation.
- **Cardiac enlargement** – due to increased stroke volume. Hyperdynamic cardiac impulse.
- **Systolic ejection murmur** – loudest in 2nd and 3rd left interspaces adjacent to the sternal edge, and due to increased velocity of blood flow associated with increased stroke volume.
- **Atrial sounds** – may be heard in inconstant relation to 1st and 2nd heart sounds.
- **Apical diastolic flow murmur** – occasional.
- **ECG (Figs. 37 and 38)** – No relation between atrial and ventricular complexes. The duration of QRS is normal.

Fig. 36: 12-lead ECG showing 2:1 AV Block

Table 29: Causes of third degree heart block

Congenital

Usually associated with VSD, rarely isolated.

Acquired

- Rheumatic heart disease
- Acute infections – Rheumatic fever, diphtheria.
- Drugs – Digitalis, quinidine
- Calcific aortic stenosis.
- Trauma (penetrating).
- Surgical procedures – After correction of VSD, or following insertion of prosthetic valves or removal of hypertrophied septum in hypertrophic cardiomyopathy.
- Cardiomyopathy (particularly infiltrative).
- Syphilitic heart disease.
- Infiltrative masses – Sarcoidosis, tubercles, abscesses from endocarditis, gummas, tumors, amyloidosis, haemochromatosis.
- Collagen diseases – Rheumatoid arthritis, dermatomyositis.
- Fistulae – Sinus of Valsalva aneurysm rupturing into right atrium.
- Unknown cause – Idiopathic fibrosis.

High block – QRS of normal pattern and duration and with ventricular rate between 40-50/min. Low block – Wide QRS complex and rate 20-40/min.

Fig. 37: Atria and ventricles depolarize independently. QRS complexes less frequent; regular at 40 to 55/minute

Differential Diagnosis

- (a) *Of bradycardia* (See Table 30).
- (b) *Of AV dissociation (with interference)* – Here the atrial impulses are not conducted to the ventricles because the AV node is still within its normal refractory period. It may occur as slowing of normal pacemaker activity or acceleration of a subordinate focus, or in presence of complete AV block (See Table 31).

Treatment of complete heart block:

1. Drugs – (i) *Isoprenaline* – 2.5 mg in 500 mL dextrose as IV infusion accelerates the heart rate in most patients. Rate of infusion adjusted to keep heart rate between 70-100/min (ii) *Atropine* – Block associated with inferior infarction is usually transient and may be reversed by 0.5-1.2 mg IV atropine.

Fig. 38: 12-lead ECG showing complete heart block (CHB)

Table 30: Differential diagnosis of Bradycardia

	<i>Sinus bradycardia</i>	<i>Partial heart block (high grade)</i>	<i>Complete heart block</i>	<i>Sino-atrial block</i>	<i>Junctional rhythm</i>
<i>Incidence</i>	Fairly common	Common	Common	Very rare	Very rare
<i>Heart rate</i>	40–60	40 or less	40 or less (except congenital, in children or due to digitalis)	About 40	About 50–60
<i>Associated condition</i>	Athlete heart, increased intracranial tension, jaundice, myxoedema	Coronary disease rheumatic fever, or diphtheria, digitalis	Same as partial heart block	Increased vagal tone, digitalis, beta-blocking agents, coronary disease, diphtheria	Digitalis intoxication
<i>Jugular venous pulsations</i>	Normal 'a' waves preceding carotid impulse	Atrial waves more than ventricular rate	Position of 'a' waves continually changes with periodic cannon waves	No waves during pause in heart sounds	Cannon waves may be seen
<i>Effect of exercise, atropine or emotion</i>	Increase in rate	Abrupt slowing	No change or slight increase	May disappear	No change
<i>Carotid sinus pressure</i>	Further slowing, especially if sensitive carotid sinus	Further slowing	No effect	Further slowing	May result in atrial standstill with persistent ventricular action
<i>Heart sounds</i>	Constant	No irregular change Atrial sounds may be heard	Changing intensity of S_1 . Cannon sounds may be heard. Atrial sound may be audible	Constant	S_1 may be intensified due to simultaneous atrial and ventricular contraction

Table 31: Differential diagnosis of AV dissociation

	Complete AV block	AV dissociation
Cause	Acute infarction, digitalis, cardiomyopathy, congenital	Digitalis, myocarditis or myocardial infarction.
Syncope	Common	Uncommon
Duration	Often permanent	Usually transient
ECG		
Atrial rate	Usually faster than vent. rate	Usually slower than vent. rate
Vent. rate	About 40/min.	Usually above 60/min
QRS complex	Supravent. or vent.	Usually supravent
P falling after T	May occur	Does not occur

Table 32: Indications of pacing

<i>Temporary cardiac pacing—</i>	
• Symptomatic complete or incomplete heart block unresponsive to medical therapy.	
• Acute myocardial infarction complicated by significant conduction defect and/or tachyarrhythmia which causes cardiovascular collapse and is unresponsive to medical therapy.	
<i>Permanent cardiac pacing—</i>	
• Symptomatic bradyarrhythmia, e.g. sick sinus	
• Intermittent Mobitz type II A-V block documented on Holter monitor.	
• Alternating RBBB and LBBB.	
• Acquired complete heart block if symptomatic	
• Symptomatic congenital heart block.	
• Drug resistant tachyarrhythmias.	
• Atrial fibrillation with bradycardia and pauses >5 s	

2. Pacing – Indications

See Tables 32 and 33 for the indications of pacing.

For emergency treatment of Adams-Stokes attacks—
See cardiac arrest.

C. Intraventricular block

1. Bundle branch block

Delay in the spread of excitation through the ventricle whose bundle is blocked so that QRS interval is prolonged to 0.12 sec or longer. See Table 34 for the causes and diagnosis of right and left bundle branch block.

2. Fascicular block (Hemiblock)

A hemiblock is when one of the two fascicles of the left bundle fails to conduct. Unless there is associated RBBB, total duration of QRS complex is not grossly prolonged.

Table 33: Indication for pacemaker in acquired AV block

1. Third-degree or high grade AV block at any anatomic level associated with—
(a) Symptomatic bradycardia
(b) Essential drug therapy that produces symptomatic bradycardia
(c) Periods of a systole >3 s or any escape rate <40 beats/min while awake, or an escape rhythm originating below the AV node
(d) Postoperative AV block not expected to resolve
(e) Catheter ablation of the AV junction
(f) Neuromuscular diseases such as myotonic dystrophy, Kearns-Sayre syndrome, Erb dystrophy and peroneal muscular atrophy, regardless of the presence of symptoms
2. Second-degree AV block with symptomatic bradycardia
3. Type II second-degree AV block with a wide QRS complex with or without symptoms
4. Exercise induced second or third-degree AV block in the absence of ischemia

Table 34: Causes and diagnosis of bundle branch block

RBBB	LBBB
<i>Causes</i>	
Physiological	IHD
IHD	Hypertension
Cong. heart dis. e.g. ASD	Aortic valve disease Cardiomyopathy
RV hypertrophy or strain e.g. pulmonary embolism	
<i>Diagnosis</i>	
Wide splitting of S ₂	Reversed splitting of S ₂
ECG: Wide QRS, S wave in lead I, R in V ₁ (Fig. 39)	ECG: Broad and slurred QRS complexes, qs wave in V ₁ (Fig. 40)

Fig. 39: 12-lead ECG showing right bundle branch block (RBBB)

Fig. 40: 12-lead ECG showing left bundle branch block (LBBB)

Left anterior fascicular block - is associated with left axis deviation $>-30^\circ$ (predominantly negative deflections in leads II, III).

Posterior fascicular block - is associated with gross right axis deviation (predominantly negative lead I and positive lead III).

Bifascicular block - Failure of conduction in two of the divisions causes RBBB with LAD, or complete LBBB.

Trifascicular block - Block in all three fascicles would result in complete heart block.

Indications for pacemaker implantation in chronic bifascicular and trifascicular block:

1. Intermittent third-degree AV block
2. Type II second-degree AV block
3. Alternating bundle branch block

4. CARDIAC MURMURS

CLASSIFICATION

- I. Innocent - Associated with no known abnormality either structural or physiological.
 - II. Physiological - Murmurs caused by disturbance in the physiology of the circulation, e.g. those related to hyperkinetic state or overactive circulation - excitement, anaemia, fever, thyrotoxicosis, pregnancy, cor pulmonale, portal hypertension and beriberi heart disease.
 - III. Relative or functional - Murmurs caused by structural disorders not involving valves or abnormal cardiac or vascular communications - murmurs caused by dilatation of heart chambers or dilatation of vessels.
 - IV. Organic - Murmurs caused by valvular disease, shunts or narrowed vessels.
- (b) *Pectus excavatum* - Many of these patients will have an innocent systolic murmur due to slight distortion of underlying structures by the deformity.
 - (c) *Straight back syndrome* - The normal anterior concavity of vertebral column in upper dorsal region is absent. This reduces the anteroposterior diameter of the thorax, and so the heart is compressed between the spine posteriorly and sternum anteriorly. Distortion of the outflow tract and great vessels leads to production of a systolic murmur in pulmonary area.
 - (d) *Pulmonary systolic murmur* - Soft systolic murmur best heard in second left intercostal space close to the sternum. It becomes louder with tachycardia and hyperkinetic states, and may disappear on inspiration.
 - (e) *Cardio-respiratory murmur* - May be produced by compression of lung segment by the left ventricle. Heard best at apex. Changes in posture and respiration produce changes in intensity and character of murmur.
 - (f) *Isolated carotid bruit* - is louder in supraclavicular fossa and over the carotids than in the aortic area; it may be associated with a faint thrill that is often abolished by head movement.

- II. **Physiological systolic murmurs** - Associated with hyperkinetic or high output states such as exercise, fever, pregnancy. Ejection systolic murmur best heard in the pulmonary area and along the left sternal border. Ejection sound may be heard. Loud first sound. Wide pulse pressure. Venous hum and S_3 often heard.

III. Functional systolic murmurs

(a) *Ejection systolic*

1. *Aortic or pulmonary ejection flow murmur* - Causes - (i) Increased volumes due to shunt flows, e.g. ASD, VSD, PDA. (ii) Increased stroke volumes due to regurgitant leaks such as aortic and pulmonary regurgitation. (iii) Increased cardiac outputs (innocent murmur) as in thyrotoxicosis, anaemia, exercise, pregnancy, and systemic arteriovenous fistulae. (iv) Increased stroke volume due to marked bradycardia as in complete AV block. (v) A narrow anteroposterior chest diameter (straight back syndrome). The loss of thoracic kyphosis in this condition produces a pulmonary ejection murmur.
2. *Aortic ejection murmur in the elderly* - About 50% over age of 50 have audible aortic ejection murmur without valve stenosis. May be due to fibrous aortic valves which do not fully open, or calcific spurs which protrude into the aortic stream when calcium is laid down at the roots of the cusps, or turbulence in the ascending aorta due to atherosclerotic plaque.

SYSTOLIC MURMURS

- I. **Innocent systolic murmurs**
 - Soft. Never more than grade 2-3
 - Short
 - Heard over limited area of precordium.
 - Increase in volume with tachycardia, and decrease or disappear when heart rate slows.
 - Vary with respiration, either increasing or decreasing in volume with inspiration.
 - Always systolic in time (except venous hum) but never diastolic.
 - Vary with posture and may disappear completely on valsalva manoeuvre.
 - Chest radiograph and ECG are normal.

Types

- (a) *Vibratory murmurs* - Short, early systolic murmur, best heard down left sternal edge and sometimes towards apex. Of musical or twanging quality, it is best heard with child lying down, is less loud in erect posture and disappears when he extends his neck and arches his back.

Table 35: Differences between organic and functional MR

	Organic MR	Functional MR
<i>Murmur</i>		
Intensity	Harsh and loud	Soft and blowing
Duration	Pansystolic	Of short duration. Often late systolic
Radiation	To left axilla or to aortic area	Little radiation Murmur may vary in intensity with change of position
<i>Sounds</i>	1st sound obscured by murmur. 3rd heart sound may be heard. P ₂ may be accentuated	1st sound normal. 3rd heart sound not heard. Mid or late systolic clicks common
<i>Thrill</i>	Systolic thrill with very loud murmurs	No thrill
<i>Cause</i>	Rheumatic fever	LV enlargement due to hypertension, myocardial infarction, etc.
<i>Associated MS</i>	Often present	No
<i>Persistence of murmur</i>	Murmur does not disappear with treatment	Murmur may disappear with improvement of circulatory status

- Ejection murmur due to flow into a relatively dilated chamber* – (i) Idiopathic or secondary dilatation of pulmonary artery. (ii) Dilatation of ascending aorta as in aneurysm or pulmonary atresia.

(b) **Pansystolic**

- Mitral regurgitation* – Due to left ventricular dilatation from any cause – hypertension, ischaemia, aortic valve disease.
- Tricuspid regurgitation* – Any condition giving rise to RV dilatation or failure e.g. pulmonary hypertension, high output states, pulmonary stenosis, atrial fibrillation.

IV. **Organic systolic murmurs**

(a) **Mid systolic**

- Aortic stenosis* – Ejection systolic murmur. Loud, harsh, best heard in second right interspace. Aortic second sound diminished or absent. Systolic thrill in aortic area. Anacrotic pulse.
- Pulmonary stenosis* – Loud, harsh, ejection systolic murmur in pulmonary area. P₂ soft and delayed or absent. Systolic thrill in pulmonary area.
- Fallot's tetralogy* – The murmur is due to pulmonary stenosis. The right ventricle has two exits so that more severe the stenosis, less the pulmonary flow and shorter the murmur.
- Atrial septal defect* – Systolic murmur heard over second and third left interspace. The murmur is due to increased flow of blood across the pulmonary valve and not to the shunt through the septal defect. Wide and fixed split of 2nd sound. Systolic thrill sometimes.
- Bicuspid aortic valve* – A soft mid-systolic murmur in aortic area preceded by an ejection click at the

apex indicates bicuspid valve without significant obstruction.

(b) **Pansystolic**

- Mitral regurgitation* – Loud blowing pansystolic murmur best heard at apex. Radiates to axilla and posteriorly. 1st sound normal or soft. A 3rd sound may be heard in severe cases, and a systolic thrill may be felt (Table 35).
- Tricuspid regurgitation* – Pansystolic, harsh blowing murmur loudest in tricuspid area. Murmur increases in intensity during inspiration. May be accompanied by palpable thrill.
- Ventricular septal defect* – Murmur depends on size of defect. With mild to moderate defect pansystolic murmur best heard in third or fourth left interspace. Systolic thrill.
- Persistent ductus arteriosus* – (i) In infants and young children, where the systemic blood pressure is relatively low only a systolic murmur is heard in the pulmonary area. (ii) With the gradual development of pulmonary hypertension, the typical continuous murmur may be replaced by a systolic murmur only.

(c) **Late systolic**

- Coarctation of aorta* – The following systolic murmurs may be heard – (i) Aortic ejection murmur produced by blood flow across normal aortic valves and often found in hypertension. When valve stenosis is present, the murmur is loud and radiates more widely. (ii) Systolic murmur due to collaterals – Murmur of varying intensity and widely distributed over collaterals both anteriorly and posteriorly. (iii) Systolic murmur due to coarctation over the site of stricture.

2. *Hypertrophic obstructive cardio-myopathy* – Murmur maximal at lower sternal border or apex. Murmur of mitral regurgitation often superimposed. Ejection systolic click never heard. Diastolic murmur of aortic regurgitation never present. Fast rising pulse. Ascending aorta seldom dilated on X-ray.
3. *Mitral valve prolapse* – Billowing or prolapse of one or both leaflets into left atrium during systole. Late systolic murmur, often musical and often associated with single or multiple clicks. On standing the click and murmur may become earlier, and in some patients a curious whoop or honking noise may be heard in systole. When the posterior leaflet is ballooning, the main stream of turbulence is anterior towards the left sternal edge and into the carotids (as in AS). When the anterior cusp is ballooning, the murmur is often radiated round to the thoracic spine.
4. *Disease of the mitral chordae* – An abnormal mitral valve with elongated chordae may become incompetent during the course of systole. There is usually a mid-systolic click initiating the murmur which runs up to the second sound. A similar situation may occur in case of papillary muscle dysfunction following myocardial infarction.
5. *Pulmonary arterial stenosis* – In case of severe PS, the pulmonary systolic murmur is loud with its peak in late systole. It is accompanied by a systolic thrill and an early or absent ejection click and the murmur does not increase in intensity on expiration.

(d) **Early systolic** – Early systolic murmur at lower left sternal border always represents a closed or virtually closed VSD, acute MR, TR with normal pulmonary artery pressure.

DIASTOLIC MURMURS

Functional diastolic murmurs

1. *Mitral* – Due to increased flow across mitral valve – (i) Left-to-right shunts (VSD, PDA), gross mitral incompetence, hyper-kinetic state, e.g. thyrotoxicosis. Shorter than murmur of organic MS, no presystolic component and usually starts with S₃. (ii) Austin Flint murmur.
2. *Tricuspid* – (i) Due to increased flow across tricuspid valve – ASD, partial or total anomalous pulmonary venous drainage, MR, TR, Ebstein's anomaly, severe anaemia, hyperthyroidism, pulmonary hypertension and cor pulmonale. (ii) With gross pulmonary regurgitation (Austin Flint murmur on the right side).

Table 36: Differences between AR and functional PR

<i>Aortic regurgitation murmur</i>	<i>Graham Steell murmur</i>
1. Other evidences of rheumatic heart disease	1. Evidence of pulmonary hypertension
2. Systolic murmur of aortic stenosis heard	2. No systolic murmur of AS
3. Wide transmission of murmur	3. Murmur not widely transmitted
4. Murmur may be louder during expiration	4. Murmur louder during inspiration
5. P ₂ not loud	5. P ₂ loud
6. Peripheral signs of aortic regurgitation	6. No peripheral signs
7. CXR — pulmonary artery normal	7. Large pulmonary artery

3. *Pulmonary* – Graham Steell murmur due to pulmonary hypertension, e.g. in MS (Table 36).

Organic diastolic murmurs

(a) **Early:** Regurgitation across semilunar valves

1. *Aortic regurgitation* – Soft or loud early diastolic murmur. High pitched and blowing, best heard along left sternal border. Associated soft ejection systolic murmur. In AR, the loudness is as much due to anatomy of the aortic valve as the degree of regurgitation. Calcified or rheumatic valves usually produce loud murmurs, while aortic dilatation produces soft murmurs.
2. *Pulmonary regurgitation* – Uncommon condition. Character same as AR murmur. Site of maximum intensity in pulmonary area and more limited radiation. May result from infective endocarditis or surgery, or idiopathic dilatation of pulmonary artery with dilatation of valve ring.

(b) **Mid or late:** Obstruction at AV valves

1. *Mitral stenosis* – Accentuated and snapping apical first sound. Low pitched, rumbling diastolic murmur with presystolic accentuation in the established case. Murmur localized to the apex. Opening snap of the mitral valve.
2. *Tricuspid stenosis* – Mid-diastolic murmur with presystolic accentuation, loudest at lower sternal edge. Murmur tends to be accentuated during inspiration. No presystolic crescendo. Opening snap.
3. *Carey Coombs murmur* – Soft low pitched mid-diastolic apical murmur due to active rheumatic valvulitis. Murmur usually disappears after acute attack.

4. *Myxoma of left atrium* – Murmur variable from time to time. Delayed mitral valve closure gives rise to split 1st sound, early systolic murmur, late diastolic sound (tumour click) and a short mid-diastolic murmur.
- (c) **Late:** Austin Flint murmur of AR, presystolic accentuation of MS.

CONTINUOUS MURMURS

- Shunt between blood vessel of cardiac chamber of high pressure to one of low pressure:**
 - Intracardiac* – Rupture of sinus of valsalva to right atrium, right ventricle or rarely pulmonary artery. The continuous murmur is heard maximally at lower left sternal border and has a diastolic accentuation.
 - Extracardiac* – PDA, aortopulmonary septal defect, pulmonary AV fistula, coronary AV fistula. Blalock-Taussig shunt.
- Blood flow across severely narrowed vessel** – Coarctation of aorta, aortic arch arteritis, pulmonary arterial stenosis, pulmonary atresia, Fallot's tetralogy.
- Increased velocity of blood flow through normal dilated vessels.**

Physiological (Innocent continuous murmurs)

See Table 37.

5. CONGENITAL HEART DISEASE

AETIOLOGY

- Sex—*Females:* ASD, PDA, more common. *Males:* Coarctation, transposition of great vessels, aortic arch disease.
 - Causes of congenital heart disease
- See Table 38 for the causes of congenital heart disease.

CLASSIFICATION

- Without intracardiac shunt (Acyanotic)**

Dextrocardia – The heart lies within the right thorax.

Types:

 - Isolated dextrocardia* – due to incomplete rotation of the heart around its long axis. The left chambers lie to the left and anteriorly, the right chambers to the right and posteriorly.
 - True dextrocardia* – with mirror-like transposition of the heart. There is a similar mirror-type transposition of the other viscera (situs inversus). Usually no other congenital cardiovascular

Table 37: Physiological continuous murmurs

Venous hum
<ul style="list-style-type: none"> Soft blowing murmur that starts in systole and continues through second sound into diastole. Heard in some children at the root of the neck or just below the clavicle on either side but more commonly on the right. Can be abolished by pressure on the jugular vein or by making the patient lie down flat. Increases in inspiration when the venous return to the heart is increased. Differs from murmur of PDA in lacking any machinery quality.
Mammary souffle
<ul style="list-style-type: none"> Continuous high pitched murmur with diastolic accentuation may be heard in last trimester of pregnancy and for 4–6 weeks in the post-partum period. Usual site along left sternal border Firm pressure with the stethoscope or with the finger lateral to the stethoscope, where the murmur is heard, gently obliterates it. May disappear when patient sits up.
Pathological
<ul style="list-style-type: none"> Bronchial collateral circulation with severe obstruction to pulmonary artery flow. An A-V fistula, either pulmonary artery to pulmonary vein or internal mammary to adjacent vein. Large subcostal collaterals in coarctation of aorta.

defects. Mirror-image X-ray picture. ECG – Mirror image of normal pattern.

Obstructive lesions

Coarctation of aorta. Discrete narrowing of aortic arch just below the ductus (post-ductal in 90%) or just above the ductus (pre-ductal—more severe) due to deformity of the wall.

History – Presentation with severe heart failure in second week of life (pre-ductal type) related to constriction of ductus arteriosus.

Symptoms – With mild degree of aortic obstruction no symptoms or symptoms due to complications.

SIGNS

- Murmurs:**
 - Systolic –
 - Aortic from dilatation of aorta
 - Of coarctation between scapulae
 - Over collaterals
 - Of AS

Table 38: Causes of congenital heart disease

Cause	Defect
<i>Maternal</i>	Patent ductus
<i>rubella</i>	ASD PS
<i>Drugs</i>	
Alcohol	VSD
Lithium	Tricuspid atresia Ebstein's anomaly
<i>Genetic</i>	
<i>Single gene defects</i>	
Noonan's syn.	Hypertrophic cardiomyopathy Pulmonary stenosis ASD
Marfan's syn.	Aortic root dilatation (and potentially aortic dissection) Mitral valve prolapse
Holt-Oram syn.	ASD VSD (occasional)
<i>Chromosomal defects</i>	
Down's syn.	ASD VSD Fallot's tetralogy Patent ductus
Edward's syn.	VSD
Patau's syn.	ASD, PDA (occasional)
Turner's syn.	Coarctation Bicuspid aortic valve Pulmonary stenosis
<i>Lesions associated with 22q11 deletions</i>	Truncus arteriosus Interrupted aortic arch Fallot's tetralogy Pulmonary atresia with VSD VSD Absent pulmonary valve syn. Anomalous origin of pulmonary artery Right aortic arch Coarctation Vascular ring

Diastolic –

Of AR

Mid-diastolic murmur at apex (due to thickening of mitral valve)

Continuous-over collaterals.

- Evidence of compensatory collateral circulation* – Dilated and tortuous internal mammary, intercostal and scapular arteries (Suzman's sign).

Fig. 41: Coarctation of aorta. Arrows point to sites of notching on the undersurface of the posterior ribs

- BP* – moderately high, and much less in lower extremities compared to upper.
- Weak femoral pulsations and radio-femoral delay.*
- Signs of LV hypertrophy.*
- Carotid 'swell'* – Excessive carotid and subclavian pulsation and suprasternal pulsation.
- 'Corkscrew' retinal vessels.*

INVESTIGATIONS

Chest radiograph

- Small or absent aortic knob.
- Figure 3 configuration of aortic shadow formed from above down by pre-stenotic dilatation, coarctation itself and post-stenotic dilatation (Figs. 41 and 42). Reverse or inverted 3 sign on barium swallow produced by the same mechanism.
- Dock's sign – Notching of ribs due to pressure of dilated intercostal arteries. Notching is bilateral in juxta-ductal type of coarctation.

ECG – LV hypertrophy develops progressively with age.

Echo – Interruption of aortic arch distal to left carotid, left subclavian or left innominate (most common to least common) and post-stenotic dilatation of aorta (Fig. 43).

Cardiac catheterization – Significant systolic pressure difference across coarctation. Angiography will demonstrate site and length of coarctation.

Fig. 42: Aortogram of a child, a case of coarctation of the aorta, distal to the left subclavian artery (LS). AP view with arrows pointing to the well-developed collateral circulation

Fig. 43: Echocardiography showing coarctation of aorta (arrow)

MRI and IV DSA – can demonstrate area of coarctation and collaterals.

Associated Anomalies:

1. Bicuspid aortic valve; AR may result
2. Persistent ductus arteriosus
3. Ventricular septal defect
4. Marfan's syndrome, Noonan's syndrome
5. Anomalous origin of subclavian artery
6. Floppy mitral valve
7. Congenital cerebral berry aneurysms

Complications:

1. Aortic rupture with or without dissection
2. Infective endocarditis.
3. Heart failure in presence of fibroelastosis at birth.

Aortic stenosis: Occurs at subvalvar, valvar or supra-valvar level. Supra-valvar AS is associated with William's syndrome. Turner's syndrome is associated with AS and coarctation.

(For Clinical features and Diagnosis, see Valvular heart disease).

Pulmonary stenosis:

History: Mostly asymptomatic in childhood. If severe stenosis, right heart failure.

Signs: Depend on degree of stenosis –

- *Systolic thrill* in pulmonary area.
- *Systolic murmur* over 2nd and 3rd left intercostal space. Murmur is louder and longer the more severe the stenosis.

Fig. 44: Chest X-ray of a patient with severe pulmonary stenosis showing post-stenotic dilatation of pulmonary trunk and left pulmonary artery

- *Systolic ejection click* (not in severe stenosis).
- Both A_2 and P_2 heard in mild cases, P_2 diminishes as the stenosis becomes more severe.
- 'a' wave seen in the neck.
- Right ventricular heave.
- Right atrial presystolic gallop in severe cases.
- Moon-shaped face and peripheral cyanosis with severe stenosis.

INVESTIGATIONS

Chest radiograph (Fig. 44)

Fig. 45: 2D echo Doppler in severe pulmonary stenosis

Fig. 46: Echocardiography in severe pulmonary stenosis

- Enlargement of RA and RV
- Post-stenotic dilatation of pulmonary artery.
- Oligaemic lung fields.

ECG - RV preponderance with P pulmonale.

Echo - Pulmonary valve thickening. Turbulent mosaic flow on colour flow mapping and gradient estimation across the thickened valve is best accomplished by continuous wave Doppler interrogation (Figs. 45 and 46).

Cardiac catheterization - Elevated RV systolic pressure with low pressure in pulmonary artery.

ASSOCIATIONS

- Rubella syndrome - Valvar and peripheral pulmonary artery stenosis.
- Pulmonary valve abnormalities may be associated with
 - Noonan's syndrome: Dysplastic valves.
 - Williams' syndrome: Supralvalvar PS with supralvalvar AS.

COMPLICATIONS

- Atrial fibrillation
- Infective endocarditis

LEFT-TO-RIGHT SHUNTS (ACYANOTIC)

ATRIAL SEPTAL DEFECT

Opening in interatrial septum due to deficiency in septal tissue.

Types of defects in order of frequency:

Secundum type: In central portion of septum.

Primum defect: Immediately above AV valves and often associated with CLEFT in anterior mitral valve leaflet. More common in females.

Sinus venosus type: Near orifice of SVC often associated with anomalous pulmonary venous drainage.

History: Asymptomatic in children. Symptoms of fatigue and dyspnoea may occur in adults.

Signs

- Visible and palpable RV.
- 1st sound often accentuated and split with loud tricuspid component. May be preceded by loud atrial systolic murmur.
- Wide fixed splitting of S_2 - Wide because of delay in RV ejection, increased stroke volume and RBBB. Fixed because the septal defect equalises the right and left atrial pressures throughout the respiratory cycle.
- Systolic thrill if loud murmur.
- Ejection click.
- Murmurs -
 - Pulmonary ejection systolic murmur due to increased pulmonary flow. Variable in intensity and accentuated by inspiration.
 - Tricuspid flow murmur - Mid-diastolic murmur near left sternal edge louder on inspiration.
 - Graham Steell murmur of pulmonary regurgitation if pulmonary hypertension.
 - Late systolic murmur (mitral valve prolapse associated with secundum ASD)
 - Murmur of mitral incompetence (with primum defect).

- Mitral stenosis murmur (Lutembacher's syndrome)
- Murmur of tricuspid incompetence-Pulmonary hypertension, primum defect, Ebstein's anomaly (with secundum defect).
- Small peripheral pulse - because of reduced LV output.
- Atrial fibrillation or flutter may precipitate heart failure.

Investigations

Chest radiograph (Fig. 47):

- Dilation of trunk of pulmonary artery and its larger branches.
- Absence of LA enlargement.
- Hilar dance on fluoroscopy.

ECG: Incomplete RBBB.

Echo: Drop-out in area of interatrial septum. Doppler colour flow imaging defines atrial septal defect flow as well as other intracardiac shunts (Figs. 48 to 53).

Catheterization: High saturation in RA. RV and pulmonary artery because of blood flow from left to right.

Associated Lesions

1. Lutembacher's syndrome - Associated MS.
2. Pulmonary stenosis.
3. Anomalous pulmonary venous drainage.
4. Holt-Oram syndrome - Skeletal deformities of forearm.

Complications

1. Pulmonary hypertension.
2. Reversal of shunt (Eisenmenger's syndrome).
3. Infective endocarditis - rare except with ostium primum defect or PS.

VENTRICULAR SEPTAL DEFECT

Opening in ventricular septum that permits communication between the two ventricles.

History: Infants with large defects develop heart failure. In about 70% of cases defects are small, and in about 60% these close spontaneously, and many more become so small that they are clinically insignificant.

Signs

Small defects - (Maladie de Roger) - Loud pansystolic murmur and thrill maximum in fourth left intercostal space.

Fig. 47: Atrial septal defect. Cardiac enlargement mainly of RV, prominent pulmonary outflow tract and large main pulmonary arteries and lobar arteries

Fig. 48: 2D echo apical four-chamber view showing a large ostium secundum ASD

Fig. 49: 2D echo showing a large ostium secundum ASD. Blue colour is the TR jet. Red-flow across ASD

Fig. 50: ASD before closure (arrow)

Fig. 51: ASD before closure showing flow across ASD

Fig. 52: ASD immediate after closure (arrow)

Fig. 53: ASD after closure showing cessation of flow

S_2 normal and widely split due to delay in onset of RV systole.

Medium and Large Defects

- Pansystolic murmur at left sternal edge, less loud than murmur of small defect, due to flow from high pressure LV to low pressure RV during systole.
 - A large defect may produce a soft murmur particularly if pressure in RV is elevated. This may be immediately after birth while pulmonary vascular resistance remains high, or when the shunt is reversed.
- Mitral diastolic flow murmur.
- P_2 accentuated and Graham Steell murmur if pulmonary hypertension.

- Hyperkinetic LV thrust and left parasternal heave if large shunt.
- Loud S₃ because of rapid LV filling.

INVESTIGATIONS

- *X-ray*: Normal if small defect, cardiomegaly and pulmonary plethora if large defect (Fig. 54).
- *ECG*: Normal if small defect. With large defect biventricular and RA hypertrophy.
- *Echo*: Imaging of defect and shunt pattern across it by colour flow mapping (Figs. 55 to 57).

Fig. 54: X-ray of a chest of ventricular septal defect with moderate shunt, increase of pulmonary blood flow

ASSOCIATED LESIONS

- Aortic regurgitation.
- Complete heart block.
- Subacute infective endocarditis.
- Eisenmenger's complex.

PERSISTENT DUCTUS ARTERIOSUS

Patency of the foetal vessel that connects aorta and pulmonary artery.

History

Patency of ductus is common in preterm infants, and spontaneous closure usually occurs. If ductus is small, and pulmonary pressure normal, survival, without symptoms, into adult life is possible.

Signs

- Gibson murmur - Continuous murmur loudest towards end of systole and early diastole (machinery or train in tunnel murmur), accentuated during expiration. With development of pulmonary hypertension, first the diastolic murmur disappears because of equalization of diastolic pressures in pulmonary artery and aorta, then the systolic murmur shortens until only a short ejection murmur persists. If the shunt becomes reversed the murmur disappears.
- Continuous thrill in pulmonary area.
- P₂ accentuated.

Fig. 55: 2D echo showing ventricular septal defect (arrow)

Fig. 56: 2D echo showing a VSD (arrow) in the high muscular septum

Fig. 57: Echo Doppler showing flow across ventricular septal defect

Fig. 58: Two-dimensional echocardiography in high parasternal view (ductal view) with color flow mapping showing patent ductus arteriosus (PDA; arrow) with left-to-right shunt. (AO: Aorta; DAO: Descending thoracic aorta; LPA: Left pulmonary artery; PDA: Patent ductus arteriosus)

- Single second sound or even reversed splitting if ductus is large because of prolonged LV systole from volume overload of LV.
- Mid-diastolic mitral flow murmur.
- Aortic ejection systolic murmur not uncommon but often masked by the continuous murmur.
- Collapsing pulse if large shunt.
- Pulsations in suprasternal notch.
- Low diastolic pressure. Exercise causes transient drop in diastolic pressure (Bohn's sign).
- LV type of cardiac impulse.
- Differential cyanosis - Upper part of body including arms less cyanosed than lower part of body if duct distal

to left subclavian artery. Right hand less cyanosed than the left hand and feet if proximal.

Investigations

X-ray - Pulmonary plethora proportional to degree of left-to-right shunt, LV enlarged and aortic knuckle prominent.

ECG - LV hypertrophy of volume overload type. PR interval may be slightly prolonged. Occasionally bifid P waves from LA hypertrophy.

Echo - Ductus can be imaged running from junction of main and left pulmonary arteries to inner curvature of aorta. Doppler colour flow mapping shows classic diastolic flow from ductus into main pulmonary artery (Figs. 58 and 59).

Cardiac catheterization: Pressure in pulmonary artery somewhat elevated. RA and RV saturations normal, but pulmonary saturation high because oxygenated blood flows from aorta to pulmonary artery (Figs. 60 and 61).

Associated Malformations

- Coarctation of aorta
- Ventricular septal defect
- Aortic stenosis
- Endocardial fibroelastosis
- Atrial septal defect

Complications

- Subacute infective endocarditis.
- Pulmonary hypertension with reversal of shunt.
- Congestive heart failure.

Fig. 59: 2D echo showing patent ductus arteriosus (PDA) (arrow) and flow across it

Fig. 60: Large PDA angiography: Amplatzer duct occluder

Fig. 61: Large PDA: Amplatzer duct occluder

III. RIGHT-TO-LEFT SHUNT (CYANOTIC)

A. COMMUNICATION BETWEEN THE TWO SIDES OF THE HEART AND GREAT VESSELS

See Tables 39 and 40 for the causes and differential diagnosis of right-to-left shunt.

Eisenmenger's syndrome: Consists of a large communication between the two sides of the heart, pulmonary arterial hypertension at systemic level, and pulmonary obstructive vascular disease that increases pulmonary vascular resistance to a level that reverses the shunt and gives rise to cyanosis.

Table 39: Causes of right-to-left shunt*Common defect:*

- Atrial septal defect
- Ventricular septal defect
- Persistent ductus arteriosus (Eisenmenger's disease)

Uncommon defect

- Aortopulmonary septal defect
- Persistent truncus arteriosus
- Transposition of great vessels or
- Corrected transposition with VSD
- Single ventricle
- Single atrium
- Total pulmonary venous drainage into right heart

History

Age at which cyanosis and symptoms appear vary according to the underlying cardiac disorder – exertional fatigue, dyspnoea, syncope, arrhythmias, haemoptysis and anginal pain as the disease progresses.

Signs

1. Central cyanosis. Differential cyanosis in case of PDA.
2. Palpable lift over hypertrophied RV and dilated pulmonary artery.
3. Pulmonary ejection murmur, soft and commonly followed by ejection click.
4. Graham-Steell murmur of pulmonary regurgitation.
5. Pansystolic murmur of tricuspid regurgitation if RV failure.
6. Raised JVP with prominent 'a' wave.
7. Small pulse volume.

Chest radiograph: Gross dilatation of pulmonary arteries with diminished peripheral markings (Fig. 62).

ECG: RV hypertrophy and P pulmonale.

Echo: Imaging of underlying cardiac defect.

Cardiac catheterization: Rise of pulmonary artery and RV pressure to systemic levels. Shunt is predominantly right-to-left. Blood returning from lungs to LA is fully saturated but in LV saturated blood is mixed with unsaturated blood from RV.

MALFORMATION OF RIGHT-SIDED VALVES

TETRALOGY OF FALLOT

Most common cause of congenital cardiac cyanosis in adults.

Table 40: Differential diagnosis of lesions responsible for Eisenmenger's syndrome

	VSD	PDA	ASD
<i>Symptoms</i>			
Dyspnoea and syncope	Common	Rare	Uncommon
<i>Signs</i>			
Cyanosis, clubbing	Usually from infancy	Differential cyanosis	Usually in adult life
<i>Prominent</i>			
'a' waves	Rare	Very rare	Common
RV lift	+	+	+++
LV lift	+ –	+ –	None
2nd sound	Single	Close split	Wide fixed split
<i>ECG</i>			
	RVH, LVH	RVH, LVH	RVH, RBBB
	P pulmonale		P pulmonale
<i>Radiology</i>			
RA	–	–	++
Pul. artery	+	+	+++

Fig. 62: Eisenmenger ductus arteriosus showing typical dilatation of pulmonary trunk out of proportion to size of hilar arteries

Combination of:

1. High large ventricular septal defect
2. Overriding aorta
3. Right ventricular hypertrophy
4. Pulmonary stenosis

History

Some infants are cyanosed at birth and most by 6 months of age. In some cyanosis may be delayed until adolescence or even adulthood as the right ventricular outflow obstruction becomes progressively severe. Some children become

cyanosed only as they become more active. These children are particularly prone to *hypoxic spells* characterised by crying, rapid deep breathing, initial deepening of cyanosis followed by pallor, limpness or convulsions and loss of consciousness. They are caused by infundibular shut down, preventing blood getting into lungs.

Squatting - Older children may suddenly squat down during exercise. This has the effect of compressing the femoral arteries and thus increasing systemic resistance thus decreasing the right to left shunt. Dyspnoea may also be relieved in this manner by pressure on IVC trapping the venous return to the lungs and reducing the amount of acid metabolites reaching the brain.

Signs

- Clubbing of fingers and toes.
- Ejection systolic murmur maximum in pulmonary area but heard all over the precordium. The murmur may diminish with increasing cyanosis since the pulmonary outflow is very narrow.
- Ejection click due to dilated aortic root may be heard.
- Single 2nd sound. A_2 being audible because the root of aorta is uncovered, P_2 usually absent.
- Continuous murmur if extensive bronchopulmonary anastomosis.
- Absent arm pulses on side of thoracotomy if previous Blalock shunt.

Chest radiograph (Fig. 63):

- RV hypertrophy
- Deep pulmonary bay due to hypoplastic pulmonary artery.

Coeur en sabot (like a wooden shoe) appearance of heart due to lifting of apex of the heart above the diaphragm from RV hypertrophy (seen in 10% of cases).

Pulmonary oligoemia.

Right aortic arch (may be seen).

ECG: RV preponderance. Rarely P pulmonale.

Echo: Visualization of VSD with override of aorta over interventricular septum and visualization of RV outflow tract and infundibular stenosis. Colour flow mapping determines relationship of bidirectional shunting across the VSD and timing of the flows in accordance with the cardiac cycle (Figs. 64 and 65).

Fig. 63: Fallot's tetralogy. The pulmonary artery is hypoplastic. The lung fields are ischaemic. The apex of the heart is tilted upwards (*coeur en sabot*)

Fig. 64: 2D echo in tetralogy of Fallot (TOF)

Fig. 65: 2D echo Doppler in tetralogy of Fallot (TOF)

Fig. 66: Angiography in tetralogy of Fallot (TOF)

Fig. 67: TOF infundibular pulmonary stenosis

Fig. 68: TOF showing subaortic VSD

Cardiac catheterization: Reduced oxygen saturation in LV. Pressure in pulmonary artery low and in RV greatly elevated (Fig. 66).

MRI (Figs. 67 and 68)

Complications

- Syncope
- Cerebral abscess (paradoxical embolism)
- Stroke due to cerebral thrombosis
- Subacute infective endocarditis
- Sudden death

Table 41 gives differences between Fallot's tetralogy and Eisenmenger's syndrome.

Acyanotic Fallot – The extent of the shunt depends on the degree of obstruction at the outflow tract of RV or at

Table 41: Differences between Fallot's tetralogy and Eisenmenger's syndrome

	<i>Fallot's tetralogy</i>	<i>Eisenmenger's</i>
Cyanosis	At birth	After first few years
P ₂	Soft	Loud
Pul. diastolic murmur	No	May be heard
Radiology	Oligaemic lungs. Good pul. bay	Pul. bay filled due to dilatation of pul. artery

the pulmonary valve. With only slight obstruction there is a bidirectional shunt with no cyanosis. Moon face is common. X-ray shows post-stenotic dilatation of pulmonary artery.

Trilogy of Fallot – PS with reversed interatrial shunt (Table 42).

TRICUSPID ATRESIA

Commonest lesion of clinical importance where central cyanosis is associated with left ventricular hypertrophy. Clubbing is marked.

EBSTEIN'S MALFORMATION OF TRICUSPID VALVE

Blowing systolic murmur secondary to tricuspid regurgitation. Early diastolic murmur over lower precordium is common. ECG – Right atrial enlargement and RBBB. X-ray – Diminished pulmonary vascularity. Enlargement of heart with box-like configuration (Fig. 69).

Table 42: Differences between tetralogy and trilogly of Fallot's

	<i>Tetralogy of Fallot</i>	<i>Trilogy of Fallot</i>
Onset of cyanosis	At birth or within a year	After few years
Squatting	Common	Rare
Facies	Not typical	Often moon face
'a' waves	Small or none	Usually large
RV heave	Absent	Present
Systolic murmur	Rarely loud	Loud with thrill
X-ray chest	Oligaemic lung fields Good pulmonary bay Right-sided aortic arch (25% cases) RV hypertrophy not marked	Oligaemic lung fields but no pulmonary bay No right sided aortic arch RV hypertrophy ++
ECG	No RBBB	RBBB may be present
Echo	Small P pulmonale	Large P pulmonale
Catheterization	Shunt across VSD Marked reduction of oxygen saturation in LV No giant 'a' waves Stenosis more often infundibular	Shunt across ASD Slight to moderate fall in oxygen saturation Giant 'a' waves Stenosis more often valvar

SEVERE PULMONARY STENOSIS WITH INTACT VENTRICULAR SEPTUM

Systolic thrill with loud harsh ejection systolic murmur in second left interspace with delayed P_2 which is diminished in intensity. ECG - RVH with strain pattern. X-ray - Post-stenotic dilatation of pulmonary artery.

MALFORMATION OF GREAT VESSEL ORIGIN

TRANSPOSITION OF GREAT ARTERIES (TGA)

The aorta arises from RV and pulmonary artery relatively posteriorly from LV. Postnatal survival depends on compensating anomalies (ASD, VSD or PDA) permitting admixture of oxygenated blood into systemic circulation. Cyanosis appears early and becomes progressively more severe. Harsh systolic murmur heard at left sternal border. ECG - RVH and strain.

X-ray - Ovoid or egg-shaped cardiac contour (Fig. 70).

Fig. 69: Ebstein's anomaly. Note the long smooth convexity of the right heart border due to RA enlargement and convex left border with flattened apex due to RV enlargement. Oligoemia

Fig. 70: Complete transposition. Typical appearance of a large 'egg on side' heart, narrow vascular pedicle and plethora

TRUNCUS ARTERIOSUS

Here a single large arterial vessel gives rise to the coronary, pulmonary and aortic arch branches. Systolic thrill and murmur over base of heart. Sometimes early basal diastolic murmur. Single 2nd heart sound. X-ray - Gross biventricular enlargement. Absence of pulmonary arc results in concavity between vascular shadow and ventricle. ECG - Biventricular hypertrophy.

TOTAL ANOMALOUS PULMONARY VENOUS DRAINAGE

All blood from the lungs enters RA by one route or another. To enable oxygenated blood to reach systemic circulation, an ASD or patent foramen ovale has to be there.

Fig. 71: Typical figure-of-eight (snowman or cottage-loaf) appearance in a case of total anomalous pulmonary venous drainage. In addition there is marked increase in pulmonary vasculature

Signs – resemble those of VSD except – (a) Presence of slight cyanosis. (b) Continuous murmur may be heard in aortic area in 25% of cases.

X-ray – Left SVC with left innominate vein and right SVC produce characteristic cardiac configuration (figure-of-eight, cottage loaf or snowman appearance) (Fig. 71).

Cardiac catheterization – O₂ content of aorta, pulmonary artery and the four cardiac chambers is the same.

INVESTIGATION OF A CASE OF CONGENITAL HEART DISEASE

Clinical:

(a) General

1. Age – Cyanosis in infancy 2As, 5Ts

- Atresia of aorta
- Atresia of pulmonary artery
- Transposition of great vessels
- Tetralogy of fallot
- Tricuspid atresia
- Total anomalous pulmonary venous drainage
- Truncus arteriosus

If child survives beyond age of 10 years most common lesions are:

- Atrial septal defect
- Persistent ductus arteriosus
- Ventricular septal defect
- Tetralogy of Fallot
- Pulmonary stenosis
- Coarctation of aorta

2. *Rubella syndrome* – may be associated with large PDA or pulmonary valve stenosis.
 3. *Clubbing* – of the digits develops in most patients with cyanotic heart disease, it is seldom present before 6 to 9 months of age.
 4. *Differential cyanosis* – of upper and lower extremities may occur because of abnormal shunting of blood from pulmonary artery to descending aorta through PDA due to increased pulmonary vascular resistance – (i) Relatively blue toes compared to fingers indicates reversal of flow (right-to-left) through ductus (Eisenmenger PDA or interrupted aortic arch). (ii) Pink toes compared to cyanotic fingers suggests some forms of complex transposition of the great arteries (TGA).
 5. *Squatting* – In Fallot's tetralogy.
 6. *Stunted growth* – and poor weight gain if marked central cyanosis or severe cardiac failure from a large right to left shunt such as VSD is present.
 7. *Face* – (a) Moon facies: High coloured facies as in Cushing's syndrome in PS. (b) Broad, high forehead, low ears, hypertelorism, wide pouting mouth and hypoplastic mandible in supra-valvar AS.
 8. *Webbing of neck* – Turner syndrome with coarctation. Noonan or Ullrich syndrome with PS.
 9. *Chest deformities* – Anterior bowing of chest wall is seen in children with large left to right shunts which cause stiff, non-compliant lungs. Presence of Harrison's sulcus in an older child, who is now well, denotes that a large VSD was present in infancy.
 10. *Extremities* – (a) Holt-Oram syndrome: Thumb may resemble a finger (fingerized thumb). Ostium secundum defect is common. (b) Tuft erythema: Red finger tips signify intermittent right to left shunts due to pulmonary hypertension and balanced shunt through ASD. (c) Ellis van Creveld syndrome: Extra finger, often extra toe. (d) Hypoplastic finger nails – ASD, usually ostium primum, or VSD, or single atrium.
- (b) Cardiac
1. *Cardiac impulse* – In presence of LVH, the apex beat is localised and thrusting. RVH produces a more diffuse pulsation felt just to the left of sternum. (i) *RVH* – Pulmonary stenosis, ASD. Cyanotic congenital heart disease always causes RVH, the only exception being tricuspid atresia which causes left ventricular hypertrophy. (ii) *LVH* – Coarctation of aorta, PDA, congenital aortic stenosis, persistent truncus arteriosus, tricuspid atresia and single ventricle. (iii) *Biventricular hypertrophy* – may occur with VSD, ostium primum defect,

pulmonary hypertension developing with PDA, persistent truncus.

2. **2nd heart sound** - In ASD widely split and fixed, in Fallot's tetralogy single and clear. Presence of split S_2 excludes diagnosis of truncus arteriosus. S_2 is loud in pulmonary hypertension and soft in pulmonary stenosis.
3. **Ejection clicks** - Aortic ejection clicks are best heard at the apex and occur with bicuspid valve and aortic valve stenosis, but not with subvalvar stenosis. Pulmonary clicks occur with moderate pulmonary valve stenosis but not in severe stenosis, where there is virtually no movement of the deformed valve.
4. **Murmurs** - (a) **Pansystolic** - In VSD along left sternal border in fourth or fifth space. Pansystolic murmur with other signs of ASD suggests septum primum defect. (b) **Early diastolic** - Pulmonary regurgitation secondary to pulmonary hypertension, aortic regurgitation often in association with coarctation of aorta, or bicuspid aortic valve, medionecrosis of aorta and in association with high ventricular septal defect. (d) **Continuous** - PDA, aortopulmonary septal defect as result of congenitally weak sinus of Valsalva, in cases of coronary arteriovenous fistula, or pulmonary AV fistula. Continuous murmur on either side of sternum can also occur in congenital pulmonary atresia. (e) **No murmur** - in a child with central cyanosis and enlarged heart suggests transposition of great vessels.
5. **Pulse** - (a) **Arterial** - Collapsing pulse in PDA, aortopulmonary defect or the rare aortic regurgitation. Femoral pulse delayed and weak or absent in coarctation. An anacrotic, small volume pulse is classically found in AS. (b) **Venous** - Prominent 'a' waves in neck in pulmonary stenosis and pulmonary hypertension.

Investigations

1. **ECG** - (a) Right axis deviation and RV enlargement in most congenital cardiac lesions in childhood and adult life. (b) Left axis deviation and LV enlargement in tricuspid atresia. (c) Biventricular hypertrophy - often with large VSD. (d) Arrhythmias - (i) WPW syndrome - especially in Ebstein's anomaly. (ii) AV block - common in corrected transposition of great vessels. May occur with VSD. (iii) RBBB in ASD and other complex defects. (iv) Arrhythmias uncommon in cyanotic CHD except in Ebstein's malformation (atrial tachycardia and atrial flutter).
2. **Chest radiograph** - (a) **Plethoric lung fields** - (i) Non-cyanotic - ASD, VSD, PDA. (ii) Cyanotic - Transposition of great vessels, truncus arteriosus, total anomalous pulmonary venous drainage or single atrium, tricuspid atresia with pulmonary stenosis, single ventricle. (b) **Oligaemic lung fields** - PS, Fallot's tetralogy, Ebstein's anomaly. (c) **Conspicuous pulsations of pulmonary arteries** (hilar dance) - ASD, to lesser extent PDA and VSD. (d) **Diminished pulsation of heart** (quiet heart) - Ebstein's anomaly. (e) **Right-sided aortic arch** - common with Fallot's tetralogy, truncus arteriosus. (f) **Dilated main pulmonary artery** in pulmonary valve stenosis or absent in pulmonary atresia. (g) **Typical cardiac silhouettes** - (i) Boot-shaped heart in tetralogy of Fallot. (ii) Egg-on-side appearance in TGA. (iii) Cottage loaf - (figure-of-eight) appearance in total anomalous pulmonary venous drainage. (iv) Box-like configuration in Ebstein's anomaly.
3. **Echocardiography** - By cross-sectional echocardiography (CSE), the inter-atrial and ventricular septa are easily visualised together with the A-V valves and any defect of clinical significance can almost always be seen, e.g. PDA or coarctation. With the ability of CSE to trace the vena cava, pulmonary veins and great arteries to and from their chambers of origin, complex lesions can be diagnosed. Doppler echocardiography can be used in conjunction with CSE to provide information on blood-flow.
4. **Cardiac catheterization** - enables estimation of pressures and saturations and pulmonary vascular resistance.

Indications:

 - (a) Where accurate diagnosis cannot be made.
 - (b) Precise hemodynamic data, including response to drugs is required.
 - (c) Peripheral structures, particularly in the lungs need to be visualised.
 - (d) Therapeutic procedures such as septostomy or balloon dilatation need to be performed.
5. **Angiography** - can be used to define for example the number and site of VSDs.
6. **MRI** - Anatomical evaluation is typically performed using an ECG-triggered SE sequence with multi-level acquisition. For physiological evaluation, ECG-triggered or ECG-reference forms of cine MRI can be used to evaluate a specific level or to survey cardiac chambers for volumetric analysis.

Management

Of Congenital heart Disease:

A. Of symptoms and/or complications

Congestive heart failure – Diuretics, digoxin, vasodilators. Oxygen, humidification, sedatives. Small frequent feeds.

Cyanosis

Inhibition of ductus closure – Cyanosis in early neonatal period is characteristic of transposition of vessels and of defects associated with reduced pulmonary blood flow. Such infants have a ductus arteriosus dependent pulmonary blood flow and deteriorate as the ductus constricts after birth. Ductus closure can be inhibited by IV infusion of Prostaglandin E1 or E2 at a rate of 0.005–0.01 µg/min. If cyanosis is severe rate can be increased initially to 0.05–0.1 µg/kg/min for 15–30 min. to achieve effective dilatation of an already constricted ductus. Side-effects—Pyrexia, hypotension and apnoeic attacks which may require intubation and positive pressure ventilation. If cyanosis not severe – Oral prostaglandin E2 62.5–125 µg/hour may be effective.

Acidosis – may develop in a severely hypoxic infant and may need treatment with sodium bicarbonate.

Polycythemia – can be progressive in presence of severe cyanosis and may predispose to cerebral infarction especially if the child gets dehydrated from vomiting or diarrhoea. In any cyanosed patient, Hb and PCV should be monitored at regular intervals. If PVC rises more than 65%, venesection (not more than 10 mL/kg at a time) or urgent surgery may be necessary. Oral iron if evidence of anaemia.

Hypoxic attacks – The child must be picked up and soothed. If not effective in reducing distress and agitation, Inj. morphine 0.2 mg/kg IM. Nursing the child in knee-chest position may help. Oxygen. To reduce frequency and severity of hypoxic attacks – Propranolol 0.5–12 mg/kg q8h by mouth as temporary measure till surgery.

Prophylaxis of infective endocarditis – Advice on dental hygiene and regular dental checks. Antibiotic cover for major dental treatment.

B. Treatment of Underlying Defect

Defects not associated with shunts –

Coarctation of aorta – In infants early onset of symptoms is related to poor perfusion of lower systemic segment after closure of ductus. Re-opening the ductus with Prostaglandin infusion may lead to improvement. Additional support with catecholamines, e.g. Dopamine 5 µg/kg/min may be necessary.

Surgery is indicated if upper segment hypertension or significant associated intracardiac defects. Resection and end-to-end anastomosis, or subclavian flap aortoplasty.

Aortic stenosis – Surgical valvotomy, or balloon valvuloplasty. If re-stenosis occurs, valve replacement may be necessary.

Pulmonary stenosis – If moderate or severe obstruction, balloon valvuloplasty. Surgical valvotomy rarely necessary. Defects with left-to-right shunts –

VSD

- **Large VSD** – Direct repair of VSD because of increasing pulmonary hypertension.
- **Moderate VSD** – Catheter studies at 1 year of age.

Operative correction or transcatheter closure is indicated when there is a moderate to large left-to-right shunt with a pulmonary-to-systemic flow ratio > 1.5:1, in the absence of severe pulmonary vascular resistance (pulmonary arterial resistance is less than two-third of systemic arterial resistance).

Mild defect – Follow-up with echo and catheter studies.

Contraindications to surgery:

- (1) $\frac{PBF}{SBF} > 2$
- (2) Greatly increased pulmonary resistance. Technique – (a) Through RV to avoid damage to AV bundle. ECG is done before closing to reverse any block due to surgery. (b) Through LV if multiple small openings. (c) Through RA into RV (incision on atrial appendage).

PDA – Premature infants – Symptoms should be treated with fluid restriction and diuretics. If no improvement – Indomethacin 0.2 mg/kg orally, rectally or IV. If ineffective surgical ligation.

Children – Even a small PDA carries risk of infective endocarditis and surgical ligation or transcatheter occlusion with detachable coils should be done as soon as diagnosis is made.

ASD – Children with ASD are often asymptomatic but it may lead to atrial fibrillation and congestive failure in adult life. Repair is therefore advisable during childhood.

DEFECTS ASSOCIATED WITH RIGHT-TO-LEFT SHUNTS

Tetralogy of Fallot

Management depends on nature and extent of obstruction to pulmonary blood flow. If marked hypoplasia of pulmonary artery – Palliation with one or more systemic-to-pulmonary shunt procedure, e.g. subclavian and pulmonary artery (Blalock-Taussig shunt).

If severe hypoxia and cyanosis are present, early surgery is necessary.

Ultimate surgical repair involves VSD closure (with a prosthetic patch) and relief of outflow tract obstruction often with placement of a transvascular gusset. In favourable cases total correction has a mortality of less than 5%.

TPGA

Initial treatment of correction of acidosis and if necessary IV prostaglandin. Corrective surgery can be carried out in neonatal period by re-implanting the aorta, pulmonary artery and coronary arteries at their normal site (arterial switch procedure). Alternately, definite surgery can be postponed in infants with intact ventricular septum and low pulmonary pressure to first year of life. Surgery then consists of atrial redirection procedure in which pulmonary veins are connected to RA and SVC and IVC are drained into left atrium.

TAPVC – Reconnection of pulmonary veins to LA and obliterating abnormal connections to systemic venous system or RA.

Tricuspid atresia – Initial– Systemic-to-pulmonary shunt operation. Definitive surgery at age of 2–4 – Returning blood from systemic circulation (via SVC and IVC) is directed into pulmonary circulation without traversing the right side of the heart except a portion of RA which is connected to pulmonary arteries directly (Fontan procedure).

6. VALVULAR HEART DISEASE

MITRAL VALVE DISEASE MITRAL STENOSIS

Causes

See Table 43 for the causes of mitral stenosis. Rheumatic fever is the most common etiology in India. As a result of rheumatic endocarditis chordal fusion, leaflet thickening or commissural fusion develops giving rise to funnel-shaped deformity of the valve with button hole orifice.

Table 43: Causes of mitral stenosis

- Rheumatic fever
- Congenital (parachute valve or commissural fusion).
- Associated with ASD (Lutembacher's syndrome).
- Hurler's syndrome (Gargoylism).
- Endomyocardial fibrosis (regurgitation more common).
- Calcified mitral annulus in elderly.
- Functional due to partial obstruction of valve orifice:
 - Left atrial tumour usually myxoma.
 - Left atrial ball valve thrombus.
 - Cor triatriatum.
 - HOCM with obstruction to left ventricular inflow.
- SLE, RA
- Juvenile MS (Table 44)

Symptoms

1. **No symptoms** – Discovered during pregnancy, routine physical examination or supervening infective endocarditis. There are no symptoms until the valve area is reduced to 1.5 cm².
2. **Respiratory symptoms**
 - (a) **Dyspnoea** – due to pulmonary hypertension. As the pulmonary artery pressure rises, exercise tolerance decreases.

Grades of dyspnoea:

 - Grade 1: No breathlessness
 - Grade 2: Breathlessness on severe exertion
 - Grade 3: Breathlessness on mild exertion
 - Grade 4: Breathlessness at rest.

Mechanism of pulmonary hypertension:

 - Backward extension of raised LA pressure.
 - Reactive arteriolar constriction.
 - Embolic obstruction to pulmonary vasculature.
 - Hypoxic vasoconstriction when CHF develops.
 - Interstitial oedema in walls of small pulmonary vessels
 - (b) **Pulmonary edema** – Usually precipitated by severe exertion, pregnancy, onset of atrial fibrillation, respiratory infection and occasionally by anesthesia.
 - (c) **Haemoptysis** may be initial symptom or occur late (Table 45).

Table 44: Salient features of juvenile MS

1. Occurrence in tropical areas.
2. Incidence early in life (<18 yrs).
3. AF rare
4. No valve calcification
5. Pin-point stenosis
6. Rapidly progressive with development of pulmonary hypertension and CHF
7. Urgent surgery necessary

Table 45: Mechanisms of hemoptysis in mitral stenosis

- Sudden large haemorrhage from pulmonary veins (pulmonary apoplexy)
- Blood-stained sputum due to pulmonary venous congestion
- Blood-tinged sputum during an attack of bronchitis
- Pink frothy sputum associated with acute pulmonary oedema
- Following pulmonary infarction
- Pulmonary haemosiderosis
- Rupture of bronchial submucosal varices
- Anticoagulant overdosage

Protective mechanisms against development of PND in long-standing MS

- (a) Pulmonary hypertension.
 - (b) Capillary-alveolar-interstitial barrier.
 - (c) Presence of broncho-pulmonary venous shunts.
 - (d) *Recurrent attacks of bronchitis* – may occur.
3. *Palpitation* – may occur with regular or irregular rhythm.
 4. *Angina pectoris* – in presence of tight MS attributed to dilatation of pulmonary artery, pulmonary vascular obstruction with right ventricular ischaemia, left ventricular ischaemia from poor cardiac output or coronary embolization.
 5. *Fatigue* – from low cardiac output.
 6. *Embolism* – Systemic or pulmonary.
 7. *Cyanosis* – usually peripheral due to low cardiac output. Central cyanosis may result from pulmonary congestion.
 8. *Symptoms due to pressure of dilated left atrium* –
 - (a) Hoarseness of voice – may progress to aphonia, due to compression of left recurrent laryngeal nerve (Ortner's syndrome).
 - (b) Dysphagia – from pressure on oesophagus.
 - (c) Collapse of lung – rare, due to compression of left main bronchus by a giant left atrium.
 9. *Infective endocarditis* – rare with pure MS.
 10. *Massive thrombus in left atrium* – is usually associated with atrial fibrillation, may cause sudden death.

Signs

Inspection

1. *Mitral facies* (Malar flush) – Cyanotic hue over cheek bones due to low cardiac output (if severe stenosis).
2. Giant 'a' waves in jugular venous pulse if pulmonary hypertension.

Palpation

1. Apex impulse normal, or brief tapping corresponding to the tap of the mitral 1st heart sound (closing snap).
2. Left parasternal heave due to RV hypertrophy.
3. Palpable P₂ in second left space.
4. Presystolic and mid-diastolic thrill may be felt at the apex.

Fig. 72: Mid- and late-diastolic (presystolic) murmur of mitral stenosis with accentuated first heart sound at the apex and opening snap

Auscultation

1. *Loud 1st heart sound* – This results from two factors –
 - (a) The high left atrial pressure keeps the mitral cusps open until the very end of diastole.
 - (b) Fibrotic changes in the mitral valve leaflets alter them in such a way that they tense more abruptly with ventricular contraction. If the valve is heavily calcified the first sound will not be accentuated.

Causes of muffled S₁ – (a) Heavily calcified valve. (b) Associated prominent MR or severe AR. (c) Prolonged PR interval (active rheumatic carditis or digitalis overdose). (d) Gross RVH with RV forming the apex. (e) Acute MI. (f) Left atrial failure.

2. *Presystolic murmur* – often a relatively early sign, usually disappears with onset of atrial fibrillation or LV failure or presence of large LA thrombus. The murmur of mitral stenosis is localised to the apex, best heard on expiration, after exercise and with the patient turned on to the left side.

Causes of softening of MS murmur – (a) Mild MS. (b) Large RV pushing LV posteriorly away from anterior chest wall. (c) Associated ASD.

3. *Mitral opening snap* – occurs as the diseased valve is snapped open forcibly by high pressure in LA. Heard best at apex shortly after 2nd sound. Shorter the interval between the sound and opening snap (2-OS interval) tighter the stenosis (Fig. 72). At times OS may be absent (Table 46).
4. *Apical mid-diastolic murmur* – occurs after the opening snap and increases in length as the stenosis becomes more severe. It eventually merges with the presystolic murmur if LV filling is severe enough for there to be turbulent filling across the valve for the whole of diastole.

Table 46: Causes of absent OS

- Mild or early stenosis.
- Long duration of preceding diastole allowing high LA pressure to fall.
- Associated AR, the regurgitant stream slowing rate of movement of the valve displacement to LV.
- Markedly calcified or fibrosed valve.
- Associated MR of moderate degree.
- Extremely low flow due to very severe stenosis, secondary pulmonary hypertension, concomitant aortic or pulmonary valve disease or myocardial dysfunction.
- Fusion or matting of chordae tendinae and papillary muscles of left ventricle.
- Large RV that pushes LV away from chest wall.

5. *Early diastolic murmur* - in pulmonary area caused by pulmonary regurgitation from stretching of pulmonary artery by pulmonary hypertension.

Degree of stenosis

1. *Symptoms*: The normal mitral valve is 4–6 cm² in area. Symptoms begin to develop when valve stenoses to 1.5 cm² and usually become severe once the area is < 1.5 cm².
2. *Signs*:
 - A₂OS interval shortens
 - Marked RV heave
 - Very loud apical S₁ (unless valve calcified or ankylosed).
 - Loud P₂
 - Long diastolic murmur
 - Graham-Steell murmur of pulmonary regurgitation
 - Low pulse volume
3. *Doppler measurement* - of the flow across the valve. Severe lesion if measured orifice area (cm²) < 1.0.

Investigations

1. **Chest radiograph** (Fig. 73)

(a) Cardiac silhouette

- Heart is not usually enlarged.
- Left atrial enlargement causes - (i) Double contour of right heart border. (ii) Elevation

Fig. 73: Mitral stenosis. An enlarged left atrial appendage (LAA) protrudes on the left border of the heart, between the pulmonary artery and the left ventricle. [A double shadow at the right heart border is due to left atrial (LA) enlargement]. Left heart border straight due to enlargement of pulmonary bay and LA enlargement (mitralisation)

of left main bronchus. (iii) Splaying of carinal angle. (iv) Posterior displacement of barium-filled oesophagus.

- Enlargement of main pulmonary artery if pulmonary hypertension.
 - Calcification in valve, or left atrium if thrombus in left atrial wall.
 - Enlargement of left atrial appendage produces localised bulge just below pulmonary artery thus straightening the left heart border.
- (b) *Lung fields* - With increasing left atrial pressure the changes seen in increasing order of severity are -
- Dilatation of pulmonary veins of upper lobes.
 - Oedema of interlobular septa (Kerley B lines) with interstitial oedema and small parietal pleural effusions.
 - Alveolar oedema, perihilar haze and effusion.
 - Prominence of upper lobe veins seen as thick branching opacities from pedicle of the heart due to increased left atrial end diastolic pressure (Moustache or Antler sign).
 - As pulmonary hypertension develops, the pulmonary venous congestion becomes less marked and is replaced by proximal pulmonary artery enlargement. With long-standing elevation of left atrial pressure, miliary mottling may appear from pulmonary haemosiderosis.
2. **ECG** - (i) Prominent, wide and notched P waves (M shaped) in leads I and II, with mainly upright P in V₁ (P mitrale). (ii) Right ventricular preponderance (Fig. 74).
 3. **Echo** - (a) Reduced closure rate of mitral anterior cusp. (Reduced EF slope). (b) The posterior leaflet is pulled in the same direction as the anterior leaflet since the chordae are fused. (c) A calcified fibrotic valve produces multiple echoes with insignificant diastolic movement (Figs. 75 to 78).

Differential Diagnosis

For the causes of diastolic apical murmur (Refer).

Cor triatriatum: Clinically, the symptoms may be identical with MS including paroxysmal nocturnal dyspnoea and haemoptysis and at times a presystolic murmur.

Management

I. Mitral valvotomy

Indications of mitral valvotomy are given in Table 47 (Fig. 79).

Fig. 74: ECG in severe mitral stenosis

Fig. 75: D2 echo in mitral stenosis

Fig. 76: Apical four chambered view showing thickened mitral valve with restricted opening in mitral stenosis

II. Medical

1. *Prevention of recurrence of rheumatic fever* – especially in younger patients. Prophylactic oral penicillin V 250 mg. b.d. or in patients who are unreliable in taking oral therapy – Benzathine penicillin G 1.2 million units IM once a month. If patient is allergic to penicillin, erythromycin 250 mg. daily by mouth.
2. *Prevention of infective endocarditis* – (Refer).
3. *Prevention of too rapid ventricular rate* – Digitalis if – (i) Atrial fibrillation. (ii) Older patients who are still in sinus rhythm to prevent paroxysmal atrial fibrillation.
4. *Prevention of pulmonary venous congestion and pulmonary oedema* – Diuretics. Surgery in patients with severe stenosis.
5. *Prevention of embolism* – Long-term anticoagulant therapy (Table 48).

Fig. 77: Parasternal short axis view in MS showing the typical 'fish mouth' appearance of the narrowed mitral valve orifice in diastole

Fig. 78: Echo Doppler in mitral stenosis

Table 47: Indications of mitral valvotomy

- Significant symptoms limiting activity
- Uncontrolled atrial fibrillation causing marked deterioration
- Episode of pulmonary oedema without obvious precipitating cause
- Following embolization
- Pulmonary oedema during pregnancy

MITRAL REGURGITATION

Causes

See Table 49 for causes of mitral regurgitation.

Symptoms

- No symptoms with mild degree of MR.
- Symptoms due to pulmonary congestion – effort dyspnoea progressing to orthopnoea and paroxysmal cardiac dyspnoea.
- Symptoms due to congestive heart failure.
- Dramatic onset of symptoms with at times frank pulmonary oedema with chordal rupture or sudden papillary muscle dysfunction.

Signs

- Pansystolic murmur** – High pitched, blowing, starts immediately after the first sound, and continues just beyond aortic valve closure because LV pressure is still higher than LA pressure at this time. Maximal at apex, radiating to axilla and left posterior or interscapular

Fig. 79: Balloon mitral valvotomy (BMV)

Table 48: Indications of anticoagulant therapy in mitral stenosis

- Moderate to severe stenosis
- Enlarged left atrium
- Atrial fibrillation
- Sinus rhythm with recurrent palpitations
- Any symptoms suggestive of arterial embolism

area of chest in the direction of the jet. As a rule more severe the degree of insufficiency louder the murmur. When regurgitation occurs principally through the posterior leaflet, the murmur may be referred to the base of the heart and may be audible even in the neck vessels (Fig. 80).

Table 49: Causes of mitral regurgitation

A. Organic MR	
<i>Common:</i>	
<ul style="list-style-type: none"> • Rheumatic fever. • Infective endocarditis • Papillary muscle dysfunction or rupture (subvalvar MR) usually due to myocardial infarction. 	
<i>Uncommon:</i>	
<ul style="list-style-type: none"> • Cardiomyopathy - Dilated, hypertrophic • Congenital – Associated with ostium primum defect. • Libman-Sacks syndrome in SLE. • Endomyocardial fibrosis. • Surgical trauma to stenotic mitral valve. • Prosthetic valve malfunction 	
<i>Rare:</i>	
<ul style="list-style-type: none"> • Mitral valve prolapse. • Floppy valve ± chordal rupture. • Calcified valve ring (usually mild and in very elderly). • Collagen abnormalities, e.g. Marfan's, Ehlers-Danlos syndrome, ankylosing spondylitis. • Kawasaki disease 	
B. Functional MR	
<ul style="list-style-type: none"> • Acute rheumatic and viral myocarditis. • Ischaemic heart disease. • Hypertension. • Aortic valve disease. • Congestive cardiomyopathy. 	

- *Soft first heart sound.*
- *Loud third heart sound* – Usually audible at apex in severe regurgitation, caused by rapid filling of LV.
- *Mid-diastolic short apical murmur* – may be heard in some cases with very large flows across the mitral valve.
- *Wide expiratory splitting of second sound* – because of short ejection time and early closure of aortic valve in severe MR.
- *Opening snap* – if severe MR or MR due to endomyocardial fibrosis.

Signs of Severe of MR

- Loud pansystolic murmur
- Systolic apical thrill
- Hyperdynamic LV impulse
- Ventricular gallop
- Mitral diastolic flow murmur

Fig. 80: Pansystolic murmur of mitral regurgitation beginning with the first sound and ending with or enveloping aortic valve closure of second heart sound. A loud third heart sound of increased ventricular filling may be heard

- Opening snap
- Left parasternal heave due to systolic expansion of LA which pushes RV forward.

Subvalvular Regurgitation

- With papillary muscle dysfunction and chordal rupture* – the systolic murmur is often short and confined to mid or late systole and resembles an ejection murmur.
- With posterior chordal rupture* – the posterior mitral leaflet balloons into the left atrium during ventricular systole, and the regurgitant jet is anteriorly directed. The murmur is therefore prominent in the aortic area, simulating aortic stenosis.

Acute MR – Murmur loud, apical and pansystolic, and often accentuated in late systole. Rapid, sharp, small volume pulse and pulmonary oedema.

Investigations

X-ray – In severe cases, LA (may be aneurysmal) and LV enlargement, later RV enlargement. If LA is disproportionately small in comparison with the large size of LV or degree of mitral regurgitation, papillary muscle dysfunction or ruptured chordae likely. With high LA pressure Kerley B lines. Small heart or slight cardiac enlargement (Fig. 81) and pulmonary oedema in acute MR (Fig. 82).

ECG – P mitral. In severe cases LVH.

Echocardiography – Rupture of chordae tendinae of mitral valve as a cause of MR may be suspected from an abnormally great separation of anterior and posterior cusp echoes, and from an abnormally large range of movement of anterior leaflet. The degree of LV dilatation reflects the severity of regurgitation (Figs. 83 and 84).

Cardiac catheterization – Adds little information about the valve lesion but the coronary anatomy helps in determining the aetiology of MR and planning treatment.

Complications – Same as MS except incidence of AF and embolism is less, and that of IE greater.

Differential Diagnosis – See D.D. of systolic murmurs.

Fig. 81: Radiological appearances in case of severe mitral regurgitation showing considerable dilatation of the left atrium and left ventricle and marked pulmonary venous congestion

Fig. 82: Acute MR. Slight cardiac enlargement, pulmonary oedema (Bat's wing appearance)

Fig. 83: Echo Doppler showing regurgitant flow in mitral regurgitation

Fig. 84: Apical 4-chamber view showing mitral regurgitant jet (arrow) travelling from LV to LA

Management

- *Medical* - As for mitral stenosis.
- *Surgical* - In severe cases replacement of mitral valve with prosthetic valve, or repair procedure.

MITRAL VALVE PROLAPSE (MVP)

This is a condition in which one or both mitral valve leaflets prolapse backward into the left atrium during ventricular systole. Prolapse is most marked during late systole when the ventricular cavity is smallest.

Mitral valve prolapse - Floppy mitral valve is classified as a heritable disorder of connective tissue because (i) It can be inherited as an autosomal dominant phenotype. (ii) A large proportion of patients have systemic features similar to those of patients with heritable disorders of connective tissue (e.g. anterior chest deformity, scoliosis, kyphosis, hypermobility of joints and an arm span > height. (iii) MVP - FMV is a common finding in patients with recognized heritable disorders of connective tissue (e.g. Marfan syndrome, Ehlers-Danlos syndrome, and adult polycystic kidney disease.

Pathogenesis

MVP is a multifactorial valvular abnormality that can be caused by histological abnormalities of valvular tissue, geometric disparities between LV and mitral valve, or various connective tissue disorders including Marfan syndrome, Ehlers Danlos syndrome, osteogenesis imperfecta and pseudoxanthoma elasticum.

Symptoms may vary from usually none to those of nonspecific chest pain, palpitation and tiredness. Prolapse associated with myocardial ischaemia may be associated with sudden death and must be distinguished from the benign MVP syndrome.

Signs

1. Typical habitus – Narrow anteroposterior chest diameter, straight back, pectus excavatum, long extremities and hyper-reflex joints.
2. Apical mid-systolic click (sometimes multiple) and/or
3. Late systolic murmur, loudest at the apex. Manoeuvres that reduce LV volume (standing, sublingual nitroglycerine) make the valve prolapse earlier and make the murmur and click appear earlier in systole, while those which increase LV volume (lying, squatting) make both occur late in systole.

Complications

See Table 50 for the complications of MVP.

Clinical associations of MVP: (a) Marfan's or Ehlers-Danlos syndrome. (b) ASD (secundum defect). (c) Heart

muscle disease – HOCM, ischaemic or rheumatic heart disease. (d) Wolff-Parkinson-White syndrome. (e) Poly-arteritis nodosa. (f) Adult polycystic disease. (g) Postvalvotomy.

The term 'Mitral valve prolapse syndrome' is used to differentiate prolapse associated with non-specific symptoms (chest pain, palpitations, pre-syncope or syncope, effort syndrome).

Investigations

- **ECG:** It may be normal or show ST and T wave changes in leads III, aVF.
- **Echo:** Single or bileaflet prolapse at least 2 mm beyond the long axis annulus, with or without leaflet thickening (Figs. 85 and 86).
- **Cardiac catheterization:** Left ventriculography often demonstrates prolapse of mitral leaflets. Degree of MR can be estimated and in patients with chest pain, coronary artery anatomy can be defined.

Table 50: Complications of MVP

- Cardiac arrhythmias (usually ventricular ectopics).
- Infective endocarditis.
- Systemic emboli (generally manifest as TIAs).
- Ruptured chordae tendinae.
- Severe MR.
- Sudden death.

Fig. 85: 2D echo and Doppler in mitral valve prolapse (MVP)

Fig. 86: 2D echo and Doppler in mitral valve prolapse (MVP)

Management

Medical

1. Reassurance regarding usually benign nature of the condition.
2. Endocarditis prophylaxis in patients with a murmur.
3. Drug treatment if arrhythmia.
4. Aspirin or anticoagulant in patients with emboli.

Surgical: Reconstruction or replacement of mitral valve in presence of severe regurgitation or evidence of progressive deterioration of LV function.

AORTIC VALVE DISEASE AORTIC REGURGITATION

Causes

See Table 51 for the causes of aortic regurgitation.

Symptoms

1. Asymptomatic.
2. Dyspnoea – on exertion.
3. Angina pectoris – on heavy exertion or coinciding with onset of heart failure.
4. Palpitation – due to forceful heart beat. Unpleasant pulsation in head and neck may occur from very large stroke volume.
5. Syncopal attacks – may occur due to cerebral anoxia.

Table 51: Causes of aortic regurgitation

A. Valve leaflet disease:

- Rheumatic fever
- Congenital: Bicuspid valve, coarctation of aorta, in association with high (subaortic) VSD, sinus of valsalva (rupture)
- Infective endocarditis (often on bicuspid valve).
- Traumatic rupture of cusps.

B. Aortic wall pathology:

- Syphilis.
- Inflammatory–Connective tissue disorder, e.g. ankylosing spondylitis, rheumatoid arthritis, SLE, Takayasu's disease, Reiter's syndrome.
- Degenerative
 - Marfan's syndrome
 - Aortic root dissection
 - Arthropathy (senile thinning and stretching of aortic wall in absence of any other pathology).

Signs

Cardiac palpation – Apical impulse displaced downward and to the left and thrusting in character. Diastolic thrill if syphilitic AR. ruptured sinus of Valsalva, or AR resulting from aortic dissection.

Murmurs

1. *Diastolic murmur* – High-pitched decrescendo murmur, maximal in early diastole, soft and blowing, with or after the second sound and masking the sound completely, maximum audibility over midsternum and to the left, transmission to the apex, best heard in held expiration with patient leaning forward (Fig. 87). In a few patients, the diastolic murmur has a rough or musical or sea-gull quality (A diastolic thrill may be felt along the left sternal border in such cases). If the murmur is best heard to the right of sternum, suspect dilatation of ascending aorta as in Marfan's syndrome, dissection of aorta or syphilis. The murmur may be even louder in high mid-left thorax, at apex, or in the midaxillary line, than in the sternal edge (Cole-Cecil murmur).

A musical murmur may extend almost throughout diastole. Musical AR murmur may be due to: (a) Perforated leaflet as in infective endocarditis. (b) Everted leaflets (often syphilitic). (c) Rupture of an aortic sinus of valsalva.

Diastolic murmur is very short in acute AR because the left ventricle which has had no time to dilate and hypertrophy, and rapid rise in LV diastolic pressure.

Murmur can be increased in intensity by squatting or isometric exercise by handgrip or administering a vasopressor drug.

2. *Systolic ejection murmur* – due to increased stroke volume of left ventricle with often an ejection click.
3. *Austin flint murmur* – An apical low-pitched diastolic murmur may occur with severe AR. It is mainly due to the regurgitant jet vibrating the anterior mitral valve leaflet and displacing it backwards into the path of inflowing blood from left atrium. It must be differentiated from an organic mitral stenotic murmur (Table 52).

Fig. 87: Early decrescendo murmur of AR

4. *First sound at apex* – often soft or early because of premature closure of mitral valve.
5. *Second sound at base* – Single in severe AR because aortic component is absent.
6. *Third sound* – and apical pansystolic murmur of MR can commonly be heard as the LV dilates.

Peripheral – Due to wide pulse pressure

- *Collapsing (water hammer) pulse* – It may be absent if:
 - (a) Associated mitral or aortic stenosis.
 - (b) Hypertension.
 - (c) Marked myocardial degeneration.
- *Visible arterial pulsations* – in neck (dancing carotids, Corrigan's neck sign).
- *Head bobbing* with each heartbeat (de Musset's sign).
- *Hill's sign* – Increase in femoral artery pressure over brachial artery pressure of more than the normal difference of 20 mm. Hg. Larger the pressure difference, more severe the degree of AR.

Table 52: Differentiating between AR with Austin Flint murmur and AR associated mitral stenosis

	AR with Austin Flint murmur	AR with associated mitral stenosis
Sex	More frequent in males	More frequent in females
Haemoptysis	Almost never	Strong evidence for mitral stenosis
Rhythm	Sinus	A. fibrillation common
Mitral 1st sound	Usually faint	Usually loud
P ₂	Normal or increased	Usually loud
Opening snap	Absent	Present
Apical diastolic murmur	Usually early and mid-diastolic	Often presystolic accentuation
Apical gallop	Present	Absent with significant MS
Diastolic pressure	60 mm or less	Usually normal
Atrial fibrillation	Uncommon	May occur
LA enlargement on ECG or X-ray	Not seen	Seen
Calcification of mitral valve	None	May be seen
Amyl nitrite inhalation	Murmur decreases	Murmur louder
Echocardiography	Mitral valve normal and no significant Doppler gradient across it	Stenotic mitral valve

Fig. 88: Dilated left ventricle and prominent aorta due to chronic aortic regurgitation

Fig. 89: Aortic regurgitation

- *Visible capillary pulsation* - in the nail beds (or mucous membrane of mouth) (Quincke's sign).
- *Pistol shot sounds* - over the femoral arteries (Traube's sign).
- *Duroziez's sign* - Diastolic murmur following distal compression of femoral artery.
- *Uvular pulsation* (Müller's sign)
- *Landolfi's sign* - Change in size of pupils with each cardiac cycle
- *Light house sign* - Alternate pallor and flushing of capillary pulsations on forehead and face.
- *Becker's sign* - Retinal artery pulsation
- *Mayne sign* >15 mm Hg fall in diastolic BP with elevation of the arm compared to the arm in normal position.
- *Gerhardt's sign* - Pulsations of an enlarged spleen
- *Rosenbach sign* - Pulsations of the liver

Clinical manifestations of a severe AR:

1. Prominent symptoms.
2. Peripheral signs well marked.
3. Difference of systolic BP between upper and lower extremities > 60 mm Hg.
4. Long duration of diastolic murmur. Duration however does not necessarily indicate severity; when the aortic valve is destroyed, the pressure equilibrates early in diastole and the murmur is brief.
5. Very low diastolic B.P
6. LV enlargement ++
7. Aortic S₂ inaudible
8. Retinal arterial pulsation
9. Pulses bisferiens (best felt in the carotids)

Fig. 90: Aortic regurgitation

Investigations

- *ECG* - Left ventricular hypertrophy, with diastolic overload pattern in severe regurgitation.
- *Chest X-ray* - Enlargement of the left ventricle, with 'duck-back' shape of left border (Fig. 88). Ascending aorta shows uniform enlargement.
- *Echocardiography* - is vital for examining aortic valve, determining size of aortic root and assessing LV function. Aetiology of AR can thus be established. Severity of regurgitation can be established from Colour Doppler study (Figs. 89 to 91).

Fluttering of anterior leaflet of mitral valve occurs when a regurgitant stream is directed posteriorly.

Fig. 91: Aortic regurgitation

Vibrations caused by the regurgitant stream may be seen on anterior mitral leaflet.

- **Cardiac catheterization** – has been supplanted by echocardiography. In adult patients, however, coronary angiography is undertaken before valve surgery and to perform aortography and left ventriculography.
- **Blood tests** – Treponemal serology and determination of inflammatory indices in patients with aortic wall disease.

Differential Diagnosis

1. Rheumatic aortic incompetence
2. Syphilitic aortic incompetence
See Table 53 for the differences between rheumatic and syphilitic aortic regurgitation.
3. Atherosclerotic incompetence – Old age, angina common. Calcification of aortic knuckle and of the aortic valve. Some degree of aortic stenosis common.
4. Infective endocarditis– Changing murmurs, fever, anaemia, enlargement of spleen, embolic phenomena, hematuria and petechiae, clubbing and positive blood culture.
5. Congenital – Young patient, gross regurgitation, presence of some other congenital lesion.
6. Traumatic rupture of aortic cusp – Sudden onset of dyspnoea following fall or accident; loud, harsh and at times musical (seagull) aortic diastolic murmur, often accompanied by a thrill.
7. Marfan's syndrome – Aortic insufficiency due to process of degeneration involving aorta. Slender body build, abnormal height with disproportionately long bones especially fingers (arachnodactyly), high arched

Table 53: Differences between rheumatic and syphilitic aortic regurgitation

Rheumatic AR	Syphilitic AR
History:	
More common before 30	More common after 30
History of rheumatic fever	History of syphilis
Duration may be long	Short duration or history
Angina pectoris rare	Angina pectoris common and earlier
Examination:	
Precordium may be prominent	No precordial prominence
Murmur best heard in third left space, usually soft and low pitched and conducted better down left side	Murmur heard best over 2nd right space, usually loud and harsh and conducted better down right side
AS may be associated	Pure aortic regurgitation
Diastolic thrill very rare	Diastolic thrill not uncommon
AR not so gross therefore peripheral signs not marked	Peripheral vascular signs marked because AR usually gross
Slight or no difference in brachial or carotid pulsations	Appreciable difference in strength of carotid or brachial pulse on either side
Mitral valve may be affected	No involvement of mitral valve.
Investigations:	
Blood: Syphilis serology negative	Syphilis serology positive
X-ray: No calcification or irregularity of aorta	Calcification confined to ascending aorta. Irregularity of aorta. No calcification of aortic valve
ECG: Heart block rare	Heart block common

palate, hyperextensible joints, kyphoscoliosis and displacement of the lens.

8. Pulmonary regurgitation – Table 54 gives differences between aortic and pulmonary regurgitation.
9. Murmur of Anterior Descending Coronary Artery Stenosis (with moderate obstruction). High pitched crescendo-decrescendo diastolic murmur, most easily audible with patient sitting up. Murmur, disappears after myocardial infarction or aortocoronary bypass surgery.

For differential diagnosis of diastolic murmurs: Refer

Management

- **Medical:** (a) Prophylaxis against infective endocarditis. (b) Therapy of heart failure if it develops.

Table 54: Differences between aortic and pulmonary regurgitation

AR	PR (Graham Steell murmur)
Water hammer pulse and peripheral signs	No peripheral signs
LV hypertrophy	RV hypertrophy
Murmur does not change on respiration	Murmur increases with inspiration
Murmur returns to normal intensity 4–5 beats after valsalva strain	Murmur resumes pre-valsalva loudness immediately

- **Surgical:** Replacement of aortic valve should be performed before heart failure can develop. Serial evaluation of end-systolic dimensions should be made and surgery considered when this (on M-mode echocardiography) exceeds 55 mm.

AORTIC STENOSIS

Causes

Table 55 lists the causes of aortic stenosis.

Symptoms

1. **No symptoms** – Most well compensated of valvular diseases. Symptoms occur when the valve orifice is reduced to 1 cm² or less, the resting peak systolic pressure difference between LV and aorta is at least 50 mm Hg.
2. **Angina** – Due to:
 - Increased oxygen demand by the hypertrophied myocardium.
 - Shortening of diastole, the time when the coronary arteries fill, caused by prolonged ventricular ejection time.
 - Squeezing effect on coronary arteries by high LV systolic pressure.
 - Involvement of coronary ostia in the stenotic process.
3. **Syncope** – Syncopal spells beginning after onset of left ventricular failure are often brought on by little if any effort and are of grave significance.
4. **Exertional dyspnoea** – Often first symptom. Orthopnoea and paroxysmal dyspnoea follow as result of left ventricular failure.
5. **LV failure** – Dyspnoea, orthopnoea, pulmonary oedema, most frequent when standing.

Signs

1. **Sustained and heaving cardiac impulse.**

Table 55: Causes of aortic stenosis

I. Valvar stenosis
• Congenital malformation (most common cause of isolated AS).
• Calcification of normal valve.
• Inflammatory fusion – Rheumatic fever (lesion is nearly always mixed stenosis and regurgitation).
• Worn bicuspid valve
II. Subvalvar stenosis
1. Fixed type – Due to fibrous ring, fibrous ring plus moderate muscular obstruction, or rarely anomalous insertion of mitral valve.
2. Hypertrophic type – due to HOCM.
III. Supravalvar stenosis
Due to ridge of fibrous tissue at upper border of sinuses of valsalva.

**Fig. 92:** Ejection systolic murmur and systolic click in aortic stenosis

2. **Systolic thrill** – in second right interspace and also sometimes along the right cervical vessels.
3. **Ejection systolic murmur** – in aortic area, rough or harsh, beginning slightly after the first sound, rising to a peak in midsystole and tapering off before the second sound (Fig. 92). Sometimes the murmur may be loudest at the apex, because the murmur sounds higher pitched at the apex (Gallavardin phenomenon) as a result of selective radiation of higher frequencies. Occasionally, the murmur becomes softer as one goes down from aortic to mitral area and then again increases in intensity (hour-glass conduction). In elderly, the murmur of AS is frequently a musical, cooing murmur localised to the apex. It is frequently audible over carotid arteries. With increasingly severe stenosis prolonging the LV ejection time, the murmur becomes longer and attains its peak later. The murmur becomes quieter in advanced disease when the force of LV contraction is weakened.
4. **Ejection systolic click** – precedes the murmur in many cases. It is caused by sudden tension of a pliable dome-shaped stenotic valve at the time of its opening. Disappears with calcification of the valve.

5. *Quiet 1st heart sound.*
6. *2nd heart sound*- Delayed with reversed splitting in severe stenosis, or faint or absent. The aortic component of S_2 is absent when the valve is rigid and the pulmonary component may be inaudible; mitral closure is often quiet. Thus only a murmur is heard, and this may be judged pansystolic because of absence of heart sounds.
7. *Atrial gallop*- may be heard over the left ventricle and in patients under 40 is a reliable evidence of severe stenosis.
8. *Slow rising sustained pulse (pulsus parvus et tardus).* When a small wave is felt along the upstroke, the pulse is called anacrotic.
9. *BP* - Low systolic with narrowed pulse pressure in severe AS.

Investigations

ECG - LV hypertrophy common, proportional to degree of stenosis. Conduction defects common.

Chest radiograph (Fig. 93) - (a) Prominent rounded left ventricle. (b) Poststenotic dilatation especially if stenosis is congenital in origin. (c) Aortic valve calcification.

Echocardiography - Both M-mode and CSE will show the stenosed valve. The valve area may be estimated from cross-sectional images and the gradient across the valve assessed from a Doppler study (Figs. 94 to 96).

Left heart catheterization - is indicated in presence of symptoms or development of LV hypertrophy with

ST-T changes in ECG. Useful for determining gradient across the valve (50 mm Hg: Moderate stenosis, 70 mm Hg: Severe stenosis), measuring cardiac output, assessing LV function and to exclude co-existing coronary disease.

Subvalvar Stenosis

1. Absence of aortic ejection click with no calcification of aortic valve.
2. Diastolic murmur due to AR more common.
3. Mid-diastolic murmur at apex.
4. Heart size tends to be larger.
5. Ascending aorta usually not dilated.

Fig. 94: 2D echo aortic stenosis

Fig. 93: Aortic stenosis. Poststenotic dilatation of the ascending aorta seen at the right heart border. Left ventricular silhouette appears convex and with the apex extending below the diaphragm

Fig. 95: Echo Doppler aortic stenosis showing turbulent flow

Fig. 96: Echo Doppler aortic stenosis

Supravalvar Stenosis

1. Characteristic facies with physical and mental retardation.
2. Systolic BP usually higher in right arm than in left arm due to stenosis of one or more branches of the aortic arch.
3. Absence of aortic ejection click.
4. No post-stenotic dilatation of aorta.

See Table 56 for the differences between valvular, subvalvular and supravalvular aortic stenosis and Table 57 for differences between HOCM and aortic valvular stenosis. Also see Differential Diagnosis of systolic murmurs.

Management

1. *Prophylaxis*—against infective endocarditis.
2. *Balloon valvuloplasty* – gives transient relief and is indicated in elderly patients with advanced symptoms.
3. *Aortic balloon valvotomy* – is confined to congenital AS and may be necessary if – (a) Total fusion of two valve cusps. (b) ECG changes of LV hypertrophy. (c) Significant pressure drop across aortic valve. (d) Eventual development of LV decompensation. (e) Risk of sudden death.

BICUSPID AORTIC VALVE

Bicuspid aortic valve is a minor congenital anomaly. Normal symmetry of aortic valve is disturbed because one leaflet is larger than the other two, the commissures of which are fused to some extent. More common in males.

Table 56: Differences between valvular, subvalvular and supravalvular aortic stenosis

Clinical features	Valvar	Sub-valvar	Supra-valvar
Physical appearance	Normal	Normal	Elfin facies
Pulse	Slow rise and sustained peak		Right brachial and carotid more than left
Ejection click	Typical	Rare	Rare
Maximum intensity of ejection murmur	1st or 2nd right interspace		1st right interspace and over right carotid
Murmur of AR	Common	Common	Uncommon

Table 57: Differences between HOCM and aortic valvular stenosis

Clinical signs	HOCM	Aortic valvar stenosis
Double apex impulse	Common	Less common
Presystolic gallop	Common	Less common
Single 2nd sound	Less common	Common
Paradoxical splitting of 2nd sound	Common	Less common
Systolic thrill	Not common	Common
Systolic murmur	Along left sternal border and at apex	2nd right interspace radiating to neck
Diastolic murmur of AR	Rare	Common
Carotid pulse	Visible, rapid upstroke	Invisible, slow upstroke
Valsalva manoeuvre	Murmur louder	Murmur softer
	Aortic stenosis	Pulmonary stenosis
Effect of respiration	Murmur decreases on inspiration	Murmur increases on inspiration
Site of murmur	Maximal intensity in 2nd right interspace	Murmur maximal along left sternal border
Ejection click	No change on inspiration	Decreases or disappears on inspiration

Clinical Features

- Ejection click
- Soft ejection murmur
- Short, high pitched diastolic murmur sometimes
- Loud A₂

Importance of Diagnosis

Valve may be affected by endocarditis, hence antibiotic prophylaxis necessary.

Tear on the valve leaflet is greater than in normal valve so that significant stenosis and/or regurgitation may develop by middle life.

TRICUSPID VALVE DISEASE TRICUSPID REGURGITATION

Causes

Causes of tricuspid regurgitation are listed in Table 58.

Symptoms: Tiredness on effort, hepatic pain on exertion, peripheral oedema, disturbing pulsations in neck.

Signs

- Systolic pulsation in jugular venous pulse.
- Pansystolic murmur in tricuspid area that increases with inspiration or exercise.
- Atrial fibrillation common.
- Pulsatile liver
 - *ECG* – RV hypertrophy and often AF.
 - *X-ray* – Enlargement of RA and RV.
 - *Echo* – may reveal systolic prolapse, ruptured chordae, or vegetations. Doppler echo can give estimate of severity of regurgitation and systolic pressure in RV. If leaflet thickening seen on CSE, lesion is organic (Fig. 97).

Treatment

Functional TR – Bed rest, digitalis, diuretics, vasodilators.

Organic TR – Replacement of valve.

TRICUSPID STENOSIS

Causes:

1. Rheumatic usually associated with MS.
2. Congenital – Tricuspid atresia and Ebstein's disease.
3. Carcinoid tumour.
4. Functional due to right atrial tumour.

Table 58: Causes of tricuspid regurgitation

A. Functional – more common.
1. RV failure from any cause.
2. Rheumatic mitral disease.
3. Pulmonary stenosis.
4. Pulmonary hypertension idiopathic, or secondary to lung disease, thromboembolism, or congenital shunting.
B. Organic – rare.
1. Congenital usually associated with Ebstein's anomaly.
2. Traumatic due to rupture of right ventricular papillary muscle.
3. Carcinoid disease.
4. Rheumatic.
5. Infective endocarditis in drug addicts.
6. Lupus erythematosus.
7. Right atrial myxoma.
8. Endomyocardial fibrosis.
9. A-V cushion defects

Symptoms

Hepatic pain on exertion, peripheral oedema, dyspnoea on exertion.

Signs

JVP raised. With sinus rhythm giant 'a' waves. First sound may be loud. Diastolic murmur at left sternal edge. Liver enlarged and may show presystolic pulsations.

ECG – RA hypertrophy but no RVH.

X-ray – Enlarged RA, lung fields usually clear.

Treatment

Replacement of the valve.

PULMONARY VALVE DISEASE PULMONARY REGURGITATION

Causes

- *Congenital* – With tetralogy of Fallot, Marfan's syndrome, Eisenmenger's syndrome, isolated, with PDA, idiopathic dilatation of pulmonary artery.
- *Acquired* – With idiopathic pulmonary hypertension, MS, IE, rheumatic fever, syphilis, carcinoid syndrome, aneurysm of pulmonary artery, pulmonary hypertension.

Signs

Early diastolic murmur similar in quality to that of AR, conducted down the left sternal border. Associated signs of pulmonary hypertension.

ECG – Right ventricular hypertrophy.

X-ray – Enlargement of pulmonary artery.

Fig. 97: 2D echo apical 4-chamber view showing regurgitant jet of tricuspid regurgitation

PULMONARY STENOSIS

Aetiology

1. Usually congenital. 2. May be associated with carcinoid syndrome. 3. Rarely associated with Kallmann's syndrome (gonadotrophin deficiency secondary to LHRH deficiency, with anosmia).

Signs

Systolic thrill in second left space with ejection mid-systolic murmur loudest on inspiration (see congenital heart disease).

7. INFECTIVE ENDOCARDITIS

Infective endocarditis (IE) is an illness caused by microbial infection of the cardiac endothelial surface. *Acute bacterial endocarditis* (ABE) is caused by virulent organisms and runs its course over days to weeks. *Subacute bacterial endocarditis* (SBE) is caused by organisms of low virulence and runs its course over weeks or months.

Risk of developing infective endocarditis is give in Table 59.

Factors determining site of infection – The common factor is a high velocity jet of blood which damages the endocardium. Mild valvular abnormalities are more susceptible to infection than severe abnormalities. A regurgitation stream and a large pressure drop across a small orifice increase likelihood of infection, e.g. mild AR or MR, or small VSD. Hypertrophic cardiomyopathy is associated with pressure gradients with high velocity jets, and infection is not uncommon.

INFECTION OF NATIVE VALVES

Massive infection of right side of heart in drug addicts who inject themselves IV under unsterile conditions. Patients with normal valves are more often infected with pyogenic organisms than those with chronic valve disease, possibly because endocarditis caused by pyogenic organisms follows direct bacterial implantation on the valve rather than infection of pre-existing platelet fibrin vegetation.

SURGICAL ENDOCARDITIS

Surgical endocarditis may follow any type of surgery and is often caused by Staph. epidermidis. *Prosthetic valve endocarditis* (PVE) can be divided into:

Table 59: Risk of developing infective endocarditis

<i>Relatively high risk</i>
• Prosthetic heart valves.
• Aortic valve disease
• Mitral regurgitation + stenosis
• Congenital heart disease
– Persistent ductus arteriosus
– Ventricular septal defect
– Coarctation of aorta
– Marfan's syndrome
– Cyanotic congenital heart diseases.
• Previous infective endocarditis.
<i>Intermediate risk</i>
• Mitral valve prolapse
• Mitral stenosis
• Tricuspid valve disease
• Pulmonary valve disease
• Asymmetrical septal hypertrophy
• Calcific aortic sclerosis
• Non-valvar intracardiac prosthetic implants
<i>Very low risk</i>
• Atrial septal defect
• Atherosclerotic plaques
• Post myocardial infarction thrombi, atrial thrombi and ventricular aneurysms
• Syphilitic aortitis
• Cardiac pacemakers
• Surgically corrected cardiac lesions (without prosthetic implants)
• Valve bearing conduits, or indwelling plastic catheters for hydrocephalus in children.

(a) *Early PVE* – where organisms gain access during surgery or through wound infection and which usually presents within 1–2 months after surgery.

(b) *Late PVE* – caused by the same range of organisms which invade native valves.

The left side of the heart is much more commonly involved because of higher oxygen saturation promoting growth of aerobic bacteria, and the higher pressure causing more intimal damage.

Right-sided endocarditis is not limited to injection drug users. Modern imaging techniques like PET scanning are helpful in localizing the focus of infection in a patient with unexplained bacteraemia.

CAUSATIVE ORGANISMS

- **Bacterial** – Common – Streptococcus viridans. Streptococcus faecalis and Staphylococcus epidermidis. Staphylococci are common in early post-operative cases and among drug addicts. Uncommon – Pneumogono- or meningococcus, B. proteus, B. pyocyaneus, Gram-negative organisms from the bowel, and HACKE (Haemophilus spp., Actinobacillus spp., Corynebacterium spp., Eikenella corrodens, and Kingella spp.).
- **Non-bacterial** – (a) Rickettsial – Coxiella burnetii. (b) Fungal – Candida, monilia, aspergillus, histoplasma and torulosis. (c) Chlamydia type B agent of psittacosis.

PORTAL OF ENTRY

- Dental extraction or scaling
- Tonsillectomy
- Genitourinary and rectal procedures – Catheterization, D and C, sigmoidoscopy
- Bedsores
- Puerperal infection
- Cardiac surgery or cardiac catheterization
- Long-standing intravenous infusions
- IV drug taking in addicts
- Insertion of IUCD

PATHOPHYSIOLOGY

Ulceration of the valvular endocardial surface promotes bacterial adherence by two possible mechanisms:

1. Direct contact between blood and subendothelial components results in production of coagulum or a small clot. Pathogens associated with IE circulating in the blood stream as a result of transient bacteraemia bind avidly to the coagulum and in turn attract and activate monocytes to produce cytokines, resulting in progressive enlargement of an infected vegetation.
2. Local inflammation promotes cells to express transmembrane proteins that bind fibronectin. Pathogens such as Staph. aureus carry fibronectin binding proteins on the surface. Staphylococcal endocarditis is often seen in patients with normal valves, and micro-ulceration are thought to be responsible for endocarditis by this mechanism.

MODES OF ONSET

1. Usually insidious with vague ill health and symptoms of fatigue, loss of appetite with or without pyrexia.
2. Influenzal onset with chills and sore throat.

3. Pyrexia of unknown origin.
4. Musculoskeletal syndrome with myalgia, joint pains, and at times fleeting arthritis like rheumatic fever.
5. Neurologic syndrome – May present as a case of focal neurological deficit due to cardioembolic stroke, meningitis, subarachnoid haemorrhage, hemiplegia, coma or convulsions.
6. Haematologic syndrome – Fever, anaemia.
7. Peripheral vascular disease – Gangrene.
8. Splenic infarct.
9. Congestive heart failure without obvious cause in elderly.
10. Unilateral blindness
11. Pneumonia
12. Kidney failure
13. Pleurisy

Atypical presentation is common in elderly or immunocompromised patients, in whom fever is often absent.

CLINICAL FEATURES

Sign of Infection

- **Fever** – variable, low grade. In acute endocarditis, hectic fever, rigors and extreme illness. No fever if CHF, chronic kidney failure, fungal endocarditis, prior antibiotic therapy, severe sepsis, or old age.
- **Anaemia** – Yellow muddy discolouration of skin.
- **Clubbing** – of fingers and toes occurs early.
- **Splenomegaly** – after about 6 weeks of illness. Sudden enlargement with tenderness and rub if infarction of spleen. Rarely gross splenomegaly.
- **Arthralgia** – Sudden transient pains in joints without any effusion.

Cardiac Signs

- **Murmur**
 - *Organic heart murmur* – due to valvular defect or congenital cardiovascular lesions.
 - *Alteration in intensity of murmur*
 - *Development of new murmurs* – due to perforation of ventricular septum, rupture of sinus of valsalva, acute MR or acute AR.
 - *Absence of murmur* – (a) Endocarditis involving mural thrombus complicating healed myocardial infarction. (b) Early acute endocarditis involving previously normal valve. (c) Tricuspid endocarditis, when it exists, may be murmur free.
- **Cardiac failure** – may occur due to toxic myocarditis. Rarely pericarditis, or coronary occlusion. In case of acute valvular regurgitation, pulmonary oedema will occur with little cardiac enlargement and with a sharp fall in cardiac output.

Systemic Embolism

Arterial

- *Cerebral* producing hemiplegia or mycotic aneurysms which may subsequently rupture.
- *Renal* causing colic and hematuria.
- *Retinal* with disturbing vision.
- *Of mesenteric arteries* causing acute abdominal pain; splenic infarction with sudden local pain and perhaps friction.
- *Peripheral vessel* resulting in gangrene of an extremity. Early prosthetic valve endocarditis emboli that occlude large vessels would suggest fungal endocarditis.

Pulmonary

Pulmonary (with left-to-right shunts or involvement of pulmonary valve). Recurrent pneumonitis (infective emboli cause abscesses) and arterial rupture.

Immunological

Skin

- *Thenar and hypothenar eminences*
 - Osler's nodes – Tender, pea-sized nodules on pads of fingers and toes. Often pale in the centre. May occur in crops. Fade after few days usually without breaking down or leaving any residue. Either due to minute emboli in superficial terminal vessels or due to vasculitis.
 - Janeway lesions – Large non-tender macules on palms and soles, it is vascular phenomenon due to septic embolization.
- *Skin and mucous membranes*
 - Petechial haemorrhages in palpebral conjunctivae, buccal and pharyngeal mucous membrane.
- *Subungual* – Splinter haemorrhages
- *Finger and toe tips* – Osler's nodes
- *Retina* – Roth spots – Lesions with a white centre and red edge. Boat-shaped hemorrhage
- *Renal* – Glomerulonephritis leading to kidney failure

COMPLICATIONS (CAUSES OF DEATH)

1. Acute valve perforation
2. Embolism and rupture of mycotic aneurysm
3. Kidney failure

INVESTIGATIONS

1. *Blood cultures* – In absence of recent or concurrent antibiotic therapy, the first 3 random blood cultures (2–4 hours apart) are positive in most patients, and blood culture is positive by third day in 90%.

2. *Urine* – Microscopic hematuria most common finding. Slight albuminuria and hyaline and granular casts also found.
3. *Haematology* – Normocytic normochromic anaemia, usually mild. May be raised ESR and raised C-reactive protein.
4. *Chest radiograph* – may be diagnostic in right sided endocarditis, with multiple shadows visible due to an embolic pneumonia.
5. *ECG* – Myocardial infarction seen on ECG may be due to coronary embolism, and a conduction defect may be due to development of an aortic root abscess.
6. *Echocardiography* – Higher sensitivity in identifying vegetation with TOE as compared to TTE. (a) Vegetations: An echodense structure attached to the valve or its supporting structures, or lying in the track of a turbulent jet, which is irregular in shape. (b) Leaflet

Table 60: Modified Duke criteria for the diagnosis of infective endocarditis

Pathological criteria
<ul style="list-style-type: none"> • Positive histology or microbiology of pathological material obtained at autopsy or cardiac surgery (valve tissue, vegetations, embolic fragments, or intracardiac abscess content).
Major criteria
<ul style="list-style-type: none"> • Two positive blood cultures showing typical organisms consistent with infective endocarditis, such as <i>Streptococcus viridans</i> and the HACEK group OR • Persistent bacteraemia from two blood cultures taken >12 hours apart or three or more positive blood cultures where the pathogen is less specific, such as <i>Staphylococcus aureus</i> and <i>Staph epidermidis</i> OR • Positive serology for <i>Coxiella burnetii</i>, <i>Bartonella</i> species, or <i>Chlamydia psittaci</i> OR single culture positive for <i>Coxiella burnetii</i> • Positive molecular assays for specific gene targets • Positive echocardiogram showing oscillating structures, abscess formation, new valvular regurgitation, or dehiscence of prosthetic valves
Minor criteria
<ul style="list-style-type: none"> • Predisposing heart disease or intravenous drug abuse. • Fever >38°C • Immunological phenomena such as glomerulonephritis, Osler's nodes, Roth spots, or positive rheumatoid factor • Microbiological evidence not fitting major criteria • Elevated C reactive protein or erythrocyte sedimentation rate • Vascular phenomena such as major emboli, splenomegaly, clubbing, splinter haemorrhages, petechiae, or purpura
Definite infective endocarditis
<ul style="list-style-type: none"> • Pathological criteria positive OR • Two major criteria OR • One major and two minor criteria OR • Five minor criteria

perforation is best seen as regurgitant jet on colour flow mapping. (c) Annular and periprosthetic echolucent spaces (abscesses) and fistula formation.

DIAGNOSTIC CRITERIA

The diagnosis of infective endocarditis requires a multifaceted approach involving clinical suspicion and examination, laboratory investigations by means of inflammatory markers and microbiological analysis, and imaging with echocardiography. The modified Duke's criteria unite these modalities to arrive at an accurate diagnosis (Table 60).

MANAGEMENT

A. Antibiotics

- *Principles* - (a) Should be given early before irremediable complications occur. (b) Adequate dosage, the amount depending on the sensitivity of the organism to the antibiotic. (c) Bactericidal antibiotics such as penicillin (including ampicillin derivatives), cephalosporins and aminoglycosides must be used alone or in combination. (d) Must be continued long enough to sterilize all vegetations and all possible embolic foci, usually 6–8 weeks.

Initial Therapy - Choice of antibiotic is determined initially by deducing the infective organism, and the antibiotic can, if necessary, be adjusted later according to laboratory guidance. Two antibiotics should be used in combination for their synergistic effect and to deter development of resistance.

If suspected Staphylococcal infection - Flucloxacillin 12–15 g/24 hours and gentamicin. To ensure high peak concentrations, antibiotics are best given by IV bolus into a central venous line in subclavian or jugular vein.

Specific therapy - When sensitivities are known (Table 61).

Duration of treatment - In absence of complications treatment is usually continued for 6 weeks, but the duration depends on the infecting organism, duration of symptoms before diagnosis, rapidity of response and presence or absence of prosthetic valve or material.

Special problems

Negative blood cultures - Causes:

1. Patient has received antibiotics in recent weeks.
2. Infection by cell-dependent or fastidious organisms including Legionella, Coxiella, the HACEK group, and fungus such as Candida, Histoplasma, and Aspergillus species. Serological testing can be particularly useful for investigating the possibility of Coxiella burnetii and Bartonella infection.
3. Infection due to Streptococcus spp. with special growth requirements.

Penicillin allergy - Patients with a history of penicillin reactions and those who develop sensitivity during the course of treatment should be given IV erythromycin lactobionate 4 g/24 hours with oral rifampicin 10 mg/kg/24 hours.

Persistence of fever - If fever remains uncontrolled with presumably adequate treatment, possibilities are - (1) Drug hypersensitivity (rash and other manifestations). (2) Local reaction at injection site. (3) Persistence of focus of infection e.g. splenic or other abscess, dental apical granuloma. (4) Bacterial L-forms resistant to usual antibiotics may have developed. (5) Increased bacterial resistance can be acquired during treatment due to inadequate initial treatment. (6) Unsuspected multiple infections. (7) Another organism may have been acquired during therapy especially if indwelling IV lines are used.

Table 61: Antibacterial regimes for endocarditis

Organism	Regimen
Strep. viridans	Penicillin G 4 million U q6h + Gentamicin 1 mg/kg q12h or Ceftriaxone 2 g od
Enterococci	Penicillin G or Ampicillin 2 g IV q6h or Vancomycin 15 mg/kg q12h + Gentamicin 1 mg/kg q8h (or Tobramycin 3–5 mg/kg q6h)
Strep. bovis, Strep. faecalis and other penicillin-resistant Strepto.	Vancomycin 10 mg/kg q12h IV Ampicillin 8 g/24 h + Gentamicin 1 mg/kg q8h or Vancomycin 15 mg/kg q12h + Gentamicin 1 mg/kg q8h
Staph. aureus	Flucloxacillin 12–16 g/24 h + Gentamicin 1 mg/kg q8h or Netilmicin 6 mg/kg q8h
Staph. epidermidis	Fusidic acid 500 mg q8h + IV Vancomycin 1 g/12h or Cefazolin 2 g IV q8h
HACEK group	Ampicillin 2 g IV q4h + Gentamicin 1 mg/kg q12h or Ceftriaxone 1–2 g IV od
Culture-ve prosthetic valve endocarditis	Vancomycin + Gentamicin + Ampicillin, or Cefoperazone 1–2 g IV b.d.
Coxiella burnetii	Doxycycline (100 mg PO q12h) + hydroxychloroquine (200 mg PO q8h), both for 18 (native valve) or 24 (prosthetic valve) months

Infection by cell-dependent organisms: Chlamydia- Doxycycline 4 g/day to start with, then 1 g/day, and replacement of infected valve. The drug can be continued indefinitely if infection cannot be eradicated or, if the valve is sound enough not to require replacement.

Fungal endocarditis - usually caused by *Candida* (Large friable vegetations seen on echo). IV Amphotericin (test dose 5 mg over 2 hours; gradual increase over 7 days to 1 mg/kg/day, to maximum of 2 g) plus oral Flucytosine 100-200 mg/day in 4 divided doses. Surgical excision of prosthetic valves or material essential.

Monitoring antibiotic blood levels - It is advisable that the peak plasma antibiotic concentration should be at least eight times the minimum in vitro bactericidal concentration. Both the minimal inhibitory concentration (MIC) and minimal bactericidal concentration (MBC) of the antibiotics administered should be determined. The two titres are normally the same and the development of bacterial tolerance can be recognised if the MBC becomes much higher than the MIC. Blood levels of the aminoglycosides should always be measured.

- B. **General measures** - (a) Complete rest in bed. (b) High protein diet with added vitamins and iron. (c) Small repeated blood transfusions if severe anaemia
- C. **Surgical measures** - Indications for surgical interventions in endocarditis are given in Table 62.

PROPHYLAXIS

Endocarditis prophylaxis is described in Table 63.

- **Noninfective endocarditis** refers to sterile platelets and fibrin formation on cardiac valves and adjacent endocardium in response to trauma, circulating immune complexes, vasculitis or a hypercoagulable state.
- **Non-bacteraemic thrombotic endocarditis:** Vegetations tend to form on congenitally abnormal valves or those damaged by rheumatic fever. It often occurs in malignancy and wasting disorder, e.g. TB, uraemia, AIDS. The initiating factor in NBTE is not known. Endothelial damage by circulating cytokines (e.g.

Table 62: Indications for surgical interventions in endocarditis

- Infection cannot be controlled medically
- Acute or chronic heart failure as a result of valve destruction especially aortic valve, septal defects, aneurysms and major emboli
- Early prosthetic valve endocarditis
- In *Candida* infection removal of prosthesis is essential
- Infected tricuspid valve (common in drug addicts) may be removed without replacement
- Detection of abscess formation by CSE since it indicates advanced infection
- Infection by resistant organism such as fungi, *Coxiella* or *Staph. epidermidis*, or by a rapidly destructive organism such as *Staph. aureus*
- Large vegetations (>10 mm) on mitral valve with high embolic potential

Table 63: Endocarditis prophylaxis

Clinical situation	Antibiotic	Dose
Standard prophylaxis	Amoxicillin	2 g PO 1 hr before procedure
Unable to take oral medications	Ampicillin	2 g IV or IM within 30 min before procedure
Penicillin allergy	Clindamycin or Cephalexin or cefadroxil or Azithromycin or clarithromycin	600 mg PO 1 hr before procedure 2 g PO 1 hr before procedure 500 mg 1 hr before procedure
For Genitourinary/Gastrointestinal (excluding oesophageal procedures)		
High-risk patients	Ampicillin plus gentamicin (within 30 min of starting procedure) followed by ampicillin or Amoxicillin (6 hr later)	2 g IM or IV 1.5 mg/kg IV or IM (not to exceed 120 mg) 1 g IM or IV
High-risk patients allergic to penicillin	Vancomycin plus gentamicin (within 30 min of starting procedure)	1 g PO or 1 g IV over 1–2 hr 1.5 mg/kg IV or IM (not to exceed 120 mg)
Moderate-risk patients	amoxicillin or ampicillin	2 g PO 1 hr before procedure 2 g IV or IM within 30 min of starting procedure
Moderate-risk patients allergic to penicillin	Vancomycin	1 g IV over 1–2 hr completed within 30 min of starting the procedure

tumour necrosis factor or interleukin which can be increased in malignancy or chronic wasting diseases might trigger platelet deposition

- **Libman-Sacks endocarditis:** Develops due to circulating immune complexes, vegetations 3–4 mm in size and composed of degenerating valve tissue. Most common on ventricular surface of mitral valve may become a nidus for infection leading to infective endocarditis seen in SLE.

8. CARDIOVASCULAR SYPHILIS

Aetiology – Age – Peak incidence between 35 and 50. Sex – Males predominate. *Latent period* – after primary syphilis 15–25 years.

CLINICAL MANIFESTATIONS

- Aortitis** – Suggestive diagnostic criteria:
 - Dilatation of ascending aorta.
 - Tambour quality of aortic second sound in absence of hypertension or atherosclerosis.
 - Systolic aortic murmur.
 - Burning retro-sternal pain and breathlessness.
 - Calcification of ascending aorta (in late stages).
- Angina pectoris** – Due to aortitis affecting nearby coronary ostia. Syphilitic angina pectoris differs from angina of atherosclerotic origin thus –
 - Duration of attacks tends to be longer.
 - Nocturnal attacks are more frequent.
 - Sublingual nitroglycerine is not so effective.
 - Myocardial infarction is uncommon, but is frequently fatal.
- Aortic regurgitation** – Refer
- Syphilitic aortic aneurysm** – occurs most often in ascending aorta.

Aneurysm of ascending aorta – (Aneurysm of signs) (Fig. 98).

Symptoms

Rare: Pain on right side of chest or back. Feeling of engorgement of face and arms on stooping. Dyspnoea or paroxysms of cough (gander or bovine cough). Occasionally haemoptysis may be the first symptom.

Signs

Inspection – Face and neck of high colour. Swelling of one or both arms and engorged veins on front of chest. Unilateral finger clubbing may be seen usually right-sided. Visible pulsating mass may be seen in 2nd or 3rd right interspace, and there may be exaggerated pulsations in the right sternoclavicular joint or in the episternal notch.

Fig. 98: Aneurysm of ascending aorta

Palpation – Diastolic shock in aortic area.

Auscultation – Ringing 2nd aortic sound. Systolic and diastolic murmurs may be heard.

Pulse – Volume reduced. BP lower on right side.

Signs of Compression

- Pressure on right eparterial bronchus may cause diminished air entry at right apex.
- Involvement of right recurrent laryngeal nerve produces at first abductor paralysis followed by complete paralysis.

Aneurysm of arch – (Aneurysm of symptoms).

Symptoms and signs

1. Due to compression of surrounding structures

- **Trachea or bronchus** – Cough, dyspnoea, haemoptysis, tracheal tug, diminished air entry in either lobe of lung and rarely bronchiectasis.
- **Oesophagus** – Dysphagia.
- **Vessels** – (i) Veins – Oedema of face and neck, distended neck veins, prominent veins on upper chest. (ii) Arteries – Radial pulse weaker and BP lower in left arm.
- **Nerves**
 - Left recurrent laryngeal – Hoarseness of voice.
 - Cervical sympathetic – Horner's syndrome.
 - Vagus – Tachycardia.
 - Phrenic – Hiccough and paralysis of left dome of diaphragm.
 - Intercostal nerves and brachial plexus – Chest pain and pain in left arm.
 - Bones** – Deep seated continuous bone pain due to erosion of bones.

2. **Systolic pulsations** – may be detected over manubrium or left interscapular region and thrill may be palpable.
- V. Myocarditis** – (i) *Diffuse granulomatous myocarditis* – Arrhythmias or congestive cardiac failure. (ii) *Localised gumma* – AV block or valvular pseudostenosis if gumma impinges on ventricular outflow tract.

MANAGEMENT OF CARDIOVASCULAR SYPHILIS

1. **Active treatment** – Benzathine Penicillin G 2.4 million units IM weekly for 3 weeks. Effects of Jarisch-Herxheimer reaction (fever, tachycardia) at the start of a course can be reduced by Prednisolone 30–40 mg in divided doses daily for 2–3 days before and after the first dose of antimicrobial, reducing by 5 mg/day thereafter. In case of penicillin sensitivity, Tetracycline 500 mg qds. or Doxycycline 100 mg b.d. for 4 weeks.
2. **Treatment of heart failure** – if present is carried out first.
3. **Treatment of syphilitic aneurysm** – Surgical excision of the aneurysm and replacement of excised portion by suitable graft.

9. ISCHAEMIC HEART DISEASE

ETIOLOGICAL AND RISK FACTORS

1. **Age** – In men and women, the mortality rate from IHD rises steeply with increasing age. It is probable that the age factor in susceptible subjects is caused primarily by the cumulative effects of multiple risk factors over time.
2. **Sex** – Male preponderance. After menopause however incidence in men and women is more or less same.
3. **Body habitus** – IHD is more common in men of endomorphic habitus – those with softness and roundness of body contour without great muscular development and with small extremities.
4. **Ethnicity** – Atherosclerosis and IHD can affect all races and ethnic groups, given the appropriate environment and circumstances. Migration studies show significant effects of environmental factors e.g. Japanese immigrants show the same rate of IHD as other Americans.
5. **Serum lipids and dietary factors** – implicated are a high intake of saturated fat and relatively low ratio of polyunsaturated to saturated fats. Intake of dietary cholesterol plays an additional but less predictable role.

Serum cholesterol (TC) – Risk of IHD increases continuously over the whole range of serum TC concentrations.

Serum HDL cholesterol – is regarded as the ‘protective’ cholesterol, low concentrations are associated with increased risk. The TC:HDL cholesterol ratio is an efficient measure of lipid-related risk.

Serum triglycerides (TG) – Elevated levels are independent risk factor. However, TG has a role as a synergistic risk factor with other lipid risk factors.

Small dense LDL (LDL phenotype B). LDL particles are heterogenous and have been characterised as small and large LDL. Patients with pattern B have small dense LDL. There is increased evidence linking LDL phenotype B to increased risk of IHD.

Lipoprotein (a) [Lp (a)] – Lp (a) is an LDL particle bound to apolipoprotein B that resembles plasminogen, and this makes lipoprotein (a) play a role in both atherosclerosis and thrombosis.
6. **Hypertension** – carries increased risk of IHD due to degenerative effects of high pressure on arterial wall.
7. **Cigarette smoking** – There is a continuous increase in risk of IHD with increased intensity of cigarette smoking, particularly in younger age groups. The prevalence of IHD also seems to be appreciably increased in pipe or cigar smokers or those who chew tobacco.
8. **Overweight and obesity** – carry a two-fold risk of a major IHD event. Increasing body wt. is associated with increasing levels of BP, serum TC, serum TGs and serum insulin, and decreased levels of HDL cholesterol and physical activity. There is now good evidence that central obesity, as measured by the waist:hip or waist:height ratio, or even simple waist circumference, is an independent risk factor for IHD.
9. **Physical activity** – Studies of work and leisure activity indicate that sustained, regular physical activity in leisure time (e.g. regular brisk walking), is protective against IHD.
10. **Diabetes mellitus** – is not an essential cause of IHD but can aggravate the development of such disease. Asymptomatic hyperglycaemia appears to be an independent risk factor for major IHD events.
11. **Family history** – IHD is known to cluster in families and a positive family history of IHD, particularly if it occurs in a first-degree relative at an early age (<50 years for men, <55 for women) is an independent risk factor for IHD.
12. **Homocysteine** – Elevated levels of homocysteine (generally >14–15 $\mu\text{mol/L}$) are associated with increased risk of CHD. It may cause vascular damage due to its deleterious effects on endothelial function, its prothrombotic, prooxidant and mitogenic effects.
13. **Emotional factors** – IHD is more likely to develop in a person with aggressiveness, competitiveness and a sense of time urgency. Also in depression.

14. **Other possible risk factors** – Programming in foetal life due to maternal malnutrition, social inequalities involving psychosocial factors and stress, infection and inflammation (currently focussed on *H. pylori* and *C. pneumoniae*), the metabolic syndrome, thrombogenic and fibrinolytic factors, postprandial lipaemia and genetic factors.

Major causal risk factors are – Cigarette smoking, high blood pressure, elevated serum cholesterol or LDL cholesterol, low HDL cholesterol and high plasma glucose.

ACUTE CORONARY SYNDROME (ACS)

ACS represents clinically acute myocardial ischaemia and comprises:

1. Unstable angina (UA)
2. Non-ST elevated myocardial infarction (NSTEMI)
3. ST elevated myocardial infarction (STEMI)

NSTEMI usually results from severe coronary artery narrowing, transient occlusion or microembolization of thrombus and/or atheromatous material. NSTEMI is defined as elevation of cardiac biomarkers in absence of ST elevation. The syndrome is termed unstable angina in absence of elevated cardiac enzymes.

STEMI results from complete and prolonged occlusion of an epicardial blood vessel and is defined based on ECG criteria.

Management of ACS should focus on rapid diagnosis, risk stratification and institution of therapies that restore coronary blood flow and reduce myocardial ischaemia.

ANGINA PECTORIS

Angina pectoris is the discomfort resulting from acute myocardial ischaemia.

Pathophysiology

Acute myocardial ischaemia occurs when myocardial oxygen demand exceeds supply

1. *Coronary atherosclerotic narrowing* (most cases).
2. *Non-atherosclerotic coronary artery disease* – Coronary spasm, coronary thromboembolism, congenital anomalies, coronary vasculitis.
3. *Valvular heart disease* – AS and/or AR. MS with pulmonary hypertension, mitral valve prolapse.
4. *Pulmonary hypertension*.
5. *Systemic hypertension*.
6. *Hypertrophic or dilated cardiomyopathy*.
7. *Anaemia* – from tachycardia and reduction in O₂ availability.

Myocardial viability

Myocardium that is dysfunctional but viable results from:

- (1) Chronic flow impairment (*hibernating myocardium*).
- (2) An episode of acute ischaemia – the duration of dysfunction depends on the severity of the ischaemic insult (*stunned myocardium*).

Precipitating Causes

1. Physical exertion
2. Heavy meal
3. Exposure to cold
4. Emotion and excitement particularly anxiety and anger
5. Hyperinsulinism in diabetic patients
6. Other causes – Straining at stool, bathing, sexual intercourse, micturition

I. Stable Angina Pectoris

Angina is said to be stable when there has been no change in the frequency, duration, precipitating factors, or ease of relief of anginal attacks during last 60 days (provided patient's activity level has not decreased during that period).

Symptoms

1. **Typical Anginal Pain or Distress:**
 - (a) *Site* – Most often over middle or lower sternum or over left precordium, at times in epigastrium. Sometimes discomfort is located only in left shoulder or left upper arm, occasionally in lower jaw, rarely in interscapular area.
 - (b) *Radiation* – May spread to right or left arm or both, neck or jaw. Occasionally pain starts in the wrists, upper arms or face and then spreads to the chest.
 - (c) *Character* – Vice-like constriction or choking. Sometimes only pressure or burning pain, rarely mere weakness of one or both arms. An important characteristic is its constancy, the pain being steady while it lasts.
 - (d) *Duration* – most commonly 1 to 4 minutes. May force patient to stop walking.
 - (e) *Provocation* – by effort specially like walking against the wind or up a climb, hurrying after meals, or unaccustomed exercise. At times due to excitement, anger, fear. In advanced cases, pain is provoked by lying down (angina decubitus) or stooping.
 - (f) *Relief* – with sublingual nitroglycerine.
2. Dyspnoea – if it occurs before the pain suggests severe ventricular disease.
3. Other Symptoms – (a) Choking sensation in throat or feeling of impending doom. (b) Belching or passage of

flatus or polyuria after an attack. (c) Dizziness, faintness or rarely syncope. (d) If pain is severe, sweating and nausea.

Signs

1. *No signs.*
2. *Signs of LV dysfunction* – Atrial or third heart sound. If LV ejection time is increased, the aortic valve closes late and second sound becomes single, or splitting is reversed.
3. *Dysfunction of papillary muscle* – can lead to transient mitral regurgitation in case of ischaemia.
4. *Signs associated with risk factors* – (a) Hypertension. (b) Hyperlipidaemia–Arcus senilis, xanthelasma, or cholesterol deposits along tendons and in skin of palms and buttocks. (c) Obesity. (d) Diabetes and its accompaniments.
5. *During the attack* – Pallor and sweating with rise of BP. Often tachycardia. Pressure on carotid sinus may produce slowing of pulse and cessation of pain.

Grading of Effort Angina

1. Ordinary physical activity, e.g. walking, climbing stairs does not cause angina. Angina with strenuous or rapid or prolonged exertion.
2. Slight limitation of ordinary activity. Walking or climbing stairs rapidly, walking uphill, walking or stair climbing after meals, or in cold or against a wind, or under emotional stress, or only during the few hours after awakening. Walking more than two blocks on the level and climbing more than one flight of ordinary stairs in normal conditions and at normal pace.
3. Marked limitation of ordinary physical activity. Walking one to two blocks on the level and climbing one flight of stairs in normal conditions and at normal pace.
4. Inability to carry out any physical activity without discomfort – anginal syndrome may be present at rest.

Clinical Variations (Atypical Forms)

1. *Site and character of pain* – Pain may start in one of the sites of radiation and may be confined to that area, e.g. only the left wrist, or pain may be sharp and occur only in the left chest.
2. *Dyspnoea* – with or without angina, and exhaustion.
3. *Episodic or chronic fatigue and exhaustion* – due to reduced cardiac output secondary to ischaemia-induced depression of myocardial contractility.

4. *Second wind angina* – Pain occurs at beginning of exertion, subsequently the patient is able to ‘walk off’ the pain.
5. *Nocturnal angina* – may develop after a period of angina of effort, or may represent the initial pattern of angina. It may be related to dreams, or latent LV failure.
6. *Angina with syncope* – may be caused by cardiac arrhythmia.
7. *Sweating and nausea (or vomiting)* because of severe pain.
8. *Bradycardia angina* – Angina results from inability of heart to accelerate adequately in response to exercise or emotion.
9. *Paroxysmal atrial fibrillation* – may be the first evidence of ischaemic heart disease particularly in middle-aged patients.

Diagnosis Tests

1. **ECG at rest** – may be normal or show ST-T changes suggestive of ischaemia, or AV or intraventricular conduction defects.
2. **Holter monitoring** – is helpful in evaluating total ischaemic burden, i.e. episodes of painful or painless myocardial ischaemia.
3. **Stress testing** – Cardiovascular stress can be provoked physically by exercise, or pharmacologically (in patients who cannot exercise).
 - (a) Exercise stress testing – With continuous ECG monitoring and intermittent BP recording is performed with a treadmill or bicycle ergometer. Standardised protocols are used (e.g. Bruce protocol), enabling performance to be assessed in same patient at different times and work-load at onset of symptoms or ECG changes to be determined. An exercise ECG is abnormal if there is horizontal or down-sloping ST segment depression of 0.1 mm or more in any lead (Figs. 99A and B).
 - (b) Pharmacological stress – (Myocardial perfusion scintigraphy) – Use of isotope labelled perfusion tracers and scintigraphic imaging to demonstrate areas of reduced myocardial perfusion is a sensitive and reliable method of establishing a diagnosis of myocardial ischaemia – vasodilator stress with dipyridamole or adenosine, as well as catecholamine stimulation with dobutamine or arbutamine. The isotope cardiovascular stress (usually thallium-201 or technetium-99 m) is injected at peak exercise and images taken with a camera immediately or shortly after exercise and compared with rest images taken a few hours later following a sec-

Figs. 99A and B: Positive exercise test. A. Control tracing before exercise within normal limits. B. Striking ST depression after exercise

ond injection of tracer. Areas of myocardial ischaemia are identified by reduced isotopic uptake in the same anatomical distribution stress images but not resting images (reversible defect).

Indications – (i) Patient unable to exercise or with limited capacity to exercise. (ii) Patient with resting or exercise-induced LBBB.

4. **Coronary angiography** – remains the ‘gold standard’ technique for diagnosis and planning treatment of IHD (Fig. 100).

Differential Diagnosis

See D.D. of myocardial infarction.

Anxiety states – (Table 64)

Investigations

Echocardiography – 2D and M-mode echocardiography are valuable in assessment of resting ventricular function and can identify areas of segmentally reduced contraction corresponding to previous MI.

Stress echocardiography – Continuous 2D-echocardiography is performed at rest and during and after stress and image comparison is used to determine the extent and distribution of wall motion abnormalities.

Stress can be provoked by exercise or by pharmacological stimulation which can be used to predict the location and severity of underlying coronary artery disease.

Intravascular ultrasonography (IVUS) – defines completely the vessel wall, plaque burden, morphology of the plaque, presence of calcification in the lesion, and luminal dimensions.

Intracoronary Doppler – Clinical applications include assessment of functional significance of intermediate lesions by coronary arteriography. With use of Doppler wire the velocities and coronary flow reserve across the lesion can be estimated.

Management

Fig. 100: Coronary angiography showing multivessel disease

Table 64: Differentiating anxiety from angina

<i>Angina pectoris</i>	<i>Anxiety states</i>
Usually in men over 50	Common in women and young men.
Pain sternal or across chest.	Pain mammary, above or below left breast.
Radiation to one or both arms, neck and jaw.	Radiation to left scapula, left arm and left side of neck.
Sensation of constriction, tightness, or pressure.	Dull ache or soreness with stabbing or shooting pain.
Provoked by effort.	Provoked by worry and fatigue.
Pain during effort.	Pain may occur after effort.
Relieved at once by halting.	May persist for hour or day, little and slow relief by rest.
Usually well apart from pain.	Symptoms of general and neurotic ill-health. Sighing respirations.

- Acute attack** – Glyceryl trinitrate 0.6 mg or isosorbide dinitrate 5 mg sublingually, or nitrite spray in a measured dose of 0.4 mg. Effect starts in 3 to 5 minutes and its action lasts for 20 to 40 minutes. Contraindicated in patients with glaucoma.
- Prophylaxis** – In chronic stable angina.

General measures

1. **Control of risk factors** – (a) Hypertension. (b) Cigarette smoking. (c) Hyperlipidaemia. (d) Obesity. (e) Correction of disorders which increase myocardial oxygen demand such as anaemia and hyperthyroidism if present.

2. *Rest and exercise* – Bed rest not essential unless frequent attacks. Moderate exercise which does not cause pain or dyspnoea allowed.
3. *Relaxation techniques* and stress management.
4. *Aspirin* – 75–150 mg/day.
5. *Sedatives* – to relieve mental tension and control emotional factors.

Antianginal agents

See Table 65 for the antianginal agents.

Symptom deterioration – Symptoms may worsen because of worsening in underlying condition, development of tolerance or poor patient compliance. Further investigation is then indicated, specifically angiography with a view to revascularization by angioplasty or surgery.

Myocardial Revascularization Techniques

Percutaneous transluminal coronary angioplasty (PTCA)

Indications

1. Chronic stable angina:

- (a) *Single vessel disease* – Diameter stenosis of >70% in an epicardial coronary artery that supplies a large area of viable myocardium with evidence of myocardial ischaemia by low level of exercise. (i) Prior cardiac arrest or sustained VT in absence of acute MI. (ii) Must undergo high risk noncardiac surgery with objective evidence of ischaemia. (iii) Symptomatic despite medical therapy or intolerant to medical therapy.

1. Unstable angina/acute coronary syndrome
2. In presence of myocardial infarction
3. Angina after myocardial infarction
4. After bypass surgery when surgical grafts get narrowed or new lesions form in native coronary arteries.
5. In patients who are at high risk for CABG, e.g. elderly, kidney failure, emphysema.
6. Multivessel disease in patients who do not wish for a surgical procedure.

2. Acute myocardial infarction:

- (a) *Primary PTCA* – Direct angioplasty without thrombolytic therapy for evolving MI results in better arterial patency compared to lytics, with improved survival and reduced recurrent ischaemia. Indications – (i) Thrombolytic therapy contraindicated. (ii) Acute MI with cardiogenic shock.

Table 65: Antianginal agents

Drug	Dose	Side-effects
Nitrates		
Glyceryl trinitrate	0.3–0.6 mg sublingual	Headache
Transdermal	5–10 mg/24 hrs.	Headache in early stages
Isosorbide dinitrate	30–120 mg in divided doses	
Isosorbide mononitrate	40–100 mg in divided doses	
β-blockers		
<i>Non-selective</i>		
Propranolol	30–360 mg in divided doses	Bronchospasm. Bradycardia
Nadolol		Cold peripheries
Pindolol		
<i>Selective</i>		
Metoprolol	50–200 mg/day	Bronchospasm
Atenolol	50–100 mg/day	Bradycardia. Cold peripheries
Bisoprolol	10–20 mg/day	Postural hypotension
Nebivolol	5–10 mg/day	
Calcium channel blockers		
Verapamil	40–120 mg. t.d.s.	Conduction disturbance
Nifedipine	10–20 mg t.d.s.	Flushing, headache,
Amlodipine	5–10 mg/day	peripheral oedema
Diltiazem	30–60 mg t.d.s.	
Potassium-channel activator		
Nicorandil	10–20 mg t.d.s.	Headache. Hypotension
Cytoprotective effects		
Trimetazidine	20 mg t.d.s.	Gastric discomfort, nausea, headache
Inhibition of SA node		
Ivabradine	5 mg b.d.	Nil. No negative inotropic effects

- (b) *Rescue (salvage) PTCA* – Emergency angiography in acute MI with ongoing chest pain and hemodynamic problems or in asymptomatic patients with anterior MI and persistent or increasing ST elevation 90 min. after thrombolytic therapy. PTCA is then performed on high grade culprit lesion with impaired flow, or occluded artery.

- (c) *Delayed PTCA* - in asymptomatic patients following successful reperfusion with thrombolytic therapy. However no difference has been shown in mortality, reinfarction or ejection fractions as compared to successful thrombolysis. Any asymptomatic patient following thrombolysis should undergo noninvasive evaluation including echocardiography and stress testing.
- (d) *PTCA for post-MI ischaemia* - Post-infarction angina is an absolute indication for angiography and revascularization.

Interventional Devices

Intracoronary stents - scaffold the arterial wall and maintain stretch of a diseased segment of artery. Uses - (a) Prevention of restenosis. (b) Treating abrupt closure or threatened closure. (c) Improving an inadequate angiographic result during PTCA. The risk of closure can be minimised by use of Absorb Bio-reabsorbable Vascular Scaffold (BVS). It functions similar to a metallic stent in the initial phase and then dissolves overtime allowing vessel to return to its natural state, other benefits are elimination of sources of vessel inflammation and provide option for future interventions unobstructed by a permanent implant. Drug eluting stents (DES) are used to avoid risk of stenosis.

Coronary atherectomy - refers to removal of atheromatous material from the coronary lesions. (a) Directional and rotational atherectomy physically cut the atheroma. (b) Rotablation abrades and pulverises the plaque. (c) Transluminal extraction atherectomy (TEC) is used for aspirating plaque and thrombus cut by the rotating blade.

Fig. 101: Coronary angiography showing single vessel disease

Coronary artery bypass graft (CABG) surgery: Indications - (a) Patients who fail to respond to medical therapy or are incapacitated by pain. (b) Those in whom anginal attacks are accompanied by major complications e.g. ventricular tachycardia. (c) Patients with stenosis of left main coronary artery or of all three major vessels.

- (a) *Saphenous vein grafts* - Disadvantage is the high percentage of significant attrition rate with atherosclerotic changes after some time (Figs. 101 and 102).
- (b) *Arterial revascularization* - The internal mammary artery is used as a conduit of choice for left anterior descending artery because of its superior patency rates. Other arterial conduits used include right internal mammary artery, gastroepiploic artery, the free radial artery.

Minimally invasive coronary artery surgery (MICAS) - attempts to avoid the use of cardiopulmonary bypass. In patient with single vessel disease, through a midsternotomy or small anterior thorax incision, the internal mammary artery is anastomosed to the coronary artery, most commonly the left IMA to left anterior descending artery, so that blood can be diverted round the blockage. Esmolol is used to reduce heart rate and contractility, thus facilitating performance of anastomosis without going on cardiopulmonary bypass.

Transmyocardial revascularization: With the help of CO₂ laser. For patients unsuitable for CABG or angioplasty procedures, such as high risk group either with extensive, long standing multivessel disease or associated with severe uncontrollable diabetes, or kidney failure, or even patients with multiple and failed CABGs.

Fig. 102: Angiography after coronary bypass graft

Variant (Prinzmetal's) angina-Diagnostic criteria:

- Anginal attacks occur at rest.
- Attacks often worse in morning.
- ECG – shows transient ST elevation instead of depression during chest pain or Holter monitoring.

Pathogenesis: Coronary vasospasm accounts for episodes. Majority of patients have associated atherosclerotic coronary artery disease.

Diagnostic Tests

1. ECG – during episode of chest discomfort. Besides ST segment elevation, transient abnormal Q waves, AV heart block, ventricular arrhythmias may be detected.
2. Coronary angiography.

Management

1. Drugs – Nitrates and calcium antagonists. Beta blockers may exacerbate.
2. Avoidance of exposure to cold environments.
3. Tobacco smoking to be discontinued.
4. Coronary bypass surgery if coronary stenosis.
5. Angioplasty – in selected patients if significant obstruction in one coronary artery. Possibility of angioplasty-induced coronary spasm.

II. Unstable Angina (UA/NSTEMI)**Diagnostic criteria of unstable angina:**

See Table 66.

Pathogenesis: In unstable angina, myocardial ischaemia results from a primary decrease in oxygen delivery rather than in increase in myocardial oxygen demand.

Statins and other drugs are recommended for all NSTEMI ACS patients irrespective of cholesterol level with the aim of achieving LDLC levels <70 mg/dL. ACE inhibitor in patients with reduced LV systolic function. ARBs in those who are intolerant.

Table 66: Diagnostic criteria of unstable angina

- Angina on effort of recent onset (one month).
- Angina of effort with increasing frequency and duration and provoked by less than usual stimuli (accelerated or crescendo angina).
- Prolonged (>20 min) anginal pain at rest
- Angina in early (<1 month) post-infarction period.
- New onset (de novo) severe angina,
- Recent destabilization of previously stable angina with crescendo angina
- Post MI angina

Coronary revascularization to relieve angina, ongoing myocardial ischaemia and progression to MI or death.

Indications

Refractory angina (e.g. evolving MI)

- Refractory angina despite intense antianginal treatment (associated with ST segment depression (<2 mm) or deep negative T waves
- Clinical symptoms of heart failure or hemodynamic instability (shock)
- Life-threatening arrhythmia (VF or VT)

Conservative and Invasive Strategy

High risk/unstable patients benefit most from early revascularization. The mode of revascularization is usually based on the severity and distribution of CAD. CPI usually performed for the culprit lesion using Bioresorbable vascular scaffold (stent). CAG is advised for complex CAD not amenable to PCI, left main with triple vessel disease, total occlusions and diffuse disease.

Long-term Management

Patients with NSTEMI ACS after initial phase carry a high risk of recurrence of ischaemic events. Therefore, active secondary prevention is an essential element of long-term management.

III. Acute ST Segment Elevation Myocardial Infarction (STEMI)**Precipitating Factors:**

- Physical exertion—Attack more often during physical effort than at rest, unaccustomed effort may precipitate attack.
- Emotional strain acute or prolonged.
- Heavy meal.
- Sudden fall of blood pressure, e.g. shock, post-operative or anaesthesia.

Symptoms

Premonitory – Patient may or may not give history of prior angina pectoris.

Clinical presentation of NSTEMI ACS is retrosternal pressure or heaviness radiating to left arm, neck or jaw which may be intermittent (usually lasting several minutes) or persistent. There are several atypical symptoms such as epigastric pain, recent onset indigestion, stabbing chest pain, chest pain with pleuritic symptoms or increasing dyspnoea. It is important to identify clinical circumstances that may precipitate or exacerbate such as anaemia, infection, fever and metabolic or thyroid disorders.

1. **ECG** may show ST segment deviation, T wave changes or may remain normal, ST segment shift and T wave changes are indicators of unstable angina. ST depression >2 mm carries and increased mortality risk. Inverted T waves, especially of ≥ 2 mm (0.2 mv) also indicate UA/NSTEMI. Q waves suggesting prior MI indicate a high likelihood of IHD.
2. **Echocardiography** and Doppler examination should be done after hospitalization to assess global LV function. ECHO also helps in excluding other causes of chest pain.

Management of NSTEMI

1. Approach

- Patients who are awaiting hospitalization are advised to chew non-enteric coated Aspirin 325 mg and use sublingual nitrate to relieve pain.
- High-risk patient should be hospitalized in CCU and observed for at least 24–48 hours.
- Fibrinolytic (thrombolytic) therapy should not be used in patients with UA or NSTEMI because they can prove harmful. Glycoprotein IIb/IIIa agents like abciximab, tirofiban and eptifibatid are mostly useful in patients undergoing percutaneous coronary intervention (PCI).

Anti-ischaemic and analgesic therapy

- O₂ for initial stabilization particularly those with hypoxaemia.
- Nitrates - Topical, oral or IV for pain relief. IV nitroglycerine is particularly helpful in those unresponsive to sublingual NTG, in hypertension and those with heart failure. Nitrates should be used with caution if systolic BP is below 100 mm Hg.
- Oral beta blockers are useful for pain relief.

2. Antiplatelet agents.

Aspirin - Initial dose of chewed non-enteric Aspirin is 162–325 mg, subsequent dose can be 75–100 mg/d on long-term basis.

- Clopidogrel in all patients with immediate dose of 300 mg followed by 75 mg/d. In patients considered for PCI, a loading dose of 600 mg is advised to achieve more rapid inhibition of platelet function. It should be given for at least 12 months unless there is excessive risk of bleeding, or Prasugrel. 60 mg as single dose initially maintenance 5–10 mg/day.

Anticoagulants include unfractionated heparin: Low molecular wt. heparin, fondaparinux and bivalirudin. (a) Enoxaparin 1 mg/kg body wt. twice daily is preferred in patients treated conservatively or by invasive strategy. (b) Fondaparinux is recommended on basis of favourable

efficacy/safety profile. Dose 2.5 mg/d. (c) Bivalirudin is recommended for urgent and elective PCI in moderate or high-risk patients. It needs bolus of heparin additionally during PCI to prevent stent thrombosis.

Symptoms: Patients may experience a range of symptoms varying from crushing retrosternal or left-sided chest pain discomfort, with associated typical symptoms to isolated dyspnoea, syncopal attacks, malaise and breathlessness. Elderly diabetic and patients on NSAIDs may suffer silent MI. These patients are commonly found to have cardiogenic shock, hypotension, arrhythmias and conduction blocks and acute LVF.

Characteristic associated with adverse outcomes

1. Older age (>75 years)
2. Systolic BP <150 mm Hg
3. Heart rate >100 /min
4. Anterior MI

Investigations

1. ECG

Progression of ECG Changes

- (a) T wave abnormalities: Symmetrically tall T waves or inverted T waves of ischaemia.
- (b) ST segment elevation in leads overlying area of infarction.
- (c) ST elevation with T inversion.
- (d) Evolution of pathological Q waves, suggesting cell death.

Diagnosing infarction in presence of LBBB: ST segment elevation with tall positive T waves is seen frequently in right precordial leads with uncomplicated LBBB. Secondary T wave inversions are present in lateral precordial leads. However appearance of ST segment elevation in lateral leads suggests IHD (specificity 92%). ST segment depression and/or deep T wave inversion in leads to V₁ to V₃ also suggests underlying ischaemia.

Localization of infarct by ECG

See Table 67 for the localization of infarct from ECG (Fig. 103).

Table 67: Localization of infarct from ECG

Area of infarct	Leads showing abnormal Q waves
Diaphragmatic	II, III, aVF
Antero-lateral	I, aVL, V ₅ , V ₆
Antero-septal	V ₁ , V ₂ , V ₃ , V ₄
True posterior	Tall R in V ₁ , V ₂
Right ventricular	Tall R in V ₃ R, V ₄ R

Fig. 103: 12-lead ECG showing acute inferior wall myocardial infarction

2. Raised biomarkers

Common biomarker

- Myoglobin* is first to rise with myocardial necrosis but its specificity is less, therefore, seldom used.
- Creatine kinase isoenzymes*. Cardiac muscle mainly contains both MM and MB isoenzymes. The CPK-MB combination is used for diagnosing MI in acute coronary syndrome.
- Cardiac specific troponins* I and T are now considered the preferred biomarker for diagnosing MI. Other causes of raised troponins are injury to cardiac muscle, e.g. cardiac catheterization, shock, cardiac surgery. While CK-MB increases 10 to 20 fold above upper limits of reference range, CTnT and CTnI increase more than 20 times. Hence how troponins are specific and sensitive markers for acute MI. CKMB is useful now for diagnosis re-infarctions remain elevated for a longer time.
See Table 68 for the summary of cardiac biomarkers.
- Heart type fatty acid binding protein (H-FABP)* has been shown to be a sensitive early marker of myocardial infarction. Cut-off value is $<5.48 \mu\text{g/L}$. Troponin negative patients with FABP $>6.48 \mu\text{g/L}$ represent a very high-risk group of patients.

3. Radionuclide imaging:

- Thallium-201 imaging* – Areas of infarction appear as fixed defects in resting perfusion scans.
- Technetium-99m labelled pyrophosphate* – Scans do not become positive until after 12–24 hours which is not ideal. The technique is useful in patients with

Table 68: Cardiac biomarkers in AMI

Biomarker	Initial elevation	Peak elevation	Return to normal
Myoglobin	1–4	6–7 hr	24 hr
MB-CK	3–12	24 hr	48–72 hr
CTnI	3–12	24 hr	5–10 days
CTnT	3–12	12 hr–2 days	5–14 days

LBBB or who are permanently paced (because in these cases ECG does not show changes of ischaemia or infarct, these being masked), or where results of enzyme tests are equivocal.

- Echocardiography** – can identify akinetic and hypokinetic regions caused by infarction but cannot discriminate accurately between old and new infarcts.
- MRI** – MRI with contrast (gadolinium) can diagnose MI accurately, showing late enhancement in infarcted zone.

Differential Diagnosis (of precordial pain):

I. Ischaemic Cardiac Pain

- Angina pectoris** (Table 69)
- Cardiac arrhythmias** – Sudden onset of arrhythmia with tachycardia may be associated with oppressive substernal pain which may be prolonged, and with sweating and dyspnoea.
- Mitral valve prolapse** – Chest pain not related to exertion, usually sharp over precordium, commoner in those with anxiety or nervous temperament. Mid-systolic click with late systolic murmur.

Table 69: Differentiating myocardial infarction from angina

	<i>Angina pectoris</i>	<i>Myocardial infarction</i>
1. Exciting factors	After exertion, cold or heavy meals	Without visible cause, usually during rest at night
2. Attitude	Immobile	Restless
3. Pain		
Site	Retrosternal	Usually retrosternal but may be precordial
Duration	Never more than 5 minutes	About half an hour or more
Radiation	To both arms, neck or jaw	Not so diffuse
Relief	Nitrites	Nitrites have no effect
4. Vomiting	Absent	Common
5. Dyspnoea	None. Only breath held	Common
6. Shock	Absent	Marked
7. Sweating	Slight	Profuse
8. Fever	Absent	Present
9. Heart sounds	Normal	Weak, gallop rhythm
10. Pericarditis	Absent	May occur
11. Pulse	Normal or rapid	Small, rapid, often irregular
12. B.P.	Normal or increased	Tendency to fall
13. Cardiac failure	Absent	Occurs early
14. Cardiac enzymes	Normal	Raised
15. ECG	Transitory change during attack	Progressive, typical changes

II. Affection of aorta

1. **Aortitis** – Uncomplicated syphilitic aortitis may be accompanied by substernal pain. The pain is localised and not influenced by exertion.
2. **Aortic dissection** (Table 70)

III. Pericarditis (Table 71)

IV. Pulmonary disease

1. **Massive pulmonary embolism** (Table 72)
2. **Spontaneous pneumothorax on left side** – Pain is usually sharper and more localised to side of chest than to sternal region. Initial spontaneous pain more transient with subsequent pain intensified with deep inspiration or change of posture. Dyspnoea only with effort, hyper-resonance,

**Fig. 104:** Time profile and limit of rise of cardiac biomarkers after acute myocardial infarction**Table 70:** Differentiating myocardial infarction from aortic dissection

	<i>Aortic dissection</i>	<i>Myocardial infarction</i>
Fainting	Common	Uncommon
Pain	Chest or back, transmitted to both arms or legs or back. Peak intensity at onset	Precordial or epigastric, transmitted to left arm. Increases in intensity after it commences
Nervous symptoms	Possible paralysis	Nil
Murmur	Aortic diastolic murmur may appear	Apical systolic murmur may be heard
BP	Usually remains high	May fall
Other arteries	May show signs of involvement	Not affected
ECG	Normal or changes consistent with pericarditis	Typical pathognomonic changes
Chest X-ray	Widening of supra-cardiac shadow. Double aortic knob may be seen.	No specific abnormality
Serum enzymes	No change	Elevated

diminished or absent breath sounds over affected part and sometimes shift of mediastinum. Chest radiograph diagnostic.

3. **Acute pleurisy** – Pain aggravated by deep inspiration and usually in axillary region. Pleural rub.
4. **Pneumonia** – If in a case of coronary occlusion there is little pain but prominent dyspnoea, fever and rales over circumscribed area of lung, pneumonia may be diagnosed. In pneumonia pain inside of chest aggravated by deep breathing. High fever and leucocytosis.

Table 71: Differentiating myocardial infarction from acute pericarditis

	<i>Viral pericarditis</i>	<i>Myocardial infarction</i>
Pain	Increased by deep breathing or lying flat or coughing. Pain radiating to trapezius.	Not affected by postural change or cough
Friction rub	Within first few hours	24–48 hours after onset of pain
Serum enzymes	Usually no change	Elevated
ECG	Raised ST segments in all three limb leads with concavity upwards No abnormal Q waves.	Reciprocal elevation and depression of RS-T in I and III, prominent Q ₁ or Q ₃

V. Mediastinal conditions

1. **Acute mediastinal emphysema** – Severe substernal pressure which may radiate to back, neck, shoulders and rarely arms. Shock rare. Loud, bizarre, crunching sounds over sternum and precordium coinciding with cardiac systole. Variation in pain with change of position. Associated subcutaneous emphysema. X-ray – Air in pleural cavity and anterior mediastinum.
2. **Acute mediastinitis** – May be associated with severe substernal pain. Clinical manifestations of primary disease, e.g. injuries to chest wall or inflammatory process in lungs, pleura, or sternum. Fine crackles over sternum on deep breathing or synchronously with heart beats.

VI. Gastrointestinal affections

1. **Acute indigestion** – Pain not typically retrosternal and no radiation. Shock absent. Marked dyspeptic symptoms. ECG – Normal.
2. **Acute cholecystitis and cholelithiasis** – Pain colicky in nature. Usually in epigastrium at onset. Radiation to back beneath right scapula or shoulder. An early sign may be a palpable distended gall bladder (Cope's sign). The GB may then expel its contents and both pain and swelling may disappear for few hours followed by localisation of pain in right hypochondrium. No dyspnoea. Jaundice may be present. History of previous attacks.
3. **Acute abdomen** – e.g. perforated ulcer (Table 73).
4. **Oesophageal chest pain** – (Oesophageal spasm, 'oesophageal colic') – Unpleasant, often severe,

Table 72: Differentiating myocardial infarction from acute pulmonary embolism

	<i>Pulmonary embolism</i>	<i>Myocardial infarction</i>
History	Convalescent	Of angina on effort
Pain	Severe, usually central chest pain	Pressing or crushing substernal, radiating to shoulder or arm
Shock	Frequently first symptom	Usually after several hours of increasing pain
Gallop	Adjacent to sternum, increased by insp.	Apical, louder during exp.
Cough	Severe	Rare
Cyanosis	May be marked	Mild or none
Haemoptysis	May occur later	None
Fever	Early, may reach high level	24–36 hours after onset, moderate
JVP	Raised	Normal
Heart sounds	Loud pulmonary 2nd sound and systolic murmur (of TR)	Feeble heart sounds or gallop rhythm
X-ray	Pulmonary infarction	Not characteristic
ECG	Right axis deviation, right atrial P waves, RBBB	Typical according to location of infarction

Table 73: Differentiating myocardial infarction from acute pulmonary embolism

<i>Acute abdomen</i>	<i>Myocardial infarction</i>
History of abdominal symptoms	History of angina
Radiation of pain over abdomen	Radiation of pain to arms
Pulse may be slow at onset	Pulse rapid
Respiration shallow and thoracic	Respiration abdominal
Rigidity external and persists	Rigidity not so board like and varies with respiration
Heart sounds normal	Diastolic gallop

dull or gripping pain in central chest, often radiating to back, epigastrium, throat and sometimes, to shoulders and upper arms. Lasts from few seconds to several minutes, and if prolonged, may be associated with vasovagal effects. History of dysphagia, heartburn, and persistence of a dull ache that lasts for hours to days after a more severe episode. Causes –

- (a) **Diffuse spasm and achalasia** – It can be precipitated by injection of methacholine or ergometrine.

- (b) *Symptomatic oesophageal peristalsis* ('nut-cracker oesophagus') - Intermittent severe chest pain resembling cardiac pain. Manometric studies will show pressure generated by peristaltic wave grossly abnormal (over 160 mm Hg).
- (c) *Reflux oesophagitis* - Some patients experience severe pain of 'spasm', superimposed on recurrent heart burn, or sole symptom of reflux and revealed by appropriate investigations.
- (d) *Ruptured oesophagus* - Severe pain in centre of chest radiating to back. Usually follows attempts to suppress vomiting. In MI, pain precedes vomiting.
5. **Hiatus hernia** - Pain usually simulates angina but if persisting over an hour resembles coronary occlusion. Both sexes equally affected. Fullness during or shortly after meals, regurgitation, belching, nausea and vomiting common. Pain at night can be prevented by sleeping propped up on pillows, aggravated by stooping or bending forward. Pain commonly burning and relieved by antacids.
6. **Acute pancreatitis** - May be associated with acute onset of substernal oppression as well as epigastric pain. Diagnosis made by presence of elevated blood amylase, and signs of upper abdominal peritoneal irritation.
7. **Internal haemorrhage** - May present as a syndrome of prolonged, sudden, severe anginal pain, shock and collapse and even ECG may show changes since the coronaries participate in the general vasoconstriction.
- VII. **Lesions of muscular system** - Skeletal muscles usually involved are pectoralis and serratus anterior. Presence of trigger areas, rheumatic tendency of patient and finding of painful motion elsewhere in the body.
- VIII. **Neurovascular affections** -
1. **Nerve root pain** - Due to skeletal lesions such as cervical disc, spondylitis; osteoarthritis, shoulder arthritis, cervical rib. Pain not related to effort, but often related to movement of neck, shoulder, arm, coughing or sneezing. Objective neurological signs may be present and local tenderness can generally be elicited.
 2. **Herpes zoster** - Chest pain may precede the eruption by three days. Pain burning or shooting in character and often associated with hyperalgesia of the area of skin supplied by the affected nerve root.
- IX. **Cardiac neurosis and neurocirculatory asthenia** - Dyspnoea in form of inability to take deep breath. Excessive tendency to sigh. Pain dull or sharp, continuous or intermittent usually in region of apex. Associated local tenderness. Palpitation and fatigability common.
- X. **Vasomotor and endocrine disorders**
1. **Ovarian dysfunction (Menopause)** - Pain in cardiac area, palpitation, dyspnoea and hot flushes. Pain usually not substernal and not provoked by exertion or excitement. May last for hours. Area of tenderness on 4th or rarely 5th rib to left of sternum at costochondral junction. Infiltration with novocaine affords relief. Vertigo and paraesthesias common.
 2. **Hypertensive crisis of phaeochromocytoma** - Palpitation, sweating, dizziness and pain. Pain anginal and may radiate to both arms. Severe headache and epigastric pain common. Marked rise of B.P. Increased urinary excretion of catecholamines and VMA.

Complications and Their Management:

A. Mechanical

1. **LV failure and cardiogenic shock** - Haemodynamic monitoring with an arterial line and pulmonary artery catheter is helpful. 2D-Echo determines the extent of myocardial involvement and other complications of AMI which contribute to cardiogenic shock.

In patients with cardiogenic shock an intra-aortic balloon pump (IABP) insertion reduces the afterload and improves cardiac output and decreases myocardial O₂ requirement. Temporary Left Ventricular Assist Device (LVAD) allows time for recovery of stunned or hibernating myocardium. Inotropic and vasopressor agents may be given at lowest possible doses. Survival improvement is associated only with PCI or CABG.

2. **RVMI** - As RV has lower O₂ requirement and is thin walled, is perfused during systole and diastole. RVMI rarely causes irreversible damage. Management - Volume loading to increase preload and CO. If volume loading fails to increase CO, inotropes may be added. Reperfusion improves RV function and decreases mortality rates. Tricuspid valve replacement or repair if severe TR.
3. **Ventricular Septal Rupture (VSR)** - Normally occurs 2-4 days after MI, a new pansystolic murmur develops especially associated with biventricular dysfunction. 2D Echo with colour flow imaging is the test of choice. Percutaneous closure with paediatric VSD occluder

Fig. 105: Ventricular septal defect after myocardial infarction

device may be useful for high-risk surgical patients (Fig. 105).

4. **Mitral regurgitation** – Severe or acute MR caused by papillary muscle dysfunction is a life-threatening complication. Vasodilator therapy is useful as it reduces SVR and increases CO. Surgical therapy: CABG + mitral valve replacement should be considered immediately. Patients with moderate MR may do well with mitral valve repair.
5. **Cardiac free wall rupture (FWR)** – Occurs in first 5 days in 50% and within 2 weeks in 90% of patients. With acute rupture there is electromechanical dissociation and sudden death. In subacute rupture patients have distended jugular veins, pulsus paradoxus, diminished heart sounds and pericardial rub. 2D-Echo reveals cardiac tamponade – RA systolic collapse, dilated IVC and marked respiratory variation in mitral and tricuspid inflow. *Treatment* – Immediate pericardiocentesis. Emergency thoracotomy with surgical repair is definitive therapy.
6. **Pseudoaneurysm** is caused by a contained rupture of the LV free wall. The outer wall is formed by the pericardium and mural thrombus. Pseudoaneurysms communicate with the body of LV through a narrow neck. Chest X-ray may show cardiomegaly with an abnormal bulge on cardiac border. 2D-echo, MRI, CT-

scan may help confirm the diagnosis. Surgical resection is advised regardless of the size of the pseudoaneurysm.

7. **True ventricular aneurysm** – Can be acute or chronic. Acute development of a large LV aneurysm can result in CHF and even cardiogenic shock. They usually occur in transmural MI involving apex of the LV. When chronic aneurysms (Figs. 106 and 107) persists for more than 6 weeks after MI, patients may have heart failure, ventricular arrhythmias and systemic embolism due to LV clot (Fig. 108) but may be asymptomatic. ECG shows persistent ST elevation. 2D-Echo helps to differentiate true aneurysm which has a wide neck, whereas a pseudoaneurysm has a narrow neck. *Management.* Heart failure with acute aneurysm – IV vasodilators, an IABP, with chronic aneurysms – ACE inhibitors, digoxin and diuretics. Anticoagulation with warfarin is indicated for patients with a mural thrombus with INR of 2 to 3 for 3 to 6 months. PCI has beneficial effects on LV remodelling. ICD is indicated in patients with intractable ventricular arrhythmias refractory to medications. Those with refractory heart failure and refractory ventricular arrhythmias should be considered for surgical resection (Dorr's procedure). Revascularization is beneficial to patients with a large amount of viable myocardium in the aneurysmal segment.

Fig. 106: Left ventricular aneurysm. A bulge on the left heart border may also be due to pericardial cyst, pericardial sac defect, myocardial mass (neoplasm, hydatid), or coronary artery aneurysm or left atrial appendage

Fig. 107: Left ventricular aneurysm

8. **Dynamic LV outflow tract obstruction (LVOT)** is uncommon and occurs due to hypokinesia of basal and mid segments of LV which decrease the cross sectional area of LVOT. The resulting increased velocity of blood flow through the outflow tract decreases pressure below the mitral valve and results in the leaflet being drawn anteriorly towards the septum (venturi effect) which further increases the LVOT obstruction and MR. 2D-echo helps evaluate the hyperkinetic segments, the LVOT obstruction and presence of systolic anterior motion (SAM) of the mitral leaflet. *Treatment* - Decreasing myocardial contractility and heart rate with beta blocker while expanding intravascular volume with several small doses of normal saline to increase preload and decrease LVOT obstruction and SAM.

B. Arrhythmic complications

Arrhythmias have an adverse hemodynamic consequence. Patients with LV dysfunction have a relatively fixed stroke volume and depend on changes in heart rate to alter CO. Tachyarrhythmias after AMI include VF, VT and AF or AFL. In general, these are treated according to advanced life support (ACLS) guidelines. It is reasonable to manage refractory arrhythmias by aggressive stimulation with beta-blockers, IABP use, emergency PCI-CABG surgery and maintaining serum potassium levels > 4.5 mEq/L. Routine use of prophylactic anti-arrhythmic drugs is not indicated for suppression of isolated (PVC) couplets, runs of accelerated VT and non-sustained VT.

Fig. 108: 2D echo showing thrombus in LV

Accelerated idioventricular rhythm (AIVR) occurs in about 20% of pts and is often observed shortly after reperfusion and is not routinely treated. Nonsustained VT (NSVT) occurring early does not appear to be associated with increased mortality risk.

VT late in course of AMI is more common in patients with transmural infarction and LV dysfunction and more likely to be sustained and cause marked hemodynamic deterioration. Rapid abolition with cardioversion/defibrillation is mandatory because it frequently deteriorates into VF. Patients with recurrent or refractory VT should be considered for specialised procedures such as implantation of AICD or surgery. Urgent attempts at revascularization (angioplasty or CABG) can help control refractory VT.

Ventricular fibrillation can occur in 3 settings in hospitalized pts with AMI. (a) Primary VT occurs suddenly and unexpectedly in patients with no features of LVF. (b) Secondary VF is often the final event of a progressive downhill course with LVF and cardiogenic shock. (c) Late VF develops after > 48 hrs and mostly occurs in patients with large infarcts and LV dysfunction. *Treatment* - Unsynchronised electrical counter shock with at least 200–300 joules as rapidly as possible. Amiodarone IV can be used for interruption of recurrent episodes. When synchronous cardioactivity is restarted by counter shock but contraction is ineffective (pulseless electrical activity), usual cause is extensive myocardial ischaemia or necrosis or rupture of the ventricular free wall or septum.

Prophylactic implantation of an ICD after AMI in patients with LEVF < 35% on echocardiography done at least 40 days post-AMI with New York Heart Association (NYHA) class II or III symptoms.

Supraventricular Tachyarrhythmias

- (a) Sinus tachycardia occurs due to anxiety, persistent pain, LV failure, pericarditis, hypovolaemia and cardioaccelerater drugs such as atropine, epinephrine or dopamine. It results in augmentation of myocardial O₂ consumption and reduction in duration of coronary perfusion. Persistent sinus tachycardia can signify persistent heart failure and suggests poor prognosis. *Treatment* - Analgesics for pain, diuresis for heart failure, beta-blockers and nitroglycerine for ischaemia and aspirin for fever and pericarditis.
- (b) AF and AFL are usually transient and due to augmented sympathetic stimulation in the atria, LV failure, pericarditis and ischaemic injury to the atria and RVMI. There is significant reduction in CO. AF is associated with increased mortality and stroke, particularly in patients with AWTMI.

Tr. Rate control with IV Diltiazem or esmolol. If patient is haemodynamically unstable, immediate intrathoracic cardioversion. If AF is present for > 48 hrs, or if the duration is unclear cardioversion should be preceded by TEE to rule out LA thrombus. If patient is haemodynamically stable, cardioversion can be done pharmacologically (amiodarone, ibutilide and procainamide) or with electrical cardioversion. Anticoagulation is necessary for 3 or more weeks, before and for another 4 weeks after cardioversion to prevent thromboembolic complications, if duration of AF is > 48 hrs, if less cardioversion without anticoagulation.

Bradycardias

- (a) Sinus bradycardia if isolated and associated with hypotension, IV atropine.
- (b) AV and intraventricular blocks - (i) 1° AV block generally does not require specific treatment. If associated with hypotension, atropine can be given. (ii) 2° AV block - (a) Type I - Atropine if patient becomes symptomatic, ventricular rate fall < 50 bpm, PVCs and BBB develops, heart failure. (b) Type II - Because of its tendency to complete heart block, temporary external or transvenous temporary pacemaker. (c) CHB - In patient with IWMI, it is usually transient with rate > 40 pm and a narrow QRS complex, pacing is not necessary unless patient has ventricular rate < 40 to 50 bmp. Permanent pacemaker is almost never indicated. (d) In patients with AWTMI the CHB often occurs suddenly and is usually preceded by intraventricular block and often type II AV block. Such patients have unstable escape rhythms with wide QRS complexes and rate < 40 bpm and ventricular asystole. Temporary pacing protects against transient hypotension and asystole but has no survival benefit. (e) Intraventricular block - RBBB alone can progress to AV block because it is often a new lesion, associated with anteroseptal infarction and is associated with increased risk. Bifascicular block carries increased risk of developing CHB, severe pump failure and high mortality and temporary pacing is advisable. Permanent pacemaker insertion may be required, if CHB persists, when sinus node function is markedly impaired or when type II 2nd or 3rd degree block occurs intermittently.

C. Ischaemic Complications

Recurrent post infarction angina may be due to either an infarct extension or reinfarction in a separate area or reocclusion of infarct related artery. If the ECG reveals ST segment re-elevation or presence of new Q waves or there is re-elevation of cardiac markers, PCI is advisable. If unavailable repeated fibrinolysis can be considered. Haemodynamically stable symptomatic patients are treated with nitroglycerine and beta-blockers. When hypotension, heart failure or ventricular arrhythmias develop during recurrent ischaemia, urgent catheterization and revascularization are indicated. With increasing use of PCI, stent thrombosis may be a cause of ischaemia.

D. Inflammatory

Pericarditis after MI is classified as early or late. Early pericarditis usually develops 24 to 96 hrs after MI. Pain

is postural, worse when supine and relieved when sitting up and leaning forward. Radiation of pain to the trapezius ridge is almost pathognomonic. ECG shows ST elevation with concave upward curve. The changes are generalized. *Tr.* – Aspirin 650 mg q4–6 hrs. Colchicine may be used in those with recurrent pericarditis. Late pericarditis (Dressler's syndrome) occurs 1 to 8 weeks after AMI. Patients present with precordial chest discomfort, malaise, fever, leucocytosis and raised ESR. 2D-echo may reveal pericardial effusion. Treatment – Aspirin. If > 4 weeks have elapsed since AMI, NSAIDs and even steroids may be used for severe symptoms.

E. Embolic Complications

Systemic embolism most often results in stroke, although there may be limb ischaemia, renal infarction or mesenteric ischaemia. *Treatment* – Heparin IV for 3 to 4 days followed by oral anticoagulation for 3 to 6 months in patients with mural thrombus and those with large akinetic areas detected by 2D-echo.

Management of STEMI

Following hospital admission

1. **Admission to coronary care unit** – Mortality from acute cardiac infarction can be reduced by monitoring of cardiac rhythm and early treatment of disorders of the heart beat.
2. **Relief of pain** – Pethidine 100 mg. IM or morphine 15 mg subcutaneously, may be repeated if pain not relieved within 30 minutes. Risk of vomiting can be reduced by combining with 10 mg triflupromazine. Rarely slow intravenous injection of 1–2 mg morphine may be necessary if pain is very intense. Nitrates and thrombolysis may also relieve pain.
3. **IV drip** – Slow IV infusion using 5% dextrose is started.
4. **Oxygen** – If cyanosis, severe or persistent pain, or pulmonary venous congestion. O₂ supplementation is considered if saturation <92%.
5. **Blood samples** – Should be taken on admission to hospital for baseline determination of electrolytes, renal function and cardiac enzymes.
6. **Rest** – Duration must be adjusted to the individual case depending on size of infarct and complications. Early mobilization helps prevent complications associated with long periods of bed rest and helps psychological recovery.
7. **Sedatives** – For relief of anxiety. Diazepam 5 mg t.d.s.
8. **Limitation of infarct size** – Reperfusion therapy in all patients presenting within 12 hrs of onset of symptoms. Indications for primary PCI:
 - Patients presenting within 12 hrs of symptoms onset and anticipated time from first medical contact to balloon inflation of 2 hrs or less.
 - Contraindications to fibrinolytic therapy.
 - Patients presenting within 12–24 hrs of symptom onset with ongoing symptoms/signs of ischaemic or hemodynamic instability.
9. **Antiplatelet drugs** – Aspirin dose (75–100 mg) and Clopidogrel 75 mg or Prasugrel 60 mg stat followed by 5–10 mg/day, or Ticagrelor 90 mg bd.
10. **Antithrombotic therapy** – Choice of fibrinolytic agent: Tenecteplase has the advantage of being fibrin specific, can be given as a bolus dose, has a low incidence of hypersensitivity reactions. Dose 0.53 mg/kg body weight.

Other alternatives are: (1) Reteplase (r-PA) - 10 U bolus dose at arrival and 10U bolus after 30 minutes, (2) Alteplase (t-PA) - Bolus of 15 mg, infusion of 0.75 mg/kg for 30 minutes (maximum, 50 mg), then 0.5 mg/kg (maximum, 35 mg) over the next 60 minutes; the total dose not to exceed 100 mg. (3) Streptokinase - 1.5 million units IV given over 30–60 min.

Contraindications to thrombolysis

(a) Absolute contraindications

- Haemorrhagic stroke or stroke of unknown origin at any time.
- Ischaemic stroke in preceding 6 months.
- CNS trauma or neoplasm.
- Recent trauma, surgery/head injury within preceding 3 months.
- GI bleeding within the last month in known bleeding disorder.
- Aortic dissection.
- Non-compressible punctures (e.g. liver biopsy, lumbar puncture).

Relative contraindications

- TIA in preceding 6 months
- Oral anticoagulant therapy
- Pregnancy or within 1 week post-partum
- Uncontrolled hypertension (BP > 180/110 mm Hg)
- Advanced liver disease
- Infective endocarditis

- Peptic ulcer
 - Refractory resuscitation
- (b) Elderly patients: There is increase in mortality rate as age increases. As per American Heart Association–
- i. Thrombolytic therapy as compared to no reperfusion therapy offers mortality benefit in elderly subjects upto age of 85.
 - ii. Nonfatal strokes are rare.
 - iii. Reduced doses of unfractionated heparin or adjusted doses of LMWH minimize risk of bleeding
- (c) Time sensitivity - Thrombolytic therapy is more time sensitive as compared to PCI.
- (d) Hemorrhage is another important issue with thrombolysis.
- (e) Reinfarction and recurrent ischaemia - Following thrombolytic therapy, there is a pro-thrombotic period. Reocclusion of the infarct related artery may be 10–30% by 3 months.

Beta-adrenergic antagonists

1. Oral β -blockers should be administered in first 24 hrs to patients who do not have heart failure, a low output state, are not at increased risk of developing cardiogenic shock or have no other contraindications to beta-blocker therapy. Care should be taken to avoid hypotension. ACE inhibitors improve survival in patients who have LVEF \leq 40% and those who are in heart failure. ARBs may be used in patients who do not tolerate ACE inhibitors.
2. IV or oral nitrates do not improve outcomes. Nitrates may be used for pain.
3. High dose statins should be started as early as possible as part of secondary prevention measures.

Management post-fibrinolytic therapy

1. Routine angiography and PCI of the infarct related artery may reduce the rates of reocclusion or reinfarction.
2. Pharmacoinvasive therapy has an important place in improving prognosis of patients after thrombolysis. It is increasingly demonstrated that patients after a successful thrombolysis should be transferred to facilities with a cardiac cath lab for coronary angiography and if need be a PCI with stent deployment.

However because of resource intensiveness of this strategy and absence of an effect on survival, most guidelines still favour a more conservative approach consisting of revascularization guided by the results of risk stratification by early exercise testing. Angiography (and revascularization) should of course be performed in the event of spontaneous ischaemia or development in mechanical complications.

Percutaneous transluminal coronary angioplasty

- (1) *As interventional post-thrombolytic procedure* - if intermittent or continuous chest pain or discomfort and persistent ST elevation on ECG.
- (2) *Primary coronary angioplasty* - Indications - (i) Patients with previous bypass surgery, or large infarcts (anterolateral or extreme inferoposterior) especially with hemodynamic compromise; this must be done within 60-120 min of presentation. (ii) Patients with ST elevation acute MI and absolute contraindication to lytic therapy (bleeding hazard). (iii) Emergency angiography and angioplasty (when appropriate) in patients with long presentation delay (>12 hrs) or in cases of atypical presentation and diagnostic uncertainty (Figs. 109 and 110).
- (3) *CABG surgery* - Indications: (i) Coronary occlusion developing during cardiac catheterization, coronary angiography or during PTCA. (ii) Patient continues to have ischaemic pain and is haemodynamically unstable and rescue angioplasty has failed, or is not feasible, or if angiography shows left main disease or multivessel disease. (iii) Infarction occurring in a 'stuttering' manner over a few days producing increasing hemodynamic instability.

Therapeutic lifestyle changes - Smoking cessation, exercise dietary modification and drugs for secondary prevention. Patient counselling and education are key to maintaining adherence to therapy in the long run.

Recent advances in management of myocardial infarction **Cardiac repair and regeneration**

1. **Stem cell therapy:** Variable degrees of improvement in cardiac function in models has been observed with transplantation of stem cells from different tissues. Intracoronary infusion of bone marrow derived mononuclear cells (BMC) within 7 days after reinfusion therapy for AMI is associated with significant improvement in LV remodelling parameters within first 4 months after AMI.
2. **Sono-thrombolysis.** Use of ultrasound waves (through transcutaneous route) along with fibrinolytic agent, the ST segment resolution was better than those who received Tenecteplase alone. Possible mechanism is release of nitric oxide by various endothelial cells and opening of collateral channels.
3. **Optimising the outcomes of PPCI**
 - (a) *Thrombus aspiration during PPCI:* Thrombus aspiration catheters have been used to improve outcome of PCI. They have reduced distal embolization and resulted in enhanced TIMI grade 3 flow, and more complete ST resolution. Results of

Fig. 109: Coronary angiography showing left main coronary artery stenting

Fig. 110: Primary angioplasty after myocardial infarction (PAMI)

thrombus aspiration compared to Balloon Angioplasty – Adjunctive aspiration resulted in enhanced rates of angiographic myocardial perfusion (blush) and ST segment resolution.

- (b) *Intracoronary GIIb/IIIa inhibitors:* Intracoronary administration of drugs increases local drug concentrations several fold. The increased concentration of inhibitors like Abciximab, Eptifibatide, Tirofiban are shown to improve outcomes of PCI safely and efficaciously in terms of reduction in infarct size and improved TIMI flow.
- (c) *Adenosine:* Intracoronary administration of vasodilators such as adenosine during and after PPCI has been shown to improve flow in the infarct-related coronary artery and myocardial perfusion.

- (d) *New oral anti-platelet drugs:* Prasugrel and Ticagrelor while the thienopyridines is not a prodrug and therefore has a faster onset of action with less variability. It causes stronger platelet inhibition, particularly in the early phase and its reversible which may be an advantage in reducing bleeding.

4. **Cardioprotection against myocardial reperfusion injury:** Restoration of blood flow to ischaemic myocardium sometimes leads to myocardial injury (ischaemic-reperfusion injury). It can take the form of (a) myocardial stunning (transient LV dysfunction after restoration of blood supply). (b) No reflow phenomenon (inability to restore blood supply at microvascular level even after opening of myocardial infarct related artery). (c) Reperfusion arrhythmia. (d) Lethal reperfusion injury leading to extension of infarct.

Remote ischaemic preconditioning is carried out (a) With brief occlusion of blood flow either to upper or lower limb by periodically inflating and releasing the BP cuff. (b) Transient balloon occlusion of the infarct related artery. (c) Use of pharmacological agents. Cyclosporine inhibits opening of mitochondrial PTP and protects myocardium from reperfusion injury. Use of cyclosporine is associated with reduction in infarct size.

- Absence of pulsation in carotid, temporal or femoral artery.

Late

- Dilated pupils.
- Unrecordable BP
- Convulsions.

10. CARDIAC ARREST

Cardiac arrest is defined as sudden failure of the heart resulting in inadequate cerebral circulation. Cardiac standstill is responsible for majority of cases, the other mechanisms being ventricular fibrillation and electromechanical dissociation.

CAUSES

See Table 74 for the causes of sudden cardiac death and Table 75 for specific causes in young.

CLINICAL FEATURES

Early

- Loss of consciousness.

Table 74: Causes of sudden cardiac death

- Myocardial infarction.
- Airway obstruction and inadequate ventilation, e.g. foreign body.
- Major obstruction to blood flow through central circulation - (a) Acute massive pulmonary embolism. (b) Following acute event e.g. arrhythmia in presence of chronic obstruction to circulation such as PS, MS or AS.
- Surgery - (a) Anaesthesia - Too rapid or unregulated administration or overdose. (b) Manipulation of viscera in chest or abdomen. (c) Massive arterial haemorrhage. (d) Hypotension. (e) Endotracheal intubation. (f) Air or fat embolism.
- Diagnostic procedures - Bronchoscopy, bronchography, IV pyelography, cardiac catheterization, angiocardiography.
- Haemorrhage - sudden and severe.
- Electrolyte imbalance - Hypokalaemia or hyperkalaemia.
- Electric shock, anaphylaxis.
- Drowning.
- Hypothermia.
- Drugs - Due to overdosage or sensitivity - digitalis, quinidine, procainamide, adrenaline, potassium, local anaesthetics, saccharated iron oxide and rarely antibiotics.

MANAGEMENT

1. Immediate Management

- *Positioning* - Put patient in supine position on firm surface such as wooden board or on the floor.
- *Chest thump* - Strike the left upper chest forcibly with the fist. This may restart the heart if arrest is due to asystole.
- *Basic CPR:*
 - Compression
 - Airway
 - Breathing

Compression - first goal of CPR is to maintain perfusion of vital organs. Chest compression allows the heart to maintain an externally driven pump function by sequential emptying and filling of its chambers.

Place the heel of the hands one over the other on the lower end of sternum and compress the sternum about 4-5 cm at a rate of 100/min.

For single rescuer, from infancy (excluding newborns) through adulthood and for adults responded to by two rescuers, a compression-ventilation ratio of 30:2 is now recommended.

For two-rescuer CPR in infants and children, the former compression-ventilation ratio of 15:2 is recommended.

Airway Maintenance

Patient breathing - Airway patency can often be obtained by simple methods - Put patient in supine position on

Table 75: Causes of sudden cardiac death in the young

1. Congenital heart disease
2. Congenital anomalies of coronary arteries.
3. Marfan's syndrome
4. Myocarditis
5. Cardiomyopathy - hypertrophic or dilated
6. Arrhythmogenic RV dysplasia

a firm surface such as a wooden board or on the floor.

(i) Jaw lift. Placing the fingers bilaterally behind mandibular angles, displace the mandible forward and anteriorly. Clear the pharynx with a finger covered with gauze piece.

(ii) Give Oxygen. (iii) Do endotracheal intubation unless contraindicated (injury to cervical spine, mechanical upper airway obstruction, severe restriction of cervical mobility or inability to open the mouth). In such a case nasotracheal intubation.

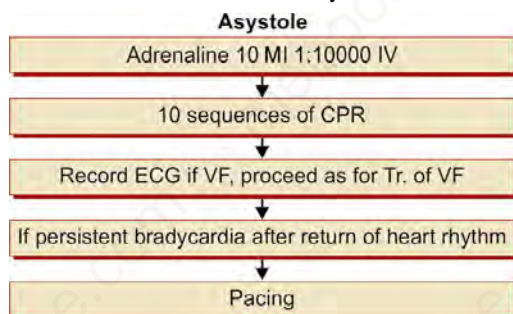

Patient Not Breathing

Mouth-to-mouth respiration – Use fingers of left hand to hold the chin forwards while extending the neck slightly with the rt. hand. By placing the edge of your hand the forehead it is possible to maintain the extended position, at the same time pinching the nose tight. Now place your lips firmly over the mouth (a handkerchief or gauze pad can be put over patient's mouth) and having taken a large breath, exhale. Look for the chest rising as you exhale. Now release your seal and wait for passive exhalation, again checking if the chest is moving. Repeat the procedure once exhalation is complete; this usually means 12 to 15 breaths per minute. Not considered very important.

Oronasal resuscitation – The nose can be used as airway particularly when one cannot get the airtight seal over the mouth or if the mouth contains blood or vomit. Use the left hand to hold the chin forwards and upwards and keep the mouth shut. If this is not possible, use a pad over the mouth to seal it. Place your mouth over the entire nose and exhale. Then follow the same procedure as in mouth-to-mouth resuscitation.

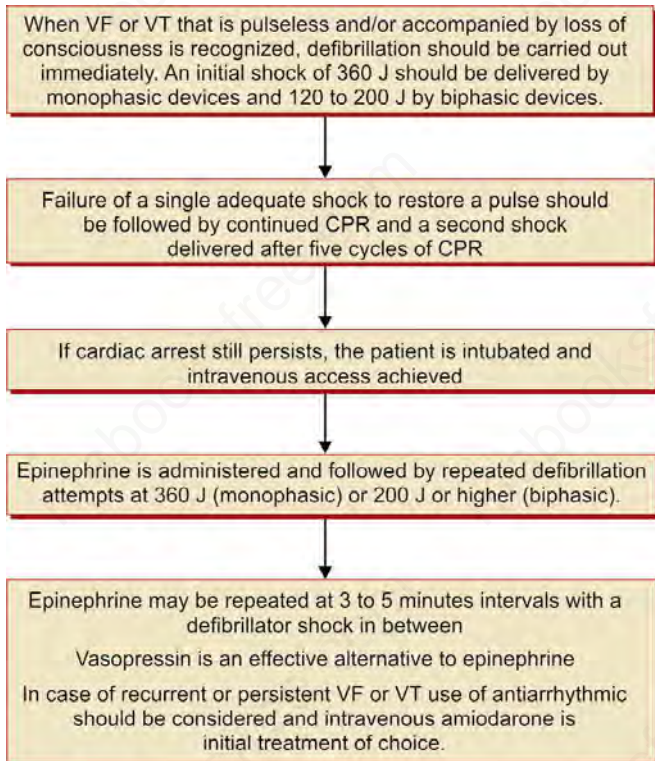

If a suitable face mask is available keep the same over the patient's mouth and nose snugly, push the lower jaw forwards and upwards with the thumb and index finger and blow the Ambu bag which is connected with the face mask. Oxygen should be connected with the Ambu bag.

2. Determination of Heart Action by ECG:

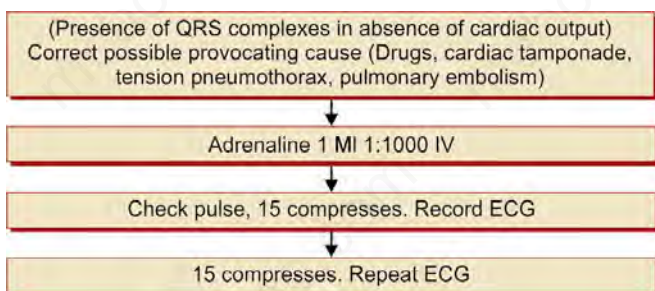

Note: Recovery from asystole is rare. It is futile to continue resuscitation for more than 15 mins.

Ventricular fibrillation

Electromechanical Dissociation

Vasopressin 40U IV is alternative to epinephrine for pulseless electrical activity. There is no role of atropine in case of asystole and given in case of bradyarrhythmia only. Sodium bicarbonate used only in cases of severe systemic acidosis, hyperkalemia with pH, pO₂ and pCO₂ monitoring at 1 mEq/kg IV.

Duration of Resuscitation

In absence of indication to stop earlier, attempts should be continued for about 30 minutes provided there is good evidence of adequate tissue oxygenation (satisfactory pH and blood gases). Exceptions are arrests associated with drowning, hypothermia and certain drug overdose. Without adequate oxygenation, irreversible brain damage

sets in after about 3 minutes and resuscitation attempts longer than 10 minutes are likely, if successful, to result in a severely disabled individual.

11. HEART FAILURE

A clinical syndrome in which due to abnormality of cardiac function, a low cardiac output and congestive symptoms are prominent.

PATHOPHYSIOLOGY

Compensatory body responses to heart failure:

1. *Alteration in heart structure* (hypertrophy, size, shape, fibrosis).
2. *Starling's mechanism* – Major determinants of cardiac output are stroke volume and heart rate. Stroke volume is determined by preload (ventricular volume at end of diastole), contractility and afterload (factors resisting ventricular ejection). When reduced myocardial contractility reduces stroke volume, cardiac output is partly maintained by the Starling mechanism. However, the resulting elevation of LV filling pressure may cause dyspnoea and other congestive symptoms.
3. *Activation of neuro-endocrine system* – in particular the sympathetic and renin-angiotensin systems. Plasma vasopressin and aldosterone are increased. These responses maintain blood pressure by causing vasoconstriction, but they can be harmful because of the extra work imposed on the heart, and renal vasoconstriction leading to fluid retention.
4. *Increased peripheral resistance and redistribution of blood flow* – Systemic vascular resistance is increased, and there is redistribution of blood flow away from skin, muscle and splanchnic circulation. Reduced blood flow to kidneys causes sodium retention.
5. *Desensitization of vessels and myocardium to agonists* – e.g. catecholamines (stimulation of sympathetic system).

LEFT HEART FAILURE (ACUTE HEART FAILURE)

Causes

See Table 76 for the causes of acute heart failure.

Clinical Features

- Severe dyspnoea (with at times pink frothy sputum)
- Tachypnoea

Table 76: Causes of acute heart failure

<i>Myocardial damage</i>
Myocardial infarction
Myocarditis
Cardiomyopathy
Cardiac depressant drugs
<i>Increased load</i>
Hypertension
Mitral and aortic valve disease
Cardiac arrhythmias
Over transfusion

- Cold clammy skin
- Tachycardia
- Low blood pressure
- Lung crackles
- Raised jugular venous pressure
- Gallop rhythm

Emergency Treatment

- Monitor ECG
- Oxygen 5–6 litres/min by mask
- Frusemide 40–80 mg iv
- Morphine 1–2 mg iv or pentazocine 30 mg IM
- Monitor urine output
- Insert intravenous line
- Consider: Dopamine 5–20 µg/kg/min iv or other inotrope (e.g. milrinone), or intra-aortic balloon pump

Investigations

History

- Chest pain, suggesting MI
- Palpitations, suggesting arrhythmias (e.g. ventricular tachyarrhythmia, atrial fibrillation)
- Drug history (e.g. cardiotoxic agents, NSAIDs)
- Previous cardiac history (e.g. valve operation, myocardial infarction)
- Chest trauma (possible cardiac tamponade)
- Serum biochemistry, blood count and cardiac biomarkers
- Echocardiogram in selected cases (e.g. valve dysfunction, suspected tamponade)

Beta natriuretic peptide (BNP) – In patients with heart failure and renal dysfunction, BNP levels give the true clinical picture, because BNP levels correlate with decreased ejection fraction in systolic dysfunction. However if BNP is

raised but ejection fraction is normal, then the rise in BNP can be due to systolic dysfunction or pulmonary embolism. In case of a raised BNP in a breathless patient diuretic therapy is initiated and patient admitted to ICU.

Interpretation of BNP levels

Normal	<100 ng/mL
Suspected heart failure	100-400 ng/mL
Probable heart failure	>400 ng/mL

When BNP >1000 ng/mL it indicates likelihood of repeated attacks of LVF.

Patients with raised BNP and hypotension are treated with inotropes.

Patients with low CVP and raised BNP are monitored by checking pulmonary pressure

Further management – depends on the underlying cause, e.g. if ischaemic, coronary angioplasty or bypass surgery may be indicated. Supportive therapy with diuretics, vasodilators (especially ACE inhibitors) and for short period IV inotropic agents.

RIGHT HEART FAILURE (CHRONIC HEART FAILURE)

Causes

See Table 77 for the causes of chronic heart failure.

Symptoms

1. Due to inadequate blood supply to the tissue – Weakness, fatigue, and decreased urinary output resulting in fluid retention and oedema.
2. Due to inability of the heart to empty properly – resulting in increased venous pressure and congestion of tissues.
 - (a) *Cerebral* – Headache, insomnia, restlessness, sluggish mental state.
 - (b) *Pulmonary* – Cough, dyspnoea (Table 78), rarely orthopnoea, Cheyne Stokes respiration.

Table 77: Causes of chronic heart failure

• Pulmonary hypertension
– Secondary to left heart failure
– Chronic lung disease (cor pulmonale)
– Pulmonary embolism
– Left-to-right shunts
• Primary pulmonary hypertension
• Right ventricular infarction
• Pulmonary or tricuspid valve disease
• Isolated right ventricular cardiomyopathy

- (c) *Portal* – Anorexia, nausea and vomiting, fullness after meals. Pain in right hypochondrium commonly aggravated on exertion (herpetic angina). In patients with long-standing congestion caused by for example cardiomyopathy, there may be steatorrhoea and protein loss.
- (d) *Renal* – Nocturia and oliguria.
- (e) *Peripheral* – Oedema of feet or generalised anasarca.

Signs

1. *Raised JVP* – Positive hepatojugular reflux.
2. *Enlarged and tender liver* – Systolic pulsation of liver if tricuspid regurgitation.
3. *Oedema* – The erect position favours collection of fluid in feet, ankles and lower portion of legs, whereas recumbent position favours accumulation in sacral region. If oedema is severe, it may be associated with hydrothorax (more often on right side), and hydropericardium and occasionally ascites.
4. *Evidence of heart disease* – Signs associated with underlying disease. Cardiomegaly with evidence of right ventricular or combined ventricular enlargement. Right ventricular gallop. Murmur of relative TR common.
5. *Peripheral cyanosis* – May occur due to slow peripheral circulation.
6. *Cardiac cachexia* – Loss of subcutaneous fat and muscle tissue.

Investigations

Confirm diagnosis

- Chest radiograph
- Echocardiogram

Table 78: The New York Heart Association classification of dyspnoea

Class	Patient symptoms
I	No limitation of physical activity. Ordinary physical activity does not cause undue fatigue, palpitation, dyspnea (shortness of breath).
II	Slight limitation of physical activity. Comfortable at rest. Ordinary physical activity results in fatigue, palpitation, dyspnea (shortness of breath).
III	Marked limitation of physical activity. Comfortable at rest. Less than ordinary activity causes fatigue, palpitation, or dyspnea.
IV	Unable to carry on any physical activity without discomfort. Symptoms of heart failure at rest. If any physical activity is undertaken, discomfort increases.

Look for underlying cause

- ECG - Ischaemia/infarction, LV hypertrophy, arrhythmia
- Echo - Valvular disease, dilated cardiomyopathy, ischaemic heart disease
- Blood tests - for rare causes, e.g. hypocalcaemic cardiomyopathy, thyroid heart disease, anaemia, iron storage diseases, amyloid, sarcoid
- Coronary angiography (occasionally) and ventricular biopsy (rarely)

Assessing severity

- Rest or exercise radionuclide ventriculography or echocardiography for ejection fraction
- Cardiopulmonary exercise testing for maximal oxygen consumption

Prognosis

- 24-hour Holter monitoring for ventricular arrhythmias
- Blood tests for associated disease: Kidney, liver, electrolyte disturbances
- Neurohormonal markers: Natriuretic peptide levels. A BNP concentration of > 22 pg/mL is diagnostic of heart failure and it rises in proportion to the severity of the disease.

Assessing ventricular dysfunction

Systolic dysfunction of LV - LV ejection fraction is the most convenient and reliable. Other methods include peak rate of pressure rise within the ventricle (positive dp/dt max), filling pressure (e.g. LV end-diastolic pressure, pulmonary capillary wedge pressure), ventricular volumes by echocardiography, radionuclear ventriculography or other imaging modalities.

Diastolic dysfunction of the heart - Commonly quantifying methods used are hemodynamic echocardiography, radionuclear or ventriculographic methods. Most commonly used methods are the rate constant of isovolumic relaxation of the ventricle during early diastole, the early-to-late peak filling velocity across the mitral valve on Doppler echocardiography, and the peak rate of ventricular filling on radionuclear-gated acquisition scans.

Management: of congestive heart failure.

GENERAL MEASURES

- Rest - Physical and mental. Rest in bed and in chair till there is no longer venous engorgement, oedema or congestion of lungs and heart rate constantly under 80 per minute for some days.
- Diet - Restricted salt intake (2 gm salt per day). Salt substitute may be used for palatability. Fluid intake

upto 1500-2000 mL. daily may be allowed. Frequent, small, bland, low caloric feeds preferred at onset of therapy.

- Other measures - No excessive alcohol intake. No smoking. Maintenance of optimal body weight. Control of BP.

Drug Therapy

Digitalis and diuretics

See Table 79 for digitalis and diuretics.

Vasodilators

The change in cardiac output in heart failure results from reduction of ventricular filling pressure (preload) and blood pressure (afterload). The haemodynamic effect of any individual vasodilator depends on the relative effect to relax veins or arterioles. Hydralazine (up to 200 mg t.d.s.) affects arterioles and prazosin (0.5 mg gradually increased to 10 mg t.d.s.) mainly the veins. Nitrates and ACEIs are intermediate.

- (a) **ACEIs** - reduce venous pressure, increase cardiac output, lower BP, increase renal perfusion, and increase blood flow to exercising skeletal muscles. Like other vasodilators, tolerance does not develop. *Side effects* - Renal failure may be aggravated and plasma potassium may increase (hence potassium supplements should be stopped). In some patients, the first dose may lower cardiac output dramatically, causing fainting. In severely diuresed patients, the drug should be started in low doses, omitting the morning dose of diuretic which is started again the next day. Dose of ACEI can be increased gradually over the following days. ARBs can be used if intolerance to ACEIs.

Indications - ACEIs are the most effective vasodilator therapy in heart failure and should be used relatively early. However, they should be used cautiously in presence of kidney failure or hyperkalaemia.

- (b) **Calcium antagonists** - are potent vasodilators and may be useful in patients with heart failure complicating hypertension or ischaemic heart disease. However, they have intrinsic negative inotropic effect and must be used with caution in patients with hypotension, low ejection fractions, or pulmonary congestion. Amlodipine is the safest.
- (c) **Carvedilol and β -blockers** - For patients with symptomatic heart failure who are not decompensated (Class II to III). Dose - Initial 3.125 mg bd, slowly titrated every 2 weeks to target dose of 25 mg bd. Metoprolol succinate 12.5 to 100 mg or Bisoprolol 12.5 to 10 mg/day.

Table 79: Digitalis and diuretics in CHF

Drug	Generic name	Avg. daily dose (mg)	Action duration (hr)	Side effects
Digitalis				
Digoxin		Loading PO: 0.25–1.5 mg/d divided doses IV: 1.2 mg, then 0.5 mg q6h till digitalization Maintenance 0.25–0.5 mg/d for 5–6 days in the week		Extra-cardiac Anorexia, nausea, vomiting, occasional diarrhoea. Altered colour vision (yellow or green) Cardiac Bradycardia or SA block, Multiple PVCs, Ventricular bigeminy, PAT, PVT, Vent. Fibrillation
Diuretics				
Type of diuretic and mode of action				
Thiazides type (medium efficacy)				
Inhibition of NaCl cotransport in distal convoluted tubule	Chlorothiazide Hydrochlorothiazide Benzthiazide Hydroflumethiazide Bendroflumethiazide Trichlormethiazide Methyclothiazide Polythiazide Cyclothiazide	500-15005 0-150 50-200 25-50 2.5-15 2-4 5-10 2-8 2-6	6-12 12-24 6-12 6-12	Hypokalaemia Hyponatremia volume depletion Contraction alkalosis Hypomagnesaemia Glucose intolerance Hypercalcaemia Hyperuricaemia Rarely impotence, acute interstitial nephritis
Related sulphonamide compounds				
	Chlorthalidone Indapamide Quinethazone *Metolazone	50-100 2.5 50-150 2.5-20	18-24 24-48	Hypokalaemia Hyperlipidaemia
Loop diuretics (High efficacy)				
Inhibition of Na-K-2Cl cotransport in ascending limb or loop of Henle	Furosemide Bumetanide Ethacrynic acid Torsemide	20-160 0.5-3 25-150 5-200	6-8	Same as above but glucose intolerance less common Calciuretic
Potassium sparing diuretics (Low efficacy)				
	Spirolactone Eplerenone	50-200 50-100	24 24	Gynecomastia Mastodynia Diminished libido Irregular menses
Blocking of sodium channels in cortical collecting tubule				
	Triamterene Amiloride	50-150 5-20	6-8 12-24	Triamterene stone Megaloblastosis GI irritation including diarrhoea Mild metabolic acidosis Dangerous hyperkalaemia (if combined with K supplements, drugs that decrease K excretion (e.g. β -blockers, ACEIs, non-steroidal, or if impaired renal function).

*Does not increase GFR and is effective with GFR < 20 mL/min.

(d) Dobutamine 15–20 $\mu\text{g}/\text{kg}/\text{min}$. in patients with acute heart failure complicating congestive heart failure.

(e) Amrinone/Milrinone – for short term IV use.

Indications

- End-stage heart failure secondary to ischaemic heart disease

- Other cardiomyopathies such as idiopathic dilated, post-viral, post-partum
- Valvular and congenital heart diseases not amenable to established corrective surgical procedure

Contraindications

- Age >65 years

- High pulmonary vascular resistance
- Incurable malignancy
- Renal failure above and below the expected pre-renal failure
- Hepatic failure which exceeds that explained by cardiac failure or when accompanied by significant coagulopathy
- Other irreversible disease such as emphysema, intractable systemic illness or amyloidosis
- Patients who are emotionally unstable and have psychological abnormalities and cannot cope up with the demands and burdens of strict compliance with medications and follow up requirements
- Infection with HIV
- History of substance abuse
- Type II DM with tuberculosis
- Peptic ulcer disease
- Unresolved pulmonary infection
- Presence of active systemic infection
- Patients with positive PPD or clinical evidence of previous TB are to be treated prophylactically with appropriate drugs for 12 months

Other Measures

1. **Sedative** – For adequate sleep.
2. **Aminophylline** – 0.25 to 0.5 gm. in 10 mL distilled water IV may help in reducing bronchospasm, stimulating ventricular contraction and the respiratory centre and acting as mild diuretic.
3. **Antibiotics** – Adequate control of pulmonary infection at the earliest.
4. **Oxygen** – Indications – (i) Failure complicated by pulmonary lesions like infarction, oedema or pneumonia. (ii) With acute myocardial infarction. (iii) Secondary to lung disease like emphysema. (iv) Patients with persistent congestion of lungs.
5. **Physical therapy** – Massage of arms and legs to maintain peripheral circulation and prevent phlebothrombosis. Gentle passive or active exercises during convalescence.
6. **Control of reversible factors** – Treatment of anaemia, thyrotoxicosis, SIE, lung infection, hypertension, or surgical correction of congenital or acquired lesion.
7. **Cardiac transplantation** – Aetiology in most is either ischaemic or dilated cardiomyopathy. Contraindications – Irreversible changes in kidney and hepatic function, advanced age, active infection, recent pulmonary infarction (< 6 weeks), diabetes mellitus (relative contraindication), elevated pulmonary vascular resistance, peripheral vascular and cerebrovascular disease, co-existing disease that may limit life expectancy, emphysema and chronic bronchitis.

8. Surgical alternatives to transplantation

- (a) **Cardiomyoplasty** – is a technique in which skeletal muscle (commonly latissimus dorsi) is used to supplement the contractile power of diseased myocardium. Advantages include absence of need for donors, external power devices and immunosuppression. It may be offered when transplantation is contraindicated or unavailable.
- (b) **Mechanical devices** – (i) Existing ventricles may be excised and a mechanical substitute implanted [total artificial heart (TAH)]. (ii) A pump may be implanted to assist the function of either or both ventricles without excising the native ventricles (ventricular assist device, VAT).
- (c) **High risk myocardial revascularization** – Hibernating myocardium is severely ischaemic, poorly contractile yet viable myocardium that recovers contractile function with restoration of adequate perfusion.

9. Other techniques

Transmyocardial laser revascularization (TMR) – Creates a series of minute channels between the left ventricular cavity and the myocardium.

Aneurysmectomy – LV function can be improved by resection of a ventricular aneurysm. Best results are obtained if adequate revascularization can be performed concurrently, and in patients with good septal contraction.

Baptista operation – Partial left ventriculectomy in patients with dilated cardiomyopathy. The reduction in LV volume is supposed to normalize the ratio of left ventricular muscle mass to cavity diameter, to a physiologically efficient level.

Biventricular pacing – This form of transvenous pacing called cardiac synchronization therapy, reverses the deleterious effects of ventricular dyssynchrony in the failing heart.

REFRACTORY HEART FAILURE

Causes

- Underlying condition amenable to medical or surgical treatment, e.g. hypertension, MS or AS, masked thyrotoxicosis, IE, constrictive pericarditis, vitamin B deficiency.

- Precipitating causes such as severe anaemia, pulmonary infection, cardiac arrhythmia or recurrent pulmonary emboli.
- Complications of therapy such as digitalis toxicity or electrolyte imbalance.

Heart failure with preserved ejection fraction (Table 80): Patients with HFpEF have normal LV end-diastolic volume and normal (or near-normal) EF and stroke volume and commonly exhibit concentric remodeling of either LV chamber and/or cardiomyocytes.

Compared with those with a reduced EF, patients with preserved EF are older.

More likely to be female; however, HFpEF occurs in both men and women throughout the 5th to the 9th decades of life.

The most common antecedent disease leading to HFpEF is systolic hypertension, which is present in more than 85% of patients, whereas ischemic heart disease is much less common than in HFrEF.

Standard heart failure therapy shown to be effective in HFrEF has not been found to reduce morbidity or mortality associated with HFpEF.

Management – It mainly involves control of hypertension.

‘Tachycardia failure’ – can be mistaken for dilated cardiomyopathy or can exacerbate failure in pre-existing cardiomyopathy. Sustained tachycardia can lead to reversible left and right ventricular dilatation and failure especially in the elderly.

Table 80: Differential diagnosis in a patient with HF and normal LV ejection fraction

• Incorrect diagnosis of HF
• Primary valvular disease
• Restrictive (infiltrative) cardiomyopathies (amyloidosis, sarcoidosis, hemochromatosis)
• Pericardial constriction
• Episodic or reversible LV systolic function
• Severe hypertension, myocardial ischaemia
• High output states (Anaemia, thyrotoxicosis, A-V fistulae)
• Chronic pulmonary disease with right HF
• Pulmonary hypertension associated with pulmonary vascular disorders
• Atrial myxoma
• Diastolic dysfunction of uncertain origin
• Obesity

Hypertensive hypertrophy with cavity obliteration (HHCO) – This is a new clinical entity with gross concentric uniform left ventricular hypertrophy with distal cavity obliteration. These patients have diastolic dysfunction with supernormal systolic function (LVEF 80%).

CHF without raised JVP

Acute MI and diabetic ketoacidosis combination.

12. SHOCK

A life-threatening state in which there is a serious reduction of cardiac output with inadequate perfusion of organs such as kidneys, brain and liver. It can occur either because the function of the heart itself is impaired, or because the heart is inadequately filled.

CLINICAL FEATURES OF SHOCK

See Table 82 for the clinical features of shock.

TYPES OF SHOCK AND THEIR MANAGEMENT

1. **Hypovolaemic** – due to decreased circulatory blood volume, e.g. internal GI bleeding or external hemorrhage, severe burns, dehydration from vomiting or diarrhoea or diabetic ketoacidosis; acute pancreatitis.

Table 81: Causes of biventricular failure

1. Myocarditis
2. Ischaemic heart disease
3. Cardiomyopathy
4. COPD
5. Severe arterial hypertension
6. Hyperdynamic circulation e.g. severe anaemia, hyperthyroidism.

Table 82: Clinical features of shock

• Cold clammy skin, profuse sweating
• Hypotension (systolic BP <100 mmHg)
• Tachycardia with thready pulse
• Rapid, shallow respiration
• Restlessness, drowsiness, confusion
• Oliguria, may progress to anuria
• Jugular venous pressure elevated in cardiogenic shock, reduced in hypovolaemic and anaphylactic shock, variable in septic shock
• Multiorgan failure

MANAGEMENT

1. **Rapid fluid replacement** – 2 litres of normal saline or Ringer lactate.
2. **Treatment of cause** – e.g. tetracycline for cholera, treatment of GI blood loss, insulin in diabetic ketoacidosis.
3. **Infusion** – Of colloids (Haemaccel or 5% albumin) if hypovolaemia associated with hypotension.

Crystalloids can be given via one vein and colloid solution another. After initial infusion of 2 L of normal saline in severe hypovolaemic shock, alternate N saline with Ringer lactate or 5% dextrose saline. Hypokalaemia is common hence 40–60 mEq of potassium in dextrose saline infusion. Repeated if necessary depending on serum potassium levels.

4. **Blood transfusion** to bring up Hb once volume replacement is achieved. If type specific blood is not available in an emergency Type O Rh-negative blood can be given.

2. Cardiogenic shock

Causes — e.g. acute myocardial infarction, acute myocarditis, acute MR, cardiac tamponade (For management see under acute MI).

3. **Septic shock** is a state of profound tissue hypoperfusion that results from septicaemia or presence of micro-organisms in blood stream.

PREDISPOSING FACTORS

- **Pre-existing disease** (impairment of immune mechanism): Diabetes, alcoholism, malnutrition, uraemia, liver disease.
- **Drug therapy** – Steroids, chemotherapeutic agents (impairment of immune function). Antibiotics (altered gut flora leading to colonization by pathogenic organisms).
- **Invasive procedures** (breach or disrupt host defence mechanisms) – Instrumentation of urinary tract, arterial and venous lines, nasotracheal tubes. Enteral feeding (upper intestinal colonization and lung aspiration).
- **Opportunistic infections** in immunocompromised patients or following organ transplantation.
- **Other infections** – Severe salmonella, *Pl. falciparum* or amoebic infection, fulminant tetanus, disseminated tuberculosis.

Causative organisms – Gram-negative and Gram-positive bacteria. Certain bacteria are associated with a particularly fulminating course. These include meningococcus (Waterhouse-Friderichsen syn.), *Staph. aureus*

(toxic shock syndrome). *Streptococcus pyogenes* (streptococcal shock syndrome).

Staphylococcal toxic shock syndrome is a potentially fatal multisystem dysfunction and occurs primarily due to TSS toxin elaborated by *S. aureus*. It occurs in diverse settings often mimicking common febrile conditions.

Pathogenesis: TSS is considered to be a super-antigen mediated disease where *S. aureus* acts as a super-antigen. These super-antigens lead to a massive release of cytokines which are responsible for a capillary leak syndrome leading to clinical signs of TSS.

Risk factors for development Staph. TSS are tampon use vaginal colonization with toxin producing *S. aureus*. It has also occurred following use of nasal tampons for procedures of ears, nose and throat, cellulitis, subcutaneous abscesses, infected burns and pneumonia and viral infections such as varicella and influenza.

Cl. Fs.: Major criteria for diagnosis are: 1. Fever > 38.9°C. 2. Rash - Diffuse macular erythroderma. 3. Desquamation 1 to 2 weeks after onset of illness, particularly of palms and soles. 4. Hypotension.

Laboratory investigations – (a) Blood culture. Three sets must be obtained before starting antibiotic therapy. (b) Cultures from other sites of sepsis. (c) Others – Arterial blood gases and coagulation screen, CXR.

MANAGEMENT

- (a) **Empirical antimicrobial therapy** (Table 83)
- (b) **Treatment of source of infection**, e.g. drainage of abscesses.
- (c) **Oxygen.** In septic shock patient is typically apnoeic and the hypoxaemia will not respond to inspired oxygen alone, indicating the need for artificial ventilation.

Table 83: Empirical antimicrobial therapy

Site of origin	Antibiotic regimen
Abdomen	3rd generation cephalosporins (ceftazidime, cefoperazone) + gentamicin + metronidazole.
Pneumonia	3rd generation cephalosporin with aminoglycoside
Neutropenia	Ticarcillin with clavulanic acid + aminoglycoside. If it persists add vancomycin. Possibility of fungal infection if no response.
Unknown source	3rd generation cephalosporin + ciprofloxacin or gentamicin + metronidazole.
Hospital-acquired infection	3rd generation cephalosporin + aminoglycoside or ciprofloxacin

Table 84: Common stimuli for anaphylaxis

1. Antibiotics: Penicillin, streptomycin, tetracycline.
2. Radio contrast media.
3. Anaesthetic agents: Lignocaine, thiopentone, scoline.
4. Blood and blood products including sera.
5. Hormones: Insulin, growth hormone.
6. Venoms: Bees, wasps, spiders.
7. Others: NSAIDs, narcotic agents, heparin, thrombolytic agents, parenteral iron dextran, foods such as shellfish, eggs.

- (d) **Correction of acidosis:** The acidosis will usually resolve as treatment of underlying disease is instituted.
- (e) **Fluid replacement:** Usually initiated with a colloid followed by crystalloid.
- (f) **Inotropic support** for maintaining BP and reducing the risk of complications such as acute tubular necrosis.
- (g) **Nutrition.**
- (h) **Anaphylactic shock:** Anaphylaxis is an acute and dramatic life-threatening immunological reaction to a drug or other stimulus (Table 84).

Clinical features - Onset may be instantaneous or within a few minutes after IV injection or at times after 1/2 hr after exposure. (a) Hypotension and circulatory collapse. (b) Severe laryngeal oedema/obstruction, angio-oedema, bronchospasm or pulmonary oedema may occur singly or in combination. (c) Tachycardia, arrhythmia, syncope and seizures on occasions constitute predominant presentation. (d) Diaphoresis, abdominal pain and diarrhoea may occur. (e) Urticaria may or may not occur.

MANAGEMENT

- Airway:** Intubation or if it is not possible secure emergency airway by puncturing the cricothyroid membrane with a large bore needle. Perform tracheostomy if intubation is not possible.
- Oxygen in high concentration.**
- Inj adrenaline** 0.5–1 mL of 1:1000 solution IM. Repeat every 5–10 mins if necessary. If no response or bronchospasm or cardiovascular collapse 5–10 mL of 1:10000 solution IV, or instil it through endotracheal tube.
- Fluid** - 1/2–1 litre of fluid usually restores BP but 6–9 L may be required for adequate restoration of fluid volume.
- Hydrocortisone** - 300 mg IV followed by 100 mg q6h to prevent late manifestations of anaphylaxis.
- Aminophylline** - 250 mg IV in 20 mL dextrose to relieve bronchospasm.
- Diphenhydramine** - 50 mg (1 mg/kg) IV slowly repeated if necessary.
- Dopamine** if hypotension persists. 5 µg/kg/min increased to 10–20 µg/kg/min. If ineffective infusion of adrenaline 3–4 µg/min initially slowly increased till rise in BP.
- IV atropine and glucagon** if patient on β-blocker failing to respond.
- Ventilatory support** - may be necessary if patient is critical. In absence of airway obstruction there is little or no role of tracheal intubation in patients who do not require ventilation. Leaving an endotracheal tube in situ and allowing spontaneous breathing serves no useful purpose as excess secretions are rarely a problem in drug associated emergencies. The tracheal tube increases the work of breathing and is uncomfortable to the conscious patient.
- Vascular shock** - Due to impeded blood flow e.g. massive pulmonary embolism, dissecting aortic aneurysm, cardiac tamponade, ball valve thrombus of left atrium, tension pneumothorax.
- Endocrine shock** - (i) Severe hypopituitarism. (ii) Myxoedema. (iii) Acute adrenocortical insufficiency. (iv) Pheochromocytoma.
- Neurogenic** - Due to interruption of neural mechanisms that maintain vascular tone, cardiac output and venous return - General or spinal anaesthesia, wounds of pleura, testicular trauma.
- Drug-induced** - Ganglion blocking drugs, nitrates, poisoning with hypnotics.

13. HYPERTENSION

Hypertension in adults age 18 years and older is defined as systolic BP of 140 mm Hg or more and/or diastolic BP of 90 mmHg or more or any level of BP in patients taking antihypertensive medication.

Arterial pressure, like most physiological measures, is variable. Hypertension can be *primary or essential* when there is no obvious precipitating factor, or the much less common *secondary hypertension* where there is some identifiable cause.

WHEN TO SUSPECT HYPERTENSION

- Family history of hypertension
- Severe hypertension >80/110 mm Hg with onset at age <20 years or >50 years
- Difficult to treat or resistant hypertension with significant end organ damage features
- Combination of pain (headache), palpitation, pallor and perspiration 4 Ps of pheochromocytoma

Table 85: Classification of BP in adults as per JNC VII Criteria

BP classification	SBP mm Hg	DPB mm Hg
Normal	< 120	and < 80
Prehypertension	120-139	or 80-89
Stage 1 hypertension	140-159	or 90-99
Stage 2 hypertension	>160	or >100

- Polyuria, nocturia, proteinuria or hematuria indicative of renal disease
- Absence of peripheral pulses, brachiofemoral delay and abdominal or other peripheral vessel bruits
- History of polycystic kidney disease or palpable enlarged kidney
- Cushingoid features, multiple neurofibromatosis

CLASSIFICATION OF BP

Classification of BP in adults as per JNC VII Criteria is given in Table 85.

Causes and risk factors for secondary hypertension

See Table 86 for the causes of secondary hypertension, Table 87 for risk factors and Table 88 for Factors influencing risk of cardiovascular disease.

INVESTIGATION OF A CASE OF HYPERTENSION

I. Evaluation - Objectives:

- To identify known causes of hypertension
- To assess the presence or absence of target organ damage
- To identify other cardiovascular risk factors or concomitant disorders that may define prognosis and guide management

II. Medical history

- Duration and level of elevated BP, if known
- Symptoms of CAD, heart failure, cerebrovascular disease, peripheral vascular disease and CKD
- Diabetes mellitus, obesity, dyslipidaemia, gout, sexual dysfunction and other co-morbid conditions.
- Family history high BP, obesity, premature CAD and stroke, dyslipidaemia and diabetes
- Symptoms suggesting secondary causes of hypertension
- History of smoking or tobacco use, physical activity, dietary assessment including intake of sodium, alcohol, saturated fat and caffeine

Table 86: Causes of secondary hypertension

Renal	
Parenchymal	Acute and chronic glomerulonephritis Chronic kidney failure Pyelonephritis Polycystic disease Wilms' tumour Diabetes mellitus Gout with kidney failure Obstructive nephropathy
Arterial disease	Atherosclerosis Renal artery stenosis Polyarteritis nodosa Renal vasculitis Focal segmental sclerosis
Post-renal transplant patient	
Endocrine	
Adrenal cortical overactivity	Acromegaly Hypothyroidism Cushing's syndrome Conn's syndrome Congenital adrenal hyperplasia Pheochromocytoma
Adrenal medullary overactivity	
Cardiovascular	
Coarctation of aorta	
Middle aortic syn.	
Drug-induced	
	Steroids Oral contraceptives NSAIDs Phenylpropanolamine and analogues Cyclosporine Erythropoietin (sustained use) Sibutramine
Miscellaneous	
	Toxaemia of pregnancy Porphyria (during acute attacks) Lead poisoning (during acute phase) Raised intracranial pressure

- Socioeconomic status, professional and educational levels
- History of use intake of all prescribed and over-the-counter medication, illicit drugs, corticosteroids, NSAID, nasal drops. These may raise BP or interfere with effectiveness of antihypertensive drugs
- History of use of oral contraceptives and hypertension during pregnancy
- History of previous antihypertensive therapy, including adverse effects experienced, if any
- Psychological and environmental factors

PHYSICAL EXAMINATION

- Record 3 BP reading separated by 2 minutes, with patient either supine or sitting position and after standing for at least 2 minutes
- Examination of pulse and the extremities for delayed or absent femoral and peripheral arterial pulsations, bruits and pedal oedema
- Look for arcus senilis, acanthosis nigricans xanthelasma and xanthomas

- Examination of the neck for carotid murmurs, raised JVP or an enlarged thyroid gland
- Cardiac examination for location of apex beat, abnormalities of rate and rhythm, fourth heart sound and murmurs
- Examination of lungs for rales and rhonchi
- Abdominal examination for bruits, enlarged kidneys, masses and abnormal aortic pulsation
- Neurological assessment and optic fundus examination

Table 87: Risk factors for hypertension

Risk factor	Comments
Genetic factors	Familial hypertension
	Polygenic influence – Genes influencing renal function and sodium metabolism e.g. tendency for hypertensives to be 'salt sensitive' and normotensives to be 'salt-insensitive' may involve polymorphism mutation at renal tubule sodium transporters.
	Similarly angiotensinogen genotypes.
Race	Hypertension more common in blacks.
Age	Prevalence increases with age.
Obesity	Especially centripetal obesity.
Alcohol	Regular consumption of alcohol has a pressor effect.
Stress	Chronic psychological stress may lead to hypertension.
Drugs	NSAIDs, oral contraceptives, sympathomimetics
Metabolic	(Refer associated clinical condition)

LABORATORY AND OTHER INVESTIGATIONS

- *Routine*
 - Urine examination for protein and glucose and microscopic for RBCs and other sediments
 - Hb, fasting blood sugar, serum creatinine, total cholesterol and potassium
- Additional investigations in special circumstances
 - Fasting lipid profile and uric acid
 - Radiograph of chest
 - Echocardiogram
 - USG for renal sizes
 - Renal Doppler study to rule out renovascular disease
 - Fundus examination
 - Thyroid hormone profile and urinary metanephrine study in young patients

Table 88: Factors influencing risk of cardiovascular disease

RF for coronary artery disease	Target organ damage (TOD)	Associated clinical conditions (ACC)
<ul style="list-style-type: none"> • Age >55 years • Post-menopausal women • Smoking and tobacco use • Diabetes mellitus • Family history of premature CAD (males < 55, females < 65) • Increased waist hip ratio • Obesity and OSA • High LDL or total cholesterol • Low LDL cholesterol and high triglycerides • High sensitivity C-reactive Protein (hs-CRP) • Estimated GFR <80 mL/min (MDRD) • Lipoproteinemia is a genetic risk factor 	<ul style="list-style-type: none"> • LV hypertrophy detected by ECG and/or echocardiogram • Microalbuminuria/proteinuria and/or elevation of serum creatinine (1.2/2 mg/dL) • Urinary ACR (albumin-creatinine ratio) • Unilateral or radiological evidence of atherosclerotic plaques in the carotids • Hypertensive retinopathy 	<ul style="list-style-type: none"> • Cerebrovascular disease • Ischaemic stroke • Cerebral hemorrhage • TIAs • Heart disease • Myocardial infarction • Angina • Coronary revascularization • CHF • Kidney disease • Diabetic nephropathy • Kidney failure (serum creatinine > 2 mg/dL) • Vascular disease: Peripheral arterial disease including non-specific aortoarteritis • Aortic dissection • Advanced hypertensive retinopathy • Haemorrhages or exudate • Papilloedema

Ambulatory blood pressure monitoring (ABPM) provides information about BP during daily activities and sleep. The devices used are either a microphone to measure Korotkoff sounds or a cuff that senses arterial waves using oscillometric techniques. *Indications* - Suspected white-coat hypertension and no target organ damage, apparent drug resistance, hypotensive symptoms with antihypertensive medication, episodic hypertension, autonomic dysfunction.

MANAGEMENT

I. Lifestyle modifications (Table 89)

II. Pharmacological treatment

Indications - (1) Malignant hypertension. (2) Hypertensive heart disease e.g. LVF. (3) Diastolic pressure 110 or more. (4) Males under 40 because the prognosis is poor if untreated. (5) Family history of early deaths due to hypertension. (6) Kidney failure with increase in serum creatinine (1.5 mg/dl).

See Table 90 for the antihypertensive agents.

Antihypertensive drug combinations

Not less than 15-20% of patients need more than two drugs to achieve goal BP

- Combination of drugs with different mechanisms of action are needed to achieve effective control of BP with minimal side effects. Combination of ACEIs with CCBs are advised
- Younger individuals have renin hypertension, hence ACE inhibitors/ARBs
- Older individuals have low renin hypertension, hence diuretics or CCBs are preferred as first line agents

- In combination, one out of two groups: ACE inhibitor/ARB or beta-blocker is combined with calcium channel blocker or thiazide diuretic.
- In refractory patients, when 3 agents are to be used ACE inhibitor or β -blocker combined with calcium channel blocker and thiazide diuretic is a good choice.

In diuretics chlorthalidone preferred over hydrochlorothiazide due to long action so once daily dose is sufficient but older patients need to be monitored for hyponatremia.

Undesirable combinations

- Low dose diuretics and calcium channel blockers
- Beta-blocker and ACE inhibitor
- Beta-blocker and verapamil/diltiazem
- ACE inhibitors and ARBs
- Two drugs from the same class

Drug interactions

- NSAIDs and COX-2 inhibitors decrease efficacy of diuretics, β -blockers and ACE inhibitors
- Concomitant use of β -blockers and non-dihydropyridine CCBs can result in heart blocks
- Cyclosporine levels are increased with diltiazem and verapamil
- Concomitant use of antidepressants with methyl dopa is to be avoided

III. Symptomatic management

1. Hypertensive crisis - comprises of:

A. **Hypertensive emergencies** - constitutes a group of clinical syndromes in which severe (DBP > 120) and rarely moderate hypertension is associated with established/ongoing target organ damage. Precipitating causes are listed in Table 91. Manifestations of hypertensive emergencies are listed in Table 92.

B. **Hypertensive urgencies** - The term is used when hypertensive crisis is not associated with target organ damage and include -

1. Accelerated malignant hypertension.
2. Atherothrombotic brain infarct with severe hypertension.
3. Rebound hypertension after sudden cessation of antihypertensive drugs.
4. Surgical: (a) Severe hypertension in patients requiring immediate surgery. (b) Postoperative hypertension. (c) Severe hypertension after kidney transplantation. (d) Severe body burns.
5. Grade I-II fundal changes.

Table 89: Lifestyle modifications

Intervention	Recommendation
• Wt. reduction	Maintain normal body wt.
• Adopt eating plan	Diet rich in fruits, vegetables and low-fat dairy products with reduced content of saturated and total fat
• Dietary sodium	Dietary sodium intake not more than reduction 2.4 g sodium or 6 g sodium chloride
• Physical activity	Regular physical activity such as brisk walking (at least 30 minutes per day, most days of the week)
• Moderation of alcohol	No more than 2 drinks (e.g. 24 oz beer, 10 oz wine, or 3 oz whiskey per day consumption in men, and no more than one drink per day in women)
• No smoking	
• Yoga, meditation and biofeedback	

Table 90: Antihypertensive drugs

I. First Line Drugs						
Class of drugs	Dosages	Indications		Contraindications		Adverse Reactions
		Definite	Possible	Definite	Relative	
Diuretics						
Hydrochlorothiazide	6.25-25	Heart failure Elderly patients Systolic hypertension	Diabetes	Gout		High doses can cause increase in serum cholesterol and triglycerides. Also glucose intolerance, hyperuricemia (gout), increased blood viscosity. Impotence.
Chlorthalidone	12.5-25					
Indapamide	1.5-2.5					
Amiloride	5-10					
Triamterene	50-100					
Spironolactone	25-50					
Beta-blockers						
Metoprolol	25.100	Angina Post MI Tachyarrhythmias Heart failure	Pregnancy diabetes	Asthma and COPD A-V block grade 2, 3	Dyslipidaemia Peripheral vascular disease Age >50 years	Bronchospasm, bradycardia, may mask insulin induced hypoglycaemia Impaired peripheral circulation, fatigue, decreased exercise tolerance.
Bisoprolol	2.5-10					
Nebivolol	2.5-5					
Combined α and β-blockers						
Carvedilol	6.25-50					Impotence Dyslipidaemia Hyperglycaemia
Labetalol	200-400					
CCBs						
Amlodipine	2.5-10	Angina Elderly systolic hypertension Diabetes	CVA	Pregnancy Lactation Bil. renal artery stenosis	Moderate kidney failure Creatinine >3 mg/dL	Oedema of ankle Flushing Headache
Diltiazem	90-360					
Verapamil	80-240					
S-amlodipine (racemic isomers)	2.5-10					
ACE-inhibitors						
Enalapril	2.5-20	Heart failure LV dysfunction Post MI Proteinuria (significant) Diabetes	CVA	Pregnancy Lactation		Cough Hyperkalaemia
Lisinopril	2.5-20					
Ramipril	1.25-10					
Perindopril	2-8					
Quinapril	10-80					
ARBs						
Losartan	50-100	DM Proteinuria LV dysfunction ACE-inhibitor induced cough	Heart failure CVA	Pregnancy Lactation Bilateral renal artery stenosis Hyperkalaemia	Moderate kidney failure (creatinine >3 mg/dL)	Headache Dizziness Hyperkalaemia
Candesartan	8-32					
Valsartan	40-160					
Irbesartan	150-300					
Telmisartan	40-160					
Olmesartan	20-40					
II. Other drugs						
Alpha-blockers						
Prazosin	2.5-10	Prostatic hypertrophy CKD	Glucose intolerance Dyslipidemia		Orthostatic hypotension CHF	Postural hypotension
Doxazosin	1-4					

Contd...

Contd...

Class of drugs	Dosages	Indications		Contraindications		Adverse Reactions
		Definite	Possible	Definite	Relative	
Centrally acting agents						
Clonidine	0.1-0.3	Resistant hypertension Hypertension in pregnancy	CKF	Pregnancy Lactation		Headache, sedation, dry mouth Rebound hypertension
Methyldopa	50-100		CKF			
Minoxidine	0.2-0.4					
Vasodilators						
Hydralazine	25-150	Resistant hypertension Hypertension in pregnancy			CAD	Postural hypertension, tachycardia, fluid retention Lupus syndrome Hypertrichosis
Minoxidil	2.5-80					
Direct renin inhibitors						
Aliskiren	150-300	Resistant hypertension		Pregnancy Lactation Bilateral renal artery stenosis Hyperkalaemia	Moderate kidney failure (creatinine >3 mg/dL)	Angioedema Hyperkalaemia Diarrhoea

Table 91: Precipitating causes of hypertensive emergencies

- Non-compliance to therapy
- Abrupt drug withdrawal
- Acute renal disease
- Acute nervous system events
- Catecholamine excess e.g. pheochromocytoma
- Alcohol
- Drugs – Steroids, sympathomimetics
- Post-infarction coronary artery bypass

MANAGEMENT

1. Hospitalization
 2. Immediate reduction of BP. Parenteral and oral drugs used in hypertensive crisis are listed in Tables 93 and 94, respectively.
 3. Epistaxis – Nose packed with absorbent cotton soaked in adrenaline solution, cauterization after active bleeding has stopped or pressure fails to control bleeding. Nasal cavity pack if source of bleeding not accessible to cauterization.
 4. LV failure – (Refer).
 5. Cerebral haemorrhage – Rapid reduction of pressure to prevent further bleeding.
 6. Dissecting aneurysm – Rapid reduction of BP. Propranolol may be useful.
- IV. Surgical treatment**
1. *Renovascular hypertension. Indications for surgery*–
(a) Age 30 years or less. (b) Severe hypertension.

Table 92: Manifestations of hypertensive emergencies

1. *End-organ damage*
 - (a) Cerebrovascular – Hypertensive encephalopathy, ischaemic stroke, haemorrhagic stroke.
 - (b) Cardiovascular – Acute LVF, acute aortic dissection, unstable angina.
 - (c) Renal – Kidney failure.
2. *Catecholamine excess syndrome* – Pheochromocytoma, clonidine withdrawal, monoamine oxidase inhibitor.
3. *Post-operative bleeding from suture sites.*
4. *Eclampsia.*
5. *Severe epistaxis.*
6. *Grade III-IV fundal changes.*

(c) BP difficult to control medically. (d) Progressive kidney failure in a hypertensive patient is due to either bilateral renal stenosis or stenosis of the artery to a single kidney. Procedures – (a) Bypass grafting of renal artery. (b) Percutaneous transluminal angioplasty – (i) Fibromuscular dysplasia. (ii) Single discrete atheromatous plaque in renal arterial midportion. (iii) Intrarenal arterial stenosis inaccessible to surgery. (iv) Transplant artery stenosis. (v) Contraindication to surgery. Nephrectomy for unilateral contracted kidney due to ischaemia or chronic pyelonephritis.

2. *Surgery for coarctation of aorta.*
3. *Surgical removal of pheochromocytoma.*

Table 93: Parenteral drugs for hypertensive emergencies

Drug	Dose	Onset of action Duration	Adverse effects	Special indications
<i>Vasodilators</i> Sodium nitroprusside	0.25-10 µg/kg/min as IV infusion	Immediate 1-2 min	Nausea, vomiting, muscle twitching, sweating, thiocyanate and cyanide intoxication	Most hypertensive emergencies, caution with high intracranial pressure or azotaemia
Nicardipine hydrochloride	5-15 mg/IV	5-10 min 15-30 min, may exceed	Tachycardia, headache, flushing, local phlebitis	Most hypertensive emergencies, caution with IHD
Fenoldopam mesylate Nitroglycerin	0.1-0.3 µg/kg/min IV inf. 5-100 µg/min IV inf.	4 h-6 min 36 min 2-5 min 5-10 min	Tachycardia, headache, nausea, flushing Headache, vomiting, methemoglobinemia, tolerance with prolonged use	Most hypertensive emergencies, caution with glaucoma IHD
Enalaprilat	1.25-5mg q6h IV	15-30 min 6-12 h	Precipitous fall in BP in high-renin states; variable response	Acute LVF. Avoid in acute MI
Hydralazine hydrochloride	10-20 mg IV	10-20 min 1-4 h	Tachycardia, flushing, headache, vomiting, aggravation of angina	Eclampsia
<i>Adrenergic inhibitors</i>				
Labetalol	20-80 mg IV bolus every 10 min 0.5-2 mg/min IV inf.	5-10 min 3-6 h	Vomiting, scalp tingling, bronchoconstriction, dizziness, nausea, heart block, orthostatic hypotension	Most hypertensive emergencies except acute heart failure
Esmolol	25-50 µg/kg/min IV bolus, then 50 – 100 µg/kg/min by inf., may repeat bolus or increase inf. to 30 µg/min	1-2 min 10-30 min	Hypotension, nausea, asthma, heart block, HF	Aortic dissection, perioperative
Phentolamine	5-15 mg IV bolus	1-2 min 10-30 min	Tachycardia, flushing, headache	Catecholamine excess

Hypertension in Special Situations

Hypertension with DM

- Lifestyle modifications more aggressive
- ACE inhibitors first line drug therapy to reduce micro and macrovascular complications. ARBs if intolerance.
- β-blockers (cardioselective) if CAD and CHF. α-blockers can be used as useful adjunctive.
- Drugs useful in diabetic patients with hypertension - methyl dopa, calcium channel blockers and labetalol. Use of diuretics during pregnancy can result in foetal growth/damage due to reduction in plasma volume. Guidelines differ about target BP as newer studies have not shown benefit of controlling BP to <130/80 mm Hg as compared to <140/90 mm Hg.

Hypertension with Cerebrovascular Disease

- Immediately after an ischaemic cerebral infarction, treatment of high BP should be withheld unless it is very high. Cautious reduction by 10 to 15% only is suggested.
- In acute disease, goal is to gradually reduce BP and monitor it for first 24 hrs in view of possibility of transient hypertension.
- Hypertensive encephalopathy should be aggressively managed.
- BP should not be reduced in ischaemic stroke patients who are not for thrombolysis. In patients with thrombolytic therapy, SBP >185 and DSP >100 mm Hg should be treated and BP maintained below 185/130 mm Hg.

Table 94: Oral drugs for hypertensive urgencies to reduce diastolic pressure gradually over 24 hours

Drug	Dose	Adverse Effects
Nifedipine	10 mg. Repeat after 30 min	Tachycardia, headache, flushing
Captopril	25 mg Repeat every 30 min as required	Angioedema, rash, acute renal failure if bilateral renal stenosis
Clonidine	0.1-0.2 mg every hr. as required upto 0.7 mg	Drowsiness, sedation, dry mouth
Nimodipine*	60 mg q4h for 21 days	Hypotension, oedema, headache
Prazosin®	1-2 mg. Repeat after 1h if necessary	First dose syncope, orthostatic hypotension, palpitations, tachycardia, headache

* For SAH through naso-gastric tube in unconscious patient.

®Especially indicated for urgencies associated with increased circulating catecholamines.

Hypertension in Women

- Side effects like ACE inhibitors induced cough, CCB induced pedal oedema and diuretic induced hyperkalaemia are seen more often in women than in men.
- Oestrogen - progesterone oral contraceptives cause increase in SBP and to lesser extent DBP.
- Use of HRT (low dose oestrogen) in post-menopausal women is contraindicated.

Hypertension and pregnancy

- DBP >110 mm Hg needs urgent attention.
- Chronic hypertension is that which is present before pregnancy or that which persists 6 weeks postpartum.
- Pre-eclampsia superimposed on chronic hypertension is diagnosed when there is a further increase in BP of 30 mm Hg systolic or 15 mm Hg diastolic, together with proteinuria or oedema.
- Transient hypertension of pregnancy (gestational hypertension) is elevation of BP during pregnancy or during first 24 hrs postpartum with no other sign of pre-eclampsia or of pre-existing hypertension.
- Antihypertensive agent used should be safe to mother and foetus. Methyldopa for women whose hypertension is first diagnosed during pregnancy. Nifedipine, labetalol can be used.
- ACE inhibitors, ARBs and sodium nitroprusside are contraindicated. Use of low dose diuretics is discouraged, since pre-eclampsia is a volume-depleted state.
- Magnesium sulphate IV is drug of choice for both prevention and treatment of seizures. IV hydralazine and labetalol are also effective.

Hypertension in the Elderly

- SBP is a better predictor of cardiovascular/cerebrovascular events, end-stage kidney disease as compared to DBP.
- Some older patients may have falsely high readings due to excessive vascular stiffness. Also as older patients are more likely to have orthostatic hypotension, BP should be measured in supine, sitting and standing position.
- Targets for BP control are <140/80 for those 55-79 years. However for those over 80, SBP of 150/90 mm Hg is acceptable.
- Low dose diuretics like hydrochlorothiazide or chlorthalidone are effective in lowering morbidity and mortality but risk of hyponatremia. These could be combined with ACE inhibitors CCBs are preferred Alpha blockers are preferred in those with BPH.

Isolated Systolic Hypertension

- BP <160 mmHg may be necessary with marked systolic hypertension, if symptoms of giddiness and light headedness when the BP is reduced to 140/90.
- Isolated systolic hypertension seen in old age, often successfully treated with life-style modification and long-acting calcium channel blockers.

Hypertension with CHF

- ACE inhibitors in patients with LV dysfunction due to hypertension.
- Low dose diuretics if associated with fluid retention.
- In patients stabilized with ACE inhibitors and low dose diuretics selective β -blockers and α - β -blocker like carvedilol may be used whenever indicated. These should be started in low doses and then gradually increased.
- Amlodipine is safe in patients with angina and LV failure, when added to ACE inhibitors, low dose diuretics and digoxin.

Hypertension with Atrial Fibrillation

- Increased LV mass and enlargement of LA have been identified as independent determinants of new onset AF. BP control is strictly required when anticoagulant is given because stroke and bleeding episodes are more frequent when SBP is >140 mm Hg.
- A history of AF and systolic heart failure is a specific indication for using β -blockers.

Hypertension with Chronic Obstructive Pulmonary Disease

- Precipitating factors such as systemic steroids, beta-agonists or nasal decongestants and stress should be looked into and modified.

- Amlodipine is relatively safe. α -blockers can be used as add-on therapy in patients with COPD.

Hypertension with CAD

- β -blockers and CCBs are drugs of first choice for angina in patients with CAD.
- Treatment with Amlodipine is associated with fewer hospitalizations for unstable angina.
- Verapamil and diltiazem reduce risk of developing MI following non-Q wave MI.
- Statins and aspirin in patients with associated CAD.

Hypertension with Dyslipidaemia

- Life style modifications of particular importance.
- Choice of anti-hypertensive agent should be made after considering the effect on profile that some of these drugs have.
- β -blockers without intrinsic sympathomimetic activity (ISA) may increase levels of triglycerides and reduce levels of LDL cholesterol.
- Despite these, they have been shown to reduce risk of sudden death, overall mortality and recurrent MI.
- Statins

Hypertension with Obesity and Metabolic Syndrome

Obesity is almost always accompanied by insulin resistance, hyperinsulinemia, impaired glucose tolerance and dyslipidaemia (Table 95). Also abnormal obesity is associated with sodium retention, endothelial dysfunction, microalbuminuria, LVH and elevated markers of inflammation.

- Essential HT is very frequently associated with a decrease in insulin sensitivity. This insulin resistance is very often associated with dyslipidaemia, metabolic syndrome or the insulin resistant syndrome.

Table 95: Diagnostic criteria for metabolic syndrome

Risk factor	Defining level
Waist circumference	
Men	>90 cm
Women	>80 cm
Triglycerides	
HDL-cholesterol	
Men	<40 mg/dL
Women	<50 mg/dL
Blood pressure	>130/ >85 mm Hg
Fasting glucose	>100 mg/dL
Diagnosis of metabolic syndrome requires three or more of the above risk determinants to be present.	

- Life style modification (diet, exercise) is the cornerstone of management in obese individuals.
- Dyslipidaemia in these patients is characterised by high TC levels and low HDL levels. Such patients require fibrates for control of dyslipidaemia.
- OSA now considered a cause of secondary hypertension is closely associated with obesity.
- On the basis of their favorable metabolic profiles, it seems that ACE inhibitors, ARBs, CCBs and α -blockers can decrease BP without worsening the metabolic abnormalities. ACE inhibitors, low-dose diuretics and non-dihydropyridine CCBs are the drugs of first choice in this setting. α -blockers have particular advantages in individuals with dyslipidaemia or glucose intolerance and may be considered as add-on agents.

RESISTANT HYPERTENSION

Resistant hypertension is defined as the failure to achieve goal blood pressure in patients who are adhering to full doses of an appropriate 3-drug regimen that includes a diuretic. Causes of resistant hypertension are given in Table 96.

Management of Resistant HT

- More aggressive salt restriction.
- Elimination of drugs interfering with action of anti-hypertensive agents.
- Multiple drugs in high dosages if no secondary cause is found.
- Newer intervention based treatment modalities such as renal sympathetic denervation therapy and carotid baroreceptor stimulation therapy are under evaluation.

ORTHOSTATIC HYPOTENSION (OH)

Normally, standing is accompanied by a small increase in DBP and a small decrease in SBP when compared with supine values. OH is present when there is supine to standing BP decrease >20 mm Hg systolic or >10 mm Hg diastolic after 2–3 minutes of standing. There is more OH in diabetics.

Causes of OH – Severe volume depletion, baroreflex dysfunction, autonomic insufficiency, and certain venodilator antihypertensive drugs, especially α -blockers and α - β -blockers. Diuretics and nitrates may further aggravate OH.

In treating older hypertensive patients, one must be aware of potential OH symptoms such as postural unsteadiness, dizziness or even fainting. Lying and standing BPs should be measured periodically in all hypertensives over age of 50.

Table 96: Causes of Resistant hypertension

• Volume overload
– Excess sodium intake
– Volume retention from kidney disease
– Inadequate diuretic therapy
• Drug-induced or other causes
– Nonadherence
– Inadequate doses
– Inappropriate combinations
– NSAIDs, cyclooxygenase 2 inhibitors
– Cocaine, amphetamine, other illicit drugs
– Sympathomimetics (decongestants, anorectics)
– Oral contraceptive hormones
– Adrenal steroid hormone
– Cyclosporine and tacrolimus
– Erythropoietin
– Liquorice and cough syrups
• Associated conditions
– Obesity
– Excess alcohol intake
• Identifiable causes of hypertension
– Chronic kidney disease
– Coarctation of aorta
– Non-specific aortoarteritis
– Cushing syn., chronic steroid therapy
– Obstructive uropathy
– Pheochromocytoma
– Primary aldosteronism
– Renal vascular hypertension
– OSA syndrome
– Thyroid or parathyroid disease

14. HEART MUSCLE DISEASE

Heart muscle disease can be idiopathic, genetic or specific. The myocardium can be affected in most types of heart disease; however, the terms 'myocarditis' and cardiomyopathy usually apply to conditions that primarily affect the heart muscle.

Specific heart muscle disease has known causes and is often associated with general systemic disease (e.g. sarcoidosis, amyloidosis).

ACUTE MYOCARDITIS

Acute damage to heart muscle by an inflammatory process. Myocarditis may resolve completely or partially, or it may deteriorate into a dilated cardiomyopathy. Viral myocarditis is the most common form. Other causes of myocarditis are listed in Table 97.

Table 97: Causes of myocarditis

Cause	Example
• Infections	Rubella, Coxsackie echoviruses, mumps, influenza, dengue, HIV, Hepatitis C
Viral	Diphtheria, pneumococcal (rare)
Bacterial	Chlamydia, Coxiella
Rickettsiae	Toxoplasma, trypanosomiasis
Parasitic	Leptospirosis
Spirochaetal	
• Immune disorders	Serum sickness, hypersensitive reaction to drugs, wasp stings, Lyme disease, Kawasaki disease
• Acute rheumatic fever	
• Physical	Radiation, severe hypothermia
• Connective tissue disease	Systemic lupus erythematosus, scleroderma, PAN
• Drugs and poisons	Carbon monoxide

Clinical Features

Symptoms – Dyspnoea, fatigue and sometimes precordial discomfort especially if associated pericarditis. Skeletal muscle pains in viral myocarditis.

Signs

- Tachycardia disproportionate to fever.
- Distended neck veins.
- Cardiac enlargement.
- Hypotension.
- S₁ soft, atrial and ventricular gallop sounds if severe disease.
- Murmur of MR and/or TR.
- Signs of CHF.
- Pericardial rub, arrhythmia and pulmonary or systemic embolization may occur.

Investigations

1. **ECG** – ST-T changes, low voltage, conduction defects and arrhythmias.
2. **Chest radiograph** – Cardiomegaly with pulmonary congestion.
3. **Echocardiography** – Useful in identifying chamber size, ventricular function, and pericardial effusion initially and serially. Doppler studies can assess MR and/or TR.
4. **Microbiological** – if an infection is suspected, appropriate specimens should be sent for microbiological investigation.
5. **Cardiac biomarkers** – Elevated levels reflect extent of myocardial necrosis.

6. *Nuclear imaging* – may identify diffuse or focal myocardial necrosis or inflammation, but the findings are non-specific. Thallium-201 perfusion scintigraphy may be abnormal due to faulty myocyte uptake, mimicking myocardial infarction.
7. *Endomyocardial biopsy* – in the acute stage will distinguish whether an acute inflammatory process is present, as opposed to a 'burnt out' cardiomyopathy.

Management

1. *Supportive measures* – Bed rest, diuretics for failure, anti-arrhythmic drugs. Prophylactic demand pacemaker may be needed for AV block in diphtheria. Steroids in viral and rheumatic carditis.
2. *Specific therapy* – Antitoxin in diphtheria, antibiotics. Beta-blockers, e.g. metoprolol may be of benefit.
3. *Corticosteroids* – may be used, e.g. in rheumatic carditis.

II. CARDIOMYOPATHY

Aetiology

Interaction of genetic factors and environmental exposure to viral antigen are thought to be aetiology of cardiomyopathy (Table 98).

Classification of Cardiomyopathies

See Table 99.

Dilated Cardiomyopathy

Dilated cardiomyopathy is characterized by a dilated hypokinetic left ventricle in absence of valvular, coronary, hypertensive or systemic disease. Right ventricular dilatation develops later.

Table 98: Aetiology of cardiomyopathy

• Idiopathic
• Autosomal dominant in about 50%
• Sporadic cases arise from new mutations which can affect proteins involved in the regulation of contraction
• Linkage to one of 4 genes:
β-myosin heavy chain gene on chromosome 14
Cardiac troponin T on chromosome 1
α-tropomyosin on chromosome 15
Myosin binding protein C on chromosome 11
• Loeffler's endocarditis
• Endomyocardial fibrosis
• Familial – Some cases

Clinical Features

are usually those of LV failure. Other presentations include systemic or pulmonary embolism, onset of atrial fibrillation, ventricular arrhythmia on routine ECG, or a mitral regurgitation murmur.

Investigations

ECG – Intraventricular conduction defect, low voltage in standard leads, high voltage in chest leads, left atrial P waves.

Chest radiograph – usually shows minimal left atrial enlargement and pulmonary venous congestion.

Echocardiography – Dilated LV with global hypokinesia which may be more marked in some areas (multifocal hypokinesia). The left ventricular thickness is usually normal. Functional MR is common (Fig. 111).

Angiography – is performed to exclude coronary artery disease.

Table 99: Classification of cardiomyopathies

Type	Features
Dilated cardiomyopathy	Enlargement of the cavity of the ventricle Low ejection fraction
Hypertrophic cardiomyopathy	Thickening of the ventricular wall associated with a small cavity High ejection fraction
Restrictive cardiomyopathy	Stiff ventricle which restricts filling. Ejection fraction maintained

Fig. 111: 2D echocardiography in dilated cardiomyopathy showing dilated LV

Management

Management is as for management of cardiac failure. Diuretics and ACE-inhibitors with addition of digoxin in advanced cases. Patients with atrial fibrillation require anticoagulant treatment. Antiarrhythmic drugs if symptomatic arrhythmias or when ectopic beats are so frequent as to cause hemodynamic deterioration.

Implanted defibrillator for any patient resuscitated from cardiac arrest and patients with recurrent ventricular tachycardia causing collapse or exacerbation of heart failure not controlled by antiarrhythmic drug treatment.

Cardiac transplantation offers long-term palliation for patients in NYHA class III or IV.

Special Forms of Dilated Cardiomyopathy

Postpartum cardiomyopathy is related to pregnancy. In worst cases, heart failure develops shortly after delivery, in milder cases symptoms occur later. Pregnancy seems to trigger an immunologically mediated myocarditis. Death may occur from overwhelming heart failure or patient may improve slowly.

Arrhythmic right ventricular cardiomyopathy (dysplasia) is inherited as an autosomal dominant condition with variable penetrance, gene defects have been matched to 14 and 1. It occurs in young males and is characterised by progressive fibro-adipose replacement of segments of the free wall of RV attributed to inappropriate focal myocyte apoptosis.

Patient may have family history of the condition or of sudden death during strenuous exercise. ECG may show inverted T waves in right precordial leads or RBBB. Epsilon wave in right-sided precordial leads. Focal or global RV dysfunction may be found on echocardiography.

Hypertrophic Cardiomyopathy

Hypertrophic cardiomyopathy (HCM) is defined as hypertrophy of the undilated left ventricle that cannot be explained by pressure or volume overload. The right ventricle is also hypertrophied.

Clinical Features

Symptoms

- Angina of effort
- Dyspnoea on effort
- Syncope
- Sudden death

Signs

- Jerky (rapid upstroke) pulse

- Palpable LV hypertrophy
- Bifid (double) apical impulse preceded by a presystolic impulse (due to LA hypertrophy)
- Systolic ejection murmur at the base
- Pansystolic murmur at apex due to MR
- Prominent 'a' waves in jugular pulse (from diminished RV compliance secondary to RV hypertrophy)

Investigations

X-ray - Heart usually not greatly enlarged, sometimes massive hypertrophy of LV.

ECG - LV hypertrophy, wide and double-peaked P waves suggesting LA hypertrophy. There may be large septal Q waves due to hypertrophy and fibrosis of the septum with a short PR interval and slurred upstroke of QRS resembling pre-excitation. Bizarre ECG changes are common.

2D-echocardiography - Obstruction in outflow tract, asymmetric septal hypertrophy (ASH), systolic movement of MV and early closure of AV (Figs. 112 to 114).

Colour Doppler ultrasound - detects LV outflow tract turbulence and when combined with continuous wave Doppler ultrasound, peak velocity of LV blood flow can be measured and LV gradients calculated.

Angiocardiography - Slit-like left ventricle with often starfish or banana appearance.

Management

- (1) β -blocker, e.g. Propranolol 10 mg t.d.s. may be increased to 200 mg daily, useful especially for angina. Verapamil if propranolol ineffective.
- (2) Treatment of arrhythmias. For atrial fibrillation cardioversion may be necessary, under anticoagulant cover.
- (3) Antibiotic prophylaxis for IE.
- (4) Surgical treatment - Septal myomec-

Fig. 112: 2D echo parasternal long axis view showing severe hypertrophy of interventricular septum and LV posterior wall

Fig. 113: 2D echo apical four-chamber view showing hypertrophied interventricular septum

Fig. 114: 2D echo showing hyper trophied obstructive cardiomyopathy

tomy if refractory symptoms. Alternative to myomectomy is injection of 1 to 3 mL alcohol into major septal perforator coronary artery to create necrosis. If severe MR, mitral valve replacement. Cardiac transplantation may be considered in case of totally refractory symptoms and poor prognosis. (5) ICD insertion is considered in these patients with family history of sudden death, unexplained recent syncope, massive LV hypertrophy-wall thickness ≥ 30 mm, diffuse late gadolinium enhancement on MRI, hypotensive or attenuated blood pressure respond to exercise, multiple/repetitive nonsustained VT.

Restrictive (Obliterative) Cardiomyopathy

RC is impairment of ventricular filling by endocardial or myocardial disease or both.

Clinical Features

- Right-sided disease* - Clinical picture resembles closely constrictive pericarditis with high central venous pressure, unimpressive ventricular pulsation and severe ascites without oedema.
- Left-sided disease* - MR tends to occur mainly in early and mid-systole producing a decrescendo systolic murmur. Systemic emboli from thrombus in left ventricle may occur. Atrial fibrillation common.

Investigations

Chest radiograph - Enormous cardiac silhouette in right-sided disease due to giant right atrium, and partly due to an associated pericardial effusion. In left-sided form LV and LA are both enlarged. A linear strip of calcification may be seen in region of LV.

Fig. 115: 2D echo showing thickened interventricular septum

Eosinophilia in blood common in EMF and Loeffler's endomyocardial disease.

ECG - Left atrial P waves. Low voltage QRS complexes usual.

Echocardiography - may show prominent bright echoes from increased endocardial collagen. Apical obliteration or thrombus, at times with calcium deposition is seen. Ventricular contractility is preserved and atrial dilatation is prominent. Doppler studies can define hemodynamic abnormalities, including diastolic MR and TR (Fig. 115).

MRI - may show prominent atrial signal in all phases of cardiac cycle, reflecting stasis of blood. It can define normal pericardial thickness and differentiate between constrictive pericarditis and RC.

Angiography – reveals mass of tissue in the ventricle, and in right-sided EMF giant RA. Ventricular cavity distortion by fibrosis and thrombosis helps in differentiation from constrictive pericarditis.

Endomyocardial biopsy – may help differentiate RC from constrictive pericarditis. It may help to diagnose one of the specific heart muscle diseases as the etiological factor.

Management

Drug therapy for CHF is mostly unsatisfactory. Anticoagulants for thromboembolic complications. Corticosteroids and immuno-suppressive drugs may help cases of EMF. Surgical resection of the obliterating endocardial tissue, with repair or replacement of regurgitant mitral and tricuspid valves can provide short-term benefit. Laser photoablation has been tried. Cardiac transplantation should be considered for end-stage disease.

Ischaemic Cardiomyopathy

Refers to a significant impairment of left ventricular function due to atherosclerotic coronary artery disease. This results in a dilated heart with symptoms and signs of intractable congestive heart failure. Thallium-201 perfusion scintigraphy demonstrates the defects and picks up the ischaemic myocardium even in the absence of angina. Positron emission tomography is useful in demonstrating ischaemic from idiopathic cardiomyopathy.

Peripartum cardiomyopathy as a diagnosis needs to be considered in antenatal and immediate postpartum, in women with clinical features of cardiac failure. It typically presents in last month of pregnancy and immediate postpartum.

Stress cardiomyopathy is a reversible form of acute cardiomyopathy that may mimic acute MI. LV contraction abnormality encompassing more than one coronary artery territory and no significant coronary stenosis on angiography.

Endocardial Fibroelastosis (EFE) – is an entirely different condition occurring in infants. It leads to early heart failure involving LV and is commonly associated with left sided congenital abnormalities such as AS and coarctation of aorta.

III. SPECIFIC HEART MUSCLE DISEASE

See Table 100 for various causes of heart muscle disease.

Clinical Features

1. Usual clinical picture like dilated cardiomyopathy (e.g. sarcoidosis, alcoholic heart disease, connective tissue disorders).

Table 100: Causes of heart muscle disease

• Infiltrations
– Primary amyloid
– Sarcoid
– Hemochromatosis
– Connective tissue disease
– Systemic lupus erythematosus
– Systemic sclerosis
– Rheumatoid arthritis
– Marfan's syndrome
• Endocrine and metabolic disorders
– Diabetes
– Acromegaly
– Hypo- and hyperthyroidism
– Glycogen storage disease
– Carcinoid syndrome
– Inherited storage diseases
• Drugs and toxins
– Antineoplastic drugs
– Alcohol
– Irradiation
• Endomyocardial fibrosis and Loeffler's (hypereosinophilic) syndrome
• Neuromuscular disease
– Friedreich's ataxia
– Dystrophia myotonia

2. Clinical features resembling restrictive cardiomyopathy (e.g. amyloidosis and eosinophilic heart disease).
3. Mimicking hypertrophic cardiomyopathy (e.g. Friedreich's ataxia).

Scleroderma Cardiac Disease

Myocardial ischaemic fibrosis can occur in systemic sclerosis. It is due to microcirculatory impairment. Repeated focal ischaemic injury gives rise to irreversible myocardial fibrosis. Microvascular coronary vasospasm is known as "myocardial Raynaud's phenomenon".

IV. CARDIAC TUMOURS CARDIAC MYXOMAS

Left Atrial Myxomas

Intracardiac myxomas are the most common benign tumours of the heart and in majority are located in LA and rise from interatrial septum. Most common in women between 30 and 60 years of age.

Clinical features – Triad of

- Embolic phenomenon – Systemic emboli involving the brain, heart, extremities, kidney and aortic bifurcation.
- Systemic symptoms – Fever, anorexia, weight loss, myalgia, arthritis, Raynaud's phenomenon, petechiae and finger clubbing (due to immunological reactions to necrotizing tumour).
- Obstructive manifestations – Obstruction of mitral valve simulates mitral stenosis producing left heart failure. A ball-valve mechanism can produce recurrent pulmonary oedema or stenosis, which can lead to sudden death.

Signs

1. Loud S₁ and accentuated S₂.
2. "Tumour plop" – Early diastolic sound produced by prolapse of the tumour through mitral valve.
3. Apical diastolic or systolic murmur or both usually present. Changing murmurs due to varying mitral obstruction.

Investigations

2D-echo – is diagnostic and reveals location, origin, and movement of the tumour (Fig. 116).

Treatment – Surgical resection of the tumour together with portion of atrial septum from which it arises.

Right Atrial Myxomas

Right atrial myxomas—are rare.

Clinical manifestations – Features of systemic venous hypertension, prominent jugular 'a' waves, oedema,

hepatomegaly and ascites. Signs – Loud early systolic sound at lower sternal border, and systolic and diastolic murmurs at tricuspid area. Echo is diagnostic.

Treatment – surgical removal.

15. NEUROCIRCULATORY ASTHENIA

Neurocirculatory asthenia (effort syndrome, soldier's heart or anxiety neurosis) is a condition of ill health of psychogenic or neurogenic origin characterised by a group of symptoms and a general incapacity in adjusting to physical or mental strain, especially in hypersensitive individuals who in extreme cases may show the condition more or less constantly with little or no provocation.

AETIOLOGY

- (a) **Age** – Commonest in young adults.
- (b) **Sex** – 60% females.
- (c) **Heredity** – Sensitive nervous system in family members.
- (d) **Aggravating factors** – Nervous strain, physical overexertion, exhausting illness or infectious disease, pregnancy.

SYMPTOMS

1. **Chest pain** – Inframammary, pinching or stabbing and fleeting, or dull pain of prolonged duration usually located near the cardiac apex, sometimes substernal, bears no relation to effort, usually associated with fatigue. Pain may radiate down the left arm, more commonly down the outer side unlike angina. Area over left breast or apex sore to touch.
2. **Dyspnoea** – common. Sensation as if the breath cannot go through. Sighing respirations characteristic; irregular breathing.

Fig. 116: 2D echo showing left atrial myxoma

3. *Palpitation* – particularly when lying on left side; often at night and at rest.
4. *Fatigue* – usually after waking in the morning, even after sound sleep. Exhaustion makes patient dread any activity.
5. *Fever* – of mild degree not uncommon. Temperature rarely more than 100.5°F and often detected after mild respiratory infection.
6. *Giddiness* – Usually light headedness or near blackout associated with sudden change of posture.
7. *Miscellaneous* – profuse perspiration, throbbing headache, trembling, irritability, flushing, insomnia, paraesthesia, diarrhoea, difficulty in concentration and mental and physical apathy.

SIGNS

None characteristic. Tachycardia, tachypnoea, sighing, tremors, moist cold palms and brisk tendon reflexes are often found as in nervous individuals. During a standard exercise test, these patients may have a lower oxygen consumption and greater rise in blood lactate than normal individuals. Slight elevation of blood pressure usually systolic.

PROGNOSIS

Good for life expectancy. Degree of incapacity depends on duration and intensity of symptoms. Outlook unfavourable if long history of symptoms, or syndrome precipitated after brief or minor strain and presence of significant psychomotor derangement. Recovery may occur after careful treatment but relapse also likely unless precipitating cause is discovered and abolished.

MANAGEMENT

- i. Psychotherapy – Reassurance and explanation of non-organic nature of complaints. Identification of factors which aggravate symptoms. A depressive disorder as the cause of the cardiac symptoms should be excluded.
- ii. Sedatives or tranquillizers may help.

16. PERICARDIAL DISEASE

PERICARDITIS

See Table 101 for the causes of pericarditis.

Table 101: Causes of pericarditis

• Idiopathic (<i>non-specific or benign</i>).
• Myocardial infarction
• Infections
– Bacterial
– Tuberculous.
– Pyogenic – Intrathoracic infection, e.g. pneumonia, empyema, septicaemia or penetrating wounds of chest.
– Viral – Coxsackie B, echovirus S, mumps, infectious mononucleosis, influenza, herpes simplex, HIV.
– Fungal – Actinomycosis, histoplasmosis.
– Protozoal – Amoebiasis, toxoplasmosis.
– Parasitic – Echinococcus, cysticercus.
– Spirochaetal – Syphilis, Lyme disease.
• Metabolic
– Uraemia
– Hypothyroidism
• Autoimmune
– Rheumatic fever
– Connective tissue diseases: Rheumatoid arthritis, SLE, scleroderma, polyarteritis nodosa, giant cell arteritis
• Tumors and infiltrations
– Carcinoma bronchus or oesophagus, lymphoma, leukaemias
• Delayed pericardial injury syndromes
– Post-pericardiotomy
– Post-myocardial infarction (Dressler's syndrome)
Radiotherapy
• Drugs – Hydralazine, procainamide, methysergide, phenytoin
• Haemopericardium
– Cardiac rupture
– Aortic dissection
– Trauma
– Thoracic surgical procedures
– Transvenous cardiac pacemaker

I. ACUTE PERICARDITIS

Symptoms

Onset – Abrupt with chills, fever and precordial pain, or insidious.

1. *Chest pain* – Main symptom. (i) Pleuritic pain aggravated by change of position, deep inspiration, coughing or swallowing. Sitting up and leaning forward may give relief. Radiation of pain to the trapezius ridge is nearly pathognomonic. (ii) Steady severe pain simulating acute myocardial infarction.
2. *Dyspnoea and short hacking cough*.
3. *General symptoms* – Fever, sweating, chills, etc. depending on cause.

Signs

1. *Tachycardia.*
2. *Rapid respiratory rate.*
3. *Pericardial friction rub* – Superficial, scratching or grating to-and-fro sound localised to a small area over the precordium, the left sternal edge being the commonest site, or heard all over the left anterior chest. Three typical components – systolic, early diastolic, presystolic. May be transient for few hours or persist for many days. Seldom exactly the same in any two successive cardiac cycles, and changing from day to day.
4. *Atrial arrhythmias* – especially atrial fibrillation not uncommon.

EGG – (Figs. 117 and 118) Shows characteristic pattern due to injury to subepicardial portion of myocardium – Elevation of ST segments with an upward concavity particularly in leads I and II in acute stage, followed after 10–14 days by return of ST segments to iso-electric line

Fig. 117: Acute pericarditis. Concave ST segments elevation in all the leads facing the injured surface except aVR which faces the cavity of the heart

with flattening or inversion of T waves. May be normal. PR segment depression is seen.

Treatment

(1) Bed rest. (2) Salicylates 2–6 gm/day and in severe cases other anti-inflammatory drugs such as indomethacin 100–200 mg/day or ibuprofen 600–1600 mg/day or prednisolone 20–60 mg/day. Initial high dose then rapid tapering protocol should be used for steroid therapy. (3) Colchicine 2–6 mg/day may help difficult cases.

II. PERICARDIAL EFFUSION

Types of Fluid

1. *Transudate*
Congestive heart failure, Nephrotic syndrome, Myxoedema, Beriberi.
2. *Exudate*
Serous – Usually tuberculosis, rarely acute benign pericarditis, or disseminated lupus erythematosus.
Purulent – Haematogenous spread or direct from empyema, mediastinal abscess, amoebic liver abscess, or infection following aspiration.
3. *Haemorrhagic*
Rupture of the ventricle in transmural myocardial infarction.
Rupture of aortic dissection or of aneurysm of sinus of Valsalva into the pericardium.
Tuberculous or malignant effusion. Thoracic trauma.
Tear of right ventricle during pericardial puncture.

Fig. 118: 12-lead ECG acute pericarditis

Symptoms

1. Small effusion - No symptoms.
2. Large or rapidly developing effusion

- **Pain or precordial distress**

Typical precordial pain - stabbing in character, worse with coughing, respiration, body movements and swallowing. Intensity varies from dull ache to severe pain. Usually, radiates to front of chest, may radiate widely to neck, arms and back.

Dull heavy oppression due to distension of pericardial sac.

Pain due to hepatic distension.

- **Symptoms due to compression** - Pericardial effusion is accompanied by rise in intrapericardial pressure which if severe (*cardiac tamponade* Table 102) impairs venous return with consequent fall in cardiac output.

Compression of heart resulting in insufficient blood to enter heart, lung and systemic arteries - Dyspnoea, faintness.

Pressure of effusion on surrounding structures such as lungs, trachea, bronchi, oesophagus and great vessels - more dyspnoea or orthopnoea, pain, cough, hoarseness and dysphagia.

- **Constitutional symptoms** - Fever, sweating, loss of weight, fatigue, etc.

Signs

Inspection - (1) Attitude - Bending forward or in the Mohammedan prayer position. (2) Bulging of precordium. (3) Apex beat not visible. (4) Jugular venous pressure elevated, y-descent is absent and inspiratory decrease in venous pressure is retained so Kussmaul sign is absent.

Table 102: Cardiac tamponade

Acute onset	
1.	Diagnostic CTVS procedures
2.	Aortic dissection (acute)
3.	Viral pericarditis
4.	Anticoagulant therapy
Slow onset	
1.	Tuberculosis
2.	Chronic kidney failure
3.	Post radiation
4.	Malignancy
5.	Rarely: Ca lung, breast, lymphomas, hypothyroidism, collagen vascular disorders, fungal infections

Palpation - (1) Apex beat feeble or not felt. (2) Pericardial rub may be felt. (3) Left lobe of liver often palpable.

Percussion - (1) Upper border of cardiac dullness in 2nd or 1st space when patient lies flat. (2) Dullness increased both to right and left. (3) Limit of dullness on left outside the apex impulse. (4) Flat percussion note over lower half of sternum (Dressler's sign). (5) Impairment of resonance in cardiohepatic angle (Rotch's sign).

Auscultation - (1) Heart sounds faint and muffled. (2) Pericardial friction rub may be heard. (3) Bronchial breathing and aegophony below angle of left scapula (Ewart's or Pin's sign). Usually attributed to collapse of the lung.

Pulse - Normal, small or pulsus paradoxus depending on the intrapericardial pressure. Pulsus paradoxus occurs when systolic pressure falls by 10 mm Hg or more on inspiration.

B.P. - With large effusion systolic pressure decreased and pulse pressure much diminished.

Beck's triad - hypotension, muffled heart sound and elevated jugular venous pressure.

Investigations

1. *Chest radiograph* (Fig. 119) - If effusion is large, water-bottle configuration in upright position, this becomes more globular in lying position. Straightening of cardiac border and widening of superior mediastinal shadow. Angle between right cardiac border and diaphragm more acute.
2. *ECG* - Low voltage of QRS complexes and T waves in all leads. With large effusion, a cyclical beat-to-beat pendular movement of the heart may produce electrical alternans.

Fig. 119: Pericardial effusion. Leather-bottle or flask shape cardiac shadow. Other causes of such cardiomegaly are - Multiple valvular disease, Cardiomyopathy, ASD, Ebstein's anomaly

Fig. 120: 2D echo apical 4 chamber view showing large pericardial effusion (arrow)

Fig. 121: CT chest shows pericardial effusion

Fig. 122: MRI showing pericardial effusion

3. *Echo* - Echo-free space around the heart. Swinging of the heart. With tamponade RV compression with decreased diameters, RV indentation in late diastole, LA indentation, LV paradoxical motion of free wall, inspiratory pulsus paradoxus with RV expansion, shift of IV septum to left, decompression of LV, coarse oscillations of LV wall (Fig. 120).
4. *CT scan* - (Fig. 121)
5. *MRI* (Fig. 122) - If effusion difficult to see on echo (poor acoustic windows or echogenic effusion), the ability of MRI to freeze cardiac motion and to image in any plane can be an advantage. When effusion is due to pericardial malignancy or to disease in adjacent mediastinum, MRI can identify malignant tissue and high signal effusion (e.g. a haemorrhagic effusion).

6. *Pericardiocentesis* - may be diagnostic of the cause in some patients.

Management

1. Supportive Measures - Bed rest. Analgesics.
2. Of Underlying Cause - (a) Tuberculous effusion - Anti-tuberculous therapy. (b) Rheumatic - Large doses of salicylates. Steroids if clinical evidence of associated carditis. (c) Purulent - Appropriate antibiotics. (d) Idiopathic - Corticosteroids may help.
3. Pericardial Aspiration

Indications - (a) Diagnostic - (i) To confirm presence of pericardial effusion. (ii) To determine the etiologic agent.

(b) Therapeutic - (i) Cardiac or respiratory embarrassment due to cardiac tamponade as indicated by tachycardia, elevated jugular venous pressure, decreased blood pressure, new symptoms including shortness of breath, fatigue and giddiness. (ii) Suspicion of purulent pericarditis. (iii) Tuberculosis.

Preparation - The procedure is carried out under sterile conditions using local anaesthesia. Premedication is seldom required.

Site - (a) Intercostal - is easier but carries risk of lung puncture or damage to coronary vessels if effusion is small. Also if fluid is pyogenic or malignant, the left pleural cavity may be contaminated. (b) Xiphoid - is less reliable but safer.

Procedure - The chosen site is infiltrated with 1% lignocaine. A 10 cm 21 gauge needle is used for aspiration.

(a) Xiphoid approach – Patient should be propped up in bed at 45° to avoid entering the stomach. The needle is inserted about 3 cm below the xiphoid process at 30° to the skin pointing towards the patient's nose. If it strikes the costal margin, it should be withdrawn and reinstated at a deeper angle. When the needle surface is against the under surface of diaphragm, the syringe will move in and out with respiration. The needle should be introduced another about 2 cm until pericardial sac is entered. Monitoring of aspiration may be assisted by echo and/or recording ECG from the pericardiocentesis needle while performing the procedure; if the needle penetrates the heart, ECG shows an injury pattern. The needle is attached to a 2 mL syringe containing little saline. As the needle is slowly advanced, intermittent suction should be applied on the syringe. For diagnosis enough fluid can be drawn and collected for analysis. If a large amount of fluid is to be withdrawn, the narrow needle should be replaced by a 16 gauge catheter needle from an intravenous placement unit (or a lumbar puncture needle). The needle is connected to a three-way tap and 20 ml syringe. If there is difficulty in aspirating the fluid, it is quite safe with the flexible catheter in the sac to turn the patient on his side.

(b) Intercostal approach – is made in 5th or 6th left intercostal space in midclavicular line. The needle is inserted at right angles to the skin pointing slightly upwards. When the needle is on the left ventricle vigorous pulsations will be transmitted.

Complications – (i) Penetration of either ventricle. (ii) Laceration of coronary artery with formation of haemopericardium. (iii) Shock. (iv) Ventricular tachycardia.

4. Corticosteroids – In acute benign pericarditis, disseminated lupus, and pericarditis following myocardial infarction or pericardiectomy. Prednisolone 20 mg t.d.s.
5. Pericardiectomy – For chronic and recurrent pericardial effusion.

III. CONSTRICTIVE PERICARDITIS

Causes of constrictive pericarditis are listed in Table 103.

Clinical Features

A. Due to impaired filling of right side of heart

Signs:

1. *Raised venous pressure* – and it may rise appreciably during inspiration (Kussmaul's sign). Sharp diastolic collapse ("y" descent) of venous pulse (Friedreich's sign) due to rapid inflow into the ventricles as the tricuspid valve opens with normal x-descent.
2. *Cardiac signs* – (a) Palpation – Apex impulse usually impalpable. Typically there is a systolic retraction of the apex beat which is followed by an abrupt outward movements as the ventricle fills rapidly in early diastole (diastolic shock). (b) Auscultation – Loud early 3rd sound (pericardial knock) due to check-rein mechanism and corresponding to the palpable diastolic shock. 2nd sound widely split with little variation with respiration. No heart murmurs or pericardial rub. Auscultation may be completely normal.
3. *Pulse* – Small and rapid. Pulsus paradoxus or atrial fibrillation may occur. Causes of absent pulsus paradoxus in constrictive pericarditis are listed in Table 104.
4. Hepatomegaly – Liver enlarged, tender but not pulsatile.
5. Ascites – occurs early with tendency to recur after tapping, and with little or no oedema of feet.
6. No orthopnoea.

Investigations

1. *Chest radiograph* – Triangular shaped heart with straightened right and left borders. Very little pulsation on fluoroscopy (quiet heart). Calcification of

Table 103: Causes of constrictive pericarditis

Common
• Tuberculosis in majority.
• Pyogenic pericarditis.
Rare
• Acute benign pericarditis.
• Following haemopericardium.
• Connective tissue diseases.
• Radiation therapy to chest.
• Uraemic.
• Idiopathic pericarditis.
• Rheumatoid arthritis.

Table 104: Causes of absent pulsus paradoxus in constrictive pericarditis

• LV dysfunction
• Positive pressure breathing
• Extreme hypotension
• Hypovolaemia
• Atrial septal defect
• Aortic regurgitation

Fig. 123: Pericardial calcification in constrictive pericarditis

Fig. 125: 2D echo showing constrictive pericarditis

pericardium diagnostic (Fig. 123). A dilated superior vena cava is a valuable sign.

2. *ECG* - Low voltage with characteristic T terminal negativity (Fig. 124). There may be atrial fibrillation.
3. *Echocardiography* - (a) Small heart with good systolic function, or small ventricles and enlarged atria so that all the four cardiac chambers may be similar in size. (b) The pericardium is seen as single or double dense rigid shell surrounding the heart which is quite immobile (Fig. 125). (c) Abrupt displacement of interventricular septum during early diastole 'septal bounce' is seen. (d) The inferior vena cava and hepatic veins are grossly dilated and Doppler studies of aorta and pulmonary blood flow with blunted respiratory function confirm pulsus paradoxus. (In contrast patients with congestive cardiomyopathy show great ventricular

Fig. 124: Low voltage complexes in constrictive pericarditis

Fig. 126: CT chest shows pericardial effusion with few air pockets (postdrainage), the fluid thickness is up to 25 mm, outer layer of pericardium is thickened. Bilateral pleural effusion is present

dilatation with poor systolic contractility and pulsus alternans.) (e) Premature opening of pulmonary valve due to elevated RV early diastolic pressure.

4. *CT scan* - (Fig. 126)
5. *MRI* - can image thickened pericardium in any plane and is unaffected by calcification artefacts.

Differential Diagnosis

1. *Restrictive cardiomyopathy* - Clinical features - No paradoxical pulse. JVP - Normal 'y' descent, no Kussmaul's sign. Prominent apical impulse. Often associated valvular incompetence. S3 low pitched. Investigations - X-ray - No pericardial calcification, cardiomegaly.

ECG - LVH, intraventricular conduction disturbance.
Echo - No pericardial thickening or effusion, LV thickening.

Catheter - LV end-diastolic pressure > RV end-diastolic pressure. Endomyocardial biopsy suggestive. Response to therapy - Reduction in height of JVP with diuretics.

2. *Cirrhosis of liver* - because of ascites, oedema. Jugular venous pressure normal or only slightly raised.
 3. *Congestive cardiomyopathy* - Marked ventricular dilatation with poor systolic contractility and pulsus alternans.
 4. *Tricuspid valve disease* - Systolic murmur of TR or diastolic murmur of TS.
 5. *RV infarction* - Other features of IHD.
- B. **Due to impaired filling of left heart** - Much less common. Patient presents with history of syncope on exertion with dyspnoea and evidence of pulmonary congestion.

Treatment

Pericardiectomy with removal of the thickened pericardium from the anterior surface of the heart. Course of antituberculous therapy even in absence of active tuberculous infection.

17. PULMONARY HYPERTENSION

A pathophysiological condition characterised by elevation of pressure in the pulmonary arterial system more than upper limit of normal, i.e. 30 mm Hg systolic, 15 mm diastolic, or 25 mm mean. Causes of pulmonary hypertension are given in Table 105.

PRIMARY PULMONARY HYPERTENSION

Symptoms

1. *Due to lowered cardiac output* - Easy fatigability, dizziness, syncopal attacks.
2. *Due to diminished coronary perfusion* - Angina-like chest pain due to RV ischaemia.

Signs

Inspection - Cyanosis usually peripheral, central cyanosis if foramen ovale becomes patent. Giant 'a' waves in jugular venous pulse.

Palpation - Left parasternal heave due to RV hypertrophy. Small arterial pulse and cold extremities. Diastolic shock in pulmonary area. Presystolic hepatic pulsation may be felt.

Auscultation -

Sounds - Narrow splitting of S₂ with increased intensity of pulmonary component, S₃ and/or S₄ gallop rhythms.

Table 105: Causes of pulmonary hypertension

Primary or idiopathic

Secondary

- **Passive** - due to increase in resistance to left ventricular filling.

- Mitral stenosis.
- LV failure.

- **Active or vasoconstrictive** - due to

- Alveolar hypoxia.
- High altitude exposure.

- **Obstructive or oblitative** - due to increase in pulmonary vascular resistance.

Obstructive

- Miliary emboli or thrombi (in small pulmonary vessels)
- Venocclusive disease

Oblitative

- Chronic bronchitis and emphysema
- Severe lung fibrosis
- Systemic sclerosis
- Polyarteritis nodosa
- SLE
- Schistosomiasis

- **Hyperkinetic** - due to increased pulmonary arterial blood flow

- PDA
- ASD
- VSD
- Total anomalous pulmonary venous drainage
- Persistent truncus
- Transposition of great vessels

- **Miscellaneous**

- Liver cirrhosis (from porto-systemic shunts)
- Sickle cell disease (due to repeated sickle crisis)
- Toxin-mediated (consumption of denatured rape seed oil)

Murmurs - (a) Systolic ejection murmur due to blood flow through dilated pulmonary artery. (b) Early diastolic murmur of relative pulmonary regurgitation. (c) Pansystolic murmur of functional TR not uncommon.

Investigations

1. *ECG* - RV and often RA hypertrophy (P pulmonale).
2. *Chest radiograph* - Prominent main pulmonary arteries, but peripheral lung fields show slight decrease in vascular markings.

Special Diagnostic Evaluation:

- (a) *Echocardiography* – Dilatation of RV and RA, paradoxical motion of ventricular septum and abnormal motion of pulmonary valve leaflets, interventricular septal flattening, tricuspid regurgitation suggestive of PH. May be evidence of underlying cardiac disease, e.g. MS. It provides estimate of pulmonary artery systolic pressure. LV systolic and diastolic function, detects systemic to pulmonary shunt.
- (b) *Cardiac catheterization* – Allows direct measurement of pulmonary artery pressure and capillary wedge pressure which is elevated if PH is due to left-sided heart disease.
- (c) *Arterial blood gases* – May show arterial hypoxaemia.
- (d) *Pulmonary function tests* – Hypoxia due to ventilation-perfusion mismatch and reduced gas transfer.
- (e) *Ventilation-perfusion lung scans* – May reveal evidence of pulmonary thromboembolism.
- (f) *High-resolution CT* of chest to exclude occult interstitial lung disease.
- (g) *High Helical CT* to detect pulmonary thromboembolism.
- (h) *Lung biopsy* – for possibility of discovering a specific unsuspected cause, as well as assessing reversibility or irreversibility of vascular changes.

Differential Diagnosis

1. *'Damped' mitral stenosis* – High pulmonary vascular resistance with attacks of paroxysmal dyspnoea and pulmonary oedema. ECG shows P waves which are combination of P-mitrale and P-pulmonale.
2. *Eisenmenger complex* – History over many years, either sex, no giant 'a' waves, more central cyanosis rather than peripheral, pulmonary ejection murmur and thrill common. Angiocardiography shows bidirectional shunt.
3. *Chronic thromboembolic pulmonary hypertension* – Refer pulmonary embolism.

Management

- (a) Of underlying cardiac or pulmonary disease if identified.
- (b) Continuous anticoagulation for patients with recurrent pulmonary emboli.
- (c) Calcium channel blocker such as nifedipine to alleviate pulmonary vasoconstriction.

- (d) Chronic oxygen therapy especially at night, may be useful in patients whose pulmonary artery pressure is shown to decrease during oxygen inhalation, to alleviate pulmonary vasoconstriction.
- (e) Other drugs
 - Prostacyclin analogue
 - Epoprostenol, a short acting vasodilator by IV infusion or Iloprost IV or via nasal route
 - Endothelial-I receptor antagonist (Bosentan) 25–50 mg bd
 - Selective phosphodiesterase - 5 inhibitor (sildenafil) 62.5 mg bd increasing to maintenance 125 mg bd
 - Ambrisentan 5–10 mg bd
- (f) Heart-lung transplantation has been attempted for far advanced cases.

PULMONARY VENOUS HYPERTENSION (PVH)

PVH is the principal disorder affecting pulmonary veins and is a common manifestation of adult heart disease (predominantly left-sided) (Table 106).

Chest Radiograph

As pulmonary venous pressure increases, radiographic signs, tend to occur in a sequence.

Interstitial oedema occurs with LA pressure of 22–30 cm H₂O. Vessels, particularly in the perihilar region and lower zones become hazy and ill-defined and airway walls thicken.

Septal (Kerley) lines appear. B lines are those most seen and are caused by oedema of interlobular septa. They are straight, short 1–2 cm, horizontal lines that touch the parietal pleura and occur commonly in the region of the costophrenic angle. Septal B lines can be distinguished from small vessels because they do not branch, touch the pleura and are dense for their width.

Laminar effusions are caused by fluid accumulation in the subvisceral pleural space, giving a band of soft-tissue density against the lateral chest wall in and just above the costophrenic angle.

Table 106: Causes of pulmonary venous hypertension

• Aortic valve disease
• LV disease: Ischaemia, reduced LV compliance (HCM)
• Mitral valve disease
• Left atrial myxoma
• Pulmonary venous obstruction (veno-occlusive disease)
• Heart failure with preserved ejection fraction

Alveolar oedema occurs when LA pressure exceeds 30 cm H₂O. Alveoli that have become filled with transudate become opaque (consolidation). Characteristically alveolar oedema is bilateral with a perihilar or lower zone predominance.

Management – treatment of underlying cause.

18. HEART DISEASE AND PREGNANCY

Normal circulatory changes in pregnancy:

1. *Blood volume* – increases gradually until term.
2. *Cardiac output* – rises by about 40% early in pregnancy and is maintained at this level up to term. After delivery, it generally returns to normal after 2 weeks.
3. *Venous pressure* – increases due to increase in blood volume.
4. *Arterial pressure* – Systolic pressure is unchanged but diastolic pressure falls giving wide pulse pressure.
5. *Regional blood flow* – Blood flow to skin and uterus gradually increases. Renal blood flow reaches maximum level in the first trimester and remains high thereafter.
6. *Pulse rate* – rises maximally between 8 and 10 weeks before delivery.

CARDIOVASCULAR MANIFESTATIONS DURING PREGNANCY

Symptoms

1. *Dyspnoea* – at rest or on exertion, may be related to hyperventilation. Orthopnoea especially in later months of pregnancy.
2. *Palpitation* – In mid and late pregnancy and puerperium. May be due to awareness of normal heart beat because of increased stroke volume or dysrhythmia.
3. *Oedema of legs* – during last 2 months due to increased venous pressure in legs, fluid retention, and reduced oncotic pressure of blood.
4. *Syncope* – in supine position because systolic pressure falls significantly due to pooling of blood in the legs.

Signs

1. *Apex beat* – displaced due to elevated diaphragm.
2. *Arterial pulse* – may be collapsing due to high stroke volume and low peripheral resistance.
3. *Heart sounds* – Loud mitral 1st sound and P2 due to forceful closure from increased stroke volume. 3rd heart sound often audible and may simulate gallop rhythm.

4. *Heart murmurs* – (a) Ejection systolic murmur at apex or base due to high stroke volume. (b) Late parasternal systolic murmur extending into diastole (mammary souffle) in late pregnancy and puerperium. (c) Flow murmur, e.g. mitral stenosis or aortic stenosis due to increased stroke volume. (d) Regurgitation murmur of MR and AR due to decreased peripheral resistance favouring forward flow.

5. *Raised JVP* – owing to high output state.

6. *Arrhythmias* – Ectopic beats, paroxysmal SVT.

7. *Hypotension* – is common due to vasodilatation, increased heat production and low resistance in utero-placental circulation.

8. *Hypertension in pregnancy* – Causes of hypertension in pregnancy are given in Table 107.

ECG – Often prominent S waves in lead I, and Q waves with inverted T waves in III, due to rotation of heart.

Chest radiograph – Increased pulmonary shadows suggesting hilar congestion. Pulmonary arterial arc prominent due to increased blood flow.

MANAGEMENT OF CARDIAC DISEASE DURING PREGNANCY

Medical Management

1. *Restriction of activity* – More hours of rest and sleep.
2. *Infections* – Respiratory tract infections and pyelonephritis should be treated promptly.
3. *Arrhythmias* – Electrical cardioversion for atrial fibrillation. Quinidine should be avoided.
4. *Anaemia* – is not well tolerated and must be treated.
5. *Antihypertensive drugs* – See Table 108.
6. *Acute pulmonary oedema* – may be precipitated by anxiety and may even occur in a young patient with moderate MS and few symptoms prior to pregnancy. It is the commonest cause of cardiac death and should be treated promptly.
7. *Cyanotic attacks* – in cyanotic congenital heart disease may prove fatal to the mother as well as to the baby. They may respond to vasopressor drugs which increase systemic resistance, or propranolol which reduces right ventricular obstruction.
8. *Peripartal cardiomyopathy* – may lead to congestive failure in late pregnancy or puerperium especially in malnourished multiparous women (see cardiomyopathies).

Table 107: Causes of hypertension in pregnancy

Chronic hypertension	BP >140 mm Hg or 90 mm Hg prior to pregnancy or before 20 weeks gestation Persists >12 weeks postpartum
Pre-eclampsia/eclampsia	BP >140 systolic or 90 diastolic with proteinuria (>300 mg/24 h) after 20 weeks gestation Can progress to eclampsia (seizures)
Chronic hypertension with superimposed pre-eclampsia	New onset proteinuria after 20 weeks in a woman with hypertension In a woman with hypertension and proteinuria prior to 20 weeks gestation Sudden 2 to 3-fold increase in proteinuria Sudden increase in BP Thrombocytopenia Elevated AST or ALT
Gestational hypertension	Hypertension without proteinuria occurring 20 weeks after gestation Temporary diagnosis May represent preproteinuric phase of pre-eclampsia or recurrence of chronic hypertension abated in midpregnancy May evolve to pre-eclampsia If severe, may result in higher rates of premature delivery and growth retardation than mild pre-eclampsia
HELLP syndrome	Peripheral smear showing evidence of haemolysis Elevated liver enzymes Low platelet count
Transient hypertension	Retrospective diagnosis BP normal by 12 weeks postpartum May recur in subsequent pregnancies Predictive of future systemic hypertension

(Refer hypertension in special situations)

Surgical Management

- (a) *Mitral stenosis* – Mitral valvotomy preferably before 20th week if persistent pulmonary congestion despite adequate medical treatment. (b) *Congenital heart disease* – Surgical interference is seldom necessary during pregnancy.

Obstetric Management

Indications for Termination of Pregnancy

- (1) *Cardiac failure* – Before 14th week – Left-sided failure if patient unsuitable for valvotomy, or CHF. After 14th week – LVF or CHF. If unsuitable for valvotomy, continuation of pregnancy unless deterioration.
- (2) *Other factors* – (a) Atrial fibrillation – if persistent. (b) Primipara over 35, pregnancies in quick succession or associated other disease. (c) Hypertension – Continuing rise of blood pressure, or malignant hypertension. (d) Coronary heart disease. (e) Primary pulmonary hypertension. (f) Congenital heart disease – Eisenmenger's complex. Evidence of development of dissection in coarctation of aorta.

Management of Labour

- (1) Second stage should be kept as short as possible with the use of forceps if needed. (2) Cardiac stress during

labour is less if patient is kept on the side. (3) Oxygen and sedation with pentazocine should be used freely if patient is in distress. (4) Prophylaxis of bacteraemia and bacterial endocarditis with broad spectrum antibiotic at commencement of labour and then six-hourly for 48 hours.

19. PAROXYSMAL DYSPNOEA

Causes and Differential Diagnosis:

- I. **Cardiac conditions**
 1. **Cardiac asthma** – (Table 109)
 2. **Acute myocardial infarction** – Pain, dyspnoea, vomiting and shock. Cardiac signs and ECG changes.
 3. **Acute right ventricular failure** – e.g. due to paroxysmal tachycardia, diphtheria, etc.
 4. **Mitral stenosis** – Dyspnoea due to acute pulmonary congestion may follow severe exertion or excitement, infection or onset of atrial fibrillation. Diastolic murmur at apex.
 5. **Aortic regurgitation** – Paroxysmal nocturnal dyspnoea often initial complaint. Cardiac and peripheral signs of aortic regurgitation.
 6. **Cardiac tamponade** – Due to rapidly accumulating pericardial effusion or haemopericardium. Beck's triad of (a) falling arterial pressure, (b) rising venous pressure, (c) small quiet heart.

Table 108: Antihypertensive drugs in pregnancy	
Drug	Comments
(a) <i>Chronic hypertension</i>	
• Methyldopa	Preferred for safety
• Beta-blockers	Reports of intrauterine growth retardation (atenolol)
• Labetalol	Increasingly preferred to methyldopa because of reduced side-effects
• Diuretics	Not first-line agents Probably safe
• ACEIs, ARBs	Contraindicated
	Reported foetal toxicity and death
• CCBs	May delay labour
(b) <i>Acute severe hypertension in preeclampsia</i>	
• Hydralazine	5 mg IV bolus, then 10 mg every 10-20 mins to maximum of 25 mg, repeat in several hrs. as necessary
• Labetalol (second line)	20 mg IV bolus, 40 mg 10 mins later, 80 mg every 20 mins.
• Sodium nitroprusside (rarely when others fail)	0.25 µg/kg/min to maximum of 5 µg/kg/min Foetal cyanide poisoning may occur if used for more than 4 hours.

II. Lung conditions

1. **Bronchial asthma** - (Refer)
2. **Acute bronchitis** - Episodes of acute bronchitis with cough, sputum and breathlessness together with rhonchi, basal crackles and expiratory wheeze may occur in older patients. The differentiation from attacks of left heart failure resulting from ischaemic heart disease is often difficult as both may co-exist.
3. **Spontaneous pneumothorax**- Severe pain in chest, shock. Hyper-resonant note and shift of mediastinum.
4. **Acute pulmonary oedema** - Due to cause other than left ventricular failure. (Refer)
5. **Pulmonary embolism** - Dyspnoea, precordial pain or haemoptysis. Local chest wall tenderness in presence of pulmonary infarction. Pleural friction rub. Central cyanosis. Left parasternal heave. D-dimer test, spiral CT pulmonary angiography, perfusion scanning of lungs.

Table 109: Differences between cardiac and bronchial asthma			
		Cardiac asthma	Bronchial asthma
1.	<i>Past history</i>	Of hypertension, aortic disease or IHD	Of previous attacks of asthma, or other allergic conditions
2.	<i>Age</i>	Onset usually after 40	Any age
3.	<i>Precipitating factor</i>	May be precipitated by exertion or acute myocardial infarction or hypertension	Trigger factors may be infection, non-specific irritants, external allergens, exercise or emotional factors
4.	<i>Symptoms</i>		
	(a) Cough	Cough and dyspnoea almost simultaneous.	Starts with dyspnoea.
		Pink frothy sputum which increases in intensity towards end of attack.	Expectoration of thick sticky sputum
	(b) Wheezing	Rare	Usual
	(c) Sweating	Prominent	Rare unless acute severe asthma
5.	<i>Signs</i>		
	(a) Inspection:		
	(i) Accessory ms. of respiration	Not active	Active
	(ii) Shape of chest	Normal	Emphysematous
	(iii) Respirations	Rapid and shallow	Rapid with prolonged expiration
	(b) Auscultation:		
	(i) Chest	Expiration not unduly prolonged	Expiration markedly prolonged
		Crackles more than rhonchi in early stages at lung bases, gradually ascending up with progress of the attack	Rhonchi more than crackles Signs diffuse all over the lungs
	(ii) Heart	A ₂ may be loud	Normal A ₂
		Left ventricular gallop	RV gallop late feature of severe bronchial asthma

Contd...

Contd...

	Cardiac asthma	Bronchial asthma
(c) Pulse	Full and bounding, or pulsus alternans	Feeble and rapid
(d) BP	Usually elevated	Normal or low
(e) Extremities	Cold	Warm (with CO ₂ retention)
(f) Signs of underlying disease	AR, AS, hypertension, or IHD	No evidence of cardiovascular disease
6. Investigations:		
Beta-natriuretic peptide	Raised	Normal
ECG	LV preponderance, acute MI or LBBB	Normal or RV preponderance Normal or hyperinflated lungs
CXR	Hilae become hazy, 'bat's wing' shadowing if pulmonary oedema	Focal or segmental atelectasis due to mucus plugs

III. Laryngeal conditions

Acute laryngeal obstruction due to - (1) Whooping cough. (2) Foreign body in larynx. (3) Retropharyngeal abscess. (4) Laryngismus stridulus. (5) Other causes of acute inspiratory dyspnoea with stridor.

IV. **"Renal asthma"** - History of kidney disease. Tiredness, weakness and dyspnoea due to uraemia and cardiac failure. Symptoms preceded by weeks or months of progressive lethargy, loss of libido and oligomenorrhoea or amenorrhoea. Oedema of feet common. Blood urea and creatinine increased.

V. Mediastinal conditions

1. *Syphilitic aortitis and aneurysm* - Paroxysmal dyspnoea especially at night common (syphilitic asthma). Paramanubrial dullness. 2nd aortic sound loud. Dilatation of aorta on X-ray.
2. *Mediastinal tumours* - Mediastinal syndrome of dyspnoea, inspiratory stridor and paroxysmal cough. Hoarseness and dysphagia with often signs of pressure on arteries, veins and nerves. Usually patient prefers to lean forward. X-ray - shadow of growth.
3. *Acute mediastinitis* - May be acute onset. Symptoms of inflammation - fever, toxemia and

leucocytosis. Pressure symptoms - dyspnoea and paroxysmal or brassy cough and cyanosis. Tenderness over sternum, cervical or dorsal spine. Dilated veins. X-ray - accentuation and broadening of superior mediastinal shadows.

VI. Miscellaneous

1. *Hysterical overventilation* - Usually young female, in presence of audience. Absence of signs of organic disease.
2. *Laryngeal crisis of tabes* - Noisy breathing, cough and acute dyspnoea. Absent knee jerks, pupillary changes, ataxia.

VII. **Acute beriberi** - Rapid onset of oedema, palpitation and dyspnoea. Dilatation of heart, gallop rhythm. Scanty urine. Usually tender calves, and absent deep reflexes. ECG - Low amplitude of QRS complexes, tachycardia and prolongation of QT interval.

VIII. **Thyroid crisis** - Signs of thyrotoxicosis. Marked tachycardia or atrial fibrillation, waterhammer pulse and visible pulsations of vessels of neck.

IX. **Thymic asthma** - Usually in infants. Dyspnoea less when child held in arms and held up or forwards and worse when made to lie down. X-ray: May show enlarged thymus.

X. **Polyarteritis nodosa** - Transient lung infiltrations and hilar adenopathy with or without eosinophilia. Presenting symptom may be asthma. Other widespread manifestations - abdominal, renal, cardiac and neurological. Fever common.

20. DISEASES OF VESSELS

DISEASES OF AORTA AND ITS BRANCHES

1. Abdominal aneurysms are commonest aortic aneurysms and usually due to atheroma.

Symptoms - Stages

1. Symptomless enlargement.
2. Onset of symptoms due to stretching - Pain across lower abdomen and lower back. Palpable aneurysm is tender.
3. Leaking aneurysm - Sudden severe pain in abdomen, flank and back, with collapse, followed by partial recovery for few hours and then further episodes leading to death within a few days.
4. Ruptured aneurysm - Sudden catastrophe without warning, or after episodes of leakage.

Fig.127: Chest radiograph showing: Atherosclerotic aortic aneurysm. There is localized prominence of the upper half of the descending aorta caused by widening of the aorta

Fig. 128: MRI showing thoracoabdominal aneurysm with thrombus (arrow)

Fig. 129: MRI showing aortic aneurysm with thrombus (arrow)

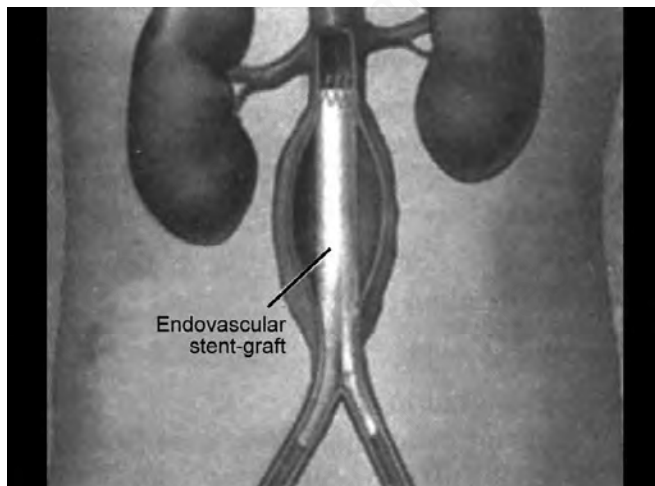

Fig. 130: Endovascular stent-graft

Investigations

1. *Chest Radiograph* (Fig. 127)
2. *Plain radiograph of abdomen* – in lateral position often shows calcification in the wall of the aorta or in the thrombus included in the sac.
3. *Aortography and/or DSA* – to determine size and extent of aneurysm.
4. *CT scanning* – useful not only for confirming diagnosis but also for determining the changes in size of aneurysm during follow-up periods.
5. *MRI* – can show full extent of aortic disease (Fig. 128).

2. **Thoracic aneurysms** involving ascending aorta, aortic arch and descending aorta are mostly due to atherosclerosis and now rarely due to syphilis. For clinical features, refer cardiovascular syphilis (Fig. 129).
Management – Surgery is indicated for abdominal aortic aneurysms greater than 5.5 cm in diameter because of risk of rupture with Dacron tube or endovascular stenting considered (Fig. 130) and if stent – graft option limited and high surgical morbidity, elective surgery if aortic diameter exceeds 6 cm.

In case of ascending aortic aneurysm, surgical replacement of aorta performed when ascending aortic

Fig. 131: MR angio showing narrowing of aorta due to aortoarteritis

diameter exceeds 5.5 cm and in setting of Marfan syndrome, bicuspid aortic valve, when it reaches 5 cm.

3. **Aortoarteritis** including both carotid arteries causes repeated syncope in young female (Fig. 131). This can be treated by replacing entire carotid arteries till the base of the skull with Dacron tube under hypothermia at 18° and circulatory arrest.
4. **Aortic dissection** – Usually in males over 50.

Classification (Stanford)

- Type A involving ascending aorta regardless of site of origin
- Type B involving descending aorta distal to the origin of left subclavian artery

Conditions associated with aortic dissection are listed in Table 110.

Clinical features – (a) Pain – Sudden onset of severe tearing pain in chest, often radiating through to the back, abdomen and thighs. Spread into the upper limbs, hand and neck may also occur if the lumen of the carotid and subclavian arteries is involved, and coronary insufficiency or infarction may occur due to dissection extending into either coronary artery. (b) Shock and prostration may be severe. (c) Absence or diminution of peripheral pulses – Weak, unequal or absent pulsations in carotid, radial and femoral arteries. (d) Hypertension in majority. (e) Death may occur from rupture into the pericardium.

Investigations

Chest radiograph – shows widening of mediastinum. If there is calcium in the aortic arch, its wide separation from the outer margin of aortic shadow is diagnostic.

Table 110: Conditions associated with aortic dissection

• Hypertension (in majority)
• Cystic medial degeneration
• Marfan's syndrome
• Ehlers-Danlos syndrome
• Previous surgery: Coronary bypass, replacement of aortic valve
• Pregnancy (usually third trimester)

ECG – LV hypertrophy but usually no ischaemic changes.

Echocardiography – may demonstrate a proximal ascending dissection, but transoesophageal echo can adequately demonstrate descending thoracic aorta. Transoesophageal colour Doppler can show the flow patterns to make the intimal tear more obvious.

MRI – demonstrates intraluminal thrombus and dissection flaps without the need for contrast medium and assesses severity of coexisting AR, periaortic hematoma and pericardial effusions.

Aortography or DSA – confirms diagnosis and outlines site of intimal tear.

CT scanning – with contrast enhancement. 1st choice of investigation.

Complications

Aortic regurgitation (developing for first time), obstruction of airways or oesophagus due to progressive obstruction of aorta.

Rupture of aorta resulting in pericardial or pleural effusion and occasionally intrabronchial hemorrhage which may result in death.

Management – (1) Admission to ICU. (2) Lowering of systolic pressure to around 100 mm Hg with sodium nitroprusside 50 mg in 250 mL of 5% dextrose (dose ranges from 0.5 to 6.0 mcg/kg/minute) or Propranolol 0.5–1 mg IV till adequate beta-blockade; can be repeated q6h, or methyldopa 250 mg IV or p.o. q6h may be combined with above drugs to maintain stable systolic BP (3) Measurement of arterial and venous pressures, and urinary output. (4) Surgery – Indications: (i) Urgent surgical consultation for all patients with thoracic aortic aneurysm and in life-threatening complication such as rupture in ascending aorta dissection. (ii) Presence of AR. (iii) Large haemorrhagic pleural effusion. (iv) Cardiac tamponade. (v) Hypertension not responding to drug therapy. (5) Medical therapy to be continued in type B dissection (tear distal to origin of left subclavian artery).

5. **Aortic arch syndrome** (middle aortic syndrome, pulseless disease, reversed coarctation, Takayasu's syndrome) is a panarteritis of aorta and its main branches and of pulmonary arteries.

Etiology- (a) Age - 20-30. (b) Sex - Mostly females. (c) Cause unknown, probably tuberculous.

Clinical Features

1. **Cardiovascular** - Diminished or absent pulsations in vessels of neck, head and arms. Syncopal attacks. Tachycardia and ectopic beats. Exertional dyspnoea, cardiomegaly and signs of cardiac failure secondary to underlying IHD. Harsh systolic murmurs over stenosed segments of a vessel and soft flow murmurs over various anastomotic channels. Hypertension, AR and aortic aneurysm.
2. **Cerebrovascular** - Focal transient symptoms in the carotid or vertebral artery territory or persistent focal neurologic deficit.
3. **Trophic changes** - Loss of teeth and hair, ulceration of nose or lips, perforation of nasal septum or palate, cataracts or facial atrophy.
4. **Symptoms of intermittent claudication** - Easy fatigability, coldness, paraesthesia, cramp-like pains if collateral circulation is inadequate.

Investigations

Angiography and/or DSA - Narrowing or occlusion of involved vessels.

ESR and leucocyte count elevated.

Differential diagnosis (Table 111)

Treatment- (i) Antituberculous drugs. (ii) Anticoagulants to prevent clotting. (iii) Surgical management depending on site of lesion - thrombo-endarterectomy, excision with graft replacement, or by-pass graft.

Table 111: Differentiating features between middle aortic syndrome and congenital coarctation

	Middle aortic syndrome	Congenital coarctation
Sex	Females predominate	Males predominate
Claudication	Marked	Uncommon
Bruit	Usually abdominal	Usually thoracic
Associated tuberculous lesion	Often	Rare
Rib notching	Rare	Usual
Aortography	Usually elongated narrow segment	Usually short narrow segment
Left subclavian involvement	Common	Very rare

6. **Subclavian steal syndrome** (Brachio-basilar insufficiency).

Mechanism - The syndrome is due to obstruction to innominate artery or subclavian below the origin of the vertebral artery. The affected arm can only receive blood supply by reverse flow down the vertebral artery into the subclavian above the obstruction. The vertebral artery draws its blood supply from the opposite vertebral artery via their junction at the base of the basilar artery. This causes an interference with the flow of blood into the brainstem, and this is exaggerated by movements of the affected arm.

Symptoms and Signs - (a) Episodes of transient vertebrobasilar ischaemia triggered off by movements of the involved arm. (b) Diminished or absent pulse in the arm, and ischaemic and trophic changes may occur. (c) A murmur may be audible at the root of the neck.

Investigation - Arch arteriography may show occlusion of one or both subclavian arteries with retrograde flow in one or more vertebral arteries to the distal part of the subclavian artery.

Management - Endarterectomy and arterioplasty of innominate or subclavian arteries (Subclavian to common carotid bypass). Percutaneous vascularization with stents (balloon expandable stents) can be used.

7. **Marfan's syndrome** - A hereditary disorder of connective tissue (abiotrophy) which affects both sexes and may be familial.

Clinical Features

(a) **Skeletal stigmata** - Slender body build, abnormal height with disproportionately long bones especially fingers (arachnodactyly), high arched palate; lax, loose ligaments with hypotonic muscles; spinal deformities, and thoracic cage deformities such as depressed sternum and pectus excavatum. (b) **Cardiovascular involvement** - Dilatation of aorta, dissecting aneurysm, aortic incompetence. (c) **Ocular abnormalities** - Dislocation of lens or myopia. (d) **Pulmonary disease** - Spontaneous pneumothorax, congenital cystic lung, congenital atelectasis.

Management - ARB - Losartan should be considered in patients with aortic root disease, stabilizes root size.

Peripheral Vascular Disease

PERIPHERAL ARTERIAL DISEASE (PAD)

PAD is a clinical term that denotes an occlusive disease arising from narrowing of the arteries distal to the arch of the aorta. Causes of peripheral arterial disease are enumerated in Table 112.

Atherosclerosis Obliterans

Risk factors – Main factors leading to progressive narrowing of the major arteries of the legs are smoking, hypertension, diabetes mellitus and hyperlipidaemia.

Symptoms

1. **Intermittent claudication** – Severe cramping pains or discomfort on walking which disappears after short rest and recurs when the walk is resumed. The symptom is due to inability of narrow arteries to provide additional blood supply necessary for the exercising muscles. The position of pain of claudication depends on the level of arterial lesion – (a) *Calf claudication* – usually due to obstruction in femoro-popliteal segment. (b) *Thigh claudication* – usually due to iliac occlusion with associated buttock claudications. (c) *Claudication of buttocks, thighs and calves* with impotency in males – Aortic bifurcation lesion.
2. **Rest pain**– is less common and suggests more advanced disease. (a) *Pain due to acute arterial occlusion* – Severe pain in tissues distal to the site of obstruction aggravated by limb movement. (b) *Pain due to*

ischaemic neuropathy – Severe burning or lancinating type of pain occurring usually in paroxysms and worse at night. (c) *Pain of pregangrene* – Burning, throbbing type of pain which may make the patient sit up in bed and hold his legs. Pain aggravated by heat.

3. **Other symptoms**– Numbness and tingling and feeling of coldness in the involved extremity. The occurrence of sepsis in minor abrasions of the feet may be the first evidence of incipient ischaemia in the limb.

Examination

- (a) **Inspection** – of feet. In presence of rest pain, feet and toes will be cold with purple or bluish discoloration. In more advanced cases (pregangrene) atrophic skin, poor colour and sluggish capillary circulation.
- (b) **Palpation** – (i) Absence of pulses below the femoral pulse (femoral artery is most commonly involved) in affected leg. If buttock or thigh claudication is present, the femoral pulse will be weak or absent indicating aortoiliac disease. At times pulsations are present at rest and disappear on exertion. (ii) Abdomen – to exclude aneurysm of abdominal aorta. (iii) Distal to obstruction limbs are cold to touch.
- (c) **Auscultation** – of abdominal aorta, iliac arteries and femoral arteries down to the popliteal fossa may reveal stenosis by presence of a bruit.

Differential Diagnosis: See Table 113 for the differential diagnosis of intermittent claudication.

Investigations

1. **Ankle brachial pressure index** – Under normal conditions, systolic BP in the legs is slightly greater than that in the upper limb. The ankle brachial pressure index calculated from the ratio of ankle to brachial systolic pressure, is a sensitive index of arterial insufficiency. The highest pressure measured in any ankle artery is used as the numerator of the index, a value > 1.0 is normal, and a value < 0.9 is abnormal.

Measurement with Doppler probe

Table 112: Causes of peripheral arterial disease

• Due to arterial obstruction
– <i>Degenerative disease of arteries</i> – Peripheral arteriosclerosis including arterial thrombosis (senile, diabetic) and embolism.
– <i>Inflammatory diseases of arteries</i> – (i) Thromboangiitis obliterans. (ii) Infections – IE, tuberculosis, syphilis, typhoid fever. (iii) Arteritis – Polyarteritis nodosa, giant cell arteritis, Takayasu's disease, rheumatoid disease.
• Vasomotor
– Vasoconstriction – Raynaud's disease, acrocyanosis, ergotism.
– Vasodilation – Erythromelalgia.
• Due to physical and chemical agents
– <i>Trauma</i> – Contusion, aneurysm, arteriovenous fistulae.
– <i>Cold</i> – Chilblain, frost bite, trench foot and immersion foot.
– <i>Chemical</i> – Phenol, ergot, thiopentone, lead.
• Due to arteriovenous communications.

Table 113: Differential diagnosis of intermittent claudication

	<i>Arterial claudication</i>	<i>Neurological claudication</i>	<i>Venous claudication</i>	<i>Rheological claudication</i>
Site of pain	Calf usually	Along a dermatome	Calf always	Usually whole leg
Pain relief	Standing still	Lying down for 1/2 hour.	Leg elevation	Standing still
Signs	Absent distal pulses	Abnormal neurological signs after exercise	Signs of chronic venous insufficiency	Bounding pulses
Confirmatory tests	Ankle: brachial systolic ratio <0.8	MRI	Doppler of legs for DVT	Full blood count and ESR

A handheld pencil Doppler probe is placed over a patent pedal artery and the foot raised against a pole calibrated in mm Hg. The point at which the pedal signal disappears is taken as the ankle pressure.

2. *Exercise test* – is performed by exercising the patient for 5 minutes say on a tread mill. The ankle brachial pressure index is measured before and after exercise. A pressure drop (due to peripheral vasodilation) of 25% or more indicates significant arterial disease.
3. *ECG* – for evidence of ischaemia.
4. *Angiography* – to define extent of disease and possibility of bypass surgery or endarterectomy.
5. *Specialist diagnostic and therapeutic devices*: (a) Pressure wires with built-in pressure sensor at tip to measure transluminal peripheral (and renal artery) gradients to determine hemodynamic importance. (b) Intravascular ultrasound for lesion assessment and for optimization after angioplasty or stenting. (c) Specific atherectomy devices to debulk, slice and remove plaque through long segments of heavily calcified lesions. (d) Excimer laser technology for endovascular ablation for total occlusions.

Management

Of chronic peripheral ischaemic disease.

A. **Medical treatment** – Indications: (a) If intermittent claudication is the only symptom and it does not interfere with the patient's employment. (b) Diabetes mellitus is not associated. (c) Presence of extensive disease contraindicates surgical interference. (d) Failure of surgery to relieve symptoms.

1. Measures to Prevent Progress of the Disease

- Rest if presence of rest pain, wound or gangrene.
 - No smoking.
 - Reduction of obesity.
 - Care of feet – Skin should be protected from trauma, shoes should be comfortable. Avoid tight garters. Trim nails carefully. Avoid sitting with legs crossed. No operative removal of corns. If skin is dry, apply oil at night and dusting powder during day. Control of fungus infection.
- (a) Antiplatelet therapy – Aspirin 75–300 mg/day, if aspirin sensitivity, dipyridamole (200 mg bd) or clopidogrel (75 mg/day) or prasugrel (10 mg/day) or Ticagrelor 90 mg bd.
 - (b) Cilostazol 100 mg bd one hr. before or two hrs. after breakfast and dinner if exercise alone is ineffective. It should not be used in patients of congestive cardiac failure.

(c) Pentoxifylline, xanthine oxidase inhibitor, decreases blood viscosity and anti-proliferative action.

(d) Control of lipaemia in atherosclerosis.

(e) Adequate control of diabetes.

(f) Control of thrombosing tendencies with long-term anticoagulants.

2. Measures to Increase Circulation

(a) *Walking* – The patient should be instructed to walk slowly upto the point of claudication several times a day.

(b) *Warm environment* – Hot bag to abdomen may cause vasodilation in lower limbs. Blood flow can often be stimulated by placing a thermostatically controlled heating unit over the lower extremities; the temperature within the box should not exceed 90°F. The source of heat is usually in the form of electric light bulbs. Heat must never be applied directly to ischaemic extremities.

(c) *Active vascular exercise* – Buerger's exercise – Legs are elevated to 60° and kept in that position for 2–3 minutes until blanching occurs. Then dangle legs for 5 minutes till maximal flushing is seen. Then keep legs in horizontal position for 5 minutes. Contraindicated if infection or open wound.

(d) *Passive vascular exercise* – (i) "Suction pressure treatment" – Alternate high and low pressure is produced in a hermetically sealed boot (Pavex boot). (ii) Saunder's oscillating bed for extremely old and debilitated patients in place of postural exercise. (iii) Intermittent venous occlusion – With a sphygmomanometer, the pressure is raised to about 60 mm Hg. For 2 minutes and released for 4 minutes, the process being repeated for half an hour.

(e) *Other measures* – to alter flow properties of blood such as haemodilution, defibrination, plasma exchange and haemorheological drugs.

B. **Interventional treatment**

(Revascularization) (See Table 114)

Procedures – (a) Percutaneous re-opening procedures – (i) Percutaneous transluminal angioplasty – is widely used for critical stenosis or occlusion. (ii) Local fibrinolytic therapy – as alternative or additional procedure to PTA, particularly if suggestion of recent thrombosis and it can be combined with thrombectomy. Streptokinase 6000 units/hr directly into the occlusion, with repeat arteriography after 6–12 hours. If significant improvement, treatment may be continued for 12–24 hours, with repeat arteriograms every 12 hours.

Table 114: Indications for revascularization

For	Against
Severe symptoms	Short history
Interference with everyday life	Continued smoking
Not better after exercise training	Severe angina or COPD
Stenosis or short occlusion	Long occlusion
Proximal disease	Distal disease
Unilateral disease	Multivessel disease

C. **Reconstructive arterial surgery** (limb salvage):

- Indications - (a) Presence of severe claudication interfering with everyday work. (b) Critical leg ischaemia with rest pain or impaired skin and tissue viability and non-healing ulcers.
- Procedure - Bypassing of occluded segment - Reconstructions above groin (aorto-iliac segment) give better results than those below the groin (femoro-popliteal segment). More distal bypasses to calf arteries only as alternative to major amputation.

Clues to renal artery stenosis

See Table 115.

Vasculopathy of specific aetiology - Non-atherosclerotic (VSE-NA) in young patient. PAD may be the first presentation of connective tissue disease (CTD) or thrombophilic state, younger age of onset, fever, wt. loss, multiple limb involvement, anaemia, high ESR, proteinuria and RBCs in urine all point to CTD, upper limb involvement being more common.

THROMBOANGIITIS OBLITERANS (BUERGER'S DISEASE)

Inflammatory occlusive disorder involving small and medium-sized arteries and veins in distal upper and lower extremities, usually in males in age group 25–40. Heavy cigarette smoking is a predisposing factor. Increased incidence of HLAB^s and A-9 antigens.

Clinical Features

1. **Migratory superficial thrombophlebitis** - Red painful areas on dorsum of foot particularly in region of ankle or lower leg and occasionally lower arm; often a vein 2 to 4 inches in length is involved. Slight malaise and little rise of temperature may be present. Lasts for 10 to 12 days and is followed by a brownish pigmentation.

Table 115: Clues to renal artery stenosis

• Known atherosclerosis
• Onset of hypertension before age of 30 or after age of 55 years
• Worsening of previously controlled hypertension
• Malignant or resistant hypertension
• Abdominal bruit
• Discrepancy of renal size
• Azotaemia not otherwise explained or worsened by ACEs or angiotensin II receptor blocker
• Recurrent congestive failure or flash pulmonary oedema in a hypertensive patient, particularly with preserved LV function.

2. **Pain** - One of the earliest symptoms, varies in intensity from mild to excruciating pain and often appears for the first time after exposure to cold. (a) Intermittent claudication occurs in almost all patients and is confined not only to calves but also occurs in feet. It is cramp-like and often occurs after progressively shorter intervals and lasts longer after cessation of activity. (b) Rest pain may be due to impending trophic disturbances. (c) Involvement of nerves causes sharp, shooting, lancinating pains in the whole extremity. Occasionally pain is relieved by keeping the leg down. Patient sits on edge of bed holding the involved foot, which is crossed over the healthy leg, in his hand.
3. **Raynaud's phenomenon** (RP) - Raynaud's phenomenon refers to reversible spasm of peripheral arterioles in response to cold or stress. RP is usually seen in distal digits but may involve nose, ears and tongue. It is characterised by triphasic response:
 - Phase 1: Pallor due to vasoconstriction of precapillary muscular arterioles.
 - Phase 2: Cyanosis due to venous pooling and deoxygenation of venous blood.
 - Phase 3: Erythema because of hyperaemia. It is associated with throbbing.

Raynaud's phenomenon should be distinguished from Raynaud's disease which is occurrence of vasospasm primarily with no association with another illness (Primary Raynaud's). RP is secondary to other conditions, most commonly an autoimmune disease (Secondary Raynaud's) (Table 116).

Clinical Stages

1. **Premonitory stage** - Often unnoticed by the patient. Characterised by attacks of recurrent phlebitis, swelling of feet, loss of hair on the legs and formation of tender nodules in skin. The stage may last from 2 to 7 years.

Table 116: Differences between primary and secondary Raynaud's phenomenon

Primary RP	Secondary RP
• Exaggerated physiological response to cold or stress	• Secondary to underlying serious disease
• Symmetrical attacks	• Asymmetric intense painful attacks
• No tissue necrosis, ulceration or gangrene	• Ulcers and digital pitting present
• Median age of onset 14 yrs	• Age at onset >30 yrs
• No Cl. Fs. of CTD	• CTD, myalgia, fever, rash, wt loss, etc.
• ESR normal, CRP negative	• ESR raised, CRP positive
• Increased frequency of migraine and Prinzmetal angina may be present	• May not be present

2. *Stage of claudication* – Severe, cramping pains on walking which disappear after short rest and recur when the walk is resumed.
3. *Stage of rest pain* – Pain comes in paroxysms even at rest, is increased by elevation and relieved temporarily by lowering of the extremity.
4. *Stage of trophic changes and gangrene* – Pain constant and excruciating, vesicles on great toe followed by ulcers or fissures. Gangrene dry or moist spreading upwards.

Investigations

Arteriography – Smooth, tapering distal segmental vessels and fine network of collateral vessels.

Excision biopsy – of involved vessels confirms diagnosis.

Management

No specific treatment. Abstinence from tobacco. Arterial by-pass of larger vessels in selected cases and also debridement depending on symptoms and severity of ischaemia. Amputation if other measures fail.

RAYNAUD'S SYNDROME AND PHENOMENON

It is characterised by sequential development of white, numb 'dead fingers' (digital ischaemia), cyanosis, rubor of fingers (and toes) on exposure to cold, and subsequent flushing phase due to rewarming.

Classification: of Raynaud's phenomenon

Primary or Idiopathic (Raynaud's Disease)

No underlying cause. Occurs usually in females between 15 to 20 years of age. Family history common. Never progresses to ulceration (Table 117).

Table 117: Causes of Raynaud's phenomenon

Primary or idiopathic (Raynaud's disease)
<i>Secondary</i>
• <i>Collagen vascular disease</i> – Scleroderma (usually benign form of CRST syndrome i.e. calcinosis, Raynaud's phenomenon, sclerodactyly and telangiectasis), SLE, RA, dermatomyositis, polymyositis.
• <i>Arterial occlusive disease.</i>
• <i>Neurological disorders</i> – Spinal cord tumors, syringomyelia, disc lesion, polio, carpal tunnel syndrome.
• <i>Exposure to cold</i>
• <i>Blood dyscrasia</i> – Cryoglobulinaemia, cold agglutinins, myeloproliferative disorders.
• <i>Trauma</i> – Prolonged use of vibrating tools, electric shock, cold injury, piano playing, typing.
• <i>Drugs</i> – β -blockers, ergot, methysergide, bleomycin, vinblastine.

Management

- (1) *Warm clothing* and avoidance of exposure to cold
- (2) *Drugs* – (a) Adrenergic blocking agents. (b) Reserpine 0.25 mg to 0.5 mg orally od, or intra-arterial infusion of 0.5 mg into brachial or radial artery reduces pain and promotes ulcer healing. (c) Calcium antagonists Nifedipine or Diltiazem. (d) Prazosin.
- (3) *Surgical sympathectomy* – if failure to respond to drugs, but effect transient.

Persistent digital ischaemia – Ischaemia of a digit or digits may last for days or weeks. Patients are usually middle age or elderly, often hypertensive. The cause is not obvious but may be due to occlusion of the digital artery by atheroma. At times polycythaemia vera or dysproteinaemia is the cause, or, in young subjects, a cervical rib may be responsible. *Treatment* – Spontaneous recovery is usual but for severe ischaemia reflex heating, analgesics and dextran infusion, and antibiotics for infection. Amputation along line of demarcation if gangrene occurs.

Cold injury – Freezing of tissues in hands and feet leading to frost bite can occur following prolonged exposure to cold. There is usually redness, blistering, infection and superficial gangrene of the digits of hands and feet. *Treatment* – Reflex heating, antibiotics and analgesics and dextran infusion. Deep tissues are usually preserved and skin gangrene separates out leaving a shrunken digit beneath.

Acrocyanosis – Reddish or bluish discolouration of hands and feet on exposure to cold occurring mostly in young women. It is thought to be due to arteriolar spasm with dilatation of venules in the skin. It may coexist with Raynaud's phenomenon. When the hand or foot is warm,

the skin becomes bright pink. Acrocyanosis may also be seen in elderly patients with cardiac disease and in neurological disorders such as stroke, poliomyelitis and multiple sclerosis. Treatment - Limbs must be kept warm. Sympathectomy may be necessary in patients with severe coldness and chilblains.

Livedo reticularis - occurs usually in young women. There is blotchy mottling and discolouration of feet and legs. It is likely to be due to patchy arteriolar vasospasm in the skin. A secondary form may occur in patients with polyarteritis nodosa or polycythaemia vera. It is as a rule localised to digits or feet and the condition may progress to gangrene.

PERIPHERAL VENOUS DISEASE VENOUS THROMBOSIS

Venous obstruction by thrombosis may be either a primary, simple, non-inflammatory process (*phlebothrombosis*), or a secondary reaction to local or distant inflammatory agents with active inflammation of the wall of the affected vein (*thrombophlebitis*).

Superficial thrombophlebitis particularly in case of migrating thrombophlebitis may involve normal veins without varicosity and is histologically characterised by chronic panphlebitis. This segmental, inflammatory phlebopathy is observed frequently in thrombophlebitis obliterans and, in carcinoma, and rarely in connective tissue disease and Behcet's syndrome.

DEEP VENOUS THROMBOSIS (DVT)

Table 118 lists predisposing factors for DVT.

Clinical Features

1. Pain usually in the calf, sometimes, also in ankle and joint. Feeling of tightness instead of pain.
2. Deep calf tenderness. Pain in calf on forced dorsiflexion of the foot (Homan's sign). Tenderness in femoral triangle.
3. Increased warmth in affected leg.
4. Fullness of superficial veins.
5. Increased local temperature.
6. Local oedema and induration.
7. Thrombosed vein may be palpable.
8. Slight cyanosis or discoloration.
9. Low grade pyrexia.
10. Sphygmomanometry cuff pain test - A BP cuff is tied round the involved part of the extremity and slowly

Table 118: Predisposing factors for DVT

Predisposing factors

• Patient factors

- Elderly
- Prolonged bed rest
- Long air travel, prolonged sitting
- Obesity
- Varicose veins
- Oral contraceptives
- Pregnancy/puerperium
- Venous compression (tumour, aneurysm)

• Medical conditions

- Myocardial infarction
- Congestive heart failure
- Malignancy (pancreas, lung)
- Inflammatory bowel disease
- Nephrotic syndrome
- Behcet's disease
- Homocysteinaemia

• Surgery

- Hip fracture
- Abdominal or pelvic surgery

• Blood disorders

- Polycythaemia vera
- Thrombocythaemia
- Myelofibrosis
- Paroxysmal nocturnal haemoglobinuria

• Deficiency of anticoagulants

- Antithrombin III
- Proteins C and S
- Factor II or V Leiden
- Antiphospholipid antibody

inflated to 200 mm Hg and then deflated. Normally discomfort is experienced during inflation at above 160 mm Hg. In venous inflammatory disease, pain is experienced between 80 and 150 mm Hg.

Compression of the left common iliac vein by right common iliac artery is probably the reason why DVT is more common in the left than in the right leg.

Diagnosis

- *B-mode ultrasound* (compression ultrasound) or color-coded duplex ultrasound allows direct visualization of the thrombosis have an accuracy of 95%.

- *Plethysmography* is an indirect method which detects abnormalities in venous outflow caused by the thrombosis.
- *D-dimer test* - A negative test rules out DVT with high probability.
- *Phlebography* is mandatory before aggressive therapies such as surgical thrombectomy or fibrinolysis.

Management

A. Of established thrombosis

1. General measures - (a) Complete bed rest until the process becomes quiescent. (b) Elevation of the extremities to diminish oedema. No active or passive movement of the limb. (c) Avoidance of coughing, straining at stool and deep breathing. (d) Dehydration should be avoided.
2. Specific drug therapy - (a) *Anticoagulants* - Heparin - 5,000 units initial bolus injection with continuous infusion or subcutaneous, followed by maintenance dose of 30,000-40,000 units/24 hours for 7 days or low molecular weight heparin once daily, combined with oral anticoagulants. Warfarin sodium is commenced at a dose of 10 mg/day after 7 days of IV heparin and then both drugs are administered together for at least 4-5 days. Warfarin should be continued for 3-6 months. Enoxaparin 1 mg/kg twice daily with normal renal function and Fondaparinux, an anti-Xa pentasaccharide, administered as a weight-based once-daily subcutaneous injection can be used instead of heparin and later switched to warfarin. (b) *Newer anticoagulant* - Rivaroxaban, a factor Xa inhibitor, for treatment of acute DVT and acute PE as monotherapy, without need of a parenteral anticoagulation overlap.
3. Surgical treatment - (a) *Thrombectomy* if free-floating thrombus in ileo-femoral segment, or in the rare patient with gangrene caused by venous thrombosis. (b) *Inferior venacaval interruption*-intraluminal (umbrella filter) or extraluminal useful in - (i) Patient with acute venous thromboembolism and absolute contraindication to anticoagulant therapy. (ii) Occasional patient with massive pulmonary embolism who survives, but in whom recurrent embolism may be disastrous. (iii) Very rare patient who suffers recurrent embolism while on adequate anticoagulant therapy.

B. Prevention of thrombosis in high-risk patients

A significant reduction in thromboembolism in the high-risk group can be achieved by treatment aimed at altering the hypercoagulable state or preventing venous stasis:

1. Anticoagulants - low dose heparin 5,000 units subcutaneously 2 hours before operation, then every 8 hours for 7 days is effective in preventing pulmonary embolism. Oral anticoagulants also useful. Low molecular weight heparin 3500U s.c. 2 hr prior to surgery, followed by 2500U o.d. for 7 to 10 days.
2. Dextran - acts by coating venous endothelium and interfering with platelet stickiness and aggregation. Danger of overloading the circulation.
3. Drugs which inhibit platelet aggregation - Dipyridamole, aspirin, clopidogrel, prasugrel, ticagrelor.
4. Early ambulation - Post-operative and post-partum. Exercise of extremities while in bed.
5. Deep breathing exercises in bed.
6. Slight elevation of foot of bed for bed-fast patients.
7. Prevention of increased abdominal pressure by tight binders, etc.
8. Correction of cardiac failure.
9. Maintenance of adequate hydration.
10. Prophylactic femoral ligation - especially if repeated embolism.

III. Obstruction of great veins

1. Superior vena caval syndrome:

Causes - *Extravascular compression* - Bronchogenic carcinoma, mediastinal tumours such as Hodgkin's disease, leukaemias, benign tumours, aortic aneurysm.

Intravascular - Thrombosis, or rarely rupture of aortic aneurysm into SVC.

Symptoms - Fullness and flushing of face. Sometimes dyspnoea or dysphagia, occasionally convulsions.

Signs - Cyanosis and oedema of face, neck and arms. Dilated and tortuous superficial veins on thorax and upper abdomen. Prominent nonpulsating jugular veins. Inspiratory filling of neck veins and positive hepato-jugular reflux if obstruction is at or below entry of azygos vein into superior vena cava.

2. Inferior vena caval syndrome:

Causes

Extraluminal compression - Ascites, abdominal tumours, tuberculous plastic peritonitis.

Intraluminal - Carcinoma of kidney invading IVC, or thrombosis extending from pelvic veins.

Symptoms and signs - Cyanosis and oedema of legs with dilated varicose veins of legs and often abdominal wall. Dilated collateral veins on abdomen and chest with reversal of flow of blood in veins of lower abdominal wall (normally from above downwards). Ulcer due to stasis may develop on the leg in chronic cases.

Haematology

1. LABORATORY DIAGNOSIS IN HAEMATOLOGY

BLOOD EXAMINATION

Complete Blood Count

A haematology analyser will measure directly:

Haemoglobin concentration.

Red cell count.

Mean (Red) cell volume (MCV).

Total white cell count (WBC).

Platelet count.

Other parameters derived by calculation are: Haematocrit (HCT) or packed cell volume (PCV). Mean corpuscular cell haemoglobin (MCH). Mean corpuscular haemoglobin concentration (MCHC). Normal blood counts vary with age and sex (Table 1).

Blood film: If any abnormality in FBC is detected a blood film must be examined.

Red cells: Appearance may suggest type of deficiency anaemia -

1. *Microcytic, hypochromic cells* in iron deficiency anaemia. Associated thrombocytosis if due to blood loss. If patient with microcytic anaemia does not respond to oral iron, possibility of β -thalassaemia minor should be considered and estimation of HBA and HBA₂ levels carried out (Fig. 1).
2. *Macrocytosis* (MCV > 100 fl) suggests vitamin B₁₂ or folic acid deficiency, while if MCV is in range of 100-110fl, it may be due to liver disease, alcohol abuse (without liver disease) or hypothyroidism, myeloma or myelodysplasia (Fig. 2).
3. *Dimorphic picture* (both small and large cells) - (i) Patients with iron deficiency responding to iron therapy. (ii) Mixed deficiency (both iron and folic acid). (iii) Sideroblastic anaemia. (iv) Post-transfusion. (v) Iron loss combined with hyposplenism - Coeliac disease, radical gastrectomy (incorporates splenectomy).

Table 1: Normal haematological values

Parameter		Normal
Haemoglobin (Hb)		13.5-17.5 g/dl
Red cell count	Males	4.6-6.5 x 10 ¹² /litre
	Females	3.8-5.8 x 10 ¹² /litre
Haematocrit (HCT)	Males	0.4-0.54
	Females	0.37-0.49
Mean corpuscular volume (MCV)		78-99 fl
Mean corpuscular haemoglobin (MCH)		27-32 pg
Mean corpuscular haemoglobin concentration (MCHC)		31-35 g/dl
RBC distribution width (A measure of variation in RBC size)		10.5-14.5
RBC mass		30 ± 5 ml/kg
Plasma volume		45 ± 5 ml/kg
Leucocytes		4.0-8.00 x 10 ⁹ /litre
<i>Differential leucocyte count</i>		
Neutrophils (40-75%)		1.5-7.5 x 10 ⁹ /litre
Lymphocytes (20-45%)		1.5-4.0 x 10 ⁹ /litre
Monocytes (2-10%)		0.2-0.8 x 10 ⁹ /litre
Eosinophils (1-6%)		0.04-0.4 x 10 ⁹ /litre
Basophils (< 1%)		< 0.1 x 10 ⁹ /litre
Platelets		150-400 x 10 ⁹ /litre
Serum iron		12-30 µmol/litre
Total iron binding capacity (TIBC)		45-70 µmol/litre
Serum ferritin	Males	24-314 µmol/litre
	Females	15-314 µmol/litre
Serum vitamin B ₁₂		2.5-20 µg/litre
Serum folate		160-640 µg/litre
Red cell folate	Males	25-35 ml/kg
	Females	20-30 ml/kg
Plasma volume		40-50 ml/kg
Red cell half-life		25-33 days
Haemoglobin A ₂		1.5-3.2% total Hb
Haemoglobin F		0.5-0.8% total Hb

Fig. 1: Iron deficiency anemia (peripheral blood). Hypochromia, microcytosis, anisocytosis and target cells are shown

4. *Polychromatic cells* (Young red cells larger than normal, greyish in appearance) suggests increase in proportion of reticulocytes, which may occur in response to bleeding or haemolysis, or during successful treatment of deficiency states.
5. *Red cell abnormalities* - common in haemolytic states - (a) *Sickle-shaped cells* in sickling disorders, the deformation resulting from partial solidification of the abnormal haemoglobin in hypoxic parts of the circulation (Fig. 3). (b) *Fragmented red cells* if damage to small blood vessels (microangiopathic haemolytic anaemia). (c) *Spherocytes* in hereditary spherocytosis (because of abnormal red cell membrane) and in auto-

Fig. 3: Sickle hemoglobin disease (peripheral blood). In homozygous disease (HbSS), sickle cells and target cells are present together with occasional nucleated red cells. Heterozygotes (HbAS) have a normal peripheral blood

Fig. 2: Megaloblastic bone marrow. The majority of cells are megaloblastic erythroblasts showing failure of nuclear development and abnormal nuclear morphology of lymphocyte are visible and platelets are scattered through the film

immune haemolytic anaemia (because small pieces of antibody-coated membrane have been removed by the spleen) (Fig. 4). (d) *Stomatocytes* are red cells which contains slit like area of central pallor and in a wet preparation they show a cup-shaped appearance. They are observed in hereditary spherocytosis, liver disease and Rh null phenotype. (e) *Target cells* - Red cells with central red area surrounded by a pale ring are found in (i) Liver disease. (ii) β -thalassemia minor. (iii) Some cases of iron deficiency (Fig. 5). (f) *Tear drop cells* - seen in myelofibrosis. (g) *Echinocytes* or burr cells - seen in uremia (Fig. 6). (h) *Acanthocytes* - seen in abetalipoproteinemia (Fig. 7).

Fig. 4: Sickle cells—note the sickle shape due to the presence of HbS (arrow)

Fig. 5: Beta thalassaemia—plenty of target cells

Fig. 6: Burr cells—note short spiny margins

Red Cell Indices

Mean corpuscular haemoglobin concentration MCHC denotes average concentration of Hb in red cells. Normal range 31–37 g/dl.

Mean corpuscular volume (MCV) indicates volume of red cells. Normal range 80–98 femto litres. If < 8 fl - 80 fl microcytes. If > 100 fl macrocytes. In certain dimorphic anaemias, MCV may be in normal range because of presence of both microcytes and macrocytes.

Mean corpuscular haemoglobin (MCH) indicates amount of Hb per red cell. Normal range 26–34 pg.

Higher CH in macrocytic anaemias. Lower MCH in microcytic hypochromic anaemias.

Inclusion Bodies in Red Cells

1. **Basophilic stippling:** Punctate basophils are granular inclusions blue black seen in megaloblastic anaemias, thalassaemias, sideroblastic anaemias, lead poisoning, alcoholism and pyrimidine-5-nucleotidase deficiency (Fig. 8).
2. **Pappenheimer bodies** are iron granules (aggregates of ferritin) in red cells due to incomplete Hb synthesis during erythropoiesis. They can be stained with Perl's stain. These red cells with Pappenheimer bodies are designated spherocytes and are seen in sideroblastic, megaloblastic and haemolytic anaemias and post-splenectomy.
3. **Howell-Jolly bodies** are nuclear remnants (aggregates of chromatin material), seen in RBCs, normoblasts. They are seen in megaloblastic anaemias (due to dyserythropoiesis, post splenectomy (due to loss of pitting function of the spleen) and in acute haemolytic anaemias (Fig. 9).

Fig. 7: Acanthocytes—note the thorn like projections

Fig. 8: Basophilic stippling—note the basophilic dots in the RBC, often due to toxic injury (arrow)

Fig. 9: Howell-Jolly body

Fig. 10: Cabot's ring which is remnant of nuclear material (arrow)

4. **Cabot's rings** are circular, oval or figure of eight shaped rings as a result of damage to lipoprotein of trauma of red cells. They are seen in megaloblastic anaemias (Fig. 10).
5. **Heinz bodies** are refractive and made up of denatured globin and are seen in G6PD deficiency, intake or exposure to oxidising drugs or chemicals and in unstable Hb disease.
6. **Haemoglobin H inclusions** are small and widely distributed β -chains in the red cells (golf-ball appearance) in α -thalassemias and in some cases of myelodysplastic syndrome (Fig. 11).
7. **HbC crystals** occur as a result of crystallization of HbC in some cases after splenectomy in homozygous haemoglobin C disease.

Fig. 11: HbH preparation showing golf-ball inclusions

White Cells

Neutrophil leucocytosis is seen during infection (particularly bacterial) and following tissue trauma or necrosis. A particularly marked neutrophilia may be termed a 'leukaemoid reaction' and may be seen in life-threatening infection, some cancers, and occasionally, in normal pregnancy. A marked neutrophilia is also characteristic of CML. *Neutropenia* - Occurs in (i) Infection - Viral, infectious mononucleosis, Tuberculosis, typhoid. (ii) Aplasia - Drug-induced: (a) Predictable (e.g. cytotoxic drugs). (b) Idiopathic. (iii) Marrow replacement - Leukaemia, lymphoma, myeloma, carcinoma. (iv) Megaloblastic anaemia. (v) Immune - SLE, Felty's syndrome.

Immature granulocytes released prematurely from the marrow in response to acute infection (Left-shift).

Leucoerythroblastic picture : Leucocyte precursors and red cell precursors (nucleated red cells) characteristic of bone marrow infiltration. 1. Myelofibrosis. 2. Marrow infiltration - Metastatic cancer (breast, prostate, small-cell lung), malignant lymphoma. 3. Osteopetrosis. 4. Metabolic-Gaucher's disease (usually with metastatic carcinoma).

Blast cells: In acute leukaemia development of leucocytes in marrow is arrested at immature stage, and in some cases this does not occur and blood picture is of neutropenia or pancytopenia (aleukaemic leukaemia).

Lymphocytosis: Often with many large reactive cells in viral infections, including infectious mononucleosis. In older patient it may suggest chronic lymphocytic leukaemia.

Platelets (Refer thrombocytopenia).

Other Blood Tests

Reticulocyte count: Reticulocytes are young (1-2 days old) red cells which still contain some residual nucleic acid material (demonstrated by a stain such as methylene blue) (Fig. 12). The count is typically raised in haemolytic states. Patients with chronic haemolysis are sensitive to events such as infection which may impair marrow compensation and the reticulocyte count may be used to anticipate a sudden fall in haemoglobin and need for transfusion.

Iron Status

Serum iron and total iron binding capacity (TIBC) are useful in diagnosis of microcytic and refractory anaemias - (a) In simple iron deficiency, serum iron low and TIBC raised. (b) Anaemia of chronic disease both iron and TIBC are depressed. In order to exclude coexisting iron deficiency, ferritin assay and marrow iron estimation may be necessary. (c) Raised serum iron and reduced TIBC - in conditions associated with increased iron accumulation, e.g. thalassemia, sideroblastic and dyshaemopoietic anaemias, haemochromatosis, transfusion siderosis (where the transferrin iron binding sites are fully saturated).

Serum ferritin is a more accurate guide to iron status. It is low in iron deficiency. Raised in iron overload.

Serum vitamin B₁₂ and folate assay should be done in patients with macrocytic anaemia, particularly if megaloblastic. Serum folate level can be increased by a recent meal.

Fig. 12: Reticulocyte preparation of a patient with hemolytic anemia

Investigation of Haemolysis

Direct Coomb's test (antiglobulin test): Here an antibody directed against human immunoglobulin is used to detect the presence of antibody on the surface of the red cells by agglutination. The test is positive in nearly all cases of autoimmune haemolytic anaemia.

Indirect Coomb's test: Antibody in serum reacts with added 'O' cell suspension. On addition of antiglobulin, agglutination suggests positivity.

Gel card direct and indirect Coomb's test: Gel cards with incorporated anti-IgC + C and also anti-IG and anti-Ig can be separately used. Based on the same principle, it is a more sensitive method.

Haemoglobin electrophoresis: The haemoglobinopathies are the result of genetically determined amino acid substitutions within the haemoglobin molecule. Some of these mutations alter the net electrical charge of the molecule, so that the abnormal haemoglobin can be detected by electrophoresis - Sick cell haemoglobin HbS as well as HbC, HbD and HbE. Carriers of β -thalassaemia can be detected by elevated HbA₂ and this can detect mothers heterozygous for sickle-cell anaemia or β -thalassaemia. This is particularly important for offering prenatal diagnosis.

Tests of Haemostasis

Coagulation tests - are performed on a blood sample anticoagulated with sodium citrate.

- Prothrombin time** - tests the extrinsic clotting pathway and is used to monitor oral anticoagulant therapy. Result is expressed as ratio compared with normal plasma.
- Partial thromboplastin (Cephalin-kaolin) time** - tests the intrinsic pathway. It is prolonged in haemophilia, patients on oral anticoagulants, heparin and in DIC.
- Thrombin time and fibrinogen titre** - assess conversion of fibrinogen to fibrin by thrombin. Thrombin time is commonly used to monitor heparin therapy and fibrinogen time to assess severity of DIC.
- Factor assays** - of individual clotting factors using adaptations of the above tests with known factor-deficient plasmas. Used for special investigation of bleeding disorders.

Normal Haematological Values

See Table 1 for normal haematological values.

Radioisotope studies – may be helpful in further investigation of haematological disease.

The following do not require imaging:

Red cell mass and plasma volume: Estimation of total volume of circulating red cells (red cell mass) is necessary for proper evaluation of polycythaemia. It is performed by labelling patient's own red cells with a suitable isotope ^{51}Cr or $^{99\text{m}}\text{Tc}$, reinjecting a measured amount, and taking a blood sample after a suitable period of equilibration to enable the dilution to be calculated. In most cases plasma volume can be derived from red cell mass and peripheral blood haematocrit (except in presence of significant splenomegaly where it is inaccurate).

Red cell survival – can be measured by injected red cells labelled with ^{51}Cr and counting the remaining radioactivity in blood samples taken at intervals afterwards. External counting over liver and spleen can give some idea of the rate of destruction of red cells at these sites. The test is time-consuming and seldom contributes much to evaluation of haemolysis.

Ferrokinetics: After IV injection iron is quickly cleared from circulation and used for erythropoiesis or stored as ferritin. The process can be measured following injection of radioactive iron salts and provides a clue into the mechanisms of various forms of anaemia, particularly those with ineffective erythropoiesis.

BONE MARROW EXAMINATION

The simplest form of marrow examination involves aspirating a small quantity of marrow from posterior iliac crest or sternum and making smears which are stained in similar manner to a blood film. Alternately histological sections can be made from aspirate marrow particles or from trephine biopsy sample.

Bone Marrow Aspiration

Indications: Investigation of:

1. Anaemias:

- **Megaloblastic anaemias:** Typical megaloblastic red-cells formation with presence of giant metamyelocytes. Similar picture also in pernicious anaemia, nutritional megaloblastic anaemia secondary to steatorrhoea, megaloblastic anaemia of pregnancy and that due to anticonvulsant drugs.

- **Haemolytic anaemia** suggested by cellular normoblastic marrow.
- **Aplastic anaemia:** Fat spaces predominate. Markedly reduced haemopoiesis.
- **Sideroblastic anaemia:** Red cell precursors containing iron granules arranged in a ring round the nucleus (ring sideroblasts).
- **Iron deficiency anaemia:** Assessment of marrow iron stores. In normal marrow 15% of red cell precursors show small iron granules within the cytoplasm.
- **Unexplained and refractory anaemias.**

2. Cytopenias

- **Thrombocytopenia:** Differentiation of various thrombocytopenias depends on qualitative and quantitative assessment of marrow megakaryocytes.
- **Neutropenias:** Marrow is normocellular and shows decreased mature neutrophils.

3. Haematological malignancy

- **Leukemias:** (i) Acute leukaemia – Infiltration with leukemic blast cells in the two common types ALL and AML are distinguished by morphological criteria and cytochemical stains. (ii) Chronic leukaemia – Aspiration allows examination of marrow cell morphology and examination for blast cells, which if above 15% may suggest impending blast transformation.
- **Lymphoma:** For pre-therapy staging process. The extent of the disease at the time of diagnosis is the best guide to prognosis and treatment since bone marrow involvement invariably indicates advanced disease.
- **Myeloproliferative disorders:** (i) Polycythemia vera – Particles aspirated are usually hypercellular; increased number of megakaryocytes are usually present and they are often large and multinucleate. (ii) Myelofibrosis – Bone marrow aspirate is usually dry. (iii) Essential thrombocythemia – Increase in number of megakaryocytes, which are often unusually large.
- **Myeloma:** Marrow infiltration with plasma cells.

4. Carcinomatous infiltration

Leucoerythroblastic anaemia in which both normoblasts (immature red cells) and myelocytes (immature white cells) are present.

5. **Infections and PUO:** (a) *Kala azar* –Amastigotes of *L. donovani* can be identified in stained material. (b) *Malaria:* Marrow tissue may reveal malarial parasites. (c) *Tuberculosis* – can occasionally be detected by culture. (d) PUO– Marrow examination is at times useful in difficult PUOs when one of these infections or malignancy is suspected.

Technique: The skin, subcutaneous tissue and periosteum over the posterior iliac crest (or manubrium sterni) are infiltrated with 2% lignocaine. The bone marrow aspiration needle is pushed through the bone with a boring motion, the guard being kept at a distance of about 1cm above the surface of the skin. When the needle has entered the marrow, the stillete is withdrawn and a long 10 ml syringe attached. Marrow aspirate is smeared onto glass slides. In selected patients, residual aspirate is placed in appropriate specimen containers for chromosomal analysis, microbiological culture, cell culture and electron microscopy and immune phenotyping.

M:E ratio – 500 marrow cells are counted, followed by calculation or percentage of different cells. Myeloid:Erythroid ratio gives the proportion of myeloid and erythroid cells. Normal M:E ratio is 3:1 to 15:1.

Assessment of iron stores on BMA:

0. No iron granules
1. Small granules in reticulum cells
2. Few small granules visible with low power lens
3. Many small granules in all marrow particles
4. Large granules in small clumps
5. Dense large clumps of granules
6. Very large deposits obscuring marrow cells

Table 2 lists causes of a 'dry' tap.

Bone Marrow Trepine Biopsy

Indications for bone marrow trephine biopsy are given in Table 3.

Technique: A Jamshidi-Swaim needle can be used to get the biopsy from the posterior iliac crest. After expulsion of 2 cm core of bone and its enclosed marrow from the needle, the biopsy specimen is smeared gently across three glass slides and then placed in fixative for subsequent histopathological processing and staining.

Iron stains: Prussian blue stains iron within erythroid cells and in marrow particles. In iron-deficient individuals, there is practically no stainable marrow iron, while the presence of ring sideroblasts is characteristic of sideroblastic anaemia.

Table 2: Causes of a 'dry' tap.

• Operator failure
• Primary myelofibrosis
• Hypercellularity (packed marrow, e.g. leukaemia)
• Lymphoma
• Carcinoma
• Hairy cell leukaemia
• Myeloid leukaemia plus myelofibrosis

Table 3: Indications for bone marrow trephine biopsy.

• To assess marrow cellularity
• Failure of marrow aspiration
• To detect focal involvement by malignant cells
• To demonstrate marrow fibrosis

Cytochemical stains– are occasionally used to help define the nature of an acute or chronic leukaemia. Lymphoblasts often give black positivity with PAS, whereas myeloblasts are Sudan-black positive, and monoblasts stain with nonspecific esterase and lysozyme. Neoblastic B cells of hairy cell leukaemia give a positive reaction with acid phosphatase.

Cell surface marker studies: The availability of monoclonal antibodies that recognise a wide variety of cell surface antigens has made it possible to identify cytological subgroups accurately, particularly those of white cell lineage. This has permitted a more accurate classification of the various forms of leukaemia, and is of therapeutic and prognostic significance.

Cytogenetic analysis: A wide variety of specific cytogenetic abnormalities are associated with subtypes of leukaemia, lymphoma and myelodysplasia, and these translocations have diagnostic and prognostic importance. Also the study of specific chromosomal changes is shedding light on the role of oncogenic activation in the genesis of neoplastic disease. For example, the Philadelphia chromosome translocation from chromosome 22 to chromosome 9 is pathognomonic of CML or Ph-positive ALL. Burkitt's lymphoma is another malignancy which is always associated with a translocation involving transposition of the *c-myc* oncogene from chromosome 8 to one of the immunoglobulin gene regions on chromosome 14, 2 or 22. These genes are then actively expressed by tumour B cells.

Clot section of the marrow: The clotted marrow is put in a vial with 10% formalin. Biopsy and sections are stained with haematoxylin and eosin. The results obtained are similar to those with a trephine biopsy.

Molecular biology techniques: It is possible to confirm the presence of clonal lymphoid proliferation by gene rearrangement studies: a B cell or T cell neoplasm will express a clonal pattern, whereas a reactive and hence non-neoplastic proliferation will not give rise to such a picture. These techniques have been further enhanced by the introduction of polymerase chain reaction (PCR), which can detect a tumour population of less than 1% cells.

2. HAEMATOPOIESIS

Haematopoiesis is the system of production of blood cells in response to the requirements of the body (Fig. 13).

REGULATION OF HAEMATOPOIESIS

- Humoral - (a) Kidney secretes erythropoietin to stimulate erythropoiesis. (b) Thrombopoietin secreted by the liver stimulates platelet production.

Fig. 13: Differentiation of haematopoietic cells

Table 4: Stem cell disorders.

- Chronic myeloid leukaemia
- Polycythemia vera
- Essential thrombocythemia
- Most acute leukaemias
- Aplastic anaemia
- Myelodysplastic syndrome
- Paroxysmal nocturnal haemoglobinuria

2. Inhibitory mechanisms - (a) Feedback mechanisms control over production of cells. (b) Role of apoptosis.
3. Cytokines produced by stromal cells.

TYPES OF CELLS

1. *Haemopoietic stem cells (HSC)* can proliferate to produce - (a) More stem cells. (b) Differentiate into progenitor cells. (c) Can produce different types of cells like RBCs, neutrophils, monocytes, platelets, lymphocytes, haemopoietic growth factors, etc. (d) A single haemopoietic stem cell can repopulate the whole marrow. Some of the stem cell disorders are listed in Table 4.
2. *Progenitor cells* - (a) are involved with one cell lineage - erythroid, myeloid, lymphoid or megakaryocytic. (b) These cells are formed from HSCs and are capable of proliferation and differentiation. (c) Early progenitor colonies may contain cells of more than one lineage, the late progenitor cells form cells of one lineage granulocytic or erythroid. These cells possess receptor for various cytokines and differentiate into maturing cells like proerythroblasts, normoblasts. Finally mature white cells, red cells and lymphocytes are produced.
3. *Maturing cells*

Haemopoietic growth factors (Cytokines) are hormone-like inducers of proliferation and differentiation of haemopoietic stem cells.

Functions of haemopoietic growth factors:

- Induce self-renewal of stem cells
- Proliferation and differentiation of progenitor cells
- Promotion of red cell and platelet production, amplification of leucocyte production

Types of haemopoietic growth factors:

- Granulocyte-Colony stimulating factor
- Granulocyte monocyte - Colony stimulating factor
- Erythropoietin

Table 5: Haematinics necessary for red cell formation.

- Amino acids for synthesis of chains of globin
- Iron for Hb synthesis
- Vitamin B₁₂ and folic acid for nucleic acid synthesis of erythroid precursors
- Zinc
- Vitamin C to raise absorption of iron from ferric to ferrous state
- Vitamin E for maintenance of integrity of red cells
- Copper helps transfer of iron cells to plasma with aid of ceruloplasmin
- Thyroxine
- Androgen
- Cobalt trace element as part of vitamin B₁₂

- Thrombopoietin

Sites of haematopoiesis have three phases:

1. Mesoblastic period in the yolk sac during 3rd week
2. Hepatic phase from 6th to 30th week
3. Myeloid period: Haematopoiesis starts in bone marrow in the 4th month and at birth marrow is the principal site for haematopoiesis.

Erythropoiesis is the process by which progenitor cells in the marrow proliferate, differentiate into normoblasts and mature into anucleated reticulocytes which enter the circulation. The normal life span of RBCs is 110-120 days. Haematinics necessary for red cell formation are given in Table 5.

Process of erythropoiesis: Erythropoiesis is regulated by erythropoietin, vitamin B₁₂, folic acid and iron.

ERYTHROPOIETIN (EPO)

It is a glycolated protein derived mainly from kidney and small portion of liver. In the kidney by interstitial cells in vicinity of proximal convoluted tubules. These cells liberate EPO in response to anoxia (e.g. high altitude, lung diseases). Indications for use of Epo are listed in Table 6.

Action: EPO acts on erythroid precursors which possess EPO receptors and these proliferate in an attempt to correct anaemia.

Algorithm of Action of Erythropoietin on Erythroid Precursors is given in Figure 14

Myelopoiesis is the process which results in production of neutrophils, eosinophils, monocytes, macrophages and dendritic cells. Stages of myelopoiesis:

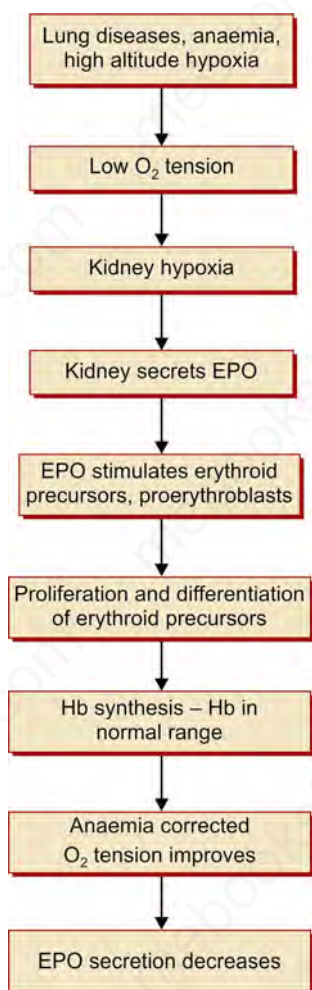

Fig. 14: Algorithm of action of erythropoietin on erythroid precursors

1. Haemopoietic stem cells – proliferate and differentiate into multipotent stem cells.
2. Multipotent stem cells (Progenitor cells) differentiate into colony forming units.
3. Colony forming units are the progenitors of granulocyte/monocyte pathway.

Red cell is a biconcave disc containing Hb and is bound by the red cell membrane. It has diameter of 7.2-7.7 microns (normocytic) with central one third pallor (normochromic)

ALTERATIONS IN SHAPE AND SIZE OF RED CELLS

1. **Macrocytosis:** Large RBCs with MCV > 100 fl, macrocytes in Folic acid and B₁₂ deficiency are oval in shape (macroovalocytes)

Table 6: Indication for use of EPO.

- Chronic kidney failure
- Patients on dialysis
- Anaemia of chronic disorders
- Anaemia in malignancy
- Anaemia in HIV infection

2. **Microcytosis:** Smaller cells with MCV < 80 fl, microcytosis with increased central pallor (hypochromic) is seen in iron deficiency anaemia and thalassemia major and minor.
3. **Anisocytosis** suggests variation in red cell size. Mild variation is normal and not significant. It is observed in megaloblastic and haemolytic anaemias.
4. **Poikilocytosis** is variations in shape of red cell, e.g. tear drop cells, oval cells, helmet cells.
5. **Elliptocytosis:** Red cells elongated and oval in shape is seen in hereditary elliptocytosis and in macrocytic anaemias.
6. **Spherocytosis:** Spherocyte is a deeply staining cell where central pallor is not seen. Found in hereditary spherocytosis and autoimmune haemolytic anaemia.
7. **Target cells:** Because of redistribution of Hb, only periphery and central regions of the cells appear haemoglobinised. Observed in sickle cell anaemia, thalassemia major, haemoglobinopathies, post-splenectomy, hepatic disease.
8. **Sickle cells:** Thin, elongated, slightly curved RBCs in sickle cell disease.
9. **Schistocytes** (Fragmented cells): Irregular shaped, speckled and triangular helmet shaped are feature of microangiopathic haemolytic anaemia, DIC and cardiac haemolytic anaemia (Fig. 15).
10. **Stomatocytes** contain a slit like area of central pallor and are seen in hereditary spherocytosis, liver disease and Rh null phenotypes.
11. **Acanthocytosis:** Large irregular red cells with irregular spicules seen in alipoproteinemia, PK deficiency, vitamin E deficiency and liver diseases.
12. **Burr cells** with many red cell projections, regularly spaced and uniform in size. Seen in uraemia and drug-induced haemolytic anaemia in infants.

INCLUSION BODIES IN RED CELLS

- **Basophilic stippling** (Punctate basophilia). Fine to coarse blue black inclusions (altered ribosomes) seen in haemoglobinopathies, megaloblastic and sideroblastic anaemias, lead poisoning and alcoholism.

Fig. 15: Schistocyte—note the broken fragments of erythrocytes (arrows)

- *Pappenheimer bodies* are sclerotic granules, aggregates of ferritin located close to the cell membrane due to incomplete Hb synthesis. Such cells are called siderocytes and are found in sideroblastic, megaloblastic, haemolytic anaemias and postsplenectomy.
- *Heinz bodies* are refractive, seen close to red cell membrane and comprise of denatured globin. They are observed in G6PD deficiency, exposure to or intake of oxidizing drugs or chemicals, unstable haemoglobin disease.
- *Bite cells*: In acute haemolytic episodes, there is presence of microspherocytes and bite cells. As the spleen removes the Heinz body, a 'bite' is created in the red blood cell.
- *Cabot's rings*. Oval, circular or figure of 8 shaped artefacts as a result of damage to lipoprotein of stroma of red cells. Seen in megaloblastic anaemia.
- *Prickle cells*. Red cells having sharp, thorn-like projections in pyruvate kinase deficiency.
- *Howell-Jolly bodies* are remnants of nuclear material seen in red cells and normoblasts after extrusion of the nucleus. Observed in megaloblastic anaemias (because of dyserythropoiesis), postsplenectomy (lost pitting function of the spleen) and acute haemolytic anaemias.
- *Haemoglobin H inclusions* are free β -chains present in red cells of α -thalassemias and some cases of myelodysplastic syndrome. They are small and distributed throughout the red cell (golf ball appearance).
- *Haemoglobin C crystals*. Following splenectomy in haemoglobin C disease, there is crystallization of haemoglobin C, the crystals being tetragonal in shape.

- *Rouleaux formation*. Red cells become aligned in aggregates to resemble a stack of coins. This is seen in conditions in which there is increase of γ -globulin, e.g. multiple myeloma, Kala-azar, Waldenstrom macroglobulinemia and chronic inflammatory disease.

HAEMOGLOBIN

Haemoglobin made up of haem and globin is the main constituent of the red cell and imparts red colour to the erythrocytes.

Haem is synthesised (60–70%) in normoblasts while 30–35% is synthesised at the reticulocyte stage. Haem biosynthesis is regulated by the enzyme ALA synthase and Haem regulates the ALA synthase activity, suppressing it when haem is high, enhancing it when it is low.

Globin synthesis. In an adult each globin molecule is made up of 2 α and 2 β chains. Synthesis of these chains occurs in normoblasts. Globin synthesis is controlled by haem which stimulates it in reticulocytes.

Forms of Hb

- Haemoglobin A, A₂ present in adults
- Foetal Hb (HbF) - present from 8th week of foetal life to birth, when it contains 80% of HbF. It is elevated in β -thalassemic syndromes. Detection of HbF > 2% in a child/adult is suggestive of some abnormality of Hb synthesis.

3. ANAEMIAS

Anaemia is a state in which the haemoglobin concentration falls below the accepted normal range depending on age and sex.

CLASSIFICATION

I. Etiological

1. **Blood loss** - Acute or chronic post-haemorrhagic anaemia.
2. **Impaired red cell formation**
 - a. *Genetic disorders of haemoglobin synthesis* - Thalassemia syndromes.
 - b. *Acquired deficiency of substances essential for haemopoiesis* - (i) Iron deficiency anaemia. (ii) Megaloblastic anaemia due to deficiency of vitamin B₁₂, folic acid, vitamin C. (iii) Protein malnutrition.
3. Haemolytic anaemias due to red cell destruction.
4. Defect in stem cell/erythroid precursor, (a) Aplastic anaemia (b) Pure red cell aplasia.

5. *Miscellaneous* - (a) Anaemia of chronic disorders- Infection/inflammatory disorders, kidney or hepatic failure. (b) Drug-induced disorders of erythropoiesis. (c) Infiltrative disorders of bone marrow - leukaemias, lymphoma, metastatic Ca, myelosclerosis.

II. According to Size of Red Cells and their Haemoglobin Content (Morphological)

- Microcytic, hypochromic (MCV < 78 fl)
- Normocytic, normochromic
- Microcytic (MCV > 100 fl)

PATHOGENESIS OF ANAEMIA

1. *Unbalanced cell growth*. Retarded DNA synthesis with normal RNA synthesis results in impaired cell division of erythroid precursors.
2. *Ineffective erythropoiesis* - Few red cells are formed because intramedullary death of intermediate and late megaloblasts.
3. *Haemolytic components* - Late normoblasts die in bone marrow because of a mild haemolytic process.

Investigation of a Case of Anaemia

I. History

Age and sex - Prematurity in infants. Females during reproductive period of life. G6PD deficiency confined to males. Sideroblastic anaemia mostly in males.

Rate of onset - Rapid onset over days, or one or two weeks suggests acute bleeding, acute leukaemia or haemolysis.

Drug ingestion - Especially aspirin and NSAIDs.

Occupation - Exposure to toxic chemicals.

Diet - History suggesting dietary deficiency.

Family history - of anaemia or jaundice common in congenital haemolytic anaemia. Occasionally in pernicious anaemia.

Bleeding - Blood loss commonest cause of anaemia - haematemesis, melaena, bleeding piles, menorrhagia, haematuria, haemoptysis.

GI system - Symptoms suggestive of peptic ulcer, cirrhosis, neoplasm, hiatus hernia. Diarrhoea often intermittent and glossitis in megaloblastic anaemias.

Reproductive system - Menorrhagia. Number and interval between pregnancies.

Urinary system - Symptoms of kidney insufficiency such as nocturnal polyuria.

Nervous system - Paraesthesia in hands and feet in deficiency anaemias.

Bleeding tendency - as suggested by easy bruising or skin petechiae, prolonged bleeding after trivial injuries, or bleeding from more than one site.

Skeletal system - Bone pains may occur in anaemias due to marrow infiltration or replacement as in multiple myeloma, leukaemia, malignant lymphomas and myelosclerosis.

II. Physical Examination

Skin - Colour of skin, petechiae and ecchymoses. In pernicious anaemia the skin may have a lemon yellow tint, and in acute leukaemia an ashen tint. In hypothyroidism coarse and dry. Petechiae in anaemia suggest diagnosis of aplastic anaemia or leukaemia.

Nails - Brittleness and longitudinal ridging common in chronic iron deficiency anaemia, occasionally koilonychia.

Conjunctivae - show pallor due to anaemia. Icterus rare, when present suggests haemolytic anaemia or hepatic disease. Mild icterus may be seen in pernicious anaemia.

Mouth - (i) Mucous membrane - Petechiae on palate, cheeks, or tongue in aplastic anaemia and leukaemia. (ii) Gums - Hypertrophy in leukaemia especially monocytic. (iii) Tongue - Acute glossitis, or smooth tongue common in megaloblastic anaemia, occasionally in iron deficiency anaemia. (iv) Pharynx - Ulceration of throat may occur in acute leukaemia, and acute aplastic anaemia. (v) Angular cheilitis suggests iron deficiency.

CVS - Cardiac murmur in SBE. Haemic murmur may be heard in anaemia. Hypertension in anaemia due to kidney insufficiency.

Abdomen - 1. *Splenomegaly* - in leukaemia, haemolytic anaemias, megaloblastic anaemias, myelofibrosis, multiple myeloma. At times in severe iron deficiency anaemia. Splenomegaly is unusual in cases of aplastic anaemia, and secondary anaemia. 2. *Abdominal lump* - e.g. in carcinoma of stomach, retroperitoneal mass of nodes in secondary carcinoma, chronic lymphatic leukaemia or malignant lymphoma. Localised tenderness may be present with peptic ulcer.

Lymph nodes - Superficial nodes may be palpable in leukaemia, malignant lymphomas and secondary carcinoma.

Bones - Bone tenderness especially sternal tenderness may occur in anaemias secondary to marrow infiltration,

e.g. in acute leukaemia, also in metastatic bone carcinoma, multiple myeloma, chronic leukaemia, myelofibrosis and malignant lymphomas.

Breasts – for evidence of carcinoma.

Rectal examination – for haemorrhoids or rectal bleeding. Size and shape of prostate gland.

Pelvic examination – in females with menorrhagia.

Fundus – Infiltration in leukaemia, retinitis in anaemia due to chronic kidney failure.

Severity of anaemia can be based on Hb levels:

Mild: Hb 9.1 -10.5 g/dl

Moderate: Hb 6-9 g/dl

Severe: Hb < 6 g/dl

Iron Distribution in Adult Male

Metabolism of iron – Iron is present in haemoglobin, myoglobin and iron containing enzymes of cytochrome system.

Haemoglobin – 2000-2500 mg

Myoglobin and enzymes: 400-500 mg

Iron stores – 500-1000 mg

Plasma iron – 2-3 mg

Storage of iron - (a) Haemosiderin - Brown pigment in reticuloendothelial cells of bone marrow. (b) Ferritin - It is present in circulation and reflects the iron stores and is used as a guide to control chelation therapy in thalassemia major.

Table 7: Causes of iron deficiency anemia.

1. *Increased physiological requirement*
 - a. *Growth spurts* – Children between ages of 6 months and 2 years, and from 11 to 16 years due to spurts of growth during these periods.
 - b. *Pregnancy*
2. *Pathological blood loss*
 - *Reproductive system*
Menorrhagia
 - *GI tract*

Bleeding	Atrophic gastritis
Oesophagitis	Inflammatory bowel disease
Oesophageal varices	Haemorrhoids
Hiatus hernia	Ca stomach, colorectal
Peptic ulcer	Hereditary haemorrhagic telangiectasia (rare)
Malabsorption	
Coeliac disease	
 - *Dietary*
Vegans
Elderly
 - *Hookworm infection*

Changes in epithelia – Since the defect is in maturation, changes are manifested in all rapidly proliferating cells in bone marrow, oral mucosal stomatitis and chelosis cells, in epithelia of small intestine.

III. Investigations – (Refer)

MANAGEMENT

1. *Correction of dietary deficiency* – Faulty dietary habits, chronic alcoholism, malnourishment.
2. *Treatment of underlying cause* – Ankylostomiasis, piles, menorrhagia, infection, chronic kidney failure, leukaemia, liver disease, collagen disease or endocrine deficiency, surgical correction of intestinal abnormalities, e.g. blind loop.
3. *Removal of toxic chemical agent or drug* – in some cases of haemolytic anaemia or aplastic anaemia.
4. *Blood transfusion* – Chief value is its immediate effect.
5. *Administration of substances specifically lacking* – Principles are – (a) Haematinic should be started only after adequate blood examination, since response to a haematinic may obscure the blood picture. (b) The specific haematinic should be given alone. (c) The haematinic should be given in adequate doses for a sufficient period of time.

MICROCYTIC, HYPOCHROMIC ANAEMIA

The microcytic, hypochromic anaemias have a low MCV/MCH and involve a disturbance of iron metabolism caused by one of:

- Iron deficiency (lack of iron)
- Anaemia of chronic disease (impaired availability of iron)
- Thalassemia syndrome (defective globin chain synthesis)
- Sideroblastic anaemia (defective haem synthesis).

IRON-DEFICIENCY ANAEMIAS

Causes of iron deficiency anemia are listed in Table 7.

Clinical Features

- A. **Manifestation of underlying condition** – e.g. pain of peptic ulcer, epigastric lump in carcinoma stomach.
- B. **Due to anaemia** – Insidious onset of easy fatigability, weakness, headache, bodyache, inability to concentrate, giddiness. With severe anaemia palpitation, exertional dyspnoea, anginal pain and congestive heart failure. Haemic murmur may be heard.

Table 8: Assessment of iron status.

Test	Iron deficiency anaemia	Anaemia of a chronic disease	Sideroblastic anaemia	Thalassemia trait
Serum iron	↓	↓	N	N/
Total iron-binding capacity	↑	↓	N	N
%Saturation	↓	N	N	N/
Ferritin	↓	N/	N	N/
Bone marrow iron stores	Absent	N/	+	N/
Sideroblasts	Absent	Absent	'Ring' sideroblasts	Present
Soluble transferrin receptor		N*	N	N*

C. Due to iron deficiency anaemia

1. *Tongue* – Smooth and pale (bald tongue). Sometimes angular stomatitis.
2. *Dysphagia* (siderophagic) – most common in post-menopausal women, results from formation of mucosal webs at junction of pharynx and oesophagus (believed to be due to reduction in iron containing enzymes in epithelium and GI tract). The combination of splenomegaly, koilonychia and dysphagia is known as Plummer-Vinson or Kelly-Paterson syndrome.
3. *Dyspnoea and palpitation* especially on exertion. Angina pectoris and intermittent claudication may be observed.
4. *Atrophic gastritis* – associated with achlorhydria.
5. *Nail changes* – Nails may be thin and fragile. Platynychia and koilonychia. More frequent in adults.
6. *Hepatosplenomegaly* – usually mild degree may occur, regresses with correction of iron deficiency.
7. *Pica* – Perversion of appetite in form of geophagy or pagophagia (excessive eating of rice).
8. *Miscellaneous* – (a) Oedema of feet due to CHF, impaired kidney function or hypoproteinemia. (b) Amenorrhoea in females, sometimes menorrhagia. (c) Increased intracranial tension and papilloedema rare. (d) In children – Long-standing anaemia can cause fronto-parietal prominence and face resembling that in Cooley's anaemia.

Also reduced attention span and poor learning. (e) Parotid gland swelling. (f) Hair loss. (g) Possibly impairment of T cell function and neutrophil killing thus promoting infection.

Investigations

1. Full blood count and blood film examination.
2. Haematinic assays (serum ferritin, Vitamin B₁₂, folate).
3. Urea and electrolytes.
4. Liver function tests.
5. Faecal occult blood.
6. Midstream urine (occult blood loss).
7. Fibreoptic and/or barium studies of GI tract.
8. Pelvic ultrasound (females, if indicated).

Diagnosis of iron deficiency anaemia:

1. Reduced Hb.
2. Reduced mean cell volume (< 76fl).
3. Reduced mean cell Hb.
4. Reduced mean cell Hb concentration.
5. Blood film: Microcytic, hypochromic red cells with pencil cells and target cells.
6. Reduced serum ferritin.
7. Reduced serum iron and total binding capacity.

Bone marrow stained for iron with Perls' stain confirms the diagnosis, presence of iron excludes iron deficiency.

Assessment of iron status in some anemias is given in Table 8.

Management

A. Eradication of the cause if possible

Treatment of ankylostomiasis, iron therapy from early stage of pregnancy, treatment of peptic ulcer, discontinuation of aspirin/NSAIDs, iron therapy for patients who have undergone gastric surgery. Correction of menstrual blood loss, and treatment of any other bleeding lesion.

B. Iron therapy

I. Oral iron therapy

1. *Calculation of daily dose:* In an average case of moderately severe anaemia, haemoglobin rises by about 1.0 g per cent per week of iron therapy. If we consider blood volume to be

4500 ml, total Hb. regenerated in a week comes to 45 g or in a day 6.4 g. Since each gram of Hb. contains 3.4 mg of iron, to produce 6.4 g of Hb iron required = 6.4×3.5 mg, i.e. about 22 mg. In moderately severe anaemia iron absorption would be about 20%, therefore oral dose of 100-120 mg. of elemental iron would suffice to provide adequate iron for optimum Hb rise.

2. **Preparations:** All ferrous salts (sulphate, gluconate, lactate, fumarate or succinate) are absorbed almost equally. Iron from ferric salts is poorly absorbed. Iron absorption is enhanced by combining iron salts with hydrochloric acid, ascorbic acid, succinic acid, fructose, cysteine, isonine and cobalt. Due to enhanced absorption, the dose of elemental iron can be reduced. This may be useful in the occasional patient who does not tolerate iron in the usual dose.
3. **Dosage and administration:** The optimum dose as stated earlier is 100-120 mg. of elemental iron per day. In order to avoid GI side-effects of therapy, it is advisable to start with a small dose (50 mg of elemental iron) and increase to full dose after few days. For sake of convenience preparations containing 30 mg or more of elemental iron per tablet or capsule are preferable so that patient can take one tablet b.d. or t.d.s. or as a single dose at bed time. Administration after food minimises gastric upset. Iron can be prescribed in the form of tablets, capsules, liquid or drops.
4. **Duration of therapy:** It takes about 8 weeks for Hb to reach normal level, irrespective of the initial Hb level. Replenishment of iron stores begins only after Hb level is normalised and this takes about 4 months. Hence iron therapy should be continued for 6 months.
5. **Side-effects:** Mainly gastrointestinal – Nausea, vomiting, epigastric pain, constipation or diarrhoea. Iron therapy may precipitate haemolysis in cases of paroxysmal nocturnal haemoglobinuria.

II. Parenteral iron therapy

1. **Indications:** (a) Intolerance of oral iron. (b) For getting rapid response – anaemia late in pregnancy, before surgery. (c) Continuous blood loss through GI tract due to inoperable conditions, e.g. intestinal polyposis or hereditary

haemorrhagic telangiectasis. (d) Malabsorption. (e) GI conditions which may be aggravated by oral iron, e.g. peptic ulcer, ulcerative colitis, bleeding piles. (f) When patient cannot be relied upon to take oral iron.

2. Preparation

Iron dextran (Imferon) – 100 mg IM by Z-track technique (Displacement of the skin laterally, before giving the injection), to avoid leakage of the drug into subcutaneous tissue with skin staining, or IV undiluted or diluted in form of drip for giving total requirement of iron at one sitting. A small test dose must be given IV before giving the total dose. Side effects – fever, joint pains, nausea, vomiting, diarrhoea, backache, bodyache, skin rashes, chest and abdominal pain, angio-oedema and fall of B.P. Anaphylactoid reaction may be fatal. Local or generalized lymphadenopathy may occur. (b) Iron-sorbitol – 100 mg by IM injection. Rapid absorption from injection site may cause saturation of iron-binding capacity, especially, if patient is on oral iron or has associated folic acid deficiency. Side effects – Flare up of urinary tract infection, fever, joint pains, nausea and vomiting.

3. Calculation of total dose – based on patient's body weight and haemoglobin level can be calculated from the formula: mg of iron $(15 - \text{Patient's Hb in gm/dl}) \times \text{wt (kg)} \times 2.3 + 1000$ mg. (Additional 1000 mg is for replenishment of iron stores).

Causes of refractory iron deficiency are listed in Table 9.

- c. **Blood transfusion:** If rapid rise of Hb is required, e.g. (a) Worsening angina or severe co-existing pulmonary disease. (b) Iron deficiency with serious ongoing acute bleeding.

Table 9: Causes of refractory iron-deficiency.

1. Failure to take iron.
2. Continued bleeding.
3. Associated infection or malignancy.
4. Inefficient preparation prescribed, e.g. slow release preparations.
5. Wrong diagnosis – Thalassemia trait, sideroblastosis (congenital).
6. Predominant deficiency of B ₁₂ or folic acid.
7. Malabsorption of oral iron.

MEGALOBLASTIC ANAEMIAS

Megaloblastic anaemias are characterized by macrocytic blood picture (MCV > 100 fl) and megaloblastic bone marrow. Causes of megaloblastic anemia are enumerated in Table 10.

Clinical Features

1. *Due to anaemia*: Shortness of breath, dyspnoea, pallor and in older subjects angina or cardiac failure.
2. *Gastrointestinal*: Diarrhoea, loss of appetite and weight. Sore tongue due to glossitis and angular cheilosis. Mild jaundice (from intramedullary breakdown of haemoglobin and shortened red cell life span) may give the patient a lemon yellow tint.
3. *Neurological*
 - a. Vitamin B₁₂ neuropathy- due to symmetrical damage to peripheral nerves and posterior and lateral columns of sp. cord, the legs being more affected than arms. Psychiatric abnormalities and visual disturbances may occur (from folate deficiency).
 - b. Neural tube defects- Folic acid supplements during pregnancy have been shown to reduce incidence of spina bifida, encephalocele and anencephaly in the foetus.
4. *CVS disease* - Raised serum homocysteine concentrations have been associated with arterial obstruction and venous thrombosis.
5. *Gonadal dysfunction* - Deficiency of either B₁₂ or folic acid may cause sterility, which is reversible with appropriate vitamin supplements.
6. Knuckle pigmentation (Fig. 16).

Laboratory Diagnosis

1. **Blood film** (Fig. 17)
 - Macrocytosis - Hb content in red cells is proportionately increased hence normal MCHC.
 - Peripheral smear - (i) Oval macrocytes. (ii) Anisopoikilocytosis. (iii) Few tear drop cells and normocytes. (iv) Few nucleated RBCs. (v) Macrocytes without central pallor. (vi) Evidence of dyserythropoiesis - basophilic stippling, Cabot ring, Howell-Jolly bodies.
 - Haemoglobin decreased.
 - Hypersegmented neutrophils may be the first evidence of megaloblastic anaemia.
 - Iron ferritin level increases.

Table 10: Causes of megaloblastic anemia.

Vitamin B₁₂ deficiency

1. Inadequate intake
 - Strict vegetarians (vegans)
 - Poor quality diet
 - Elderly
2. Impaired absorption

Gastric

- Pernicious anaemia
- Congenital intrinsic factor deficiency
- Gastrectomy

Small intestinal disease

- Bacterial overgrowth (blind loop syn.)
- Crohn's disease and resection of terminal ileum
- Tropical sprue and non-tropical sprue
- Selective ileal malabsorption of B₁₂
- Fish tapeworm disease
- Coeliac disease (folic deficiency more common)
- Miscellaneous - HIV infection, severe pancreatic disease, drugs (e.g. colchicine, neomycin, metformin)

3. Increased requirement

- Pregnancy
- Disseminated cancer

Folic acid deficiency

1. Inadequate intake

- Malnutrition
- Old age
- Poverty
- Alcoholism
- Goat's milk
- Kwashiorkor

2. Impaired absorption

- Coeliac disease
- Dermatitis herpetiformis
- Tropical sprue
- Congenital folate malabsorption
- Oral contraceptives

3. Increased requirement

- Infancy, pregnancy
- Hyperplastic marrow due to haemolytic anaemia

4. Impaired utilization

- Folic acid antagonists
- Methotrexate
- Pyrimethamine
- Trimethoprim
- Anticonvulsant drugs

5. Increased loss (combined folic acid and vitamin B₁₂ deficiency)

- Tropical sprue
- Non-tropical sprue
- Haemodialysis

Fig. 16: Knuckle pigmentation

Fig. 17: Pernicious anaemia—macrocytosis with multilobed neutrophil

Fig. 18: Pernicious anaemia—megaloblasts in bone marrow

2. **Bone marrow** (Fig. 18)

- Hypercellularity with marked erythroid hyperplasia.
- Megaloblasts are larger than normoblasts and have sieve like nuclear chromatin. Evidence of dyserythropoiesis.
- Myelopoiesis - Giant metamyelocytes and giant band forms with abnormal nuclear shapes.
- Megakaryocytes with hyperlobulation and immature nucleus.
- Dimorphic anaemia - Macrocytes and hypochromic microcytes in cases of combined B₁₂/Folate and iron deficiency.

Changes in epithelia - With a defect in nuclear maturation changes are seen in all rapidly proliferating cells in oral mucosal cells, bone marrow, epithelial cells in small intestine.

3. **Biochemical estimations**

- Serum folate levels - Decrease determined by isotope dilution method, microbiologic assay.
- Serum vitamin B₁₂ levels - Decrease determined by isotope dilution technique or microbiological assay.
- Increased levels of methylmalonic acid in serum and urine in B₁₂ deficiency.
- FIGLU excretion in urine in excess in folic acid deficiency.
- Deoxyuridine suppression test for deficiency of both vitamin B₁₂ and folate.
- Schillings test of vitamin B₁₂ absorption. Radioactive vitamin B₁₂ is used to assess intrinsic factor (IF) and Vitamin B₁₂ to distinguish megaloblastic anaemia due to IF deficiency (pernicious anaemia) from other causes of B₁₂ deficiency.
- Serum homocysteine levels - Increased in folate and B₁₂ deficiency.

Diagnosis of Megaloblastic Anaemia

- Oval macrocytes in peripheral smear.
- Hypersegmented neutrophils.
- Megaloblastic erythropoiesis in bone marrow.
- Response to B₁₂/Folate therapy.

Causes of macrocytic anaemia with nonmegaloblastic (normoblastic) bone marrow are listed in Table 11.

Blood and bone marrow response to vitamin B₁₂/folic acid therapy: (a) Megaloblastic erythropoiesis returns to normoblastic erythropoiesis within 24 hours. (b) Reticulocytes increase from third day onwards. (c) Neurological symptoms - Increase in paraesthesias in first 6-7 days followed by progressive improvement.

Macrocytic anaemia in combination with other anaemias

1. B₁₂ folate + iron deficiency anaemia - (a) Macrocytosis is masked. (b) Marrow reaction is macronormoblastic or megaloblastic and micronormoblastic.
2. B₁₂/Folate deficiency + thalassemia trait - Macrocytosis is masked.

Treatment

1. **Vitamin B₁₂ deficiency** - (a) *Initial* -Hydroxycobalamin 1000 µg IM, 6 injections in 2-3 weeks. (b) *Maintenance* - 500-1000 mcg IM every 3 months for life. In follow-up of patients with pernicious anaemia, a regular check must be kept for carcinoma of stomach. Iron deficiency due to atrophic gastritis, and hypothyroidism are important complications in patients on adequate maintenance. For patients sensitive to B₁₂ injections or those who refuse injections, oral B₁₂ (cyanocobalamin) in large daily doses (100 µg or more).
2. **Folate deficiency** - (a) *Initial* - Folic acid 5 mg. daily by mouth for at least 4 months. Folic acid in such big doses should not be given until B₁₂ deficiency has been excluded, since folic acid may precipitate B₁₂ neuropathy in a severely deficient B₁₂ patient. (b) *Maintenance* - Need depends on whether the underlying cause can be reversed, e.g. gluten-free diet in coeliac disease.

Anaemia of chronic disease - is common in chronic infection, inflammation, connective tissue diseases and neoplasia and chronic liver disease. It may be idiopathic. The severity of the anaemia and morphological features depend on the duration of the underlying process. The anaemia is normocytic, normochromic initially, if the inflammatory process continues, it becomes microcytic and hypochromic. The microcytosis usually follows hypochromia. *Treat* underlying cause. Iron and folic acid. Transfusion of packed RBCs if indicated. Folic acid 5 mg daily. Pyridoxine 200-400 mg daily, discontinue if response after 3 months. Regular packed cell transfusions to maintain Hb. Elderly may require iron chelation therapy with desferrioxamine if serum ferritin level exceeds 2000 µg/litre.

Thalassemia trait: Thalassemia may be suspected when serum iron is normal or increased. MCV, MCH and RBC morphology are disproportionately abnormal relative to haemoglobin level, and RDW is normal. Haemoglobin studies including measurement of HbA₂ and HbF, and pos-

sibly examination for HbH bodies may be diagnostic. There should be no doubt about the diagnosis in a patient with raised serum iron and ferritin levels. NESTR of test: Family studies provide confirmation, but globin chain analysis or molecular technology may be required.

Sideroblastic anaemias - are a heterogenous group of refractory anaemias characterized by - (a) Presence of ring sideroblasts in bone marrow (Fig. 19). (b) Dimorphic blood picture - RBCs are microcytic hypochromic along with normocytic/macrocytic red blood cells. (c) Ineffective erythropoiesis. (d) Increased iron stores.

- **Aetiology** of sideroblastic anaemias - (1) Hereditary. (2) Acquired. (i) Idiopathic. (ii) Secondary to myelodysplastic syndromes, myeloproliferative disorders, leukaemias. (iii) Reversible type due to alcoholism, isoniazid, pyrazinamide, deficiency of copper or pyridoxine, lead poisoning.
- **Treatment** 1. Removal of cause where possible. 2. Vitamin. B₁₂, folic acid. 3. Iron depletion measures - (a) Chelating agents. Desferrioxamine 40 mg/kg/d infusion SC for 12 hours. 5 days in a week. (b) Phlebotomies, if anaemia is not severe.

PERNICIOUS ANAEMIA (PA)

Aetiology

(a) *Age* - 40-60. (b) *Sex* - more in females. (c) *Race* - incidence highest in North Europeans. (d) *Family history* - The disease is about 20 times more common in close relatives (sibs, parents and children). (e) *Cause* - It is an autoimmune disease in which antibodies to gastric parietal cells produce gastric atrophy and achlorhydria and antibodies to intrinsic factor interfere with its role in vitamin B₁₂ absorption.

Fig. 19: Sideroblastic anemia

Table 11: Causes of macrocytic anaemia with non-megaloblastic (normoblastic) bone marrow.

• Alcoholism	• Reticulocytosis
• Liver disease	• Cytotoxic therapy
• Hyperthyroidism	• Chronic myeloproliferative disorder
• Aplastic anaemia	• Myelodysplastic syndromes

Cl. Fs. – Triad of weakness, sore throat and glove and stocking paraesthesia at presentation.

Associated Disorders

(a) In patient or in relatives – thyroid disease (Primary hypothyroidism, Hashimoto's disease or thyrotoxicosis), Addison's disease, hypoparathyroidism, immunoglobulin deficiency, and possibly with diabetes mellitus. (b) Correlation with early greying of hair, vitiligo, blue eyes and blood group A in patients or their close relatives. An association with human leukocyte antigen (HLA) 3. (c) Carcinoma stomach is three times more common.

Diagnosis

1. Laboratory studies – see macrocytic anaemia.
2. Endoscopy – to confirm atrophic gastritis and exclude gastric Ca or polyps which are 2-3 times more common.

Treatment – Injection of Hydroxycobalamin 50 µg every 4-8 weeks continued for life.

HAEMOLYTIC ANAEMIAS

A haemolytic anaemia is a reduction in the number of circulating red cells from their premature destruction.

Pathophysiology

When the normal lifespan (120 days) of red blood cell is shortened to such a degree that the bone marrow is incapable of maintaining a normal red cell mass leads to tissue anoxia. This results in increased output of erythropoietin stimulating production of red cells from the bone marrow. When the rate of destruction is in excess of eight times the normal, even a normal marrow cannot compensate and haemolytic anaemia results. Destruction of red cells can occur intravascularly, extravascularly or more commonly in both sites.

Classification of haemolytic anemias is given in Table 12.

Acanthocytosis of red cells and thrombosis, ophthalmoplegia and pigmentary retinopathy, may be involvement posterior columns and spinocerebellar tracts.

Recognition of Haemolytic State

1. **Evidence of increased RBC destruction**
 - Anaemia
 - Spherocytes, sickled cells, fragmented cells (damaged RBCs)
 - Increased urine urobilinogen
 - Increased serum unconjugated bilirubin

- Decreased haptoglobin
 - Increased serum lactate dehydrogenase
 - Haemoglobinemia
 - Haemoglobinuria
 - Haemosiderinuria
 - Haptoglobin absent or markedly reduced
 - Reduced RBC survival
2. **Evidence of increased rate of red cell production** – Bone marrow expansion – Hypercellularity, especially of erythroid component may lead to skeletal deformity.
 3. **Compensatory mechanisms**

Erythroid hyperplasia – Tissue hypoxia increases erythropoietin production, which in turn stimulates erythropoiesis, causing increase in number of marrow red cell precursors. With further stimulation, the volume of marrow increases, and when chronic haemolysis has been present from early childhood, there may be expansion of marrow cavities of the skull, vertebrae and long bones, causing marked skeletal deformities.

Stress cells and reticulocytosis – When erythropoiesis is under pressure, newly developed red cells are released from the marrow, causing large, deep-staining macrocytes ('stress' or 'skip cells') to appear in the blood and a variable reticulocytosis.

Effect of oxygen affinity – The degree of compensation in haemolytic process is modified by the oxygen affinity of the red cells. This is determined by the type of Hb and the level of intracellular phosphate. In pyruvate kinase deficiency, increased level of intracellular phosphate may explain how quite low levels of Hb are tolerated.

Failure of compensation – Anything which impairs the marrow's ability to compensate for haemolysis will lead to a fall in reticulocyte count and worsening of anaemia.

4. Associated effects of a haemolytic state

- (a) Depletion of folate stores.
- (b) Viral infection particularly with human parvovirus B₁₉' causes a transient failure of erythropoiesis and dramatic fall in Hb level in a patient with haemolytic anaemia.
- (c) Work hypertrophy of the spleen.

Table 13 lists important laboratory findings in haemolytic anaemias.

Clinical Manifestations

1. Pallor – severity as per degree of anaemia
2. Hyperdynamic circulation
3. Icterus – mild to moderate
4. Splenomegaly
5. Gall stones.

Table 12: Classification of haemolytic anemias.**Intrinsic RBC abnormality (inherited)***Membrane defect*

- Hereditary spherocytosis
- Hereditary elliptocytosis
- Stomatocytosis, Acanthocytosis

Metabolic defect

- Shunt pathway – G6PD deficiency
- Embden - Meyerhof pathway – Pyruvate kinase deficiency

Haemoglobin defect

- HbD, HbE and other haemoglobinopathies
- Thalassemias

Extrinsic RBC abnormality (acquired)*Antibody - mediated*

- Haemolytic blood transfusion reaction – ABO
- Haemolytic disease of the newborn
- Autoimmune haemolysis
- Warm or cold antibody
- Drug-induced

Nonantibody mediated

- RBC fragmentation
- Prosthetic heart valve
- Thrombotic thrombocytopenic purpura
- Haemolytic uremic syndrome
- Pre-eclamptic toxemia
- Disseminated intravascular coagulation
- Meningococcal septicaemia
- Paroxysmal nocturnal haemoglobinuria
- Infections
- Plasmodium falciparum malaria
- Clostridium welchii
- Mycoplasma pneumoniae
- Infectious mononucleosis
- Chemicals and drugs
- Oxidant drugs
- Dapsone, salazopyrine
- Arsine, primaquine
- Nitrites
- Burns
- Fresh water drowning
- Paroxysmal nocturnal haemoglobinuria (acquired membrane defect)
- March haemoglobinuria
- Severe vitamin E deficiency

Test for Diagnosis of Haemolytic Anaemia*Basic tests*

- Direct antiglobulin test – for investigating any suspected immunological disorder (particularly warm-type)

Table 13: Laboratory findings in haemolytic anaemias.

• S. bilirubin (unconjugated)	Raised
• Urine urobilinogen	Raised
• Rate of bilirubin production	Raised
• Red cell life span	Decreased
• Haptoglobin	Decreased (++)
• Serum LDH	Raised

- Haemoglobin electrophoresis, sickle test, HbA₂ and HbF levels, H-body preparation, testing of haemoglobin instability, globin chain analysis
- Complement fixation test for PNH
- Glucose-6-phosphate dehydrogenase screen assay, pyruvate kinase assay
- Osmotic fragility and autohaemolysis for hereditary spherocytosis/elliptocytosis, RBC membrane analysis
- Serum LDH levels increased

Specific test

Chromium - 51 - labelled RBCs

Can be tracked for survival and site of destruction

Treatment

Patients with compensated haemolytic process require no treatment. Otherwise, management is general and specific. Folic acid 5 mg is given routinely, and lifelong in those with inherited haemolytic disorders.

I. CONGENITAL HAEMOLYTIC ANAEMIAS**A. Red cell enzyme deficiencies**

1. **G6PD deficiency** – G6PD protects red cells against oxidant damage, e.g. from certain drugs (mainly sulphonamide and antimalarials chloroquine and primaquine). G6PD deficiency is an X-chromosome linked trait. *Clinical features* – (a) Drug-induced haemolytic anaemia. Ingestion of the drug is followed by fever, malaise, prostration, passage of dark urine, and acute anaemia. (b) Favism. (c) Neonatal jaundice. (d) Congenital non-spherocytic haemolytic anaemia. Haemolysis during intercurrent acute illness. *Diagnosis* – established by enzymatic assay.

It is seen in region endemic for Plasmodium falciparum, as it is known to confer resistance against this infection.

Treatment: Avoidance of drugs (Table 14), fava beans. In case of hemolysis develop no specific treatment unless severe, in those cases blood transfusion considered. If acute renal failure develops, hemodialysis may be needed.

G6PD variants

Class I Hereditary	Nonspherocytic haemolytic anaemia
Class II	Severe deficiency
Class III	Mild to moderate deficiency
Class IV	Non deficient variant

2. *Pyruvate kinase (PK) deficiency* - usually presents early in life with haemolytic anaemia, jaundice and splenomegaly or sometimes with neonatal jaundice. Because of PK deficiency synthesis of ATP is impaired and thus life span of RBCs is reduced. Diagnosis can be confirmed by PK assay of red cells. *Treatment* - As there is increased turnover of cells, oral folic acid supplementation is given. Splenectomy is useful in severe cases. Prenatal screening advised to mother who had child with pyruvate kinase deficiency.

B. Haemoglobinopathies

Haemoglobinopathies are inherited disorders of haemoglobin structure or its production. Human haemoglobin is a globular protein and consists of a protein part (globin), combined with four haem groups.

Classification

1. *Structural haemoglobinopathies* - A structural abnormality of one of the globin chains, usually caused by a single amino acid substitution.
2. *Thalassemsias* - which are caused by an inherited defect in the rate of synthesis of one or more of the globin chains. This results in underproduction of haemoglobin, and imbalanced globin chain synthesis - with precipitation of the chains produced in excess, and the formation of rigid inclusions (Heinz bodies).

A. SICKLE CELL DISORDERS**Genetic Sickle Cell Disorders**

Sickle cell disorders are characterized by presence of HbS-sickle haemoglobin which give sickle shape to RBCs in a state of reduced oxygen tension.

1. **Sickle cell trait** - Less than 50% HbS per cell is usually not associated with clinical abnormality. Infarction of spleen may occur during anaesthesia, and hematuria is not uncommon.
2. **Sickle-cell anaemia** - Anaemia from about third month of life, since HbS is more than 70% in red cells.
3. **Sickle cell disease** - This refers to all disease states in which at least one gene is of HbS.

Table 14: Drugs and chemicals that should be avoided by persons with G6PD deficiency.*Sulpha drugs*

- Sulphanilamide
- Sulphapyridine
- Salazopyrine
- Septran
- Dapsone

Antimalarials

- Primaquine

Analgesics

- Aspirin
- Acetanilid
- Phenacetin

Nitrofurans

- Nitrofurantoin
- Nalidixic acid
- Furazolidine

Miscellaneous

- Vitamin K analogues
- Naphthalene
- Toluidine blue
- TNT
- Probenecid
- Dimercaprol

Pathogenesis: Clinical problems in sickle cell disease relate to veno-occlusion caused by polymerization of deoxygenated haemoglobin S. This results in the pathognomonic change in the shape of erythrocytes to the sickle shape that stiffen the RBC membrane, increase viscosity and cause dehydration due to potassium leakage and calcium influx. The most common clinical feature is the painful vaso-occlusive crisis resulting from blockage of small vessels. However, large vessels disease also occurs, resulting in - Thrombotic cerebrovascular accidents, acute sickle chest syndrome, and placental infarction.

Clinical Features

1. **Delayed growth and development**
2. **Enlargement of spleen** after 6 months. Later at 5-6 yrs of age, reduction in size due to multiple infarcts from veno-occlusion of branches of splenic artery. In adults, spleen may be totally replaced by fibrous tissue (autosplenectomy).

3. **Leg ulcers** – Shallow ulcers near ankle due vascular stasis and often after trauma.
4. **Hand-foot syndrome** – Painful swelling of hands and feet. Vaso-occlusive crisis and dactylitis leads to destruction of metacarpals, metatarsals and phalanges.
5. **CNS** – Brain syndrome in a few children, occlusion of cerebral vessels leads to stroke.
6. **Infections** – Pneumococcal pneumonia, meningitis due to hyposplenism, osteomyelitis due to salmonella from repeated bone infarcts.
7. **Cardiomegaly** due to hyperdynamic circulation as a result of chronic anaemia.
8. **Hepatomegaly**
9. **Gall stones** – Pigment gall stones increase in frequency from childhood to adult.
10. **Ocular complications** – Occlusion of retinal vessels causes retinal changes such as ‘salmon patches’, intraretinal haemorrhages, A-V anastomosis.
11. **Abdominal pain** occurs due to infarcts of abdominal viscera due to vaso-occlusive crises.
12. **Priapism** – due to stagnation of blood in corpora cavernosa.
13. **Skeletal changes** – In a young child there is widening of the diploe of the skull leading to new bone formation with resultant ‘crew cut appearance’ in X-ray. Bone and joint ischemia leading to aseptic necrosis seen in femoral and humeral head. Unusually susceptibility to osteomyelitis, caused by salmonella.

Complications of Crises in Sickling Syndromes

Sickling and periodic exacerbations (crises) when patient is exposed to extreme hypoxia vaso-occlusive syndromes.

- **Painful crises** are usually the result of either reduced blood flow leading to tissue infarction, or sequestration of sickled RBCs in various organs. Crises can be precipitated by infection, dehydration and exposure to low temperatures. In first year of life, a common presenting feature is painful swelling of hands and feet ‘hand-foot syndrome’. In older children and adults, severe pain in the limbs and back associated with fever and prostration. Less commonly sickling may give rise to cerebral or pulmonary infarction.
- **Aplastic crises** are characterized by falling Hb level, and absent reticulocytes and are caused by parvovirus B₁₉ infection.
- **Haemolytic crises** – Marked increase in haemolysis.
- **Sequestration crises** occur when sickled RBCs pool in spleen, liver or lungs. Splenic enlargement is a life-threatening complication seen in early childhood. It is

characterized by massive enlargement of the spleen, together with sharply falling Hb level and rising reticulocyte count. A serious chest syndrome can occur, with bilateral radiographic changes, tachycardia, fever, profound hypoxemia and rapidly falling Hb level. The steady state Hb level is 5-11 g/dl. Blood film shows polychromasia, target cells and irreversibly sickled RBCs.

Sickle cell Hb C (SC) disease tends to have a milder clinical course than sickle cell anaemia. However in addition to complications seen in sickle cell disease, there is a higher risk of proliferative retinopathy due to retinal veno-occlusion.

Haematology in Sickle Cell Anaemia

- Anaemia – moderately severe
- WBC – slightly elevated
- Platelets – elevated
- Peripheral smear – Anisopoikilocytosis
There are sickle cells, target cells and ovalocytosis. Also polychromatophilia with few stippled RBCs.

Diagnostic Tests

1. **Sickling test** – Sickling is induced by adding reducing agent like 2% sodium metabisulphite to blood.
2. **Hb electrophoresis** can be performed on cellulose acetate membrane or starch agarose. HbS is a slow moving Hb as compared to HbA and HbF.
In HbS, HbS constitutes 70-90% of total Hb but HbA is nil. This differentiates homozygous (SS) from heterozygous state (SA), since the latter demonstrates two bands of HbS and HbA.
3. **HbF estimation** since HbF is 10-30% in homozygous state and is helpful in assessing course of the disease.
4. **High performance liquid chromatography (HPLC)** gives exact amount of HbA, HbS, HbF and HbA₂.
5. **Globin chain analysis** may be required to assess the genetic basis of disease and differentiate it from various heterozygote states.
6. **HbS solubility** is based on the fact that sickle Hb is insoluble in deoxygenated state.

Management

- a. Between crises – Patient should be given folic acid regularly, and infection treated early with antibiotics. Hydroxyurea helps by – (i) Reducing incidence of sickling crises. (ii) Increase in HbF levels in RBCs which can carry more O₂ and reduce tissue hypoxia. (iii) Lowering of blood viscosity thereby reducing occurrence of veno-occlusive crises.

- b. During crises – Rest, analgesics, hydration, correction of acidosis, plasma volume expander and oxygen.
- c. Blood transfusions – if PCV falls dangerously, cerebrovascular symptoms in early childhood, recurrent pulmonary thrombotic episodes, and to suppress the sickling process, e.g. to permit major surgery, during pregnancy or to ‘break’ a cycle of painful crises.
- d. Further management – Bone marrow transplantation offers opportunity for cure. Criteria for acceptance – (i) Sibling matched for HLA. If sibling match not present, to consider a matched, unrelated donor. (ii) Presence of one or more of – Neurological deficit, CVA or SAH. (iii) Two or more episodes of acute sickle chest syndrome or stage I and II chronic sickle lung disease. (iv) Recurrent severe and debilitating pain. (v) Problems for future medical care.
- e. **Gene therapy is under investigation.**

B. THALASSEMIAS

Thalassemsias are genetic disorders of Hb synthesis in which there is reduced production of one or more chains of Hb. This results in a relative excess production of either α chains or β chains, which without their partner chains are unstable and precipitate in RBCs or their precursors. The inclusion bodies produced by this process increase the rigidity of RBCs and result in their destruction, either in the marrow or the circulation or both. Hence the anaemia of thalassemsias results from ineffective erythropoiesis due to intramedullary RBC destruction, and a shortened RBC survival caused by haemolysis.

Thalassemsias are classified, according to the particular globin chain that is ineffectively produced (Table 15). In α thalassemsias there is reduced rate of chains synthesis. β thalassemsias are associated with a deficiency of β chains.

In β thalassemsias, a chain synthesis continues beyond the neonatal period, and most patients have an increased proportion of HbF ($\alpha_2\gamma_2$). In α thalassemsias, the imbalance produces an excess of β chains, which form β tetramers (HbH), in adult life, and an excess of γ chain, which form γ tetramers (HbBart's) in infancy.

Molecular Basis of the Thalassemsias

Molecular biology has provided an understanding of the nature of the defects in thalassemsias syndromes. There are two genes present on each chromosome 16 – a_1 and a_2 .

The β genes are located on chromosome 11 alongside the γ and δ genes. A large number of molecular defects are associated with a thalassemsias phenotype, most of the defects in β thalassemsias are small, often single base-pair changes.

There is marked phenotype variation in this condition because of heterogeneity at the molecular level. Some patients have mutations that result in failure to produce any globin chain (β^0 mutations), whereas other mutations allow globin chain production at a reduced rate (β^+ mutations). In α thalassemsias, gene deletions are the most common molecular defects, but, because any individual inherits four genes, there are broadly four phenotypes corresponding to deletion of one, two, three or four genes.

β - Thalassemsias

Occur predominantly in Mediterranean region and Middle and Far East. Clinically, β thalassemsias is a condition of variable severity, ranging from the most severe thalassemsias (associated with $w\beta^0$ mutations), to the mild heterozygous forms in which the patients have mild microcytic hypochromic anaemia.

β -thalassemsias Major – (Homozygous β -thalassemsias)

Special tests for diagnosis.

- HbF levels are high since γ -chain synthesis continues in absence of β -cell formation.
- Hb electrophoresis – demonstrates bands of both HbA and HbF in β -thalassemsias.
- Globin chain synthesis show lack of synthesis of β -chains hence a:b globin chain synthesis ratio is altered (normal 1:1).
- DNA analysis is useful in assessing the severity of the disease and diagnosis.
- Biomagnetic liver spectrometry evaluates haemolysis of the liver.

Table 15: Classification of thalassemsias.

β -thalassemsias	α -thalassemsias	Misc. thalassemsias syndromes
Thalassemsias major	Hydrops foetalis	HB-S Thalassemsias
Thalassemsias intermedia	HbH disease	HbE - Thalassemsias
Thalassemsias trait	Thalassemsias trait	HbD - Thalassemsias
	$\alpha\beta$ -Thalassemsias	HPFH- Hereditary persistency of foetal haemoglobin

Pathophysiology of β -thalassaemia

1. *Accumulation of free α -chains* in normoblasts which fail to mature and die in the marrow (apoptosis) which results in ineffective haemopoiesis.
2. *Extravascular haemolysis* - Red cells formed from abnormal normoblasts are destroyed in the spleen causing haemolytic anaemia.
3. *Changes in bone marrow and bones* - Development of anaemia due to short red cell survival, stimulates EPO production which acts on bone marrow leading to erythroid hyperplasia of bone marrow causing expansion of medullary cavities of bones, widening of both outer and inner tables of the skull and of long bones.
4. *Extramedullary haemopoiesis* causes hepatosplenomegaly.
5. *Iron overload* is due to haemolysis of RBCs, increased absorption of iron from GI tract, repeated blood transfusions. Iron gets deposited in endocrines, liver, heart, bone marrow, spleen, pituitary and islets of Langerhans.
4. *Facies* - Frontal bossing due to thickening of cranial bones and prominent cheek bones due to overgrowth of zygomatic bones.
5. *Mild haemolytic jaundice*
6. *Bone changes* - X-ray shows expansion of diploe with thinning of outer and inner tables. 'Hair on end' appearance due striations at right angles to inner table (Fig. 20). X-rays of metacarpals and metatarsals and phalanges show a 'mosaic' pattern because of trabeculations.
7. *Increased susceptibility to infections*
8. *Hepatomegaly* - Due to extramedullary haemopoiesis in first 3-4 years. Later on further enlargement due to haemosiderin deposits in Kupffer cells.
9. *Cardiac involvement* - Myocardial haemosiderosis may result in arrhythmias and cardiac failure.
10. *Endocrines*
 - Stunted growth from GH deficiency
 - Delayed puberty due to hypothyroidism
 - Hypoparathyroidism can cause osteoporosis and fractures
 - Diabetes mellitus due to iron deposits in islets of Langerhans

Clinical Features

1. *Onset* - Affected children fail to thrive from about third month and become progressively more anaemic.
2. *Increasing pallor*
3. *Splenomegaly* - Haem siderosis with extramedullary haematopoiesis

Fig. 20: The skull in thalassemia showing the 'hair-on-end' appearance of skull vault. Such appearance can occur in -1. Other haemolytic anaemias such as sickle cell disease, hereditary spherocytosis, elliptocytosis, and in pyruvate kinase deficiency. 2. Neoplasms - Neuroblastoma metastasis, hemangioma, plasmocytoma. Rarely meningioma and osteosarcoma. 3. Miscellaneous - Cyanotic congenital heart disease, severe iron deficiency anaemia in childhood.

Investigations

1. *Haematological*
 - Anaemia - Moderate to severe with 10-12 gm/dl. RBCs are microcytic hypochromic. Target cells are present and basophilic stippling is common. Also presence of tear drop, elliptical, fragments in red cells and at times red cell with Howell Jolly body (Fig. 21).

Fig. 21: Thalassemia major showing microcytic hypochromic cells, nucleated RBC and anisopoikilocytosis

- Reticulocytosis
 - Leucocytosis with few metamyelocytes and myelocytes
2. **Biochemical**
 - Reduced serum haptoglobins
 - Bilirubin (unconjugated) increased and urine urobilinogen increased
 - Iron status – (a) Serum iron and ferritin markedly increased. (b) Total iron binding capacity (TIBC) reduced.
 3. **Bone marrow**
 - Erythroid hyperplasia with reversed M:E ratio
 - Normoblastic erythropoiesis
 - Ineffective erythropoiesis – Some normoblasts die in the marrow without maturing into red cells
 - Myelopoiesis and Megakaryopoiesis
 - Increased bone marrow iron

Other special tests:

1. HbF levels are high.
2. Hb electrophoresis – Bands of both HbA and HbF in β -thalassemia.
3. Global chain synthesis – α - β globin chain synthesis ratio altered (normal 1:1) due to lack of synthesis of β chains.
4. DNA analysis – useful for predicting disease severity and diagnosis.
5. Liver spectrometry for detecting haemosiderosis of liver.

Management

1. **Blood transfusions** to keep Hb between 9-11 gm%, if infant's Hb. 6-7 gm% and failure to thrive. Transfusions are given every 2-4 weeks.
2. **Iron chelation** – (a) Desferrioxamine (DFX) as S.C. infusion using a syringe driver pump/infuser.
Indications – (a) S. ferritin level > 200 mg/L. (b) Deferiprone orally is fairly well tolerated. S. ferritin needs monitoring. (c) Deferasirox orally, if Deferiprone is not given because of side-effects.
Side-effects include arthralgia, anorexia, liver dysfunction.
3. **Splenectomy** – Hypersplenism due to splenomegaly causes neutropenia and increased need for blood transfusion. Splenectomy reduces severity of neutropenia and subsequent infections.
4. **Bone marrow transplantation** – Indication for BMT is in cases where matched siblings are available in a family, if not available, to look for a matched related donor. This is curative for the patient.

Prevention of Thalassemia Major

1. **Thalassemia trait in parents** – If antenatal check up reveals trait (by assessing HbA₂ levels (4-8%), then father should be assessed for thalassemia trait and, if positive then CVS (chronic villous sampling) is necessary.
2. **Antenatal VS** – at 9-10 weeks of gestation analysis of foetal DNA. If foetus is homozygous for thalassemia, termination of pregnancy is advisable.
3. **Thalassemia screening** – All mothers with Hb < 11gm% during their first antenatal check-up should be screened for Hb estimation. If MCV < 70 fl, MCH < 23 and RBC count of 7.5 million. If HbA₂ estimation 4-8% a diagnosis of thalassemia trait is suggested.

Thalassemia Intermedia

Patients who inherit mutations which lead to only mild reduction in β chain synthesis have a much less severe disorder. They are usually not transfusion dependent, though splenomegaly and hypersplenism may warrant splenectomy.

Heterozygous β -thalassemia (β -thalassemia trait)

Those affected are usually asymptomatic and diagnosis is made on discovery of hypochromic anaemia in absence of iron deficiency or other causes. Mild to moderate splenomegaly in about one-third. HbA₂ elevated.

Diagnosis of Thalassemia Trait

1. **Nestroft test** – is naked eye red cell osmotic fragility test. In case of positive test, HbA₂ estimation is done for confirmation.
2. **HbA₂ estimation** is 4-8% and is carried out by HPLC.

α -thalassemia

Clinical phenotypes:

- i. α -Thalassemia-2 trait - Single gene deletions – (Silent carrier state).
- ii. α -Thalassemia-1 trait – Two copies of the gene are deleted. Mild hypochromic microcytic anaemia.
- iii. **Haemoglobin H disease** – Three copies of the gene are deleted. Characterised by variable degree of anaemia with splenomegaly and typical thalassemic blood picture. *Diagnosis* confirmed by Hb electrophoresis which shows variable amounts of HbH. *Management* – Symptomatic with blood transfusions, use of haematinics and judicious use of splenectomy and iron-chelating agents.

- iv. **Haemoglobin bart's hydrops syndrome** – results from deletion of all four α genes and is a common cause of stillbirth in some races. Affected babies have total absence of α chain synthesis and produce largely HbBart's hydrops foetalis.
- v. **Haemoglobin constant spring (HbCS)** – Single base mutation results in formation of elongated α chains, and an abnormal Hb (HbCS). Clinical picture similar to haemoglobin H disease.

C. DISORDERS OF RED CELL MEMBRANE

1. **Hereditary Spherocytosis** – Haemolytic anaemia associated with intermittent jaundice and splenomegaly. Complications include haemolytic or aplastic crises related to infection, gallstone formation, development of haemochromatosis, and chronic leg ulceration. *Diagnosis* – Many spherocytes on blood film. Increased red cell osmotic fragility. *Treatment* – Splenectomy.
2. **Hereditary Elliptocytosis** – Symptomless or may be associated with haemolytic anaemia and splenomegaly. Diagnosis by presence of more than 25% oval red cells in peripheral blood. *Tr.* – Splenectomy is indicated in patients who have symptoms.
3. **Acanthocytosis** – Red cells with spikes found in association with total absence of β lipoprotein. Presence of malabsorption, CNS involvement and retinitis pigmentosa. Anaemia absent or mild.
4. **Stomatocytosis** – Red cells with a staining pattern in which there is a gap in the middle of the cell (resembling a mouth). Sodium influx produces a swollen water-loaded cell which is destroyed in the spleen leading to haemolytic anaemia. Splenectomy of benefit in a severe case.

II. ACQUIRED HAEMOLYTIC ANAEMIAS (DUE TO EXTRACORPUSCULAR DEFECT).

A. Immune Haemolytic Anaemias

1. **Haemolytic disease of the new born:** The term 'iso-immune haemolytic disease of the newborn' is used to describe a group of conditions resulting from the transplacental transfer of maternal blood group antibodies capable of destroying the infant's red cells.

The condition generally results from the passage of antibodies of the rhesus (anti-D, anti-C, anti-E) or ABO blood groups systems.

Rhesus iso-immune disease affects Rh-positive fetuses of Rh-negative mothers, but requires a previous sensitizing agent. This is usually the transplacental passage of foetal red cells into the maternal circulation during a previous pregnancy, but may also result from transfusion of Rh-positive blood. The most prevalent antibody is anti-D, despite the use of anti-D prophylaxis. Other antibodies (e.g. anti-Kell) can be responsible.

Haemolytic disease involving the ABO group system does not require prior sensitization, because anti-A and anti-D antibodies occur naturally. Although these account for about 50% of all cases of neonatal haemolytic disease, the clinical pattern is much less severe than that caused by rhesus incompatibility.

2. **ABO incompatibility:** Spontaneously occurring IgG isoantibodies may appear within the ABO blood group system from previous isoimmunisation or for no obvious reason. ABO incompatibility is responsible for about half of all cases of neonatal haemolytic disease. ABO incompatibility rarely causes dangerous neonatal haemolysis.

Clinical Features

I. Haemolytic disease of the foetus

- a. *Macerated foetus.*
- b. *Hydrops foetalis* – Severe oedema, pallor, yellow vernix, hepatosplenomegaly and petechial bleeding. The foetus usually dies in utero about 6 weeks before term or may die within a few hours after birth.

II. Haemolytic disease of the newborn

1. *Icterus gravis neonatorum* – The baby is not born jaundiced but becomes so within a few hours of birth. Jaundice reaches a maximum by the third or fourth day. At bilirubin levels of 20 mg/100 ml (345 μ mol/litre) or more kernicterus may develop with lethargy, hypotonia and poor feeding. This goes on to a state characterised by head retraction and generalized hypertonia. Mild cases may survive to develop the post-kernicterus syndrome of athetoid cerebral palsy, nerve deafness and dental enamel dysplasia.
2. *Haemolytic anaemia* – Mildest form of the disease due to only slight sensitization of the mother. Mild neonatal icterus may be present.

Management

- a. **Intrauterine foetal transfusion** – Haemolysis of foetal blood is accompanied by production of bilirubin

which passes into the amniotic fluid which can be obtained for examination by paracentesis. Increased levels of bile pigment in the fluid, or high level with no evidence of fall on subsequent investigation indicates severe haemolytic disease. It is not safe to induce labour before 34-36 weeks, and if treatment is required as indicated by amniocentesis, intrauterine transfusion should be attempted. This is carried out between 24 and 36 weeks and is repeated every 10-20 days until the foetus is considered to be viable.

- b. **Exchange transfusion** - At birth cord blood should be taken for estimation of Hb and bilirubin levels. An Hb level 12g/dl or less, or bilirubin of 75 mmol/litre or more, indicates need for exchange transfusion. The principle of exchange transfusion is based on the alternate injection and withdrawal of blood from the infant.
- c. **Phototherapy** - reduces hyperbilirubinemia associated with haemolysis. It is useful when bilirubin is rising slowly and may reduce need for subsequent exchange transfusions.

Monitoring

For those at risk from haemolytic disease of the newborn.

(a) *Maternal antibody levels* - Screen mothers at first antenatal visit and again at 30 weeks. In affected mothers, the antibody levels indicate when foetal blood sampling is required. (b) *Amniotic fluid bilirubin* - Optical density of amniotic fluid at 450 nm reflects the amount of bilirubin present. A rising value indicates severe haemolysis and impending hydrops foetalis. (c) *Foetal blood sampling* - allows measurement of haemoglobin blood group antigens and antiglobulin (Coomb's test). (d) *Ultrasound* - is not a reliable predictor of hydrops foetalis.

Quantity of blood exchanged - 80 ml per lb of body weight i.e. twice the expected blood volume of the patient. Therapy of choice both for correction of anaemia and for control of hyperbilirubinemia. *Indications* - Prematurity, history of severe erythroblastosis or kernicterus in previous siblings, development of signs of central nervous system involvement, hypoalbuminemia, or a level of Hb of 12 g/100 ml (12 g/decilitre) or under, or a bilirubin level of 4 mg/100 ml (68 µmol/litre) or more. Repeated transfusions may be necessary to maintain level of serum bilirubin at less than 20 mg per 100 ml. In case of ABO incompatibility fresh group O blood of the same Rh (D) group should be used.

The mother should not be permitted to nurse the infant with erythroblastosis, because anti-Rh agglutinins have been found in breast milk.

Prevention

It is possible to prevent sensitization of an Rh negative mother by administering anti-D (Rh) immunoglobulin 100 µg IM within 72 hours after delivery of an Rh positive baby. A Kleihauer test should be performed on the mother's blood and, if foetal cells are detected at a frequency of more than 1 in 600, further anti-D should be given. Anti-D should also be given to Rh-negative females after abortion for threatened ante-partum haemorrhage and obstetrics manoeuvres, or other traumatic event during pregnancy. 50 µg is given before 20th week of pregnancy, and after this 100 µg.

3. **Autoimmune haemolytic anaemia (AIHA)** - can be classified according to whether the antibody reacts with red cells best at body temperature (warm antibodies) or at lower temperatures (cold antibodies).
 - a. *Warm antibody haemolytic anaemia* - Most patients have autoantibodies of the IgG class on their cells. About half the patients have underlying disease such as lymphoma, chronic lymphocytic leukaemia, SLE, or ovarian malignancies. *Clinical picture* - ranges from mild haemolysis to life-threatening anaemia. Patient is jaundiced and may have splenomegaly. *Diagnosis* - Blood film shows polychromasia with spherocytes and reticulocytosis. Positive Coomb's test. IgG can be detected in about 50% of cases. *Treatment* - Steroids IV in severely ill patients, oral prednisolone 60 mg/day for mild cases, later dose is reduced to that which will maintain an adequate Hb level; if this fails splenectomy. If both these fail immunosuppressive therapy with azathioprine or cyclophosphamide or IG intramuscular.
 - b. *Cryopathic haemolytic syndromes* - (Cold immune haemolytic anaemias) - There are 2 disorders in which increased red cell destruction occurs at temperatures below normal body temperature:
 - i. *Cold agglutinin disease* - A marked elevation of cold agglutinins may occur either transiently in association with mycoplasma pneumoniae and infectious mononucleosis or more persistently as part of idiopathic cold agglutinin disorder of old age, or in association with neoplasms particularly reticuloses. *Clinical picture* - is variable. In acute variety - caused by Mycoplasma infection there is a brisk haemolytic episode with haemoglobinuria 2 to 3 weeks after a short respiratory illness. In chronic idiopathic form - anaemia with Raynaud's phenomena and

occasional haemoglobinuria. It has anti-I antibody, of IgM type. It reacts strongly with RBCs at lower temperature, so hemolysis takes place when person is exposed to cold. *Diagnosis* - Cold agglutinin titre markedly raised, positive direct Coomb's test, protein electrophoresis usually shows a 'monoclonal' IgM band. *Treatment* - Patient should wear warm clothing and avoid cold weather. Chemotherapy, if underlying lymphoma.

- ii. Paroxysmal cold haemoglobinuria - Rare disease characterised by intermittent attacks of intravascular haemolysis and haemoglobinuria. It's self limited. It has anti-P specific antibody, called Donath-Landsteiner antibody. It reacts with RBCs at low temperature 4°C, but when temperature shifts to 37°C hemolysis takes place in presence of complements. There are two forms of the disease - (i) Chronic relapsing illness associated with congenital syphilis (now extremely rare). (ii) Acute transient variety which may be precipitated by virus infection such as mumps or measles. Severely anaemic patients may require transfusion.

4. **Drug-induced autoimmune haemolytic anaemia-**

One of three mechanisms - (a) Innocent bystander - Antibody develops against the drug which forms a complex with it, and this attaches to the red cell membrane. Complement is then bound and causes destruction of the red cell, e.g. quinine. (b) Drug acts as hapten - Drug binds firmly to red cell membrane and antibody is formed with specificity for the drug-membrane complex, e.g. penicillin. (c) True autoimmune haemolytic anaemia, e.g. methyl dopa, levodopa, procainamide, mephenamic acid.

B. Non-immune acquired haemolytic anaemias

1. Due to trauma to red cells

- a. *Microangiopathic haemolytic anaemia* - characterized by intravascular haemolysis and fragmentation and distortion of red cells caused by disease of small vessels. *Types* - (i) Haemolytic uremic syndrome - Acute haemolytic anaemia with renal failure in infancy and childhood. (ii) Malignant disease - Disseminated mucous-secreting carcinomas, particularly of stomach. (iii) Thrombotic thrombocytopenic purpura - Acute haemolytic disorder with neurological and renal manifestations. In addition there is

generalized purpura and haemoglobinuria. (iv) Other disorders - DIC, collagen vascular disorders, toxæmia of pregnancy, septicaemia, purpura fulminans and malignant hypertension.

- b. *Cardiac haemolytic anaemia* - Abnormal turbulence caused by repair or replacement of aortic or mitral valve, or teflon-patch repair of septal defects, or severe AR or AS. Patient develops moderate to severe intravascular haemolysis with haemoglobinuria and haemosiderinuria. Iron deficiency may result from iron loss through the kidneys.
- c. *March haemoglobinuria* - A condition characterised by attacks of haemoglobinuria following strenuous physical exercise. A similar picture has been described in those who practise karate.

2. Resulting from infection

- a. *Septicaemia* - Haemolytic mechanisms vary. Treatment consists of control of underlying infection and blood transfusion.
- b. *Parasitaemia* - e.g. malaria or Bartonella bacilliformis.
- c. *Other infections* - Leishmaniasis, cholera, toxoplasmosis. Occasionally viral infections such as mumps and infectious mononucleosis.

3. Due to chemicals and toxins:

- a. *Heavy metals* - Lead poisoning (Lead also interferes with Hb synthesis).
- b. *Gases* - Inhalation of arsine gas (workers in metal-refining industries).
- c. *Sodium or potassium chlorate*.
- d. *Physical agents* - anaemia due to 100% oxygen inhalation in astronauts.
- e. *Insect stings and snake bite*.

4. Acquired defects of the red cell membrane

- a. *Liver disease* - Red cell survival may be shortened, the degree of haemolysis is usually mild. Occasionally acute haemolysis with upper abdominal pain may occur in alcoholics with liver disease, usually after a bout of drinking (Zieve's syndrome).
- b. *Paroxysmal nocturnal haemoglobinuria (PNH)* - occurs usually in third to fifth decade and is characterised by chronic intravascular haemolysis with exacerbations (typically in the morning), haemoglobinuria and a thrombotic

tendency. Diagnosis – Complement fixation tests. Treatment – Eculizumab block breakdown of red cells. Bone marrow transplant can prove curative.

4. BONE MARROW FAILURE

NORMAL MARROW FUNCTION

The normal adult marrow produces about 1.7×10^{11} red cells (17 ml), 1.0×10^{11} neutrophils and 2×10^{11} platelets each day. All peripheral cells arise from common progenitor cells known as pluripotent stem cells. An important property of these cells is selfrenewal, which ensures a continuous supply throughout life. Each pluripotent cell is capable of producing an individual clone consisting of a number of red cells, granulocytes, platelets and lymphocytes, together with their intermediate progenitor cells.

The term 'bone marrow failure' encompasses conditions in which there is a primary failure, at the haemopoietic precursor level, to produce one or more of the circulating blood cell lineages. The term usually excludes pancytopenia associated with marrow infiltration (as in acute leukaemia) and those that arise predominantly from peripheral destruction. Bone marrow failure may be inherited or acquired. Bone Marrow failure syndromes are listed in Table 16.

APLASTIC ANAEMIA

Aplastic anaemia (AA) is a group of disorders in which haemopoietic cells of bone marrow are replaced by fat resulting in progressive cytopenia. Causes of aplastic anaemia are enumerated in Table 17.

Severity of acquired aplastic anaemia is determined from peripheral blood and bone marrow examination as given in Table 18.

Clinical Features

Onset – Insidious, sometimes abrupt onset and course.

1. *Symptoms due to anaemia* – Weakness, fatigability, lassitude, dyspnoea on exertion.
2. *Symptoms due to thrombocytopenia* – Bleeding into skin either as ecchymoses or petechiae, epistaxis, menorrhagia, bleeding from gums and alimentary tract. Rarely cerebral haemorrhage. Presence of spontaneous bleeding indicates severe marrow failure with platelet counts below 20×10^9 /litre.

Table 16: Bone marrow failure syndromes.

Inherited
<i>Neutropenia</i>
• Fanconi's anaemia
• Pancytopenia
• Dyskeratosis congenita
• Shwachman Diamond syndrome
• Pearson's syndrome
• Reticular dysgenesis
• Amegakaryocytic thrombocytopenia
<i>Single cell cytopenia</i>
• Red cell aplasia
– Diamond-Blackfan syndrome
• Neutropenia
• Kostmann syndrome
– Shwachman Diamond syndrome
– Reticular genesis
• Thrombocytopenia
• Amegakaryocytic thrombocytopenia with absent radii (TAR)
<i>Acquired</i>
• Aplastic anaemia
• Pure red cell aplasia
• Others
Congenital dyserythropoietic anaemias
Myelodysplastic syndromes
Sideroblastic anaemia
Porphyrias
Leukemias

3. *Symptoms due to neutropenia* – Fatigue, sore throat, ulceration of mouth and pharynx, fever with chills, sweating. Chronic skin infection, recurrent chest infections, with severe neutropenia and risk of overwhelming septicaemia.

Abnormalities associated with Fanconi's anaemia – Short stature, hyper-pigmentation of skin, malformation of skeleton, microsomy, macrocephaly, malformation of kidneys, mental retardation, cryptorchism.

Laboratory Investigations

Peripheral blood – shows anaemia, neutropenia. Also reticulocytopenia.

- Typically large size RBCs and commonly increase in MCV. Low reticulocyte count. Some variation in RBC size and shape; however extreme abnormalities suggest

Table 17: Causes of aplastic anaemia.

Arsenic

possibility of hypoplastic myelodysplastic syndrome (MDS) or presence of a clone of paroxysmal nocturnal haemoglobinuria (PNH) cells. Presence of nucleated RBCs also raise possibility of PNH or MDS.

- Lymphocytic count normal or reduced, but morphology normal except for increased granulation (so-called toxic granules).
- Abnormal cells (including blasts and hairy cells) must be sought – these cells are absent in aplastic anaemia.

Bone Marrow

- Bone marrow aspirate* is usually a dry tap or marrow fragments are obtained which demonstrate – (i) Marked hypocellularity with replacement of marrow cells by fat, focal areas of haemopoiesis are present in initial stages. (ii) Paucity of erythroid, myeloid and megakaryocytic precursors.

Table 18: Severity of acquired aplastic anaemia.

	<i>Peripheral blood</i>	<i>Bone marrow</i>
Very severe	• Neutrophils $< 0.2 \times 10^9/L$	• 25% normal cellularity
	• Platelets $< 20 \times 10^9/L$	• Moderately hypocellular (<30 of remaining cells haemopoietic)
	• Reticulocytes $< 20 \times 10^9/L$	
	• Transfusion dependent	
Severe	• Neutrophils $0.5 \times 10^9/L$	• As for very severe
	• Otherwise as for very severe	
Non-severe	• Neutrophils $0.5-1.5 \times 10^9/litre$	
	• Platelets $20-100 \times 10^9/litre$	• Hypocellular
	• Reticulocytes $20-60 \times 10^9/litre$	

(iii) Lymphocytes and plasma cells predominate.
(iv) Stem cell pool reduced to $\leq 1\%$ of normal at time of presentation in severe cases.

- Bone marrow trephine biopsy* – (i) Marked reduction in cellularity, replacement by fat which is infiltrated by lymphocytes and plasma cells. (ii) Increase in mast cells. (iii) Increased bone marrow iron (Fig. 22).

Management

1. Supportive care with blood products

- Packed red cells for anaemia
- Platelets for thrombocytopenia
- G-CSF/GM-CSF to increase neutrophil count

- Control of infection** – Opportunistic infections (particularly bacterial or fungal) may occur in patients with neutrophil counts of $< 0.2 \times 10^9/L$ (ANC < 1500). Such patients should be isolated with prophylactic antibiotics, particularly against fungal and Gram-negative infections.

3. Restoration of marrow activity

Immunosuppressive therapy – has been found effective in producing remission in aplastic anaemia. The most effective agent is antithymocyte globulin (ATG) or anti-lymphocyte globulin (ALG).

ATG is given IV into central vein over 12-16 hours daily for 5 days. Fever, rigor and rashes are common during first 2 days, and serum sickness may occur 7-10 days later. Two-thirds of patients achieve remission. Methylprednisolone is administered with ATG to avoid immune reaction against heterologous globulin.

Fig. 22: Bone marrow in a patient with aplastic anemia. Notice there are very few cells except for the fat cells

Fig. 23: Bone marrow aspirate from a case of pure red cell aplasia showing normal myeloid precursors with marked paucity of erythroid precursors

Addition of cyclosporine to ATG may increase the likelihood of remission, particularly in patients with severe aplastic anemia. Immunosuppressive therapy is most effective in patients with non-severe aplastic anaemia. If the first course fails to produce a response at 4-6 months, a second course may be given.

Stem cell transplantation – *Allogenic bone marrow transplantation* is an effective means of curing the disease. Results are best seen in children and young adults with severe aplastic anaemia and in older adults with very severe disease.

Stem cells mobilized in the peripheral blood following treatment of the donor with granulocyte stimulating factor (G-CSF) are an equally effective source but bone marrow harvest of stem cells is preferred due to common incidence of GVHD.

Conditioning of stem cell transplantation is with AGL and cyclophosphamide. Cyclosporine is used with methotrexate post-transplantation to reduce the incidence of graft failure and graft-versus host disease. Successful results are achieved in about 80% of patients.

Neutropenia

Neutropenia is the term used when neutrophil count is $<1.5 \times 10^9/L$. Neutropenia is caused by (a) Suppression of myelopoiesis. (b) Peripheral destruction. (c) Peripheral pooling. Causes of Neutropenia (agranulocytosis) are listed in Table 19.

2. PURE RED CELL APLASIA

Pure red cell aplasia is an uncommon condition, probably of immune origin, in which RBC precursors are unable

to mature to produce reticulocytes and hence mature RBCs.

Causes

Congenital: Blackfan-Diamond syndrome. Anaemia is present from birth or develops within the first year of life and may be associated with other congenital abnormalities. Corticosteroids are effective in some patients; otherwise transfusion remains the mainstay of treatment.

Acquired 1. Autoimmune – SLE, NHL 2. Thymoma associated 3. Viral and bacterial – Hepatitis. Parvovirus B₁₉, EBV associated. 4. Drugs – Phenytoin, azathioprine, anti-TB drugs. 5. Tuberculosis associated. 6. Idiopathic.

Laboratory diagnosis – (a) Peripheral blood – Normocytic, normochromic anaemia with marked reticulocytopenia. Neutropenia with platelet count $<20 \times 10^9/L$. (b) Bone marrow – Almost total absence of erythroid precursors with normal myelopoiesis and megakaryopoiesis in PRCA. (Fig. 23) In parvovirus B₁₉ infection smear shows giant proerythroblasts with dog's ears-like cytoplasmic protrusions. Diagnosis parvovirus requires detection of its DNA sequence in blood.

Treatment – RBC transfusions till marrow recovers. If no response, long term transfusion with regular iron chelation. Thymectomy for thymoma. Corticosteroids with addition of azathioprine. Cyclosporine may be useful in resistant cases. For persistent parvovirus B₁₉, intravenous immunoglobulin therapy advocated (Dose- 0.4 mg/kg/day for 5 days).

Table 19: Causes of neutropenia (agranulocytosis).**Drug-induced***Antibacterial*

- Chloramphenicol
- Cotrimoxazole
- Doxycycline
- Ciprofloxacin
- Cephalosporins
- Gentamycin
- Nitrofurantoin

Anti-inflammatory

- Radiation
- Felty's syndrome
- Cyclic neutropenia

5. AMEGAKARYOCYTIC THROMBOCYTOPENIA

Thrombocytopenia associated with absence or marked reduction of megakaryocytes in bone marrow, is a rare, chronic condition affecting children and young adults.

Cl. Fs. – Skin purpura, bleeding gums and buccal haemorrhages. Children may present with easy bruising.

Bone marrow examination reveals the diagnosis.

Management – About 1/3 patients slowly develop classical aplastic anaemia, and respond to treatment with anti-lymphocyte globulin. Another 1/3 progress to MDS (more common in older patients), and ALG is worth trying. The remainder may remain stable for many years, occasionally requiring platelet transfusion.

6. PORPHYRIAS

Porphyrias are a group of inherited or acquired disorders due to a defect in the enzymes of haemosynthesis resulting in accumulation of intermediate products and affecting erythropoiesis.

Types

1. *Hepatic type* – Liver mainly affected. (a) Acute intermittent porphyria. (b) Hereditary coproporphyria. (c) Porphyria cutanea tarda.

Cl. Fs. (a) Neurological symptoms of rapid onset with high levels of ALA and PBG in blood and urine. (b) Cutaneous sensitivity to sunlight.

2. *Erythropoietic type* – Cutaneous photosensitivity is main clinical manifestation.

7. DISORDERS OF HAEMOSTASIS

Haemostasis is a tightly regulated homeostatic mechanism that maintains blood flow under physiological conditions and permits rapid, localized coagulation in the event of tissue damage. A delicate balance exists between four major components – the vascular endothelium, platelets, the coagulation pathway and fibrinolysis.

1. **Endothelium** – Under resting conditions, the endothelium prevents thrombus formation (Fig. 24). It acts as a physical barrier separating haemostatic from reactive endothelial components, and its surface charge may help to repel platelets. It possesses anticoagulant properties attributable to:

- Constitutional expression of thrombomodulin and heparan sulphate
- Endogenous synthesis of ectoenzymes, which degrade platelet agonists such as ADP
- Endogenous synthesis of the vasodilators prostacyclins (PGI₂) and nitric oxide (NO), which inhibit platelet aggregation.

Tissue damage leads to exposure of the endothelial basement membrane and extracellular matrix. Collagen (principally types I and III), von Willebrand factor and fibronectin promote platelet adhesions to the site of

Fig. 24: Endothelial hemostatic function – In the resting state (upper surface), the endothelium functions as an effective anticoagulant. Its negative surface charge repels platelets, and nitrous oxide and prostacyclin inhibits platelet function. Anticoagulant properties are enhanced by surface expression of thrombomodulin and heparan sulphate. However, after stimulation by cytokines or tissue damage, the endothelium rapidly becomes prothrombotic (lower surface). Platelet adhesion is promoted by exposure of subendothelial collagen and von Willebrand factor. Meanwhile, tissue factor secretion initiates fibrin generation and clot formation, while fibrinolysis is inhibited by secretion of plasminogen activator inhibitor, Anticoagulant properties are also modulated by reduced surface expression of surface thrombomodulin

injury, and the endothelium becomes prothrombotic after stimulation by endotoxin or the cytokines interleukin-1 (IL-1), tumour necrosis factor (TNF) and interferon- α . Tissue factor is expressed (initiating the coagulation pathway), fibrinolysis is impaired by secretion of plasminogen activator inhibitor, and surface expression of the anticoagulant thrombomodulin is reduced.

These procoagulant events are regulated to prevent excessive thrombosis by poorly understood mechanisms, endothelial cells secrete tissue plasminogen activator (tPA), initiating fibrinolysis, and thrombin becomes an effective anticoagulant after binding to thrombomodulin.

2. **Platelets** – are an integral component of haemostasis and circulate in close contact with the endothelial cell wall. Adhesion to the cell wall is prevented by high local concentrations of PGI₂ and NO, though they attach rapidly following endothelial disruption. In all blood vessels blood flow is faster towards the centre than close to the vessel wall; as a consequence there is a shear effect between adjacent layers of fluid that is maximal nearest the wall-shear forces of 500-5000/second can be attained within arterioles. Under such conditions, the interaction between platelets and von

Willebrand factor is vital in mediating irreversible adhesions to damaged endothelium. Under lower flow conditions, collagen, fibronectin and fibrinogen may be able to mediate platelet adhesion independently (Fig. 25).

Adhesion and aggregation – von Willebrand factor is a large, multimeric protein synthesized by the endothelium and secreted into the subendothelium. Following endothelial damage it binds to extracellular collagen, primarily through the A₃ domain. Platelet tethering to exposed thrombogenic surfaces occurs when the platelet glycoprotein GpIb-IX-V complex binds to the A1 domain of von Willebrand factor; this is possible despite rapid flow rates because of the fast association rate of the reaction. The multimeric nature of von Willebrand factor and consequent increased local concentration of A1 binding sites also potentiates adhesion. However, the platelet complex dissociates rapidly, allowing the platelets to continue rolling slowly along the endothelium. During this phase platelets are activated and the platelet GpIIb-IIIa receptor undergoes conformational change, allowing to bind both von Willebrand factor and fibrinogen, and resulting in irreversible platelet adhesion and aggregation, respectively.

Fig. 25: Platelet function – Specific platelet surface glycoprotein receptors mediate platelet adhesion, aggregation and activation. Platelet adhesion to damaged endothelium is achieved by the binding of von Willebrand factor to the GpIb component of the GpIb-IX-V complex. Aggregation follows, secondary to bridging of the altered GpIIb-IIIa receptors of adjacent platelets by fibrinogen. Other agonists (e.g. ADP, collagen) bind to specific receptors and initiate platelet activation through activation of phospholipase C. This enzyme catalyses the cleavage of phosphatidyl inositol biphosphate to inositol triphosphate and diacylglycerol. Diacylglycerol activates protein kinase C, while inositol triphosphate mobilizes calcium ions from the dense tubular system, hence activating phospholipase A₂ and myosin light chain kinase. Phospholipase A₂ liberates arachidonic acid from phospholipid and, via the action of cyclooxygenase and thromboxane synthetase, leads to synthesis of secretion of the thromboxane A₂. With thromboxane A₂, phosphorylated products of myosin light chains and the intracellular protein p47 stimulates secretion of the contents of the dense bodies lysosomes and granules

The dimeric nature of fibrinogen molecule allows inter-platelet bridging and growth of the primary platelet clot.

Activation – Platelet activation is caused by binding to the specific receptors of various agonists including thrombin, thromboxane A₂, ADP, collagen and arachidonic acid. Signal transduction is mediated by G proteins and intracellular cAMP; increased cAMP concentrations inhibit platelet adhesion, aggregation and release. Following platelet activation adenylate cyclase activity is reduced and cAMP levels therefore fall. Activation of phospholipase C results, and this cleaves phosphatidyl inositol biphosphate to inositol triphosphate and diacylglycerol. Inositol triphosphate mobilizes calcium; thus many calcium-dependent reactions ensue, including phosphorylation of the myosin light chain, which initiates the contractile reaction of the release mechanism, secretion of platelet granule contents, and liberation of arachidonic acid from membrane phosphatidyl choline.

Platelet activation is accompanied by structural changes. The normal smooth, biconcave disc shape is lost, platelets become spherical with protuberant pseudopodia, and their granules move centrally secondary to activation of the cytoskeletal contractile apparatus secretion follows. Subsequent contraction of cytoskeletal microfibrils may cause clot retraction and promote platelet plug formation. Coagulation is also enhanced by exposure of negatively-charged platelet phospholipids and receptors for specific plasma clotting factors (particularly activated factor V (Va) derived from platelet a granules), which provide the pro-coagulant surface necessary for assembly of the enzyme-cofactor complexes of the coagulation pathway.

Coagulation – It is recognized that the tissue factor – factor VII complex (TF VII) activates both factors IX and X, and that the intrinsic and extrinsic pathways are integrated *in vivo* (Fig. 26).

Factor VII and its cofactor (tissue factor) initiate haemostasis. Tissue factor is a glycoprotein constitutively

Fig. 26: Hypothesis of blood coagulation – Tissue factor has an integral role in the initiation of coagulation, through activation of factor VII. Activated factor X (Xa) is generated by factor VIIa, tissue factor complex. Because of factor Xa-dependent inactivation of VIIa/TF by tissue factor pathway inhibitor, factors IX and XI are required to generate sufficient tenase complex to ensure thrombin generation. The central role of thrombin is shown above. Coagulation is limited by the action of the anticoagulant system

expressed on the surface of fibroblasts; endotoxin II-1 and TNF may induce its synthesis and expression in monocytes, macrophages and endothelial cells. Following endothelial damage, factor VII or Factor VIIa binds to exposed tissue factor, increasing enzymatic activity. This interaction also promotes the ability of trace amounts of factor Xa, (and, less efficiently, factor IXa) to activate factor VII, though it remains unclear how these trace amounts are formed. Small quantities of VIIa are produced continuously under basal conditions, possibly secondary to factor IX activity (basal factor VIIa levels are reduced in haemophilia B). Alternatively, autoactivation of TF.VII might have a role. Once assembled, activated TF.VII (TF.VIIa) activates limited amounts of membrane-bound factors IX and X.

The factor Xa produced initially by this mechanism generates enough thrombin to induce local platelet aggregation and activation of the critical cofactors V and VIII, but is insufficient to sustain haemostasis because of rapid factor Xa dependent inactivation of TF.VIIa by tissue factor pathway inhibitor. Instead, marked amplification is achieved via the action of factors IXa and VIIIa. Factor XIa may be required to produce additional factor IXa, if the amount generated by TF.VIIa is insufficient or fibrinolysis is particularly active. This is consistent with the clinical presentation of factor XI deficiency, in which spontaneous hemorrhage

is rare but traumatic and postoperative haemorrhages are relatively common from tissues with high fibrinolytic activity. The precise mechanism of factor XI activation remains unclear but appears to involve thrombin and possibly auto-activation. Although important *in vitro*, the remaining components of the intrinsic system do not appear to have an important haemostatic role.

The tenase complex (factor Xa - factor Va) rapidly converts prothrombin to thrombin. Thrombin hydrolyses arginine-glycine bonds in fibrinogen to form fibrin monomers, and activates factor XIII, which stabilizes the fibrin clot through cross-linkage. It also has a positive feedback role, promoting activation of factor XI and the cofactors V and VIII, and thus ensuring rapid coagulation.

Anticoagulant pathways – Anticoagulants are an integral part of the haemostatic pathway and prevent catastrophic disseminated thrombosis. Antithrombins (serpins) inhibit the serine proteases of the coagulation system, and protein C system neutralizes activated coagulation factors. Although at least serpins have been identified, only antithrombin (formerly antithrombin III) and heparin cofactor II are haemostatically significant. Antithrombin forms a stable 1:1 stoichiometric complex with its substrates (predominantly factor Xa and thrombin). Heparin

promotes antithrombin inactivation of thrombin and factor Xa (the former 2000-fold), thus accounting for its therapeutic efficacy.

Thrombin may bind to surface-bound thrombomodulin, losing its procoagulant properties and becoming a highly effective anticoagulant. Formation of this complex increases the rate of activation of factor C 20,000 -fold. In addition the cofactor protein S forms a Ca^{2+} - dependent complex with protein C, increasing the phospholipid-binding potential and hence activity of protein C. Activated protein C rapidly degrades factors Va and VIIIa and enhances fibrinolysis, thus limiting excessive coagulation.

Fibrinolysis - The primary platelet clot is strengthened by fibrin formation, and tensile strength is further increased by fibrin polymer cross-linking mediated by factor XIIIa. Factor XIIIa also binds antiplasmin to fibrin, and thus may protect the clot against fibrinolysis (Fig. 27). However, fibrinolysis is a prerequisite for normal haemostasis, as shown by the possible thrombotic

tendency of patients with plasminogen deficiency. Tissue plasminogen activator (tPA) is released from endothelial cells and converts plasminogen to plasmin (a serine protease). This reaction is promoted when tPA is fibrin-bound and is subject to positive feedback - plasmin cleaves tPA into a two-chain molecule, increasing binding site exposure and promoting complex formation. Plasmin hydrolyses arginine and lysine bonds, resulting in proteolysis of various substrates including fibrinogen, fibrin and factors V, VIII and XIII. Fibrin and fibrinogen cleavage generates fragments X and Y, which inhibit thrombin and fibrin polymerization respectively, in addition to other smaller fibrin degradation products.

Excessive fibrinolysis resulting in fibrinogen consumption and hemorrhage is prevented by inhibition of both tPA and plasmin by plasminogen activation inhibitor and α_2 - antiplasmin.

Plasmin cleaves fibrin, leading to sequential formation of fragments X, Y, D and E, which exhibit positive feedback; hence, fibrinolysis is stimulated once initiated. However, tissue plasminogen activator and plasmin become more

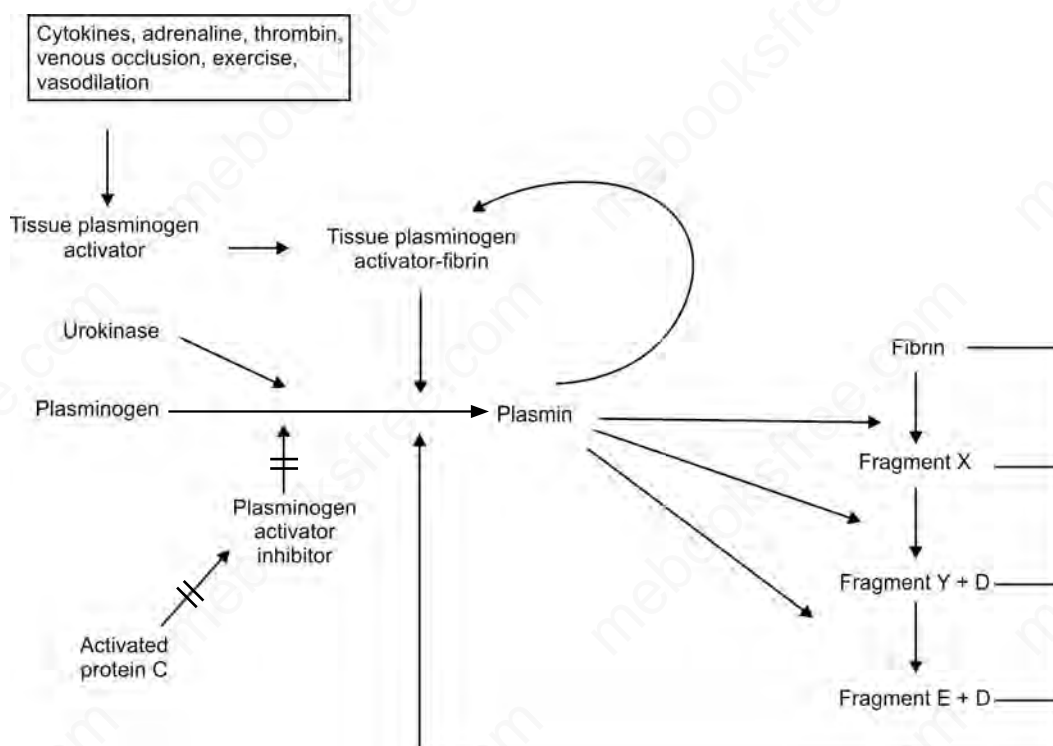

Fig. 27: Fibrinolysis - Tissue plasminogen activator is released from endothelial cells in single-chain form. This has significant proteolytic activity, which is enhanced both by fibrin binding and by plasma binding cleavage to the two-chain form. Plasmin also exerts positive feedback by converting native plasminogen (glutamate plasminogen) to lysine-plasminogen, which has preferential Fibrin binding. This increases plasmin production, localizes fibrinolysis to the fibrin clot and protects the plasmin generated from inhibition by α -antiplasmin

accessible to their inhibitors as the clot dissolves, and this helps prevent excessive fibrinolysis.

Congenital coagulation disorders - Three diseases haemophilia A, haemophilia B (Christmas disease) and von Willebrand disease account for more than 90% congenital coagulation disorders, which can cause abnormal bleeding.

HAEMOPHILIA A AND B

Haemophilia A (deficiency of factor VIII c) is about 5 times more common than haemophilia B (deficiency of factor FIX). Both exhibit X-linked inheritance (Haemophilia A due to F8 gene mutation and Haemophilia B due to F9 gene mutation) - all the daughters of patient with haemophilia are carriers of the disease and all the sons are normal. Female carriers may have a sufficiently low factor level to appear as if they have mild haemophilia; this occurs because of extreme ionization. In general, the severity of haemophilia is similar between generations dependent on the resting levels of factor VIII c or FIX (Table 20).

CLINICAL FEATURES

At birth - New born with haemophilia are usually healthy, though bleeding from the cord and cephalohaematoma may occur.

Infant - is usually asymptomatic until 6-12 months, when bruising becomes more obvious. Bleeding from the mouth is common.

During childhood - in severely affected individuals, spontaneous bleeds may occur into the joints and muscles, including the psoas muscle.

Adults - Frequency of spontaneous bleeding usually decreases, but joints may already have been damaged. Intracranial hemorrhage is a life-threatening complica-

tion. Spontaneous bleeds are common in mildly affected individuals, but after injury bleeding continues until appropriate therapy is given.

Laboratory investigations - APTT is prolonged in haemophilia A and B, but PT is normal. Specific factor assay demonstrate reduced factor VIII c in haemophilia A and factor IX in haemophilia B. If the clinical history is strongly suggestive of haemophilia, normal APTT does not exclude the diagnosis.

Complications of Haemophilia

1. *Hepatitis* in patients who received multiple transfusion of FFP or cryoprecipitate.
2. *AIDS* in a patient not screened for HIV and treated with FFP or cryoprecipitate.
3. *Anaemia* from excessive bleeding.
4. *Contractures in muscles* following intramuscular hematomas.
5. *Spontaneous intracranial hemorrhage* in severe haemophilia.

Management - Replacement of the missing factor:

Factor VIII dose = (Target Factor VIII levels - Factor VIII baseline levels) × body weight in kg × 0.5 unit/kg (as one unit of FVIII per kilogram of body weight increases the plasma FVIII level by 2%).

Factor IX dose = (Target Factor IX levels - Factor IX baseline levels) × body weight in kg × 1 unit/kg (as FIX recovery after infusion is usually only 50% of the predicted value).

- a. Recombinant FVIII or FIX Dose is calculated by above mentioned formula. Half life of FVIII is 8-12 hours so given twice daily, whereas FIX half life being 24 hours given once a day. Other FVIII preparations used in haemophilia A are (i) Fresh frozen plasma FFP. (ii) Cryoprecipitate. They are indicated in major bleeds, surgery or dental extractions.

Table 20: Severity of haemophilia A.

Severity	FVIII activity of normal	Age of presentation	Clinical effect	Haemarthrosis
• Mild	6-30%	Young adults	Severe trauma or surgery	Rare
• Moderate	1-5%	Children 1-5 years	Bleeding on slight injury	Uncommon
• Severe	<1%	At birth	Spontaneous bleeding episodes often	Frequent
Factor replacement in haemophilia				
Units = % rise in factor required body wt. (kg)				
Factor IX deficiency, K = 1				
Factor VIII deficiency, K = 2				

- b. Desmopressin (DDAVP) - 0.3 µg/kg iv combined with an antifibrinolytic agent increases factor VIII levels in haemophilia A, and may be used to avoid treatment with blood products. It's not useful in severe cases as there is no storage for release. Antifibrinolytic agents have been combined with factor concentrates when bleeding is external (e.g. in dental extraction) but have not usually been used with factor IX concentrates (because of the risk of thrombosis) or in haematuria (because of the risk of clot retention).

Prophylactic treatment - is useful in selected patients. Factor VIII inhibitors develop in 10-25% of haemophilia A sufferers, and it is likely that high-purity concentrates are more likely to promote inhibitor development. Factor IX inhibitors are uncommon in haemophilia B.

Genetic counselling is important in families affected by haemophilia. Direct defect analysis using DNA technology is now being used in antenatal diagnosis.

VON WILLEBRAND'S DISEASE

Von Willebrand's disease is an autosomally inherited bleeding disorder caused by a qualitative or quantitative defect in von Willebrand factor (vWF). Both sexes are affected. The disease may be classified into 3 main types:

- *Type 1* - Partial quantitative deficiency of vWF (autosomal dominant, 70% of cases)
- *Type 2* - Qualitative deficiency of vWF (autosomal dominant/recessive, 25%)
- *Type 3* - Almost complete absence of vWF (autosomal recessive, 5%).

Acquired VWD is a rare disorder, most commonly seen in patients with underlying lymphoproliferative disorders, including monoclonal gammopathies of undetermined significance (MGUS), multiple myeloma and Waldenström's macroglobulinemia.

Clinical features - Milder forms may present in second or third decade; clinically significant disease usually presents earlier. Mucosal bleeding (particularly epistaxis) and bleeding after injury or surgery are the main symptoms. Joint and muscle bleeds are rare.

Lab. investigations- (a) Prolonged bleeding time because of defect on platelet formation. (b) APTT slightly prolonged. (c) Ristocetin-induced aggregation defective (diagnostic of vWD). (d) Platelet count normal.

Management - (a) DDAVP combined with an antifibrinolytic agent is sufficient for haemostatic control in most patients; blood products should be avoided if possible. (b)

Intermediate-purity factor VIII concentrates or specific vWF concentrates are used when DDAVP is contraindicated. (c) Cryoprecipitate.

ACQUIRED DISORDERS OF COAGULATION

1. *Vitamin K deficiency*
 - Anticoagulant drugs - Coumarins, heparin
 - Biliary obstruction
 - Vitamin K malabsorption
 - Haemorrhagic disease of newborn
2. *Disseminated intravascular coagulation*
3. *Others:*
 - Massive blood transfusion due to deficiency of labile haemostatic factors particularly V and VII and platelets
 - Liver disease
 - Multiple myeloma

DISSEMINATED INTRAVASCULAR COAGULATION (DIC)

DIC is a syndrome in which either the extrinsic or intrinsic factor or both are activated resulting in multiple fibrin clots in small blood vessels. Causes of DIC are enumerated in Table 21.

Clinical features of acute DIC are listed in Table 22.

Laboratory Diagnosis

Acute DIC - (a) FDP levels assayed as the plasma digestion product of factor XIII cross-linked fibrin (D-dimer) may be increased by secondary fibrinolysis. (b) PT may be prolonged. (c) Prolonged APTT. (d) Reduced platelet count (e) Presence of schistocytes on blood smear (f) Fibrinogen levels reduced only in severe cases (g) Antithrombin III or plasminogen activity <60% of normal.

Chronic DIC - (a) FDP and D-dimer levels elevated. (b) Within normal range to high clotting time, PT or APTT (c) Normal or raised concentration of circulating fibrinogen. (d) Reduced number of platelets. (d) Short clot lysis time, evidence of fibrinolysis. (e) Fragmentation of red cells may occur in presence of kidney or malignant disease but less compared to acute DIC.

Management

1. **General measures**- (a) Correction of primary condition. (b) Restoration of fluid balance. (c) Treatment of shock, acidosis and hypoxia.

Table 21: Causes of DIC.

Acute DIC	
1. Obstetric complications	<ul style="list-style-type: none"> Amniotic fluid embolism Eclampsia Premature separation of placenta Retained dead foetus/placenta
2. Malignancies	<ul style="list-style-type: none"> Acute promyelocytic leukaemia Adenocarcinoma (metastatic mucus secreting)
3. Infections	<ul style="list-style-type: none"> Septic abortion Gram negative sepsis Clostridium welchii septicaemia Meningococcal septicaemia Falciparum malaria
4. Miscellaneous	<ul style="list-style-type: none"> Severe burns Heat stroke Snake bite Anaphylaxis Severe trauma Post surgery PNH Fat embolism
Chronic DIC	
1. Malignancies	<ul style="list-style-type: none"> Leukaemia Solid tumours
2. Obstetrics	<ul style="list-style-type: none"> Retained products of conception/dead foetus
3. Hematologic	<ul style="list-style-type: none"> Myeloproliferative neoplasms PNH
4. Inflammatory	<ul style="list-style-type: none"> Ulcerative colitis Crohn's disease Sarcoidosis

2. **Specific therapy**- (a) *Heparin* - indicated in deep vein thrombosis of lower limb, pulmonary embolism or peripheral gangrene. *Dose* - 15,000-25,000 units/24 hours. (b) *Replacement of coagulant factors* - Platelets or fresh whole blood is required when haemorrhagic state is increasing despite general and specific measures. Fresh frozen plasma (FFP) and platelet concentrates (at a dose of 1 -2 U/10 kg body weight in marked

Table 22: Clinical features of acute DIC.

<i>Bleeding</i>	<ul style="list-style-type: none"> Spontaneous bruising Petechiae Prolonged bleeding from venepuncture sites, arterial lines, etc. Bleeding into GI tract or lungs Secondary bleeding after surgery Coma (intracerebral bleeding)
<i>Clotting</i>	<ul style="list-style-type: none"> Acute kidney failure (ischemia of renal cortex) Venous thromboembolism Skin necrosis or gangrene Liver failure (due to infection and hypotension) Coma (cerebral infarction)

thrombocytopenia) are satisfactory fractions. Low levels of fibrinogen (<100 mg/dL) or brisk hyperfibrinolysis will require infusion of cryoprecipitate. The replacement of 10 U of cryoprecipitate for every 2-3 U of FFP is sufficient to correct the hemostasis. (c) *Inhibition of excess fibrinolysis*.

OTHER ANTICOAGULATION DISORDERS

Haemorrhagic disease of the newborn

Vitamin K deficiency in the neonate due to defective synthesis of vitamin K from delayed colonization of the gut:

- Bleeding from umbilical cord stump or melena 2-3 days after birth. Intracranial bleeding or intramuscular hemorrhage may occur.
- Prolonged PT and APTT.
- Vitamin K given parenterally produces quick response.

Liver disease

- Deficiency of factors synthesised in the liver (II, VII, IX, X). Low levels of FV and fibrinogen, if severe liver disease.
- PT, APTT prolonged.
- GI hemorrhage from gastritis or peptic ulcer common.

Table 23: Severity of hemorrhage and platelet count.

Platelet count (10^9 /litre)	Clinical effect
• > 500	• Hemorrhage or thrombosis
• 100-500	• No clinical effect
• 50-100	• Moderate hemorrhage after injury
• 20-50	• Purpura may occur
	• Hemorrhage after injury
• < 20	• Purpura common • Spontaneous bleeding from mucous membranes • Intracranial hemorrhage (rare)

PLATELET DISORDERS

Normal platelet count is $150-450 \times 10^9$ /litre, regardless of age. The severity of hemorrhage is directly related to platelet count (Table 23).

Thrombocytopenia is the condition in which platelet count falls below 100×10^9 /L. Causes of thrombocytopenia are listed in Table 24.

IDIOPATHIC THROMBOCYTOPENIC PURPURA (ITP)

It is characterized by Immune Mediated Destruction

Clinical features:

Acute thrombocytopenia – If severe and of sudden onset, may cause widespread purpura, bruising, mucosal bleeding, cerebral and GI haemorrhage. Fundal haemorrhage, persistent headache and other signs of increasing intracranial pressure suggest intracranial bleeding. Children with acute thrombocytopenia are at less risk than adults. When the condition develops after viral infection, e.g. measles, EBV infection, the duration is brief, active treatment is not required and recovery is nearly always complete.

Chronic ITP – is most common in young adults, especially women. Most patients have purpura, epistaxis, and often menorrhagia. Symptoms tend to fluctuate, with fairly long remissions as well as periods when symptoms increase spontaneously. Commonly occur after a viral infection. Table 25 compares features of acute ITP and chronic ITP.

Severity of bleeding in ITP is determined by platelet count (Table 26).

Investigations

- Blood**
Thrombocytopenia
Hb decreased

Table 24: Causes of thrombocytopenia.

1. Decreased platelet production	
Hypoplasia of megakaryocytes	
• Chlorothiazide, ethanol	
• Amegakaryocytic thrombocytopenia	
2. Increased platelet destruction	
a. Idiopathic	
Immune thrombocytopenia	
b. Secondary	
(i) <i>Immune mechanisms</i>	
• Collagen vascular disease	
• Lymphoproliferative disorders	
• SLE	
• Drug-induced	
Diclofenac	Isoniazid
Digoxin	Quinine
Tamoxifen	Gold salts
Heparin	Glibenclamide
(ii) <i>Non-immune mechanisms</i>	
• DIC	• Acute leukaemia
• TIP	• Myelosuppressive drugs
• Aplastic anaemia	• Cyclophosphamide, busulphan, etc.
3. Abnormal pooling of platelets	
• Splenomegaly, congestive, neoplastic	
4. Other causes	
• Hepatitis	
• Malignancy	
• Pregnancy	
• HIV infection	
• Infectious mononucleosis	
• Parvovirus	

Antiplatelet antibodies

- Bone marrow**
 - Megakaryocytic hyperplasia
 - Non-functioning megakaryocytes. Absence of budding of platelets from cytoplasm
 - Erythroid hyperplasia due to anaemia
 - Iron stores diminished, if severe bleeding is one of the features

Management of chronic ITP:

- Conservative treatment**
 - Bleeding not severe* – Wait and see policy especially in children and young women upto the age of 25, because spontaneous remission, often permanent occurs in number of patients. Initiate treatment when PCT <30,000.

Table 25: Features of acute ITP and chronic ITP.

	Acute ITP	Chronic ITP
• Age	• Children 2-8 yrs	• Adults 20-45 yrs
• Sex	• Equal	• M : F 1-3
• History of preceding viral infection	• In most pts.	• —
• Onset	• Sudden	• Insidious
• Duration	• 2-8 weeks	• Months to yrs
• Spontaneous remission	In majority	Rare
• Platelet count	• $< 20 \times 10^9/L$	• $30-60 \times 10^9/L$

- b. *Severe bleeding* – (i) Blood transfusion. (ii) Prednisolone – 40 mg a day for 2 weeks. Sometimes permanent remission. Observe patient at intervals for next 12 months. If purpura disappears partially or completely but platelet count remains low, 5-15 mg. of prednisolone daily for a further period of at least 3 months in the hope that permanent remission will occur.
- Immunosuppressive therapy** – Drugs such as azathioprine or cyclophosphamide are sometimes used in patients who are refractory to splenectomy and steroids or develop relapse.
 - Immunoglobulin preparations** – IV infusions of large doses result in reticuloendothelial blockade, and may be warranted in life-threatening situation.
 - Rituximab** weekly in doses of 375 mg/m^2 can produce remission for a period of time.
 - TPO receptor agonists – Romiplostim (given subcutaneously) and another orally eltrombopag (given orally) effective in raising platelet counts in patients with ITP and are recommended for adults at risk of bleeding who relapse after splenectomy or who have been unresponsive to at least one other therapy, particularly in those who have a contraindication to splenectomy.
 - Splenectomy – *Indications* – (a) Chronic cases, particularly adults, who have not had sustained response to steroids, and in whom troublesome bleeding persists after 6 months. (b) Symptoms severe and platelet count very low. (c) Signs of incipient central nervous system haemorrhage. (d) Girls approaching age of onset of menstruation. (e) Young married women likely to become pregnant. (f) First 5 months of pregnancy. (g) Steroid refractory.

Table 26: Platelet count and severity of bleeding in ITP.

Platelet count ($\times 10^9/L$)	Severity of bleeding
> 50	No spontaneous bleed
10-50	Bleeding in skin and mucus membranes
< 10	Post-traumatic bleeding, serious GI, and genitourinary bleeding

VASCULAR DISORDERS

Intact vascular endothelial function and the ability of vessels to contract are essential components by which blood loss is controlled. Abnormal vessel walls can result in excessive bleeding which is usually bleeding into the skin (petechiae or bruising) or mucous membrane (nose bleeds or GI blood loss). Routine laboratory screening tests for haemostasis are normal.

Causes

A. Hereditary

- Hereditary haemorrhagic telangiectasis (HHT)** is inherited as autosomal dominant, a gene causing HHT has been identified. HHT is characterised by structural abnormalities of blood vessels resulting in telangiectases– thin-walled, dilated, convoluted tubules connecting directly to dilated arteries that bleed easily. The skin, nose and GI tract may be affected, and bleeding may be mild or sufficiently severe to require multiple blood transfusions. A-V malformations comprising direct connections between a branch of an artery and a vein are seen in a minority of patients; these may be found in the lung (causing cyanosis or polycythemia) and in the brain (causing stroke or leading to brain abscess).

Diagnosis – is based on family history and presence of telangiectases or at endoscopy.

Management – Local measures to control bleeding and correction of anaemia with iron. Regular transfusion may be required. Genetic counselling should be offered.

- Ehlers-Danlos syndrome** is a disorder of collagen with a variable inheritance pattern. Patients have hyperflexible joints and elastic skin, and bleed abnormally following injury.
- Marfan syndrome.**
- Thrombopoietic agonists** like Romaplastin.

B. Acquired:

- Scurvy** – Vitamin C deficiency causes an acquired abnormality of collagen leading to bleeding gums, and perifollicular and subperiosteal hemorrhage. Administration of vitamin C produces rapid improvement.

- **Henoch-Schonlein purpura** – is an immune - complex mediated hypersensitivity reaction leading to vasculitis. It occurs most commonly in children after acute infection. Patients present with purpura (typically affecting the buttocks and extensor surfaces, of the legs), but the condition is usually self-limiting.
- **Corticosteroid-induced purpura** – may occur in patients receiving long-term corticosteroid therapy and in Cushing's syndrome.
- **Senile purpura** – results from atrophy of the tissues that support cutaneous blood vessels.
- **Purpura associated with infection** – Bacteria, viruses and Rickettsia may cause purpura by direct vascular damage or as a result of immune complex formation. Overwhelming infection (particularly meningococcal septicaemia) is often associated with purpura, thrombocytopenia and DIC.
- **Simple easy bruising** is common particularly in young women.
- **Fat embolism.**

8. ANTICOAGULANT DRUGS

Anticoagulation prevents pathological clot formation (e.g. on heart valves or atria) and stops prolongation and embolization of clots already developed in veins. The type, intensity and duration of anticoagulation depends on the indication for treatment (Table 27).

ANTICOAGULANT DRUG THERAPY

Tests to perform– Before starting warfarin or heparin a clotting screen (prothrombin time, partial thromboplastin time and thrombin time) and platelet count are performed. LFTs should be checked before starting warfarin. Serious kidney dysfunction should be excluded before starting low molecular weight heparin.

Table 27: Indications for anticoagulation.

Prophylaxis of deep venous thrombosis
Treatment of deep venous thrombosis/pulmonary embolism
Atrial fibrillation
Dilated cardiomyopathy
Mural thrombus post-myocardial infarction
Rheumatic mitral valve disease
Atrial fibrillation for cardioversion
Recurrent deep vein thrombosis/pulmonary embolism (in patients on warfarin)
Mechanical heart valves

Heparin

Unfractionated heparin is extracted from porcine mucosa. It is a heterogenous mixture of polysaccharide chains of molecular weight 3-30 kDa.

Low molecular weight heparins are produced by depolymerisation, yielding chains of 4-6 kDa. Both forms can bind and activate antithrombin (AT), accelerating the interaction of AT with activated factor X (Xa) by 1000 fold.

Difference between unfractionated and LMWH:

1. LMWH has an anti-Xa activity of >90%, unfractionated heparin has < 30% at prophylactic doses.
2. LMWHs after s.c. injections are better absorbed and have a greater bioavailability.
3. The half-life of s.c. LMWHs (3-6 hrs) is 2-4 times that of unfractionated heparin. Urinary excretion of LMWH is reduced by kidney impairment.
4. LMWH has a lower affinity for platelet factor and therefore a lower incidence of HIT.

Dosage and administration

Therapeutic doses of heparin vary from molecules used (Table 28) and require daily monitoring (APTT 1.5-2.5 times control); prophylactic doses are determined by thrombotic risk and do not require laboratory testing. Monitoring of LMWH is necessary only in kidney failure and pregnancy.

Complications

1. **Bleeding** – is not directly related to heparin dose, though the risk is low at prophylactic doses and is increased by concurrent illness, age and aspirin use. Risk is less with LMWH. Protamine 1 mg/100 units, reverses the action of unfractionated heparins, less effective against LMWH.
2. **Thrombocytopenia** – is caused by both types of heparin. A fall in platelet count is occasionally seen soon after starting heparin; it has neither haemorrhagic nor thrombotic consequences.

Heparin - induced thrombocytopenia with thrombosis (HITT) can lead to venous and arterial gangrene. This reaction is mediated by an IgG antibody against complexes of heparin and platelet factor 4. It usually develops after 5 or more days therapy, but can appear sooner in patients exposed to heparin (usually unfractionated) and causes platelet activation.

3. **Osteoporosis** – can develop after several months heparin treatment.

Warfarin

Warfarin (a coumarin) is the standard oral anticoagulant, Vitamin K-dependent factors II, VII, IX and X and coagula-

Table 28: Heparin treatment regimens.

Drug	Indication	Recommended Regimen (Once - Daily Subcutaneous Injection)
Dalteparin	• Prophylaxis – moderate risk	2500 units ¹
	• Prophylaxis – high risk	5000 units
	• Treatment of deep vein thrombosis/pulmonary embolism	200 units/kg
	• Treatment of unstable coronary disease	120 units/kg 12-hourly
Fondaparinux	• Risk of HITT lower than with LMWH	2.5 mg od
Enoxaparin	• Prophylaxis – moderate risk	20 mg (2000 units)
	• Prophylaxis – high risk	40 mg (4000 units)
	• Treatment of deep vein thrombosis/ pulmonary embolism	1 mg (100 units)/kg 12-hourly
	• Treatment of unstable coronary disease	1 mg (100 units)/kg 12-hourly
Tinzaparin	• Prophylaxis – moderate risk	3500 units
	• Prophylaxis – high risk	50 units/kg
	• Treatment of deep vein thrombosis/ pulmonary embolism	175 units/kg
Reviparin	• Prophylaxis – moderate risk	1432 U bd
	• Prophylaxis – high risk	3436 U bd
Nadroparin	• Prophylaxis – moderate risk	3075 U bd
	• Prophylaxis – high risk	6150 U bd
Certoparin	• Prophylaxis – moderate risk	3000 units
	• Prophylaxis – high risk	3000 units
Unfractionated heparin (sodium or calcium)	• Prophylaxis – moderate risk	5000 units 12-hourly
	• Prophylaxis – high risk	5000 units 8-hourly
	• Treatment of deep vein thrombosis/ pulmonary embolism	5000 units i.v. followed by 1000-2000 units/hour i.v. infusion monitored by activated partial thromboplastin time

Moderate risk – general surgery, age > 40 years, no additional risk factors.

High-risk – major orthopaedic surgery, major general or gynaecological surgery with additional risk factors (malignancy, history of venous thromboembolism, varicose veins, obesity, immobility, sepsis, thrombophilia).

tion inhibitors proteins C and S require carboxylation to form functional complexes; warfarin inhibits this process.

Warfarin is absorbed rapidly. Plasma peak levels are achieved in about 1.5 hours and $t_{1/2}$ is 2-3 days. Onset of action depends on the levels of factors II, VII, IX and X.

Dosage and monitoring

The dose is usually 3-9 mg/day, but can range from 0.5 mg/day to 25 mg/day. The dose is adjusted from day 2, on the basis of 'international normalised ratio' (INR), usually > 2-2.5 on 2 consecutive days.

High doses of warfarin can result in rapid reduction of the anticoagulant proteins C and S, and can result in thrombosis of subcutaneous vessels and skin necrosis. To prevent this, heparin is given before starting warfarin in all patients with venous thrombosis, or a history or family history of venous thromboembolic disease, it should be con-

tinued until INR is > 2 for 2 days. In patients requiring anticoagulation for indications other than thrombosis (e.g. atrial fibrillation), a history of venous thrombosis should be excluded before starting warfarin, and the starting dose should not exceed 5 mg daily.

Problems during Warfarin Therapy

1. Drug interactions – Many drugs interact with warfarin (e.g. amiodarone) and certain antibacterials (particularly ciprofloxacin, erythromycin and metronidazole) increase INR. NSAIDs and antiplatelet agents (dipyridamole, aspirin and clopidogrel) increase GI tract bleeding. Corticosteroids, thyroxine, allopurinol, omeprazole and lipid-regulating drugs enhance action of warfarin. Paracetamol (> 28 tablets / per week) can increase INR. Antiepileptics, rifampicin and griseofulvin usually antagonize warfarin.

Other factors affecting warfarin requirements – include CHF, liver impairment, variations in alcohol intake, marked variations in diet, vomiting and diarrhoea.

Recommendations for high NIR (without bleeding):

- INR > target range with no bleeding – Omit warfarin for 1-2 days, recommence at lower dose
 - INR > 8.0 with no bleeding – Omit warfarin until NIR < 5%, give vitamin K 0.5-2.5 mg p.o., if there are risk factors for bleeding.
2. **Bleeding**– Risk of bleeding rises with INR > 5, but serious (e.g. intracranial) hemorrhage can occur even at target INR. Major bleeding, irrespective of INR, requires prothrombin complex concentrate, 50 units/kg, or fresh frozen plasma, 15 mg/kg. Vitamin K can be given p.o. or slow iv. Minor bleeding (e.g. epistaxis, bruising, subconjunctival hemorrhage) should be assessed and warfarin reduced or withheld as necessary. Local measures to stop bleeding may be necessary.
 3. **Surgery** – Patients taking warfarin should not undergo surgery unless INR has been adjusted beforehand.

Acenocoumarol

Dosage – Initial 8-16 mg to maintain prothrombin time 2-3 times control value. It generally takes 7-10 days to stabilize the patient on a regular dosage. As compared to Warfarin, the drug has better anticoagulant stability and INR value within the therapeutic range over a significantly longer duration of treatment period.

Dabigatran Etxilate

Superior to warfarin preventing systemic embolism with reduced risk of bleeding. **It inhibits thrombin action.** Dose - 150 mg b.d. Dose not require anticoagulant monitoring.

Precaution: Kidney function to be ascertained on an ongoing basis, if it declines, e.g. hypovolemia, dehydration or with certain comedications. *Contraindications* - Severe renal impairment, patient with a bleeding diathesis or patients with spontaneous or pharmacological impairment of haemostasis.

Rivoraxban and Apixaban- newer oral anticoagulant. It inhibits action of factor Xa. Used for thromboprophylaxis in cases of elective knee or hip arthroplasty.

9. MYELODYSPLASTIC SYNDROMES

CLASSIFICATION OF MDS

The myelodysplastic syndromes (MDS) constitute a heterogeneous group of malignant bone marrow disorders characterised by ineffective haemopoiesis and increased risk of leukemic evolution (Table 29).

Pathogenesis

MDS is a clonal disorder of an early haemopoietic progenitor or stem cell. Increased apoptosis in the progenitor is a hall mark of MDS. No single genetic lesions has been shown to be sufficient for developing the disease.

Clinical Features

Generalised weakness, easy fatigability anemic features predominate early in course. Children with Down syndrome are susceptible to MDS and a family history may indicate a hereditary form of sideroblastic anemia, Fanconi anemia or a telomeropathy.

Treatment

1. *Transfusion* - (a) RBC transfusion to avoid significant anaemia. (b) Platelet transfusion if significant thrombocytopenia.
2. *Iron chelation* - Desferrioxamine s.c. or IV infusion, or oral iron chelators like deferiprone or deferasirox.
3. *Erythropoietic growth factors* - EPO s.c. inj. 1-3 times/wk, in a weekly dose of 30,000 to 60,000 units. Patients with refractory anaemia and ringed sideroblasts respond better to EPO and G-CSF combination than EPO alone.
4. *Lenalidomide*. 10 mg/days for 21 days on and one week off. Indicated in low risk and intermediate risk MDS patients.
5. *Hypomethylating agent* is recommended as first line therapy in patients with high risk MDS, therefore not eligible. Decitabine which is an alternate to 5-AZA cytidine allogeneic stem cell transplantation. 5-AZA cytidine 75 mg s.c. or IV daily for 7 days, the cycle to be repeated every 4 weeks with minimum of 4 cycles.
6. Immunosuppression- also may produce sustained independence from transfusion and improve survival. ATG, cyclosporine and the anti-CD52 monoclonal antibody alemtuzumab are especially effective in younger MDS patients.
7. *Allogeneic stem cell transplantation*. Disease recurrence and nonrelapse mortality are major causes of treatment failure.

Chronic Myeloproliferative Disorders

Classification of CMPD (WHO): Based on cell line, which is predominating hyperplastic.

- Chronic myeloid leukaemia bcr-abl chromosome positive
- Chronic neutrophilic leukaemia
- Chronic eosinophilic leukaemia, not otherwise specified
- Primary myelofibrosis

Table 29: Classification of MDS (WHO).

Disease	Peripheral blood picture	Bone marrow features
1. Refractory cytopenias with unilineage dysplasia (RCUD)		
a. Refractory anaemia (RA)	<ul style="list-style-type: none"> Anaemia Rare blast <1% 	Erythroid dysplasia with <5% blasts
b. Refractory neutropenia (RN)	Neutropenia; blast <1%	Granulocytic dysplasia with <5% blasts
c. Refractory thrombocytopenia	Thrombocytopenia; blast <1%	Megakaryocytic dysplasia with <5% blasts
2. Refractory anaemia with ring sideroblasts (RARS)	<ul style="list-style-type: none"> Anaemia; no blast 	<ul style="list-style-type: none"> Erythroid hyperplasia with dyserythropoiesis < 15% ring sideroblasts, <5% blasts.
3. Refractory cytopenia with multilineage dysplasia (RCMD)	<ul style="list-style-type: none"> Bi/pancytopenia Rare blasts <1% 	Dysplasia of ≥ 2 of the 3 haemopoietic cell lines \pm ringed sideroblast < 5% blasts.
	No Auer rods	No Auer rods
4. Refractory anaemia with excess blasts-1 (RAEB-1)	<ul style="list-style-type: none"> < 5% blasts Bi/pancytopenia 	5-9% blasts Dysplastic changes in $\geq 1\%$ haemopoietic cell line.
5. Refractory anaemia with excess blasts-2 (RAEB-2)	<ul style="list-style-type: none"> 5-19% blasts Cytopenias 	10-19% blasts. Myelodysplasia of ≥ 1 cell line.
	\pm Auer rods	\pm Auer rods
6. MDS unclassified (MDS-U)	<ul style="list-style-type: none"> No blasts. Cytopenias 	< 5% blasts Granulocytic or megakaryocytic dysplasia If no dysplasia, MDS-associated karyotype
7. MDS with isolated del (5q)	<ul style="list-style-type: none"> < 1% blasts Anaemia Platelets/N 	Isolated 5q31 deletion < 5% blasts \uparrow /N megakaryocytes with hypolobated nuclei
8. Childhood MDS including refractory	Pancytopenia	<5% blast and hypocellular marrow cytopenia of childhood (provisional) (RCC)

- Polycythemia vera
- Essential thrombocythemia
- Myeloproliferative disorder - unclassifiable
- Mastocytosis

POLYCYTHEMIA VERA

Polycythemia vera is one group of polycythemic states that are defined by raised haematocrit (> 0.51 in men, > 0.48 in women), in which phenotypically normal red cells, granulocytes and platelets accumulate in the absence of a recognizable physiologic stimulus.

Etiology

The etiology of PV is unknown. Chromosome abnormalities such as deletion 20q and trisomy 8 and 9 have been documented in up to 30% of PV patients. However, a mutation in the autoinhibitory pseudokinase domain of the tyrosine kinase JAK2, causing constitutive kinase activation appears to have a central role in the pathogenesis of PV.

Vascular complications are the most common presenting feature, and may be arterial particularly cerebral thrombosis and including digital microvascular occlusion, or venous. Increased viscosity caused by raised haematocrit and increased number of platelets (often abnormal in function) contribute to the vascular occlusive tendency. There is paradoxical increased risk of hemorrhage. Due to the large turnover of hematopoietic cells, hyperuricemia with secondary gout, uric acid stones.

Table 30 gives diagnostic criteria of polycythemia vera.

Investigations

Exclusion of causes of secondary erythrocytosis
Hypoxemia (with activation of normal erythropoietic mechanism).

- Chronic lung disease
- Cyanotic congenital heart disease
- Sleep apnoea
- High oxygen affinity haemoglobins

Table 30: Diagnostic criteria of polycythemia vera.

Major criteria		Minor criteria	
A1	Raised RBC mass	B1	Thrombocytosis (platelet count > 400×10^9 /litre)
A2	Absence of cause of secondary erythrocytosis	B2	Neutrophil leucocytosis (neutrophil count > 10×10^9 /L)
A3	Palpable splenomegaly	B3	Splenomegaly demonstrated on isotope scanning/ultrasonography
A4	Clonality marker (acquired abnormal marrow karyotype)	B4	Characteristic growth of burst-forming units, erythroid or reduced serum erythropoietin

Polycythemia vera is established by presence of A1 and A2 plus A3 or A4 or any two B.

Renal (with inappropriate secretion of erythropoietin)

- Hypernephroma
- Polycystic kidneys
- Postrenal transplantation

Miscellaneous (ectopic and/or inappropriate secretion of erythropoietin)

- Hepatoma and liver disease
- Cerebellar haemangioblastoma
- Familial autonomous high erythropoietin production

Further investigations may be necessary to fulfil the criteria shown.

1. *An abnormal acquired karyotype* is regarded as evidence of clonal evolution and is a major diagnostic criterion in polycythemia vera. No single karyotypic abnormality is common to all patients; trisomies of 1, 8, 9 and deletions of 13q and 20q are among the more common.
2. *Palpable splenomegaly* in presence of absolute erythrocytosis and no cause for secondary erythrocytosis is also a major diagnostic criterion.
3. *Bone marrow* - Hypercellularity with multilineage hyperplasia and large megakaryocytes with hyperlobulated nuclei are the classical features (Fig. 28).
4. *Raised serum uric acid*
5. *Decreased erythropoietin levels*
6. *Transcobalamin I and III* increased suggesting increased granulocyte turnover.
7. JAK-2 mutation

Differential Diagnosis

Relative erythrocytosis is characterised by normal RCM, but raised PCV. It is often associated with obesity, alcohol, smoking and hypertension.

Fig. 28: Polycythemia vera—bone marrow showing trilineage proliferation

Idiopathic erythrocytosis is diagnosed in patients with raised RCM but no identified cause of secondary erythrocytosis and insufficient diagnostic criteria for polycythemia vera. This is a heterogeneous group that may include early or unrecognised stages of polycythemia vera or secondary erythrocytosis, and some rare causes of erythrocytosis (e.g. truncation of erythropoietin receptor).

Management

1. *Venesection* - repeated every 2-3 months to maintain the hemoglobin level at <14 g/dL and hematocrit <45% in men and 12 g/dL and hematocrit <42% in women is mandatory to avoid thrombotic complications.
2. *Cytotoxic therapy* - Hydroxyurea 0.5-1.5 mg/day, reduces need for venesection and controls platelet count. Earlier therapies with radioactive 32-phosphorus injections (which suppressed all haemopoiesis) and intermittent low dose busulphan (which controlled mainly the platelet count), now tend to be reserved for the elderly.
3. *Low-dose aspirin* - is particularly useful in patients with micro-vascular occlusion.
4. *Anagrelide* a phosphodiesterase inhibitor is preferable to hydroxyurea because it lacks marrow toxicity.
5. *Interferon- α* reduces JAK₂ (defected by PCR) expression in PV patients and can control the disease.
6. Nonspecific JAK2 inhibitor ruxolitinib- undergoing clinical trials in PV patients intolerant to hydroxyurea.

Note: Patients with polycythemia vera very occasionally undergo transformation to acute (usually myeloblastic) leukaemia (3-5% at 10 years) with hydroxyurea therapy, more following ^{32}P treatment.

ESSENTIAL THROMBOCYTHEMIA

Persistently raised platelet count ($> 600 \times 10^9/\text{litre}$) and abnormal increase in megakaryocytes in bone marrow the principal feature of primary thrombocythemia. Causes of thrombocythemia are listed in Table 31.

Investigations

Blood

- Raised platelet count ($>600 \times 10^9/\text{L}$)
- Platelets large and hypogranular (Fig. 29)
- NAP score raised

Bone Marrow

- Megakaryocytic hyperplasia (Fig. 30)
- No evidence of collagen fibrosis

Clinical Features

1. *Asymptomatic* - In about one-half of patients raised platelet count is an incidental finding.
2. *Symptoms due to vascular occlusion*, particularly of small vessels - Cerebral, coronary, splanchnic and deep veins may be affected. Microvascular occlusions present as erythromelalgia (burning pain in extremities) or gangrene of the digits, particularly the toes.

3. *Bleeding* - May occur after minor trauma, particularly in individuals with platelet counts $< 1000 \times 10^9/\text{litre}$.
4. *Splenomegaly* - is modest and occurs only in few. In common with other myeloproliferative disorders, patients have a low but definite risk of transformation to acute leukaemia or myelofibrosis.

Management

- *Hydroxyurea* reduces platelet count; reduction to $< 400 \times 10^9/\text{litre}$ reduces incidence of vascular occlusions. In older patients, and in those with previous thrombotic lesion (or other risk factor for thrombosis), it is used with low dose aspirin.
- Platelet pheresis, if haemostatic problem.
- Anagrelide in patients with recurrent thrombosis.

Fig. 29: Peripheral smear showing marked thrombocytosis

Fig. 30: Essential thrombocythemia—bone marrow biopsy showing megakaryocyte clustering

Table 31: Causes of thrombocythemia.

I. Primary/Clonal

- Essential thrombocythemia
- Chronic myeloid leukaemia
- Polycythemia vera
- Myelofibrosis

II. Secondary/Reactive

- Infections
- Inflammatory disease
- Malignancies
- Post-hemorrhage
- Post-splenectomy
- Post-surgery
- Miscellaneous - After exercise, parturition, iron deficiency anaemia, hereditary thrombocythemia

PRIMARY MYELOFIBROSIS (AGNOGENIC MYELOID METAPLASIA)

In PMF there is marrow fibrosis with extramedullary haemopoiesis in spleen.

Clinical Features

- Weakness or tiredness due to anaemia
- Bleeding episodes due to thrombocytopenia may occur
- Hepatomegaly - Mild due to extramedullary haemopoiesis
- Splenomegaly, moderate to massive. Large areas of extramedullary haemopoiesis in spleen.

Haematological Findings

- Leucoerythroblastic peripheral blood picture (myelocytes and nucleated RBCs) and teardrop cells in peripheral smear
- Elevated Neutrophil alkaline phosphatase score (Normal 40-100)

Bone Marrow

- Dry tap on BM aspiration
- BM trephine biopsy - Increased reticulin fibril network
- Decreased cellularity but increased megakaryocytes
- Dilated marrow sinusoids

Phases of Myelofibrosis

1. Prefibrotic cellular phase with immature and dysplastic megakaryocytes
2. Fibrotic stage
3. Osteomyelosclerosis

Management

Supportive therapy - Transfusion of RBCs, platelets. Treatment of infection. Androgen and recombinant erythropoietin therapy may help in reducing need for transfusions.

Chemotherapy - can be useful, particularly in the proliferative phase of the disease when it can reduce splenomegaly. Hydroxyurea is preferred to alkylating agents, which have a higher leukaemogenic potential.

JAK₂ inhibitors, if JAK₂ mutation is present, useful for reducing splenomegaly and alleviating symptoms.

α-interferon is useful in some cases.

Splenectomy - The risks (bleeding, thromboembolism, infection) must be weighed against the discomfort of splenomegaly, frequent transfusions and thrombocytopenia

induced bleeding. Splenic irradiation can be a palliative measure. High-dose corticosteroids can be helpful in severe neutropenia.

Allogenic bone marrow transplantation - should be attempted only in younger patients with poor prognostic features because of the procedure - related morbidity.

Causes of Secondary Myelofibrosis

- Metastatic carcinoma in BM
- Hodgkin's disease with BM involvement
- Chronic myeloid leukaemia
- Hairy cell leukaemia
- SLE
- Post-irradiation
- Leishmaniasis
- HIV infection
- Tuberculosis

10. LEUKEMIAS

A clone of malignant cells derived from myeloid or lymphoid stem cells. In *acute leukaemia* the clones are primitive (blast cells) in type, whereas in *chronic leukaemia* the abnormal cells retain most of the features of their normal counterpart. In children 85% of leukaemias are of lymphocytic type; in adults acute myeloid leukaemia is the most common type.

ACUTE LEUKEMIAS

Acute leukaemias are characterised by an uncontrolled growth of immature haemopoietic cells at the expense of normal marrow tissue. Although acute leukaemia is primarily a disease of the bone marrow, leukemic cells usually circulate in the blood, and may infiltrate other tissues.

Acute leukaemias are divided into two main groups:

- Acute lymphoblastic leukaemia (the blast cells arise from a committed lymphoid cell line)
- Acute myeloid (the precursor cells involved in the malignant process would have normally matured into RBCs, granulocytes or platelets - the cells normally termed 'myeloid').

Table 32 gives WHO classification of leukaemias (Fig. 31).

Aetiology

1. *Unknown* (usually)

Table 32: WHO classification of AML.

• AML not otherwise specified
- Minimally differentiated (M0-5%)
- Without mutation (M1-10%)
- With mutation (M2-30-40%)
- Acute myelomonocytic (M4-15-20%)
- Acute monoblastic and monocytic (M5a, 5b, 5-8%)
- Acute erythroid (M6-5-6%)
- Acute megakaryoblastic (M7-3.5%)
- Acute panmyelosis with myelofibrosis (M7, rare)
- Acute basophilic (very rare)
• Myeloid sarcoma (Chloroma, granulocytic sarcoma, extramedullary masses of monoblasts or myeloblasts)
• AML with recurrent genetic abnormalities
- AML with inv(16) (p13.1;q22) or t(16;16)(p13.1;q22); CBFB-MYH11
- AMPL variants – t(15;17)(q22;q12); PML-RARA
- AML with t(8;21) (q22;q22); RUNX 1-RUNX1T1
- AML with t(9; 11) (p22;q23); MLLT3-MLL
- AML with t(6;9)(p23;q 34); OEK-NUP2 7 4
- AML with inv (3) (q 2 1 q26.2) or t(3;3)(q 2 1; q26.2); RPN 7 -EVI 7
- AML (megakaryoblastic) with t(1;22) (p 1 3;q 1 3); RBM 75-MKL 7
- Provisional entity AML with mutated NPM1
- Provisional entity AML with mutated CEBPA
• AML with myelodysplasia related changes
- MDS or MDS/MPD following or without antecedent MDS
• AML + MDS following therapy related (alkylating agents, topoisomerase inhibitors, other types).
• Myeloid proliferations related to Down syndrome
- Transient abnormal myelopoiesis
- Myeloid leukemia associated with Down syndrome
• Blastic plasmacytoid dendritic cell neoplasm

2. **Radiation** – Association between radiation-induced genetic damage to the haemopoietic progenitors and the development of myelodysplasia and acute leukaemia is seen after nuclear disasters (e.g. Hiroshima, Nagasaki, Chernobyl). Patients who have received radiotherapy may develop leukaemia.
3. **Chemicals and drugs** – e.g. chronic benzene exposure and use of cytotoxic and immuno-suppressive agents.
4. **Genetic (hereditary) factors** – Genetic disorders like:

Down's syndrome	Klinefelter's syn.
Bloom's syndrome	Osteogenesis imperfecta
Fanconi's anaemia	Wiskott-Aldrich syn.
Ataxia telangiectasia	Leukaemia in siblings

5. **Viruses** – The rare adult T cell leukaemia lymphoma syndrome associated with infection by the human lymphocyte virus I infection.

Clinical Features

Common symptoms and signs at presentation result from leukemic cells, bone marrow failure or organ infiltration.

Onset – Abrupt or insidious, abrupt onset common in children.

1. **Symptoms due to anaemia** – Tiredness, weakness, fatigability, marked pallor.
2. **Haemorrhagic manifestations** – Skin petechiae, bruises, bleeding from gums and nose, or persistent bleeding after tooth extraction or tonsillectomy. Gastrointestinal, renal, and bleeding into nervous system may occur. Impairment of vision from haemorrhage in eye or vertigo from haemorrhage in ear.
3. **Infections** – (a) Infective lesions of mouth and throat – Ulceration of mouth and pharynx. (b) Anal, rectal and vaginal ulceration may occur. (c) Herpes simplex infection of face. (d) Infections of respiratory tract such as bronchitis and pneumonia. (e) Of skin namely cellulitis and multiple boils.
4. **Symptoms of cellular hyperviscosity** – due to high counts of circulating blasts ($> 10 \times 10^9/\text{litre}$) – Headache, confusion, fits, focal neurological signs, coma.
5. **Tissue deposits of leukemic cells**, e.g. gum hypertrophy common in myelomonocytic and monocytic varieties of AML (Fig. 32).
6. **Lymphadenopathy and hepatosplenomegaly** – more common in ALL.
7. **Organ infiltration** – (a) **CNS** – Although meningeal involvement is uncommon at presentation, it occurs in 75% of children with ALL. Intracerebral deposits or infiltration of cranial or peripheral nerves. (b) **Skin** – Bluish nodules or dusky red patches. (c) **Kidneys** – leading to kidney failure. (d) **Other sites** – Testes, ovaries, liver, gut particularly stomach, and serous membranes such as pleura and peritoneum.
8. **Bone pains** – common; tenderness of sternum. Osteolytic bone lesions and pathological fractures may occur.
9. **Constitutional symptoms** – Fever, malaise, prostration.
10. **Roth's spots** – White-centered retinal haemorrhages in AML.
11. **Acute haemostatic failure** – In the promyelocytic (M3) variant of AML, release of cytoplasmic granular contents readily activates coagulation and fibrinolytic systems, giving rise to acute haemostatic failure.

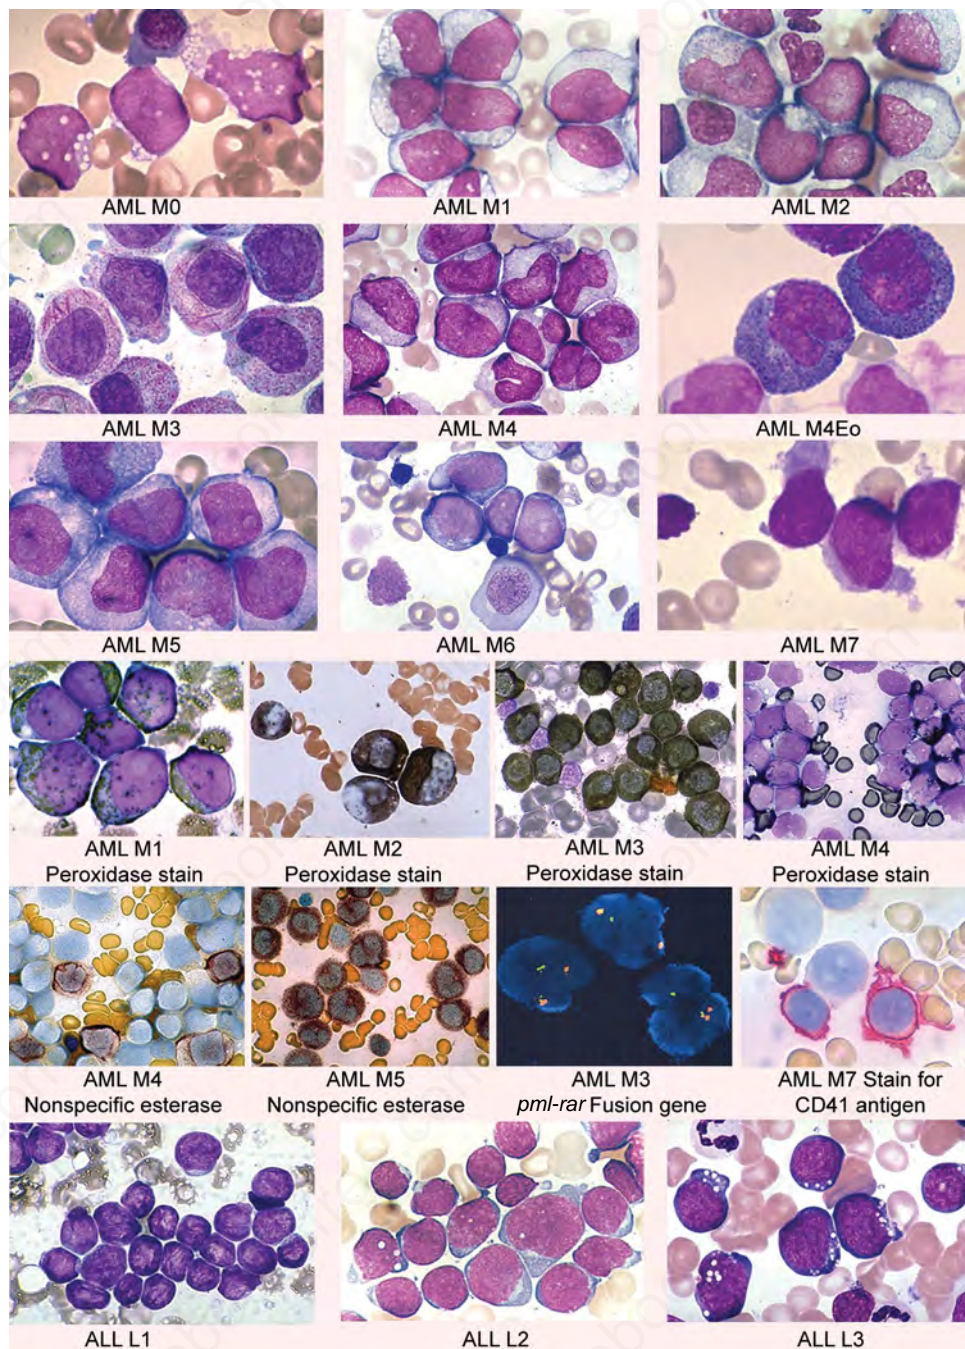

Fig. 31: Acute leukaemia (Myeloid and lymphoid)

12. *Leucostasis* is a fatal complication in granulocytic leukaemia. Some patients with acute myeloid leukaemia have hyperleukocytosis (WBC counts: $1,000,000 \text{ mm}^3$). *Leucostasis* is a clinicopathological syndrome caused by sludging of circulating leukemic blasts in tissue microvasculature. Leu-

costasis can affect any organ but symptoms usually arise from involvement of lungs, heart, brain and testes. Clinical presentation in the lung may simulate infection, embolisation and acute respiratory failure.

Table 33 gives differences between ALL and AML.

Fig. 32: Gum Hypertrophy

Fig. 33: Acute myeloblastic leukemia (peripheral blood). The myeloblast in the center of the field contains a cytoplasmic auer rod

Investigations

AML - (1) *Total white cell count* - > 500,000/cmm unless aleukaemic leukaemia. (2) *Peripheral blood film* - Increased number of typical or atypical myeloblast; Auer rods may be found in the cytoplasm. (Fig. 33) (3) *Bone marrow aspirate* - More than 30% blast cells. Marrow often entirely replaced by myeloblasts and promyelocytes. Positive Sudan black reaction.

Table 34 gives differences between Lymphoblast and Myeloblast.

ALL

1. *Total white cell count* - More than 50,000 blast cells/cmm (less than 1,000 white cells if aleukaemic leukaemia). (Fig. 34) Can present as neutropenia or pancytopenia.

Table 33: Differentiation between ALL and AML.

Features	ALL	AML
Age	Common in children	Common in adults
Bleeding at onset	Uncommon	More common
Lymphadenopathy	Common	Usually absent
Hepatosplenomegaly	Mild	Mild
Gum hypertrophy	No	Seen in M4/M5 type
CNS affection	More common	Less common
Skin infiltration	No	Seen in M4/M5
Ocular affection	More common	Less common
Testicular affection	In few	No
Blood findings		
Blast cells	Lymphoblasts smaller than myeloblasts, round or convoluted nucleus	Myeloblasts are larger with multiple nuclei
Auer rods	Not seen	Present in 10-20%
Tdt in blasts	In majority	Rare
Overall prognosis	Good	Bad

Table 34: Differentiation between lymphoblast and myeloblast.

	Lymphoblast	Myeloblast
Cell size	Small or moderate	Moderate or large
Nuclear chromatin	Coarse	Fine
Nucleoli	1-2	2-5
Auer rods	-ve	+ve
Accompanying cells	Lymphocytes	Promyelos, myelos, metas and neutrophils
Myelo peroxidase	-ve	+ve
Sudan black B	-ve	+ve
PAS stain	Black positivity	-ve in blasts

2. *Bone marrow* - Hypercellular with depression of normal erythropoiesis, granulopoiesis and thrombopoiesis. As compared to myeloblastic leukaemia the nuclei are round, the cells smaller, the nuclear/cytoplasmic ratio higher, and the number of nucleoli fewer.

Other Investigations

1. *Coagulation screening* - may give abnormal results particularly in promyelocytic leukaemia.
2. *Biochemical screening* - particularly, if leucocyte count is very high, when there may be evidence of renal impairment and hyperuricemia.

Fig. 34: Acute lymphoblastic leukemia showing numerous lymphoblasts

3. **Chest radiograph** – to exclude presence of mediastinal mass (present in upto 70% of patients with T cell ALL). In childhood acute ALL, lytic bone lesions may also be seen.
4. **Immunophenotyping** – of the antigens present on the bone marrow or peripheral blasts is the most reliable method of determining whether the leukaemia is lymphoid or myeloid, and cytochemistry helps to confirm myeloid or monocytic origin.
5. **Cytogenetic and molecular studies** – often detect abnormalities within the leukemic clone that can have diagnostic or prognostic value, e.g. the Philadelphia chromosome, which is the product of a translocation between chromosome 9 and 22, the presence of which confers very poor prognosis in ALL.
6. **Lumbar puncture** – with CSF cyrospin is an important initial staging investigation to detect leukemic cells in CSF, indicating involvement of CNS.

Differential Diagnosis

1. **The two types of leukaemias** – are clinically indistinguishable except that in ALL there is a slightly greater tendency to lymphadenopathy. The clinical features of various subtypes of AML are similar, but patients with acute monocytic or myelomonocytic leukaemia may present with swollen gums, and those with acute promyelocytic leukaemia with a severe haemorrhagic disorder due to disseminated intravascular coagulation. T-cell leukaemia is predominantly a disease of males and is often associated with presence of a mediastinal mass. Distinction between lymphoblastic and myeloblastic leukaemia may be difficult on morphological grounds.

2. **Lymphadenopathy** – Infectious mononucleosis.
3. **Hepatosplenomegaly** – Myeloproliferative or lymphoproliferative disorder, myelodysplasia, metabolic storage or autoimmune disorders, visceral leishmaniasis.

Management

1. **Chemotherapy** – At presentation the tumour load is 10-12 cells. Chemotherapy can reduce this by 3-5 logs. Hence the patient has still 10⁸ leukemic cells when the marrow examination shows complete remission. To achieve long-term cure, the patient hence needs further therapy. The initial high-dose chemotherapy in order to reduce leukemic cells to below the levels of morphologic detection is labelled *induction*. This is followed by another dose of chemotherapy to further reduce the leukemic burden – called *consolidation*. Low-dose chemotherapy administered for a period of 18 months to 2 years is described as *maintenance therapy*. High-dose chemotherapy given more than 6 months after induction is termed *late intensification* (Table 35).

Table 35: Chemotherapy for ALL and AML.

Phase	ALL	AML
Induction	Vincristine (iv)	Daunorubicin (iv)
	Dasatinib (if pH +ve ALL)	Cytosine arabinoside (iv)
	Prednisolone (po)	
	L-asparaginase (iv)	
	or Daunorubicin (iv) or Dauromycin (iv)	
CNS prophylaxis	Methotrexate (intrathecal)	
Consolidation	Daunorubicin (iv)	High dose Cytosine arabinoside (iv)
	Cytosine arabinoside (iv)	
	Etoposide (iv)	
	Methotrexate, 6-thioguanine Dexamethasone	
Maintenance	Prednisolone (po)	<i>Post-remission therapy</i>
	Vincristine (iv)	Myeloablative therapy followed by BMT in relapse or those with high risk chromosomal changes
	6-mercaptopurine (po)	
	Methotrexate (po)	

Acute promyelocytic leukemia - Tretinoin (45 mg/m² per day orally until remission is documented) plus concurrent anthracycline-based (i.e. idarubicin or daunorubicin) chemotherapy. It leads to CR rates of 90-95%. Arsenic trioxide improved outcome, if used after achievement of CR and before consolidation therapy with anthracycline based chemotherapy.

2. Bone marrow transplantation -

BMT in ALL - Allogenic BMT is an option in adult ALL patients entering first remission who have an HLA - identical sibling, provided they are reasonably fit and < 55 years.

BMT in AML - In adult AML - Because intensive chemotherapy (particularly involving high-dose cytarabine) has been shown to achieve survival rates comparable with allogenic BMT in first remission, BMT reserved for refractory cases and those with poor cytogenetics. In patients without a suitably matched donor, high-dose chemotherapy with autologous transplantation of haemopoietic stem cells derived from peripheral blood or bone marrow is an alternative treatment strategy.

3. Supportive care

(a) *Anaemia* - Hb level should not be allowed to fall below 8 g/dl by transfusing 4 units of packed RBCs. If platelet count is less than 10×10^9 /litre, platelet transfusion should precede RBC transfusion to reduce risk of haemorrhage. (b) *Bleeding* - Transfusion of pooled or single donor platelets. (c) *DIC* (Most often with acute promyelocytic leukaemia) - Fibrinogen replacement, platelet transfusion twice daily and anticoagulation. (d) *Infection* - Good nursing, isolation, prophylactic GI tract decontamination, antibiotics. Attention to fluid balance. Topical fungal infections may be prevented by giving oral fluconazole or non-absorbable amphotericin. *Pneumocystis jiroveci* pneumonia is a considerable risk during ALL maintenance therapy; low dose co-trimoxazole prophylactically throughout. Herpes simplex infection - Acyclovir 200 mg 5 times/day. Cytomegalovirus infection - Combination of ganciclovir and immunoglobulin. (e) *Hyperuricemia* - can be prevented by adequate hydration, and pretreatment with allopurinol which should be continued until peripheral blood is cleared of blast cells.

CHRONIC LEUKAEMIAS

Chronic Myeloid Leukaemia

Chronic myeloid leukaemia (CML) is a clonal disorder of a pluripotent stem cell. Normal blood cell production is almost completely replaced by leukemic cells, which how-

ever still function normally. It can occur at any age but the peak incidence is at age 40-60 years. Most cases of CML occur sporadically, the only known predisposing factor is irradiation, e.g. Japanese survivors of atomic bomb and in patients who received radiotherapy for ankylosing spondylitis.

Pathogenesis

1. BCR - ABL fusion gene in erythroid, myeloid and megakaryocyte precursors.
2. Philadelphia chromosome, it is formed as a result of reciprocal translocation of genetic material between long arm of chromosome 22 and chromosome 9.

Clinical Features

Common

1. *Non-specific* - Loss of weight, fatigue, malaise, excessive perspiration (due to increase in metabolic rate).
2. *Splenomegaly* - Size of the enlarged spleen tends to correspond to total leucocytic count.
3. *Bleeding* - Excessive menstrual or other bleeding. Bruising or purpura may occur or spontaneous hematoma.
4. *Anaemia*.
5. *Bone pain* - due to extension of haemopoiesis throughout the long bones. Sternal tenderness.

Rare

- Splenic infarction
- Leucostasis
- Gout
- Retinal haemorrhages
- Priapism
- Fever

Differential Diagnosis

1. Leukaemoid reaction

Differentiation of Leukaemoid reaction and CML

	Leukaemoid reaction	CML
Splenomegaly	No	Yes
TLC	$10-50 \times 10^9/L$	$100-500 \times 10^9/L$
Toxic granules in neutrophils	+ ve	- ve
Basophilia	- ve	+ ve
Eosinophilia	- ve	+ ve
Ph chromosome	- ve	+ ve

2. Myelofibrosis (Refer)

Investigations

Peripheral blood - WBC count - $10-500 \times 10^9$ /litre, with excess of neutrophils, myelocytes and blasts (Fig. 35). Basophilia and eosinophilia are prominent and thrombocytosis is common.

Fig. 35: Chronic granulocytic (myeloid) leukemia (peripheral blood). There is an increased number of granulocytes, most of which are mature neutrophils. A few more primitive cells are also present

Bone marrow – is hypercellular with marrow fibrosis and Gaucher like cells and the marrow or peripheral blood can be studied cytogenetically. High myeloid-to-erythroid ratio of 15-20:1.

Neutrophil alkaline phosphatase (NAP) – is low and is therefore useful in excluding reactive neutrophilia.

Serum vitamin B₁₂ – increased

Serum uric acid – increased

Cytogenic analysis – documenting *t(9;22) (q34;q11.2)* seen in 90% patients.

Clinical course – After a chronic phase of an average 2-3 years duration, the disease enters an accelerated and then a blastic phase, the leukaemia cells of which can be immunophenotype as either myeloid (about 60%) or lymphoid (about 40%) in origin.

Treatment of Ph-positive CML

Chronic phase

1. Tyrosine kinase inhibitor (TKI) therapy with Imatinib 400 mg od as first line.
2. Other 2nd generation TKI advocated in first line therapy as alternative are Bosatinib and Nilotinib.
3. Ponatinib is a third generation TKI to be used in case of resistance to first or second generation TKIs, also recommended in activated phase and blast phase.
4. Zinatinib is now used in case of very high counts.

5. Allogenic stem cell transplant with HLA matched related or unrelated donor, recommended in case of TKI intolerance, resistance or on progression to accelerated or blast phase in combination with Ponatinib.

Matched-sibling allogenic SCT – In spite of hazards, it is the only definite potentially curative treatment and should be offered to younger patients with CML who have an HLA – identical sibling.

Before transplantation, the patient undergoes a ‘conditioning regimen’ – busulphan followed by cyclophosphamide can be effective instead of cyclophosphamide followed by total body irradiation.

Relapse after allogenic BMT – The best method of treating patients who relapse is transfusion of T lymphocytes collected from the original donor by leukapheresis.

6. Omacetaxine, a protein synthesis inhibitor with presumed more selective inhibition of the synthesis of the BCR-ABL1 oncoprotein.

Advanced phase disease

Cl. Fs. – Excessive sweating, persistent fever, or otherwise unexplained symptoms of anaemia, splenic enlargement or infarction, hemorrhage or bone pain. In most cases the blast crisis is myeloid (resembling AML), and in a fifth of cases lymphoid blast crisis occurs.

Laboratory Fs. – (a) Rapid white cell doubling time. (b) WBCs poorly responsive to full doses of cytotoxic drugs. (c) Anaemia or thrombocytopenia. (d) Persistent thrombocytosis ($> 100 \times 10^9/L$). (e) > 10 blasts in peripheral blood or marrow. (f) > 20 blasts promyelocytes in blood or marrow. (g) Acquisition of ‘non-random’ chromosomal changes in addition to presence of Ph chromosome.

Management:

Lymphoid blast crisis – Treatment similar to ALL.

Myeloid crisis – Prognosis is grave and few of the drugs used in treatment of AML offer more than temporary relief.

CHRONIC LYMPHOCYTIC LEUKAEMIA

Chronic lymphocytic leukaemia (CLL) is a heterogeneous group of lymphoproliferative disorders due to accumulation of neoplastic lymphocytes in peripheral blood (Lymphocytic count $> 10 \times 10^9/L$), $> 30\%$ lymphocytes. Mature lymphocytes in blood are monoclonal β cell.

Aetiology

- a. Genetic factors – High incidence in some families.

- b. TNF- α – CLL cells produces TNF- α and TNF- β which causes proliferation of leukaemia cells and transforming growth factor respectively.
- c. IL-2 induces proliferation of CLL cells and inhibits apoptosis of these cells.

Clinical Features

- Asymptomatic – in about 25% and discovered on routine examination.
- Painless lymphadenopathy
- Infections – due to suppression of immunoglobulins – bacterial pneumonia and herpes virus infections.
- Symptoms due to bone marrow failure (anaemia, thrombocytopenia)
- Hepatosplenomegaly – in later phases of the disease
- Skin infiltration – with nodules or diffuse erythematous infiltration (homerouge).

CLL is associated with autoimmune haemolytic anaemia and/or thrombocytopenia.

Treatment can be continued with Imatinib. In case of Imatinib resistance, second generation kinase inhibitors can be used, e.g. Dazatinib, Bosutinib, Nilotinib, or newer generation Ponatinib.

Initial assessment should include:

- Complete family history of leukaemias and lymphomas
- Physical examination
- Blood cell and reticulocyte counts
- Lymphocyte morphology Immunophenotyping from bone marrow or peripheral blood
- ESR
- Renal and liver biochemistry
- Serum immunoglobulins
- Direct Coomb's test
- Bone marrow aspirate and trephine for cytogenetic study
- Chest radiography and abdominal ultrasonography and/or CT.

Other tests (e.g. lactic dehydrogenase (LDH), β_2 -microglobulin, soluble CD23 levels), serum immunoglobulin levels.

Table 36 gives staging systems in CLL.

Investigations

1. **Peripheral blood** – (a) Lymphocytosis. CLL lymphocytes are small with clumped chromatin; larger nucle-

Table 36: Staging systems in CLL.

Staging	Clinical features	Median survival, in years
Rai system		
0: Low risk	Lymphocytosis only in blood and marrow	>10
I: Intermediate risk	Lymphocytosis + Lymphadenopathy	7
II: Intermediate risk	Lymphocytosis + Lymphadenopathy + splenomegaly \pm hepatomegaly	7
III: High risk	Lymphocytosis + anemia	1.5
IV: High risk	Lymphocytosis + thrombocytopenia	1.5
Binet system		
A	Fewer than three areas of clinical lymphadenopathy; no anemia or thrombocytopenia	>10
B	Three or more involved node areas; no anemia or thrombocytopenia	7
C	Hemoglobin ≤ 10 g/dL and/or platelets $< 100000/\mu\text{L}$	2

ated cells (e.g. prolymphocytes) may be seen, but comprise less than 10% in typical CLL (Fig. 36). (b) Smudge (basket cells). Some of the lymphocytes rupture while making the peripheral smear.

The immunophenotype of CLL is unique and distinct from other B cell disorders.

2. **Liver and renal biochemistry** – are usually normal, but there may be hyperuricaemia, mildly raised serum LDH and β_2 - microglobulin, and hypogammaglobulinaemia. (Partly responsible for high incidence of infections).
3. **Bone marrow aspirate** – (a) Hypercellularity. (b) Lymphocytic infiltration; this is confirmed on trephine biopsy, which allows assessment of the pattern of infiltration. Mature lymphocytosis is a diagnostic feature. (c) In course of time, the neoplastic lymphocytes replace normal cells of erythroid, myeloid and megakaryocytic cells.
4. **Abdominal CT** – for lymphadenopathy, splenomegaly.

Transformation in CLL – (a) Richter's syndrome: Progressive splenomegaly lymphadenopathy, fever. Poor prognosis. (b) Prolymphocytic leukaemia. (c) Multiple myeloma.

Fig. 36: Showing chronic lymphocytic leukemic cells

Fig. 37: Hairy projections on lymphocytes in hairy cell leukemia

Differential Diagnosis

1. Other B cell disorders (e.g. prolymphocytic leukaemia, lymphomas in leukemic phase)
2. T cell disorders and reactive T cell lymphocytosis (caused by virus infections or post-splenectomy)
3. Polyclonal B cell lymphocytosis

Treatment

Age < 70 or older patients without sequential comorbidities

- FCR Fludarabine, Cyclophosphamide, Rituximab
- FR Fludarabine + Rituximab
- PCR Pentostatin + Cyclophosphamide + Rituximab
- BR Bendamustine + Rituximab

Age ≥ 70 or patients with comorbidities even, if younger

- Chlorambucil ± Rituximab
- BR Bendamustine + Rituximab
- Cyclophosphamide, Prednisolone + Rituximab
- Alemtuzumab
- Rituximab
- Fludarabine ± Rituximab

If with deletion (17p)

- FCR
 - FR
 - High dose methyl prednisolone + Rituximab
 - Alemtuzumab ± Rituximab
- Allogenic transplant an option for patients in CR/PR after chemotherapy.

Newer agents

- a. Anti-CD20 monoclonal antibodies of atumumab and obinutuzumab, activity in previously treated patients.
- b. Ibrutinib - an irreversible inhibitor of Bruton's tyrosine kinase, and
- c. Idelalisib - an inhibitor of phosphoinositide- 3-kinase delta.

The ideal combination and sequence of these therapies have not been defined.

HAIRY CELL LEUKAEMIA (HCL)

Hairy cell leukaemia (HCL) is an old age B cell lymphoproliferative disorder characterized by presence of hairy cells in peripheral blood, pancytopenia and splenomegaly.

Cl. Fs. (a) Wt. loss, fatigue. Fever can be presenting symptom. (b) Splenomegaly moderate to massive. (c) Easy bruising (due to thrombocytopenia) and infections. (d) Hepatomegaly in 1/3 of patients.

Investigations

1. *Blood* - (a) Pancytopenia. (b) Hairy cells or Large-cells with fine cytoplasmic processes (hair on the cell surface) (Fig. 37). E/M reveals presence of hairy processes -Microvilli and rod shaped structures (ribosomal lamellar complexes) in cytoplasm. (c) Cytochemistry - TRAP (Tartarate resistant acid phosphatase) positivity in cytoplasm is characteristic of HLL. (d) Immunophenotyping CD19, 20 and 22 positive. CD25, CD11, CD103 positivity are pathognomonic of HCL.

2. *Bone marrow* (a) Aspirate - Dry tap in majority. (b) Trephine biopsy - Honey comb appearance due to infiltration by marrow cells. Each nucleus is seen separately resembling 'fried egg' (pathognomonic of HCl).
3. *Spleen* - Leukemic infiltration of red pulp.

Treatment

- i. Cladribine - Single cycle in dose of 1 mg/m²/day infusion
- ii. If no response to cladribine, pentostatin 4 mg/m² by rapid IV injection or IV infusion in dextrose saline.
- iii. Rituximab can be added to chemotherapy for better response.

PROLYMPHOCYTIC LEUKAEMIA (PLL)

Patients present with splenomegaly without lymphadenopathy and high rapidly rising lymphocyte count. Diagnosis is confirmed by a majority of prolymphocytes (twice the size of CLL lymphocyte) with large, central nucleolus. *Treatment* - Splenectomy usually of benefit and purine nucleoside may help.

ADULT T CELL LEUKAEMIA (ATLL)

Associated with human - T lymphocyte virus. *Clinical presentation* is often acute with mediastinal mass, massive splenomegaly, high TLC and hypercalcaemia. *Diagnosis* - ATLL lymphocytes have a convoluted, 'clover-leaf' nucleus and consistent CD4⁺ phenotype. Prognosis is poor.

11. LYMPHOMAS

The lymphomas or reticulososes consist of diseases characterized by enlargement of lymph glands, splenomegaly, greater or lesser degree of constitutional disturbance and ultimately fatal outcome.

The following diseases are classified as malignant lymphomas:

1. Hodgkin lymphoma
2. Non-Hodgkin lymphoma
3. Multiple myeloma
4. Waldenstrom macroglobulinemia

CLASSIFICATION OF LYMPHOMAS

WHO classification of the mature B-cell, T-cell and NK-cell neoplasms.

Mature B-cell Neoplasms

- Chronic lymphocytic leukaemia/small lymphocytic lymphoma
- B-cell prolymphocytic leukaemia
- Splenic marginal zone lymphoma
- Hairy cell leukaemia
- Lymphoplasmocytic lymphoma b Waldenstrom's macroglobinaemia.

Plasma Cell Myeloma/Plasmacytoma

Extranodal marginal zone B-cell lymphoma of MALT type
Mantle cell lymphoma
Follicular lymphoma
Nodal marginal zone B-cell lymphoma (± monocytoid B cells)
Diffuse large B-cell lymphoma (including subtypes)
Burkitt's lymphoma/Burkitt's cell leukemia
Primary mediastinal large B-cell lymphoma
Plasmablastic lymphoma
Primary effusion lymphoma
Large B-cell lymphoma arising in HHV-8+ multicentric Castleman's disease
Intravascular large B-cell lymphoma
ALK+ large B-cell lymphoma

HODGKIN'S DISEASE

Hodgkin's disease is a clinically and histologically distinct lymphoproliferative disorder of unknown etiology. The type lymphocyte predominance is a clinically distinct B cell lymphoma often presenting with isolated enlargement of a peripheral lymph node. The nodal sclerosing type constitutes 70-80% of cases of the disease and classically presents with mediastinal and cervical node disease.

Aetiology

(a) *Age incidence* - Bimodal with peak incidence at 25 and another at 70. (b) *Sex* - More in males 1.5:1. (c) *Viruses* - Numerous serological and molecular studies have demonstrated an association between Epstein-Barr virus (EBV) infection and HD. In HD associated with EBV, the virus is localised to Reed-Sternberg cells, EBV latent gene products are expressed and the EBV infection is clonal. EBV association is strongest in children and the elderly with mixed cellularity HD, and more tenuous in young adults with nodular sclerosing HD. Lymphocyte-predominant HD is invariably negative. HIV-associated HD is invariably EBV positive and patients are more likely to be IV drug

abusers and have the mixed cellularity or lymphocyte-depletion subtype. (d) *Reproductive factors* – have a role in women. Parity is protective. (e) *Genetic factors* – Familial aggregation studies and HLA associations suggest an inherited susceptibility to HD. In young adults, almost 100-fold increase is seen in monozygotic twins, and a 7-fold increase in siblings. (f) *Other factors* – HD has occasionally been linked with certain occupations particularly exposure to wood dust. Occupational exposure to benzene and use of nitrous oxide as a dental anaesthetic are also possible risk factors.

WHO classifies Hodgkin's lymphoma as given in Table 37.

Histopathology

Most of the cells in the involved tissues are benign (95%) and Reed - Sternberg-like cells may be seen in various other reactive and malignant processes. Immunophenotyping is an important aid to diagnosis. In classical HD, scattered binucleate or multinucleated Reed-Sternberg cells and mononuclear Hodgkin's cells are seen, associated with a reactive cellular infiltrate of lymphoid cells, eosinophils and other inflammatory cells. (Fig. 38) The precise origin of Reed-Sternberg cells is unknown; they are thought to be derived from a lymphocyte lineage, though various studies report B, T or null cell characteristics.

Clinical Features

- I. **Local signs**– (a) *Lymphadenopathy* – Contiguous involvement of superficial lymph nodes in neck usually first to enlarge, at first one side, then the other. Sometimes axilla, groins, mediastinum or abdomen. Painless, leathery to feel and discrete. Characteristic appearance in advanced cases is a pyramidal swelling with its base at the clavicle and its apex at the angle of the jaw. When more than one region is involved, the areas are usually contiguous, suggesting that spread is predominantly through the lymphatics. Alcohol-induced pain in the nodes may occur but is rare. (b) *Splenomegaly* – in two-third cases, usually of moder-

ate degree, occasionally marked. (c) *Hepatomegaly* – in 50%, moderate, non-tender enlargement of liver.

Involvement in Hodgkin's is usually seen above the diaphragm. Below the diaphragm is not seen commonly.

II. Systemic symptoms

1. Cachexia and loss of weight. (10% of body weight within 6 months prior to diagnosis).
2. Fever – (i) Mild grade remittent like tuberculosis most common or (ii) Undulant type of pyrexia of several days duration interrupted by periods of remission (Pel-Ebstein) or (iii) Continued type resembling typhoid.
3. Night sweats.
4. Pruritus generalized and refractory.
5. Infection – not uncommon. Herpes zoster, tuberculosis, or fungal disease.
6. Anaemia – may be due to haemolysis, hypersplenism, ineffective erythropoiesis, and haemodilution resulting from an expanded plasma volume.

III. Due to metastatic growths or infiltrations

1. Skin – Pruritus, localized or generalized brownish eruption, erythema, herpes zoster, etc.
2. Bones – Localized pain and tenderness. Sclerotic deposits on radiography (ivory vertebrae).
3. Nervous system – Paraesthesia and pains. Diplegia or paraplegia.
4. Mediastinal pressure – Dyspnoea, cyanosis and stridor, dysphagia.
5. Respiratory tract – Laryngeal paralysis, collapse of lung, pleural effusion and bronchiectasis.

Table 37: WHO classification of Hodgkin's lymphoma.

• Nodular lymphocyte predominant Hodgkin lymphoma (<5%)
• Classic Hodgkin lymphoma (95%)
• Nodular sclerosis lymphoma
• Mixed cellularity lymphoma
• Lymphocyte-rich lymphoma
• Lymphocyte depleted lymphoma

Fig. 38: Reed-Sternberg cell

6. Gastrointestinal - Intestinal obstruction, jaundice and ascites. Malabsorption due to obstruction of lacteals.
7. Genitourinary - Hematuria, pyuria, retention of urine, pain in the back, a mass in the flanks or symptoms suggestive of disease of prostate or testis.

IV. **Due to immunologic changes**- (a) Lowering of resistance to infection. (b) Haemolytic anaemia.

Staging - Provides information of prognostic significance and selection of appropriate therapy:

Stage I: Involvement of single LN region or localized involvement of a single extralymphatic organ or site (IE).

Stage II: Involvement of 2 or more LN regions on same side of diaphragm (II) or localized involvement of a single associated extralymphatic organ or site or its regional LN with or without involvement of other LN regions on same side of diaphragm (IE). Number of LNs involved may be indicated by a subscript (e.g. II₃).

Stage III: Involvement LN regions on both sides of diaphragm (III) which may also be accompanied by localized involvement of an associated extralymphatic organ or site (IIIE), by involvement of spleen (IIIC) or both (IIIE,S).

Stage IV: Disseminated (multifocal) involvement of one or more extralymphatic organs with or without associated LN involvement, or isolated extralymphatic organ involvement with distal (non-regional) nodal involvement.

Suffixes are added to the anatomical stage

- A No systemic symptoms
- B Systemic symptoms - Unexplained fever $>37^{\circ}\text{C}$, weight loss

Fig. 39: Hodgkin's lymphoma. Masses of enlarged lymph nodes in the mediastinum. For causes of bilateral hilar enlargement (See chapter 16)

- E Involvement of a single extranodal site, contiguous or proximal to known nodal site
- X Bulky disease (>10 cm mediastinal mass)

Investigations

1. Laboratory investigations: (a) FBC: Nonspecific anaemia of chronic disease common, and lymphopenia (particularly of CD4 T cells). Eosinophilia in about 15%. (b) ESR commonly elevated and with LDH is a useful indicator of disease activity.
2. Lymph node biopsy: Excision biopsy is required where the entire LN removed and sent for analysis. It shows characteristic histology - (a) Presence of Reed-Sternberg cells (absence does not rule out Hodgkin's disease). (b) Pleomorphic pattern of cell types - lymphocytes, eosinophils and stroma which destroys normal architecture of the gland.
3. Imaging: (a) *Plain chest radiograph* [Fig. 5.12 (Fig. 39)]. (b) *PET - CT* is the most important baseline investigation for staging purposes, and to determine precise extent of disease. It can also detect presence or absence of bone marrow involvement after chemotherapy.
4. Bone marrow: Aspiration biopsy indicated in stage II disease and higher staging.

Differential Diagnosis: See differential diagnosis of lymphadenopathies.

Table 38 gives differences between Hodgkin's disease and non-Hodgkin's lymphoma.

Management

1. **Early-stage disease** - Brief chemotherapy followed by involved field irradiation is the best choice for non-bulky clinical stage IA and IIA HD. IFRT is given to all sites of bulky disease post ABVD. Minimizing both chemotherapy and radiotherapy should reduce the risk of infertility, premature menopause, cardiovascular disease and second neoplasms.

Table 38: Differences between Hodgkin's disease and non-Hodgkin's lymphoma.

	<i>Hodgkin's disease</i>	<i>Non-Hodgkin's lymphoma</i>
Incidence	Stable	Increasing
Age	Median 29 years	Increasing
		Incidence with age
Sites	Nodal; supra-diaphragmatic	Nodal or extranodal; any site
Cl. Fs.	Mediastinal mass, itching, alcohol-induced pain	Nil specific
Prognosis	70-80% cure	Highly variable by type; most incurable

Table 39: ABVD combination.

Drug	Dosage
Adriamycin (Doxorubicin)	25 mg/m ² IV days 1 and 15
Bleomycin	10 unit/m ² IV days 1 and 15
Vinblastin	6 g/m ² IV days 1 and 15
Dacarbazine	375 mg/m ² IV days 1 and 15

2. **Advanced-stage disease** – is treated with combination chemotherapy. ABVD (Table 39) has replaced MOPP (risk of leukemia with this regimen) as the standard regimen. ABVD has less long-term toxicity (including sterility and second malignancy), though other toxicities (e.g. pulmonary fibrosis, cardiomyopathy) may occur, particularly when ABVD is given with radiotherapy.

However, combined modality therapy is considered standard treatment in patients with bulky mediastinal HD followed by involved field radiotherapy (IFRT).

Give 12 cycles with 2 week's rest between the end of one course and beginning of next (1 course = 2 cycles).

Disadvantages: Acute toxicity, febrile neutropenia and potential long-term side-effects (infertility pulmonary fibrosis and second malignancy, including AML).

Advantage: Better overall response rates and less likely to cause sterility.

Alternating MOPP with ABVD gives very good response.

Immunotoxin, brentuximab vedotin, that selectively targets cells expressing CD30 can be combined with ABVD regimen.

Therapy for relapse: High-dose therapy and autologous stem cell transplantation is standard treatment for HD in first or subsequent post-chemotherapy relapse.

Long-term Complications and Treatment

- About 30% men are infertile at presentation, but sperm banking should be considered even in those with low sperm count before systemic chemotherapy is given.
- Amenorrhoea develops in about 25-75% of young females.
- Mantle irradiation can cause acute radiation pneumonitis and chronic lung damage.
- About one-sixth of patients cured of HD develop a second malignancy within 15 years of treatment, such as AML, NHL and solid tumors often within the radiation field (lung, breast).

NON-HODGKIN'S LYMPHOMA (NHL)

NHL is a heterogenous group of malignant diseases characterized by replacement of normal lymphoid structure by diffuse and nodular collections of abnormal lymphocytes.

Classification of Non-Hodgkin Lymphoma (NHL)

Mature T-cell and NK-cell Neoplasms

- T-cell prolymphocytic leukaemia
- T-cell large granular lymphocytic leukaemia
- b Chronic lymphoproliferative disorder of NK-cells
- Aggressive NK cell leukaemia
 - Systemic EBV positive T-cell lymphoproliferative disorder of childhood
 - Hydroa vacciniforme-like lymphoma
 - Adult T-cell leukemia. lymphoma
- Extranodal NK/T-cell lymphoma, nasal type
- Enteropathy-associated T-cell lymphoma
- Hepatosplenic T-cell lymphoma, subcutaneous panniculitis-like T-cell lymphoma
- Mycosis fungoides
 - Sezary syndrome
 - Primary cutaneous CD30 positive T-cell lymphoproliferative disorders b Lymphomatoid papulosis b Primary cutaneous anaplastic large cell lymphoma
- Primary cutaneous gamma-delta T-cell lymphoma
 - Primary cutaneous CD8 positive aggressive epidermotropic
 - Cytotoxic T-cell lymphoma
 - Primary cutaneous CD4 positive small/medium T-cell lymphoma
 - Peripheral T-cell lymphoma, NOS
 - Angioimmunoblastic T-cell lymphoma
- Anaplastic large-cell lymphoma, ALK positive
 - Anaplastic large-cell lymphoma, ALK negative

Aetiology – in most cases is unknown.

Predisposing Factors

1. **Infections**
 - Bacterial (e.g. *H. pylori*)
 - Viral (e.g. human T cell lymphocytic virus 1, E-B virus), hepatitis C infection.
2. Immunodeficiency
 - Immunosuppressive therapy (post-transplantation)
 - HIV infection
3. Autoimmune disorders
4. Ionizing irradiation
5. Carcinogenic chemicals
6. Inherited disorders
 - Ataxia telangiectasia
 - Xeroderma pigmentosum

- Bloom's syndrome
- Fanconi's syndrome
- Immunodeficiencies (e.g. Wiskott-Aldrich syndrome)

Clinical Features

- *Painless lymphadenopathy* – often widespread and not necessarily contiguous
- *Constitutional (B) symptoms* – fever, sweats, anorexia, weight loss
- *Respiratory symptoms* – from pleural effusion, mediastinal node enlargement or parenchymal lung involvement
- *Involvement of other sites* – (a) Skin – Sezary's syndrome/mycosis fungoides. (b) Tonsils and adenoids. (c) Salivary glands. (d) Gastrointestinal tract. (e) CNS – HIV- related and lymphoblastic. (f) Jaw – Burkitt's lymphoma and (g) Testis.

Investigations

Laboratory Features

Haematology – The following may be observed, particularly in more advanced disease:

- Normochromic, normocytic anaemia
- Leucoerythroblastic anaemia (bone marrow infiltration)
- Hypersplenism
- Neutropenia and thrombocytopenia
- Autoimmune cytopenias (direct antiglobulin test positive)
- Circulating lymphoma cells (follicular, mantle cell and large cell lymphomas)
- Raised ESR/C-reactive protein. Raised LDH, LDH correlates with disease load.

Biochemistry

- Raised LDH and hypoalbuminemia (Features of advanced disease and of prognostic significance)
- Paraproteins (IgM, IgG or IgA) more common in indolent lymphomas
- β_2 -microglobulin may be elevated especially in myeloma
- Normal immunoglobulins reduced
- Hypercalcemia often seen in ATLL and myeloma
- Abnormalities of liver or kidney function may reflect involvement with disease

Immunohistochemistry: Detection of immunological markers, which may be performed on circulating lymphoma cells or on fixed tissue sections from lymph nodes or other sites is essential for diagnosis and classification.

Molecular biology: Clonality of tumours may be demonstrated using Southern blot or polymerase chain reaction analysis to detect immunoglobulin and T cell receptor gene arrangements. Specific translocations have been identified in certain NHL subtypes and can be helpful in diagnosis.

Diagnosis and Staging

Diagnosis – is based on history, examination and histology. The morphological, immunological and cytogenetic characteristics of histological material obtained from excision biopsy of lymph node or extranodal tumour help in determining the type of NHL.

- PET- CT first line most important investigation can detect bone marrow involvement
- Bone marrow aspirate and trephine biopsy
- Examination of oropharynx (Waldeyer's ring), particularly in primary gastrointestinal NHL
- Lumbar puncture in high-grade lymphoma
- Liver biopsy, MRI as indicated

Staging – is essentially same as for Hodgkin's disease.

Differential diagnosis is usually from other causes of lymphadenopathy

1. Hodgkin's lymphoma
2. Infection – Tuberculosis, EBV, cytomegalovirus, HIV, toxoplasma, histoplasmosis
3. Autoimmune disease – RA, SLE
4. Sarcoidosis
5. Carcinoma
6. Leukaemia

Treatment

Low grade lymphoma

'Watch and wait' policy until there are indications for active treatment:

- B symptoms. Organ involvement compromising its function
- Bone marrow failure
- Bulky disease
- Disease progression.

Treatment given with R-CHOP (Table 40) in B-cell NHL and CHOP alone in T-cell NHL (commonly but other regimens can be used depending on type of lymphoma).

Response depends on type of lymphoma

R: Bendamustine used in Follicular + Mantle cell NHL

FCR: Fludarabine, Cyclophosphamide, Rituximab

Table 40: R-CHOP regimen.

- Rituximab 375 mg/m²/day
- Cyclophosphamide 750 mg/m²/day
- Adriamycin 50 mg/m²/day
- Vincristine 1.4 mg/m²/day (Max. 2 mg)
- Prednisolone 100 mg/m² × 5 days
Given every 21 days × 6 cycles.

Intermediate-grade

Stage I disease – (Follicular NHL only) can be controlled by radiotherapy alone in upto 80% of patients. Addition of chemotherapy for patients with poor prognostic factors (e.g. bulky disease, B symptoms, raised LDH).

Stage II-IV disease – Combination chemotherapy such as R-CHOP which has the advantage of being relatively well tolerated and easily administered.

The outlook is poor in those in whom initial therapy fails because of resistance or relapse. Salvage therapy with autologous bone marrow transplantation is successful only in patients who remain sensitive to cytotoxic drugs, and is superior to conventional dose chemotherapy.

High-grade Lymphoma

CNS-directed prophylactic therapy (i.e. systemic high dose and/or intrathecal methotrexate) is required because of the high risk of CNS disease.

ALL regimens are generally used. In poor-risk patients, high-dose therapy and bone marrow transplantation during first remission.

Rituximab (Anti-CD20 monoclonal antibody).

3 weekly in combination with chemotherapy in a dose of 375 mg/m² in 500 ml normal saline after premedication (oral paracetamol with steroid and antihistamines). The infusion is started at 5 mg/hr for first one hour. If no reaction, infusion rate is increased so as to complete it over 3-4 hours.

Use of Rituximab is recommended in all lymphomas with CD20 +ve.

Extranodal lymphomas – occur in about 25% of patients.

(a) Gastric MALT lymphoma may respond to anti-*Helicobacter* therapy alone. (b) Monocytoid B cell lymphoma often arises in the salivary glands and is associated with Sjogren's syndrome. (c) Cutaneous T cell lymphoma responds to skin-directed therapy such as psoralen, ultraviolet A therapy, electron beam therapy and photophoresis.

Table 41 summarizes chemotherapy regimens in non-Hodgkin's lymphoma.

Table 41: Chemotherapy regimens in non-Hodgkin's lymphoma.

Single agents	Dose/Route/Days
Cyclophosphamide (every 1-2 wks)	500 mg/m ² po/iv 1
Fludarabine (4 wkly)	25 mg/m ² iv 1-5
Combination therapy	
<i>CHOP (3 wkly)</i>	
• Cyclophosphamide	750 mg/m ² iv 1
• Doxorubicin	50 mg/m ² iv 1
• Vincristine	1.4 mg/m ² (max. 2 mg) iv 1
• Prednisolone	10 mg po 1-5
<i>CVP (3 wkly) (in elderly pts.)</i>	
Cyclophosphamide	720 mg/m ² iv 1
Vincristine	1.4 mg/m ² (max 2 mg)
Prednisolone	100 mg po 1-5
<i>FMD</i>	
• Fludarabine	25 mg/m ² iv 1-3
• Mitoxantrone	10 mg/m ² iv 1
• Dexamethasone	20 mg/m ² po/iv 1-5
<i>PMITCEBO (continuous)</i>	
• Mitoxantrone	7 mg/m ² iv 1
• Cyclophosphamide	300 mg/m ² iv 1
• Etoposide	150 mg/m ² iv 1
• Vincristine	1.4 mg/m ² (max. 2 mg) iv 8
• Bleomycin	10 mg/m ² iv 8

Supportive care – Patients must be warned about possible side-effects of treatment. In the short-term, these include nausea, hair loss, bone marrow suppression, mucositis and tumour lysis syndrome. Patients may require antiemetics, infection prophylaxis and transfusion support. Initiation of chemotherapy in patients with high tumour load can result in rapid cell lysis, which may lead to metabolic disturbances. This can be largely avoided by adequate hydration (4 litres/day), allopurinol 300 mg od, and alkalization may be necessary. Infections should be treated with iv antibiotics. Folinic acid is given to reduce toxicity of high dose methotrexate. Growth factors to accelerate neutrophil recovery.

MULTIPLE MYELOMA

Multiple myeloma (MM) is a malignant disease of plasma cells in the bone marrow. It is characterized by excess production of a monoclonal immunoglobulin molecule, which can be detected in the serum, urine or both, and is

often associated with bone pain, anaemia and kidney failure, hypercalcaemia.

The incidence increases with age, most patients are over age of 60 years. The cause is unknown in most patients, though exposure to radiation is known to increase the risk.

PATHOGENESIS

For unknown reasons, one clone of plasma cells overgrows and produces one particular immunoglobulin molecule (a monoclonal immunoglobulin or paraprotein).

1. **Proliferation** of plasmoblasts plasma cells.
 2. **IL-6** – plays an important role in proliferation of plasma cells and also lytic lesions of bones. It is also responsible for anaemia due to inhibition of erythropoiesis.
 3. **Kaposi sarcoma associated herpes virus (KSHV)** in dendritic cells secrete IL-6.
 4. **Pre-existing MGUS** (monoclonal gammopathy of uncertain significance) predisposes to development of MM.
 5. **Chronic exposure to low dose irradiation**, e.g. in workers of nuclear power plants, uranium mines.
 - In 80% of patients, there is a paraprotein in the serum, usually of the IgG or IgA class. The abnormal cells may also produce free light chains, small enough to cross the glomerulus, and pass into the urine as Bence-Jones protein, often causing tubular damage.
 - In 20% of patients, free light chains are only produced (Bence-Jones-only myeloma) and there is no paraprotein in the serum (free light chain disease). Non-secretory myelomas are now known to consist of excess free light chain disease and are usually seen in elderly patients. Commonly diagnosed when a patient suddenly develops ARF or is detected with unexplained rise in serum creatinine. Also can be detected when a patient has reduced Hb with no obvious cause.
- destruction is activation of osteoclasts by cytokines (e.g. tumour necrosis factor TNF) produced by malignant plasma cells; the osteoclasts secrete interleukin-6 (IL-6), a growth factor for plasma cells.
2. **Anaemia** is a common presenting feature.
 3. **Kidney failure.** It is most commonly caused by Bence-Jones protein, which damages the tubules as it passes through the kidneys. Other factors that can cause or contribute to renal failure include hypercalcaemia, infection, and dehydration.
 4. **Infections** – due to impaired humoral and cell-mediated immunity leading to increased susceptibility to bacterial and virus infection. Chest infections common.
 5. **Neurologic** – Spinal cord/root compression.
 6. **Due to M-proteins**
 - Cryoglobulinemia
 - Hyperviscosity affects CNS, retina, CVS
 - Bleeding tendency - due to adhesion and aggregation of platelets
 - Coagulation cascade affection from formation of complexes with factors V, VII, VIII, I, II.
 7. **Amyloidosis.** About 10% of patients develop primary (AL) amyloidosis. The kidney is usually affected; deposition of amyloid in the glomeruli leads to generalized proteinuria and nephrotic syndrome. Peripheral neuropathy (particularly carpal tunnel syndrome) and CHF may occur.
 8. **Metabolic disturbances** If ARF – hypernatremia, hyperphosphatemia
 9. **Constitutional symptoms**
 - Weight loss
 - Fever
 - Malaise
 10. **Asymptomatic patients.** Diagnosis following finding of raised ESR or abnormal protein electrophoresis on routine screening or investigation for an unrelated problem.

CLINICAL FEATURES AND COMPLICATIONS

1. Bone disease

- Bone pain is the most common presenting symptom
- Pathological fractures
- Generalized osteoporosis may lead to compression fractures of vertebrae causing back pain and occasionally cord compression. The cause of bone

Investigations

1. Blood

- Reduced Hb. TLC and PLT usually normal
- Rouleaux formation due to increased globulins
- Serum B₁₂ microglobulin is useful prognostic marker and is usually raised
- Hypercalcemia
- Kidney function tests – Raised serum urea, creatinine, uric acid and potassium

2. Bone marrow (Fig. 40)

- Increased number of myeloma cells >10% diagnostic. M0yeloma cell is large in size with round to oval eccentric nucleus and pale blue cytoplasm. But may be normal as bone marrow investigation is usually patchy. Bone marrow biopsy is difficult due to extremely soft and spongy nature of the bones.
- Some cases show “flame cells” with peripheral cytoplasm sowing flare, “grape cells” showing rounded immunoglobulin inclusions, and “Russel bodies” in the cytoplasm.

3. Skeletal survey with X-rays of long bones, skull (Fig. 41), vertebrae (Fig. 42).

Fig. 40: Plasma cells, in bone marrow in multiple myeloma. Note: The plasma cells (arrows)

Fig. 41: X-ray skull showing multiple lytic lesions suggestive of multiple myeloma

4. Serum and urine protein electrophoresis.

5. Serum immunofix and free light chain ratio.

6. 24-hour urine for immunofixation.

7. Bence-Jones protein in urine.

Smouldering syndrome – (a) ‘M’ proteins in serum >30 g/L and/or BM plasma cells >10%. (b) No related organ impairment, no tissue lesion.

Active myeloma requires one or more of the following:

Calcium >11.5 g/dl

Creatinine >2 mg/dl

Anaemia <10 g/dl or 2 g/dl < normal.

Diagnostic criteria for multiple myeloma are listed in Table 42.

Diagnosis of myeloma requires minimum of one major and one minor criteria that must include 1+2.

Fig. 42: Multiple Myeloma Spine

Table 42: Diagnostic criteria for multiple myeloma.

Major criteria	Minor criteria
1. Plasmacytoma on tissue biopsy	1. Bone marrow plasmolysis with 10-30% plasma cells
2. Bone marrow plasmacytosis with > 30% plasma cells	2. Monoclonal spike present, but less than levels defined
3. Monoclonal globulin spike on serum electrophoresis: IgG > 35%, IgA > 20 g/L. Light chain excretion on urine electrophoresis 1 g/24 hrs in absence of amyloidosis	3. Lytic bone lesions
	4. Normal IgM < 500 mg/L IgA < 1g/L or IgG < 6 g/L

Diagnosis of myeloma requires minimum of one major and one minor criteria that must include 1+2

Differential Diagnosis

- Cirrhosis, TB, AILD (angioimmunoblastic lymphadenopathy with dysproteinemia)
- MGUS (monoclonal gammopathy of uncertain significance)
- Waldenstrom's macroglobulinemia

Management

1. Immunomodulation – with drugs like Pomalidomide, lenalidomide. Thalidomide is now used usually in combination with Bortezomib, and Dexamethasone.
2. Proteasome inhibitors – Bortezomib (first generation), Carfilzomib (second generation). Lenalidomide 25 mg/day in patients with newly diagnosed MM is highly effective.

Recommended combinations

- Bortezomib + Lenalidomide + Dexamethasone or Bortezomib + Thalidomide + Dexamethasone
- Other drugs used in combination

Melphalan, Liposononabid, Doxorubicin + Cyclophosphamide

3. Autologous transplant – For second line therapy in refractory case. Can be used as alternative to above agents with similar results.
4. Bisphosphonates – Used monthly as part of all treatment regimes in myeloma patients.
5. Autologous BM transplantation carries a low risk and is suitable for patients upto 65 years of age. Duration of remission and survival appear to be prolonged compared with conventional chemotherapy.
6. Stem cell transplantation – Peripheral blood cell (PBSC) accelerate myelopoiesis.

With the new drugs available, transplant can now be used as a salvage therapy, as survival rates are equivalent.

Supportive Treatment and Treatment of Complications

Bone disease – (a) Localized radiation is used to treat painful bony lesions, pathological fractures and myelomatous tumors that impinge upon vital structures. (b) Bisphosphonates inhibit osteoclastic activity. Zoledronic acid given in a dose of 90 mg by 4 hour. iv infusion every 4 weeks. With this the incidence of pain, analgesic usage, skeletal events become significantly less.

Renal failure – can often be prevented by high fluid intake, correcting dehydration and treating hypercalcaemia. Patients with established renal failure may need dialysis. Early initiation of this may improve the likelihood of recovery of renal function.

Anaemia – usually improves when the disease responds to treatment. Blood transfusions may be needed, if anaemia is severe.

Infection – should be treated promptly and vigorously. Patients should be given influenza vaccine annually.

Prognostic Factors

- Tumour load – (a) Myeloma staging of tumour burden. (b) Serum microglobulin levels. Higher levels bad prognosis. (c) Other factors for poor prognosis – (i) Serum creatinine levels. (ii) Morphology of plasma cells. (iii) Diffuse plasma cell infiltrate in BM trephine biopsy.

Related Disorders

Localized plasmocytoma – Collection of plasma cells at single site. Usually part of generalised myeloma but isolated tumors can occur, most often in upper air passages and less likely to disseminate than those in the bone.

Benign paraproteinemia and indolent myeloma – Paraprotein concentration is less than 30 g/L and bone marrow contains less than 5% plasma cells. Some cases of benign monoclonal gammopathy may progress to multiple myeloma.

Plasma cell leukaemia – In peripheral blood more than 2×10^9 plasma cells/litre can occur at presentation, or in terminal phases of multiple myeloma. Associated with aggressive clinical course, soft tissue deposits and marrow failure.

Waldenstrom's macroglobulinemia – A rare disease low grade lymphoplasmocytic lymphoma occurring in the elderly, an IgM paraprotein is responsible for the disease, which in some cases leads to hyperviscosity syndrome causing impairment of retinal and cerebrovascular blood flow. *Cl. Fs.* (a) Pallor. (b) Mucosal bleeding. (c) Lymphadenopathy. (d) Hepatosplenomegaly. (e) Raynaud's phenomenon. (f) Diffuse osteoporosis.

Management – (a) Combination chemotherapy- Bendamustine and Bortezomib; Rituximab can be added to this combination (b) Plasmapheresis, if hyperviscosity syndrome.

Heavy chain disease (HCD) – Rare B cell proliferation in which there is secretion of heavy chains uncoupled with light chains. γ -chain disease starts with diffuse infiltration of the gut and may evolve into gut associated lymphoma. Palatal oedema can cause dyspnoea. There is lymphadenopathy, fever, anaemia M component is < 20 g/L. Rapidly progressive.

Cryoglobulinemia– Cryoglobulins are immunoglobulins which precipitate when cooled. Their presence may give rise clinically to Raynaud's phenomena, acrocyanosis, arthralgia, purpura and in severe cases isolated neurological lesions, kidney failure and hepatic failure.

POEMS syndrome– Rare variety of multiple myeloma consisting of polyneuropathy, organomegaly, endocrine disorders, monoclonal proteins and skin changes. Prednisolone 25-60 mg/m² BSA/day may be added in older patients but should be discontinued as soon as remission is achieved (50% reduction in paraproteins).

HAEMOPHAGOCYTIC LYMPHOCYTOSIS

HLH is a rare but potentially life-threatening condition characterized by uncontrolled activation of macrophages and lymphocytes. Paediatric age group is most commonly affected but it can occur at any age. It is not a single disease and can be encountered with a variety of underlying diseases (Table 43).

The pathological hallmark of the syndrome is excessive proliferation of macrophages and histiocytes which phagocytise other blood cells leading to the clinical symptoms (Fig. 43).

Clinical picture of HLH can be induced by a number of infectious organisms - viruses, (EBV, HIV, human herpes virus 8), mycobacteria and fungi. Most commonly associated malignancy is lymphoma. HLH has also been described in association with inborn error of metabolism like Lysinuric Protein Intolerance (LPI).

Table 43: Classification of haemophagocytic lymphocytosis.

1. <i>Inherited</i>
• Known genetic defects (perforin, syntaxin 11)
• Unknown genetic defects
• Immune deficiency syndrome
• Chediak Higashi syndrome
• X-linked lymphoproliferative syndrome
2. <i>Acquired</i>
• Exogenous agents (infectious organisms, toxins)
• Infection - Associated Haemophagocytic syn.
• Endogenous
– Rheumatic diseases
– Macrophage activation syndrome

12. BLOOD TRANSFUSION

INDICATIONS FOR THE USE OF BLOOD AND BLOOD PRODUCTS

Whole Blood Packed RBCs

1. *Acute blood loss*
 - > 20% of blood volume loss – trauma, surgery, GI bleeding
2. *Treatment of symptomatic anaemia*
 - Investigate cause and treat appropriately.
 - Symptoms should be the guide not haematocrit
3. *Bone marrow failure*
 - Caused by bone marrow disease
 - During chemotherapy and/or radiotherapy, including bone marrow transplantation
4. *Thalassaemia*
 - Other inherited transfusion-dependent anaemia
5. *Exchange transfusion*
 - Neonates with haemolytic disease of the newborn
 - Adults with sickle cell disease
 - Severe falciparum malaria

In an average adult, 1 unit of whole blood or 1 unit of RBCs (250-300 ml) raises Hb by 1g.

Fresh Frozen Plasma

1. *Acquired coagulation defects*
 - With clinical evidence of bleeding
- Massive blood transfusion

Fig. 43: Hemophagocytosis-of-neutrophil by macrophage. Note the engulfed neutrophil (arrow)

Advanced liver failure
Disseminated intravascular coagulation
Patients on oral anticoagulants

- Need for emergency invasive procedure when other interventions are too slow or ineffective
2. *Plasma exchange*
 - Thrombotic thrombocytopenic purpura
 3. *Inherited coagulation defects*
 - If no specific coagulation factor concentrate

Platelets

1. *Therapeutic transfusion in patients who are bleeding*
 - Platelet count $< 10 \times 10^9$ /litre
 - Following massive transfusion with dilutional thrombocytopenia
 - Diffuse intravascular bleeding (correction of any coagulopathy)
 - Platelet dysfunction caused by drugs (aspirin) or congenital platelet disorders
2. *Prophylactic transfusion in thrombocytopenia*
 - Acquired bone marrow failure caused by bone marrow disease or chemotherapy/radiotherapy.
Transfusion, if platelets $< 10 \times 10^9$ litre (or $< 20 \times 10^9$ /litre if other risk factors)
 - To cover surgery in thrombocytopenic patients
Major surgery (complex cardiac surgery, liver transplantation) $> 80 \times 10^9$ /litre
Other invasive procedures $> 50 \times 10^9$ /litre
1 unit of platelets (1 pool) is the dose for an average adult

Cryoprecipitate

1. *Acquired coagulation defects*
 - With clinical evidence of bleeding
 - Low fibrinogen may be useful guide:
 - Usually follows use of fresh frozen plasma
 - Massive blood transfusion
 - Disseminated intravascular coagulation
 - Advanced liver failure
2. *Chronic kidney failure*
Helps control bleeding
3. *Inherited platelet function disorders*
Helps control bleeding, if bleeding time is prolonged
4. *Inherited coagulation defects*
 - If no specific coagulation factor concentrate
An adult dose is 10-20 donor units

Table 44 summarizes of indications for use of blood components.

COMPLICATIONS OF BLOOD TRANSFUSION

1. *Haemolytic reactions*: Due to ABO incompatibility with destruction of donor cells
 - a. Immediate (Serious) – Fever with chills, backache, breathlessness, tachycardia and hypotension.
 - b. Delayed (Mild) – 2 to 4 weeks later with fever, icterus and anaemia.
2. *Infections*
 - HIV can be transmitted by both plasma and cells
 - Hepatitis B and C (now rare because of proper screening)
 - Malaria
 - Yersinia and pseudomonas
 - Cytomegalovirus infection
 - Chagas' disease
 - Babesiosis
3. *Febrile reaction* – Onset of fever within $\frac{1}{2}$ - 1 hr due to sensitization due to white cell antigens.
4. *Allergic reaction* manifests as urticaria, bronchospasm and rarely anaphylaxis.
5. *Circulatory overload* may result in acute pulmonary oedema in elderly and in pregnancy.
6. *Transfusion siderosis* (iron overload) can occur in thalassemia, aplastic anaemia and pure red cell aplasia. Iron is deposited in spleen, liver, heart, bone marrow.
7. *Physical effects of transfusion*
 - Thrombophlebitis is common in cases with indwelling catheters
 - Air embolism is now rare because of plastic bags and closed tubing system

Table 44: Summary of indications for use of blood components.

Component	Indications
1. Whole blood	<ul style="list-style-type: none"> • Acute hemorrhage • Exchange transfusion
2. Red cells (PCV 70%)	<ul style="list-style-type: none"> • Severe anaemia
3. Platelets in plasma $< 10,000$	<ul style="list-style-type: none"> • Thrombocytopenia
4. Fresh plasma 200-300 ml	<ul style="list-style-type: none"> • DIC and multiple factor deficiencies
5. Cryoprecipitate	<ul style="list-style-type: none"> • Burns
5-15 ml containing 100U FVIII and 200 mg fibrinogen	<ul style="list-style-type: none"> • Haemophilia • Fibrinogen deficiency • Von Willebrand's disease

8. *Transfusion associated Graft versus Host disease* – In an immunocompromised patient, mature T cells act as immunocompetent cells in the graft and mount GVHD in an immunocompromised host.
9. Transfusion related acute lung injury (TRALI)– Patient develops non cardiogenic pulmonary oedema with bilateral chest infiltrate on X-ray and hypoxia during or within 6 hours of transfusion.

Plasmapheresis – is a procedure used to reduce plasma concentration of proteins, lipids, protein-bound hormones or toxins, antigens, antibodies or immune complexes. *Indications* – Symptomatic hyperviscosity syndrome main indication. Also myasthenia gravis (selected cases), thrombotic thrombocytopenic purpura, Goodpasture's syndrome, immune-complex mediated vasculitis. One to two plasma volumes can be exchanged in 1-3 hours.

13. ANTIPLATELET DRUG THERAPY

Platelet activation and aggregation play the central role in the normal haemostasis and disorders of thromboembolism. The mass aggregation of platelets form plugs, which, together with vessel constriction, maintains haemostasis in small vessels until the platelet plug is reinforced by fibrin.

An important aspect of platelet function and contribution to thrombus formation is their interaction with vascular endothelium. Injury to endothelium leads to adhering of platelets to subendothelial collagen and their activation. Platelets also release thromboxane, prostaglandin (PG) G_2 and H_2 and ADP which act as mediators to activate the platelets. Table 45 summarizes antiplatelet agents.

Table 45: Antiplatelet drugs.

Drug	Dose	Mode of action	Comments / Adverse-effects
Aspirin	75-325 mg/d	Inhibition of platelet prostaglandin synthesis Unopposed action of prostacyclin	Upper GI disturbances, increased risk of haemorrhagic strokes
Ticlopidine	250 mg bd	Inhibition of ADP-mediated platelet activation and release of platelet granule constituents and prolongation of bleeding time	Bone marrow depression Monitoring essential for first 12 weeks. Superior to aspirin for chronic peripheral arterial disease
Clopidogrel	75 mg od	Blocking of P2 TAC receptors on platelets	No adverse effects of ticlopidine, more rapid onset of action.
Dipyridamole	50 mg tds before food	Phosphodiesterase inhibitor. Also inhibits uptake of adenosine	Postural hypotension, headache, dizziness, nausea. More effective, if combined with aspirin or warfarin for prophylaxis in pts. with prosthetic heart valves
GPIIb/IIIa antagonists Abciximab	0.25 mg/kg bolus iv followed by 0.0125 µg/min (max 10 µg/min) infusion for 12 hrs	Decrease thrombus formation and risk of vaso-occlusion at the site of PCI	Increased risk of mucocutaneous and procedure related bleeding. Thrombocytopenia
Eptifibatide	180 µg/kg iv bolus x 2 10 min apart, followed by 2 mg/kg/min infusion for 18-24 hrs.	Can be give intracoronary safely and effectively for reduction of infarct size in MI	
Prasugrel	5-10 mg/d	Action similar to Clopidogrel	
Ticagrelor	90 mg/bd	Not a prodrug Faster onset of action	Causes stronger platelet inhibition Reversible, which may be an advantage in reducing bleeding
Cangreolar	IV bolus of 30 µg/kg followed by an infusion of 4 µg/kg/min for at least 2 hrs	Reversible inhibitor of P2Y12	No serious bleeding effect
Vorapaxar	—	Orally active inhibitor of protease-activated receptor 1 (PAR- 1)	Increased intracranial bleeding

14. THE SPLEEN

FUNCTIONS OF THE SPLEEN

1. *Phagocytosis and sequestration* – Effect or damaged cells, antibody-coated cells and micro-organisms are removed by phagocytic cells in capillaries and sinuses. Reticulocytes are sequestered in the spleen for first 2-3 days following their release from the bone marrow, and red cell inclusions, such as Howell-Jolly bodies (nuclear remnants), Heinz bodies (denatured haemoglobin), siderotic granules (iron) and malaria parasites are removed from red cells.
2. *Immunological functions* – The spleen has an important role in the generation of an IgM response following antigen exposure, particularly polysaccharide antigens. It is also the source of opsonin ‘tuftsin’, a tetrapeptide that promotes neutrophil phagocytosis.
3. *Pooling of red cells and platelets* – Platelets (20-40%) and red cells (about 5%).
4. *Extramedullary haemopoiesis* – The spleen is a major haemopoietic organ in early foetal life. It retains the potential to support haemopoiesis in later life, reverting to an active haemopoietic organ in presence of bone marrow fibrosis (myelofibrosis) or erythroid hyperplasia (autoimmune haemolytic anaemia or thalassaemia).

Causes of splenomegaly are listed in Table 46.

CLINICO-PATHOLOGICAL FEATURES OF SPLENIC DISEASE

- I. **Local effects** due to moderate to massive enlargement such as abdominal discomfort, dyspepsia, and symptoms due to pressure on bladder or colon.
- II. **General effects**
 1. *Hypersplenism* – The syndrome is diagnosed when the following are found together in absence of immature cells in peripheral blood – (a) Detectable splenomegaly, (b) anaemia, leucopenia or thrombocytopenia, (c) normal or hypercellular bone marrow. Several different mechanisms may be responsible in an individual patient.
 2. *Red cell destruction* – in conditions characterised by specific abnormality of red cell viz. hereditary spherocytosis, haemolytic crisis of hereditary elliptocytosis and warm-antibody type of autoimmune

Table 46: Causes of splenomegaly.

Infections

- *Bacterial* – Septicaemia, typhoid, infective endocarditis, tuberculosis, syphilis, brucellosis.
- *Viral* – Hepatitis, infectious mononucleosis.
- *Protozoal* – Malaria, kala-azar, trypanosomiasis.
- *Rickettsial* – Typhus.
- *Fungal* – Histoplasmosis.
- *Parasitic* – Hydatid, bilharziasis.

Circulatory

- Congestive heart failure.
- Portal hypertension.
- Hepatic or portal vein thrombosis.
- Splenic vein obstruction.
- Splenic artery aneurysm.

Haematological

- *Haemolytic disorders* – Hereditary spherocytosis, elliptocytosis, warm-antibody AHA, pyruvic kinase deficiency, thalassaemia, haemoglobinopathies (some), paroxysmal nocturnal haemoglobinuria.
- *Haematological malignancy* – Acute leukaemia, chronic myeloid leukaemia, chronic lymphoid leukaemia and lymphomas.
- *Myeloproliferative disorders* – Polycythemia vera, primary myeloid metaplasia.

Inflammatory and collagen disorders

- Acute rheumatic fever
- Felty's syndrome
- Systemic lupus erythematosus.

Granulomatous disorders

- Sarcoidosis
- Berylliosis

Metabolic storage diseases

Gaucher's disease, Niemann-Pick disease, Hurler's syndrome, histiocytosis X.

Splenomegaly of unknown ethology

Tropical splenomegaly, non-tropical splenomegaly.

Miscellaneous – Iron deficiency anaemia, pernicious anaemia, amyloidosis, myeloma, mastocytosis, splenic cysts, primary and secondary tumors, thyrotoxicosis.

haemolytic disease. Lesser degrees of red cell destruction occurs when there is marked splenic enlargement.

3. *Red cell pooling* – occurs in most enlarged spleens and is a drain on red cell volume from functional circulation of blood.

4. *Hypervolemia* - Marked splenomegaly leads to hyperkinetic portal hypertension produced by high blood flow through the enlarged spleen.
5. *Thrombocytopenia* - In about 80% cases of chronic ITP there is excessive platelet destruction predominantly in the spleen. It may also occur in chronic lymphocytic leukaemia and SLE.
6. *Leucopenia* - Leucopenia, and especially neutropenia, is commonly found in conditions where there is a splenomegaly, such as Felty's syndrome.

INVESTIGATION OF A CASE OF SPLENO-MEGALY (OR HEPATOSPLENOMEGALY)

History

1. *Age* - Childhood cirrhosis between ages of 1 and 3 years.
2. *Sex* - Haemochromatosis more common in males.
3. *Family history* - in hereditary spherocytosis, haemochromatosis, Gaucher's disease.
4. *Personal history* - as regards diet, alcoholic intake.
5. *Past history* - of fever with rigors in malaria, history of jaundice and gastrointestinal bleeding.
6. *Fever* - Infections like malaria, kala-azar, typhoid, miliary tuberculosis, subacute infective endocarditis, brucellosis, etc. Leukaemia, lymphomas, disseminated lupus, sarcoidosis.
7. *Pruritus* - polycythemia (especially after a bath).
8. *Haemorrhages* - with extreme weakness in leukaemia.
9. *Pallor* - in leukaemia, haemolytic diseases.
10. *Bone pain* - Multiple myeloma, Gaucher's disease.
11. *Haematemesis* - may suggest cirrhosis.

Physical Examination

1. *Degree of splenomegaly*
 - a. *Large to huge* - Chronic myeloid leukaemia, hairy cell leukaemia, lymphocytic lymphoma, malaria, kala-azar, bilharziasis, myelofibrosis.
 - b. *Moderate* - All above plus Hodgkin's disease, leukaemias, polycythemia, portal hypertension, chronic haemolytic anaemia, tuberculosis, storage diseases.
 - c. *Slight* - All above causes, acute and subacute infections, plus other causes of splenomegaly.
2. *Generalized lymphadenopathy* - Lymphoma, leukaemia, mononucleosis, generalised tuberculosis, endocarditis, brucellosis, Felty's syndrome, kala-azar in children, sarcoidosis.

3. *Palpable liver* - Malaria, kala-azar, leukaemia, infective hepatitis, portal hypertension, subacute infective endocarditis, tuberculosis, sarcoidosis, Hodgkin's disease, syphilis, severe haemolytic anaemias, congestive splenomegaly, reticulosis, myeloid metaplasia, amyloidosis, lipoid storage diseases, bilharziasis.
4. *Pallor and icterus* - Haemolytic anaemias, cirrhosis of liver.
5. *Petechiae and ecchymoses* - Acute leukaemia, terminal stage of chronic leukaemia, leucosarcoma with bone marrow metastasis, subacute bacterial endocarditis, SLE.
6. *Plethoric appearance* - Polycythemia vera.
7. *Pigmentation* - Grey-brown pigmentation best seen on medial and flexor aspects of the arms in hemochromatosis.
8. *Arterial spiders and palmar erythema* - in cirrhosis.
9. *Tremors* - in Wilson's disease and neurological complications of cirrhosis.
10. *Pinguecula* - in Gaucher's disease.
11. *Kayser-Fleischer ring* - at the periphery of the cornea in Wilson's disease.
12. *Bone changes* - Gaucher's disease, myelofibrosis, multiple myeloma, amyloidosis, metastatic carcinoma.
13. *Isolated splenomegaly* - Malaria, non-specific hyperplasia, primary splenic neoplasms, Gaucher's disease, sarcoid.

Investigations

1. **Blood Picture and Blood Tests**
 - a. *Leucopenia* - Typhoid, malaria, kala-azar, syphilis, tuberculosis, sarcoid, portal hypertension, non-specific hyperplasia, neoplasm of spleen such as primary lymphosarcoma, haemangioma or cyst; rheumatoid arthritis (Felty's syndrome).
 - b. *Leucocytosis* - Pyogenic infections, infectious mononucleosis, leukaemias, polycythemia, most haemolytic anaemias.
 - c. *Lymphocytosis* - Infectious mononucleosis, brucellosis, tuberculosis.
 - d. *Pancytosis* - Polycythemia.
 - e. *Reticulocytosis* - Haemolytic anaemia.
 - f. *Thrombocytopenia* - Leukaemia or other malignancy.
 - g. *Blood smear* - for diagnosis of malaria, leukaemia, polycythemia, infectious mononucleosis, hereditary spherocytosis.

- h. *Blood culture* – in subacute infective endocarditis.
- i. *Special tests* – (a) Serum bilirubin – in haemolytic anaemias. (b) Standard agglutination test – for brucellosis. (c) Blood test – for syphilis. (d) Paul-Bunnell test – for infectious mononucleosis. (e) Tests for abnormal haemoglobins, and Coomb's test in thalassaemias (Cooley's anaemia). (f) Rectal biopsy or aspiration of subcutaneous fat from anterior abdominal wall for systemic amyloidosis. (g) Serum iron – raised in haemochromatosis. (h) Serum copper – low levels in Wilson's disease. (i) Auto antibodies – ANA, Anti-ds-DNA, Anti-sm in SLE.
2. **Radiology** – (a) *Plain film of abdomen* – for detecting splenic enlargement. Enlargement may also produce a raised left hemi-diaphragm, and displace adjacent organs in a barium meal or barium enema film or IV urogram. (b) *Chest* – for miliary tuberculosis, sarcoidosis, Hodgkin's disease and histoplasmosis. (c) *Bones* – Expansion of lower ends of long bones especially femur in Gaucher's disease, increased density in myeloid metaplasia, and 'hair-on-end' or 'brush' appearance of skull in thalassaemia.
3. **Radioisotopic Spleen Scanning** – Techniques include ⁹⁹Tc-colloid liver-spleen scan, computed tomography and ultrasound scanning of the left upper quadrant. Utility – (a) Detects enlargement of spleen. (b) It can indicate focal lesions, infarcts, splenic rupture, accessory spleen and absence or hypoplasia of the spleen. (c) Sequential estimates of organ radioactivity after injection of chromium 51-labelled autologous red cells gives estimate of red cell pooling and destruction in haemolytic anaemias. If splenic destruction is significantly greater than the apparent red cell loss in the liver, it provides supportive evidence for value of splenectomy. (d) Similar studies with isotope-labelled platelets can be used in thrombocytopenic states.
4. **Liver biopsy** – Sarcoidosis, collagen disease, Hodgkin's disease, amyloid disease, haemochromatosis, histoplasmosis.
5. **Bone marrow examination** – Haematological malignancy including leukaemia, myeloproliferative disorders, lymphoma, myeloma, kala-azar.
6. **Lymph node biopsy** – of value in tuberculosis, Hodgkin's disease, sarcoid and histoplasmosis.
7. **Skin tests** – Tuberculin test – -ve in sarcoidosis.
8. **Tests for portal hypertension** – Refer.
9. **Serum proteins** – Elevated globulin with reversed albumin globulin ratio in multiple myeloma, cirrho-

sis of liver and occasionally lymphosarcomatosis and disseminated lupus.

10. **ESR AND LDH** – commonly elevated in lymphoma.
11. **Splenectomy** – as a diagnostic measure in the presence of obscure anaemia with leucopenia and thrombocytopenia with splenomegaly.

Differential Diagnosis of Chronic Splenomegaly

1. Cirrhosis of liver

- Symptoms and signs of hepatocellular failure – Spider naevi, liver palms, alopecia, gynecomastia and testicular atrophy in males, icterus, foetor hepaticus. Palpable enlarged liver.
- Evidence of portal hypertension – Ascites, prominent veins on abdomen, haematemesis, piles.
- Diagnosis by liver biopsy, demonstration of oesophageal varices by barium swallow, laparoscopy and scanning.

2. Infections, subacute and chronic

a. Chronic malaria

- History of fever with rigors with classical features of the attack – cold stage, hot stage, sweating stage.
- Spleen very large and firm.
- Liver may be enlarged.
- Severe anaemia.
- Malarial parasites in peripheral blood or sternal marrow.
- Leucopenia.
- Therapeutic test with adequate dose of anti-malarial drug during fever.

b. Kala-azar

- Residence in endemic area.
- Splenomegaly – which may be massive.
- Recurrent fever – Double rise of temperature in 24 hours may be seen.
- Liver enlarged but not grossly like spleen.
- Anaemia.
- Loss of hair and pigmentation of skin.
- Generalized lymphadenopathy – especially in children. Nodes are soft, non-tender.
- Other features – Cough, haemorrhagic features (notably epistaxis).
- LD bodies – on stained material from bone marrow or splenic aspirate.

c. *Subacute infective endocarditis*

- Unexplained fever.
- Presence of cardiac murmur.
- Presence of petechiae, anaemia, peripheral emboli; clubbing of fingers.
- Red cells in urine.
- Positive blood culture.

d. *Brucellosis*

- History of ingestion of raw milk, or occupation hazard in veterinary surgeons, laboratory personnel or slaughter house workers.
- Patient not toxic in spite of high fever.
- Spleen of moderate size, rarely massive.
- Liver may be enlarged particularly, if spleen is very large.
- Back pain common.
- Culture of organism from blood or bone marrow. Complement fixation and anti-human globulin tests in chronic infection.

e. *Tuberculous splenomegaly* - In rare cases tuberculous enlargement of spleen occurs with little involvement of other organs. Blood picture shows anaemia, leucopenia, or thrombocytopenia, either singly or in combination. Weakness, lassitude, loss of weight and often pyrexia. Bleeding may occur. X-ray of spleen may demonstrate areas of calcification.

f. *Bilharziasis* (Egyptian splenomegaly) - (i) History of residence in endemic area. (ii) Preceding toxic stage with urticaria, fever, diarrhoea. (iii) Emaciation. (iv) Hepatomegaly and progressive splenomegaly. (v) Dilatation of abdominal veins. (vi) Ascites in terminal stages. (vii) Ova in stools and positive complement deviation test. (viii) Aspiration liver biopsy will show evidence of cirrhosis and causative ova.

3. **Myeloproliferative disorders**

a. *Chronic myeloid leukaemia (Chronic phase)*

- Fatigue, weight loss, sweating, anaemia.
- Haemorrhages - easy bruising, ecchymoses.
- Splenomegaly with or without hepatomegaly.
- Blood findings - Raised white cell count ($30-400 \times 10^9/l$). Differential shows granulocytes at all stages of development. Blast cells.

b. *Polycythemia vera (PV)*

- Most patients over 40 years of age.
- Symptoms due to hyper-viscosity - a. Mild headache. b. Neurological disturbance - Ataxia, vertigo, confusion. c. Visual disturbance - Blurring of vision, dilatation and segmentation of retinal veins, 'sausage' appearance of retinal veins.
- Symptoms due to haemorrhages - Epistaxis, gastro-intestinal or genitourinary bleeding.
- Palpable splenomegaly, raised haematocrit. Bone marrow - Hyperplasia of all marrow elements and large megakaryocytes with hyperlobulated nuclei.

c. *Myelofibrosis*

- Generalized symptoms of marked lassitude, loss of weight and night sweats.
- Splenomegaly may be massive, pain due to splenic infarct.
- Anaemia with leucoerythroblastic blood picture. Erythrocytes show characteristic tear drop poikilocytes.
- Neutrophil alkaline phosphatase score elevated (Normal 40-100)
- Bone marrow - difficult to aspirate. Trepine biopsy shows increased number of megakaryocytes and increased reticulin and fibrous tissue replacement.
- X-ray - Ground glass appearance of bones of axial skeleton.

d. *Primary thrombocythemia*

- Bleeding - from GI tract or spontaneous bleeding after minor trauma resulting in large haematomas. Purpura rare.
- Gross splenomegaly does not occur.
- Very high peripheral platelet count and increased number of megakaryocytes in bone marrow.

4. **Lymphoproliferative disorders-**

a. *Chronic lymphocytic leukaemia*

- Mostly in second half of life and more in males.
- Lymphadenopathy, infiltration of salivary glands, infiltration of serous membranes resulting in pleural or pericardial effusion, skin infiltration with nodules.
- Peripheral lymphocytosis and increase in mature lymphocytes in bone marrow.

b. *Hodgkin's disease*

- Most often in young adults.
- Localized, painless lymphadenopathy – in neck, axilla or inguinal region in decreasing order of frequency.
- Occasionally involvement of mediastinal nodes, spleen, liver and extralymphatic deposits in skin may be presenting symptom. Pruritus.
- Systemic symptoms – Fever, sweating, weight loss.
- Diagnosis – Presence of Reed-Sternberg cells in gland biopsy.

c. *Non-Hodgkin's lymphoma*

- Low grade and large cell lymphomas predominantly in elderly.
- Painless peripheral lymphadenopathy.
- Symptoms related to vascular occlusion – Cerebral, coronary, splanchnic and deep veins.
- Weight loss, fever, night sweats.
- Hepatosplenomegaly
- Clinical features due to involvement of unusual sites, e.g. skin (Sezary's syndrome/mycosis fungoides), tonsils and adenoids, salivary glands, GI tract, lungs, CNS (HIV-related and lymphoblastic), jaw (Burkitt's lymphoma) and testis.
- Detection of immunological markers on circulating lymphoma cells or fixed tissue from lymph nodes or other sites.

6. **Anaemias**a. *Chronic haemolytic anaemia*

- Anaemia varies from time to time but develops rapidly with haemolytic crises.
- Jaundice usually mild and of lemon yellow tint.
- Features of chronic cholecystitis due to pigment gallstones.
- Ulcers of the legs and pigmentation from old ulcers, usually over the malleoli may be seen.
- Evidence of haemolysis in blood – Reticulocytosis and upto 1 normoblasts per 100 leucocytes.

b. *Iron deficiency anaemia*

- Mild degree of splenomegaly with hepatomegaly.

- Nail changes – Platynychia and koilonychia.
- Smooth and pale tongue.
- Associated condition, e.g. bleeding piles, hook-worm infection, menorrhagia, etc.
- Decreased red cell count, haemoglobin and haematocrit with hypochromia in peripheral smear.

c. *Megaloblastic anaemia*

- Diarrhoea, loss of appetite and weight.
- Mild jaundice may give the patient a lemon yellow tint.
- Glossitis and angular cheilosis.
- Liver usually not enlarged.
- Macrocytosis with MCV usually above 100 femtolitres. Bone marrow – Megaloblastic erythropoiesis.

7. **Multiple myeloma**

- Middle-aged or elderly.
- Bone pain – commonest symptom involving thoracic and lumbar spine.
- Generalized osteoporosis common.
- Anaemia.
- Kidney failure.
- Recurrent infection.
- Diagnosis – (a) Plasmocytosis on bone marrow aspiration. (b) Monoclonal globulin spike on serum or urine electrophoresis. (c) Well-defined lytic bone lesions.

8. **Collagen diseases**a. *Systemic lupus erythematosus*

- Mostly in women.
- Multisystem disease with fever, arthritis, skin and renal involvement.
- Lymphadenopathy.
- Hepatic enlargement.
- LE cells in peripheral blood or bone marrow.

- b. *Felty's syndrome* – Chronic splenomegaly, neutropenia, with chronic rheumatoid arthritis in adults. Other features which may be observed are weight loss, pigmentation of skin, hepatomegaly, moderate lymph node enlargement and ulceration of the leg.

9. **Tropical splenomegaly syndrome (TSS)**

- Gross splenomegaly in immune adults from areas of endemic malaria.
- High serum IgM.
- Moderate hepatomegaly.
- Hepatic sinusoidal lymphocytosis.
- Regression of above features with antimalarial treatment and prolonged prophylaxis.

10. **Sarcoidosis**

- Lymphadenopathy hilar and elsewhere
- Extrathoracic sarcoidosis – Skin, CNS, bone, heart
- Splenomegaly
- Hypercalcemia
- Diagnosis by biopsy of lymph node, chest radiograph

11. **Amyloidosis** Primary (AL), Secondary (AA)

- Nephrotic syndrome, renal impairment
- Cardiac – Restrictive cardiomyopathy, dysrhythmia
- Macroglossia
- Hepatosplenomegaly
- Diagnosis: Biopsy of rectal mucosa or abdominal fat.
- Bence-Jones proteins in urine

12. **Lipoid granulomatosis (Table 47)**

In children

- Congenital syphilis* – Spleen usually enlarged two fingers breadth below the costal margin, smooth and firm. Dermal and visceral manifestations of syphilis. Positive tests for syphilis.
- Infantile childhood cirrhosis* – Predominantly in boys aged 1-3 years. Progressive hepatic failure with hepatomegaly, splenomegaly, jaundice and ascites.
- Thalassemia major* – (i) Mongoloid facies. (ii) Splenomegaly usually marked, moderate to marked hepatomegaly. (iii) Periodic attacks of fever common. (iv) Blood – Target or oval cells, many normoblasts. (v) X-ray skull – Thickening of diploe, thinning of inner and outer tables with perpendicular striations between the two layers – “hair standing on end” appearance.
- Still's disease* – Rheumatoid type of arthritis, splenomegaly, fever and anaemia, lymphadenopathy and leucocytosis.
- Hurler's syndrome* – Dwarfism, hepatosplenomegaly, coarse facies, corneal clouding, joint contractures, mental retardation, umbilical hernia, hirsutism, macroglossia, thoracolumbar kyphosis.

Splenectomy: Indications in haematological disorders-

Table 47: Lipoid granulomatosis.

	<i>Gaucher's disease</i>	<i>Niemann-Pick's disease</i>	<i>Hand-Christian disease</i>
Familial predisposition	Frequent	None	None
Age	Onset in childhood	Infancy	Early childhood
Spleen	Marked splenomegaly	Moderate splenomegaly	Slight to moderate splenomegaly
Other features	Chronic progressive anaemia	Slight or no anaemia	Diabetes insipidus
	Leucopenia	Leucocytosis	Exophthalmos
	Hemorrhages	Gastro-intestinal disorders	Defects in membrane bones
	Cortical thinning of long bones	Retarded development	Retarded development
	Skin and conjunctival pigmentation	Brown skin pigmentation	
Course and Prognosis	Chronic course	Short course. Fatal within 2 years	Slow course. Fatal in 50%

A. **Diagnostic** – Splenomegaly is occasionally an isolated finding and the cause may not be identified despite investigations, e.g., simple cyst or haemangioma, chronic granulomas, plasmocytoma and in some atypical cases of lymphoproliferative disorders. In such cases splenectomy may be justified for diagnostic reasons. The fact that the spleen is of normal size does not exclude possibility of the organ being affected by lymphoma.

B. **Therapeutic**

- Rupture of the spleen* – With a normal spleen severe trauma is required to cause rupture. The diseased spleen may rupture with trivial trauma, e.g., in infectious mononucleosis, acute and chronic leukaemias, myelomatosis, autoimmune haemolytic disease and congestive splenomegaly.
- Local effects of splenic enlargement* – such as discomfort due to massive splenomegaly, dyspepsia, recurrent infarction, perisplenitis.
- Correlation of cytopenias* – (a) *Absolute indications* – (i) Hereditary spherocytosis and haemolytic variant of hereditary elliptocytosis. (ii) Chronic idiopathic thrombocytopenic purpura. Even if platelet count does not return to normal, it may be possible to lower the dose of steroids. (iii) Primary hyper-

splenism – non-tropical variety for correction of cell deficits and to exclude other diagnoses requiring additional therapy. (b) *Relative indications* – (i) Warm-antibody autoimmune haemolytic disease when IgG or IgA antibodies are attached to the red cells. (ii) To relieve cytopenias resulting from red cell and platelet pooling, haemolysis and platelet destruction in cases with moderate to massive splenomegaly, e.g., chronic lymphocytic or granulocytic leukaemia, Gaucher's disease. (c) *Doubtful outcome but severe* (at times life-threatening) *condition* – Thrombotic thrombocytopenic purpura, pyruvic kinase deficiency, some cases of PNH, and the improvement of the effect of platelet transfusions in aplastic anaemia.

Hypersplenism: A peripheral blood cytopenia which is cured by splenectomy. It is due to pooling of cells within the spleen and rapid destruction of cells within the spleen.

Diagnosis

1. Splenomegaly.
2. Peripheral blood cytopenia.
3. Normal or hypercellular marrow.
4. Demonstration of shortened red cell survival.

Treatment: Splenectomy, if causative underlying disorder cannot be corrected, e.g. lymphomas, β -cell hairy cell leukaemia. Felty's syndrome, Gaucher's disease.

Hyposplenism – indicates diminished or absent splenic function.

Causes

- Splenectomy
- Splenic agenesis
- Splenic atrophy and functional hyposplenism and bone marrow transplantation
- Sickle cell disease
- Splenic irradiation
- Essential thrombocythemia
- Adult coeliac disease and dermatitis herpetiformis
- Ulcerative colitis
- Crohn's disease
- Systemic lupus erythematosus
- Infiltration (lymphoma, amyloid)

Haematological Changes

Red cells: Presence of Howell-Jolly bodies, and other red cell inclusion acanthocytes and target cells.

White cells: Neutrophil leucocytosis, which settles within few weeks. Modest lympho and monocytosis persist indefinitely.

Platelets: Count rises immediately after splenectomy, usually peaking at 7-12 days and returning to normal within 2 months.

Post-splenectomy sepsis: Rapid onset and fulminant course, associated with multiple organ failure and DIC. Risk of infection persists throughout life, but is greatest in those under 5 years of age, in those splenectomised for malignant disease. Most are due to *Strep. pneumoniae*, others are *H. influenzae* and *N. meningitidis*, malaria, babesiosis.

15. BONE MARROW TRANSPLANTATION

Transplantation is the reconstitution of the full hemopoietic system by transfer of the pluripotent cells present in the bone marrow (stem cells). This usually requires prior ablation of patient's own marrow by intensive chemotherapy or chemoradiotherapy.

TYPES OF TRANSPLANTATION

1. **Allogenic transplantation**– is when another individual acts as the donor – usually a sibling of the patient, sometimes a normal volunteer. All cases, however, require a full or near HLA match – that is they should be HLA compatible.

Indications

When it is the sole chance of cure:

- Primary immunodeficiency syndrome
- Aplastic anemia
- Thalassaemia
- Myelodysplasia
- Multiple myeloma
- Sickle cell disease
- Inborn errors of metabolism
- Chronic myeloid leukaemia

When it is probably better than conventional treatment:

- AML (first or second complete remission)
- ALL (first or second full remission)
- In children in whom ALL is the commonest leukaemia, most will be cured by standard chemotherapy alone, and transplantation is only reserved for relapse.

2. **Autologous transplantation**– is when patient acts as his or her own source of stem cells.

Probable benefit

Relapsed Hodgkin's lymphoma
ALL (first or second complete remission)
Relapsed testicular cancer

Possible benefit

CML
Disseminate breast cancer
Disseminate lung cancers
Other solid tumors
Severe autoimmune disease

Proved benefit

Relapsed non-Hodgkin's lymphoma (intermediate and high grade)
AML (first or second complete remission), Multiple myeloma.

Complications

Early complications of transplants

Chemoradiotherapy

- Nausea and vomiting
- Reversible alopecia
- Fatigue
- Dry, inflamed skin
- Mucositis
- Veno-occlusive disease

Infections

- Bacterial (Gram -ve and +ve)
- Viral-Herpes zoster virus, cytomegalovirus (particularly pneumonitis)
- Fungal – Candida, aspergillus
- Atypical organisms – Pneumocystis pneumonia, toxoplasma, mycoplasma, legionella

Acute graft versus host disease (allograft only)

- Rash
- Diarrhoea
- Jaundice

Graft versus host disease – is an immune reaction between donor and recipient. It is mediated by T cells in the graft, which recognise and attack antigens in the host tissue. Acute GVHD develops within 3 months post-transplantation. Chronic GVHD develops in transplant patients **between 3 months to 2 years.**

Clinical Features

Acute

- Erythematous, maculopapular rash
- Liver disease
- Profuse diarrhoea
- Jaundice

Chronic

- Sclerotic atrophic skin
- Sicca syndrome
- Mucosal ulceration
- Malabsorption syndrome
- Recurrent chest infections
- Cholestatic jaundice
- Joint movement restriction
- Hyposplenic infections
- Myelosuppression

Late complications of transplantation

- Relapse of the original underlying disease
- Infertility (both sexes)
- Hypothyroidism
- Secondary malignancy
- Late sepsis due to hyposplenism
- Cataracts (secondary to total body irradiation)
- Psychological disturbance

16. THE BLOOD IN SYSTEMIC DISEASE

ANEMIA OF CHRONIC DISORDERS

Mechanism

- Slightly shortened RBC survival
- Improved bone marrow response to anemia
- Increased synthesis of ferritin (and other acute phase proteins)
- Defective transfer to iron from reticuloendothelial stores to RBC precursors
- Impaired transferrin production

Pathogenesis. ACD is characterized by:

- Relatively low erythropoietin level
- Reduced RBC survival as a result of phagocytosis by macrophages
- Reduced intestinal iron absorption • Retention of iron in macrophages

Malignant Disease

Anemia often results from anemia of chronic disorders, and is commonly associated with raised ESR. Anemia can be due to loss of blood in patients with GI malignancy.

Reactive bone marrow may lead to leucocytosis and/or thrombocytosis. In extreme cases (usually associated with necrotic tumors or widespread malignancy), the leucocytosis may mimic CML.

Bone marrow infiltration typically gives a leucoerythroblastic blood picture. This appearance is nonspecific and occurs in various conditions that infiltrate the bone marrow.

Haemostatic failure may be caused by microangiopathic hemolytic anemia (typically associated with mucin-secreting adenocarcinomas) or DIC (particularly prostate carcinoma).

Infection

Bacterial infections - (a) *Disseminated TB* can produce features that mimic disseminated malignancy and myeloproliferative disorders. (b) *Clostridium welchii*. Severe infections may be associated with acute haemolysis.

Viral infections - (a) Symptomatic thrombocytopenia occurs occasionally in patients with rubella, infectious mononucleosis or varicella-zoster virus. (b) In viral haemorrhagic fevers, haemorrhagic features vary from mild thrombocytopenia to severe bleeding tendency.

Parasitic disease - (a) Eosinophilia in helminthic infections. (b) Anemia in hookworm disease. (c) Malaria is associated with anemia with a complex pathophysiology.

Autoimmune disease Autoimmune phenomena seen in RA, SLE, giant cell arteritis, scleroderma, ankylosing spondylitis and polyarteritis nodosa, include hemolytic anemia, thrombocytopenia and leucopenia.

Renal disease Kidney failure is commonly associated with anemia that principally results from lack of erythropoietin production. Uraemia adversely affects platelet function and may lead to a bleeding diathesis. Occasionally eryth-

rocytosis or polycythemia is caused by an erythropoietin secreting kidney tumour.

GI disease Anemia secondary to GI blood loss, and effects of malabsorption. Inflammatory bowel disease may be associated with anemia of chronic disorders.

Liver disease Anemia has some features of anemia of chronic disorders. Anemia may be macrocytic and target cells may be seen in the blood. Thrombocytopenia is common. Haemorrhagic diathesis due to impaired synthesis of clotting factors.

Endocrine disorders RBC mass is increased in hyperthyroidism and decreased in hypothyroidism, reflecting the requirements for oxygen delivery. Hypothyroidism is commonly associated with macrocytosis. Anemia in hypopituitarism.

Cardiac disorders Cyanosis and polycythemia in children with congenital heart disease. In severe cases, polycythemia may be associated with thrombotic episodes or other haemostatic abnormalities, suggesting a degree of intravascular consumption. Low grade haemolysis is sometimes seen in patients with severe aortic disease, and less often in mitral stenosis. It probably results from abnormally turbulent flow, which is more commonly seen following mechanical valve replacement.

Respiratory disorders Neutrophil leucocytosis in bacterial infection, e.g. pneumonia. Secondary polycythemia in COPD. Mycoplasma pneumonia is associated with circulating cold agglutinins in 75%. Pulmonary eosinophilia is a group of conditions in which eosinophil count is raised together with pulmonary infiltrates.

Endocrine Disorders

1. PITUITARY GLAND

Most patients with functioning adenomas present with signs and symptoms related to hormonal hypersecretion including:

- Acromegaly (via the action of GH and insulin-like growth factor I—IGF-I)
- Cushing's disease (via the action of ACTH and cortisol)
- Amenorrhoea-galactorrhoea syndrome (via the action of prolactin and subsequent suppression of the pituitary gonadotropins).

ACROMEGALY

Acromegaly is a clinical condition resulting from prolonged excessive circulating levels of growth hormone (GH) in adults. Acromegalic gigantism results from acromegaly in young individuals before epiphyseal fusion. Causes of acromegaly are given in Table 1.

Clinical Features

1. Local space-occupying effects:

(a) *Inside pituitary fossa:* Bitemporal loss of vision due to compression of visual pathways.

(b) *Outside pituitary fossa:*

- Diplopia (cranial nerve palsies with extraocular muscle dysfunction).
- Papilloedema due to upward growth and obstruction of CSF flow into third ventricle.
- Personality changes, focal hemispherical neurological signs and epilepsy (growth into frontal and temporal lobes).

Table 1: Causes of acromegaly

1. Pituitary adenoma (95%)
2. Excessive secretion of GH releasing hormone (GHRH) from carcinoid tumors (particularly bronchial), pancreatic islet cell or adrenal tumours.
3. Ectopic GH-secreting pancreatic islet cell tumours.
4. As part of multiple endocrine neoplasia type 1.

2. Due to GH excess (Table 2)

Table 2: Clinical features due to GH excess

(a) General

- Fatigue
- Weight gain
- Heat intolerance
- Increased sweating

(b) Skeletal changes

- Enlargement of hands and feet, spade like hands.
- Enlargement of supraorbital ridges.
- Enlargement of facial bones and prognathism.
- Spacing apart of teeth.
- Clavicles thickened.
- Changes in spine—osteoporosis, kyphosis, lordosis and scoliosis.
- Carpal tunnel syndrome.

(c) Skin and subcutaneous tissues

- Tongue enlarged with difficulty in articulation.
- Thickening of lips and nose.
- Skin coarse and greasy.
- Thickening of soft tissues of hands and feet.
- Hypertrophy of muscular system in initial stages.
- Mammary hyperplasia.
- Hypertrichosis.

(d) Cardiovascular

- Hypertension,
- Cardiac failure or acromegalic cardiomyopathy,
- Coronary artery disease
- Arrhythmias.

(e) Respiratory

- Deep voice due to enlargement of larynx.
- Lungs enlarge proportionately with thorax.

(f) *Metabolic:* Impaired glucose tolerance in about 25%.

(g) *Malignancy:* Prevalence of malignant disease (particularly colonic cancer) is probably increased.

3. Effects of pituitary tumor

(a) Headaches. (b) Upward extension of the tumor may occasionally cause compression of IIIrd, IVth or VIth cranial nerves. (c) Related to other hormones (i) Hyperprolactinaemia is common. Women may present with amenorrhoea and galactorrhoea or infertility, and men with low libido and impotence. (ii) Hypopituitarism occurs unless the tumour is small. Loss of anterior pituitary hormone secretion is seen as early failure of luteinizing hormone and, much later, thyroid stimulating hormone (TSH) and adrenocorticotrophic hormone (ACTH). Hypothyroidism and hypoadrenalism occur as a result of decreased secretion of TSH and ACTH.

4. Related to other hormones

(a) *Galactorrhoea*, due to (i) Concomitant adenomatous secretion (in 30%). (ii) Compression of posterior pituitary stalk by adenoma causing reduced ingress of prolactin-inhibitory factor (PIF). (c) Reduced pituitary TSH secretion leading to compensatory elevation of hypothalamic TR secretion with resulting stimulation of prolactin release.

(b) *Polydipsia* due to (i) Osmotic diuresis due to glucose intolerance. (ii) Diabetes insipidus. (iii) Dehydration secondary to hyperhidrosis.

(c) *Variable deficiency of GnRH* (Gonadotrophic releasing hormone). ACTH (Adrenocorticotrophic hormone). TSH (Thyroid stimulating hormone).

Investigations

A. Imaging

- Radiography** - (a) Skull - (i) Enlarged sella turcica (in 90%). (ii) Enlarged frontal sinuses, increased skull thickness. (iii) Macrognathia, wide-spaced teeth (Fig. 1).
 - Fingers - 'Arrowhead' tufting of finger tips.
 - Heel-pad sign - Heel pad >23 mm thick may indicate acromegaly.
- CT scanning** - if pituitary fossa abnormal on plain radiograph. A large adenoma is easily detected in CT scans taken after IV contrast. Coronal scanning with high definition may show characteristic features of an intrasellar micro-adenoma.
- MRI** - Sagittal view is useful in identifying relationship between suprasellar and infrasellar structures. It is better than CT scanning in distinguishing optic pathway from suprasellar component of a tumor.
- Imaging of chest and abdomen** - in whom CT scanning or MRI does not reveal pituitary adenoma.

Fig. 1: Skull in acromegaly. Note enlargement of sella turcica and of frontal bones, generalized thickening of skull bones and prognathism. Other causes of enlarged sella - Primary hypothyroidism, pregnancy, empty sella syndrome (classically in obese hypertensive multipara)

B. **Biochemical diagnosis** - GH levels elevated but the degree of elevation does not correlate with any manifestation of the disease.

- **Glucose tolerance test** - is the accepted diagnostic method measuring glucose and GH. In healthy individuals, GH becomes undetectable during the test.
- **Insulin-like growth factor I (IGF-I) levels** - GH stimulates production of IGF-I predominantly in the liver; IGF-I levels can be determined to assess disease activity in acromegalics, reflecting overall GH secretion. Unlike GH, IGF-I levels do not fluctuate widely throughout the day.

Management

Treatment should aim to reduce GH levels to < 5 mU/liter

- Surgery** - by transphenoidal route is the first-line treatment in most pts; up to 90% microadenomas are cured.
- Radiotherapy** - is often advised if initial attempts at surgery do not reduce GH levels to 5 mU/l (Implantation of radioactive isotope yttrium-90 into substance of pituitary gland). It causes a major reduction in GH levels during first 2 years. Hypopituitarism may occur.
- Medical therapy** - used principally as adjunct to ablative treatment of pituitary tumor.
 - Long-acting somatostatin analogues - Octreotide reduces GH levels to <5 mU/L in about 50% of patient. Dose: 100 µg t.d.s. can be increased up to 1500 µg/day. Long-acting injections have effects that persist for one month. Sandostatin - LAR is

a sustained-release, long-acting formulation of octreotide incorporated into microspheres that sustain drug levels for several weeks after intramuscular injection. GH suppression occurs for as long as 6 weeks after a 30-mg intramuscular injection; long-term monthly treatment sustains GH and IGF-I suppression and also reduces pituitary tumor size in 50% of patients. Lanreotide autogel, a slow-release depot somatostatin preparation, is a cyclic somatostatin octapeptide analogue that suppresses GH and IGF-I hypersecretion after a 60-mg subcutaneous injection. Side-effects - Initiation of therapy may cause colicky abdominal pain and diarrhea. Gallstones are a long-term side effect in about 30% of patients.

- (b) GH-receptor antagonist - Pegvisomant is administered s.c. as 40 mg/day dose followed by self-administration of 10 mg/day. Based on serum IGF-2 levels, the dose is titrated at 4-6 weeks intervals to maximum 40 mg/day. Liver function needs monitoring.
- (c) Dopamine agonists - Bromocriptine and cabergoline may modestly suppress GH secretion in some patients. Very high doses are usually required to achieve modest GH therapeutic efficacy.

ADULT GROWTH HORMONE DEFICIENCY (AGHD)

Symptoms are nonspecific and include abdominal obesity, reduced strength and exercise capacity, impaired psychological well being, reduced vitality and mood disturbances.

CUSHING'S DISEASE

Cushing's disease results from basophilic adenoma of anterior pituitary. (see Cushing's syndrome).

PROLACTINOMA

Prolactin secretion is under tonic inhibitory control by hypothalamic dopamine, such that interruption of the pituitary stalk produces Hyperprolactinaemia. Clinical features of prolactinoma are listed in Table 3. Causes of hyperprolactinaemia are given in Table 4.

Investigations

- Serum thyroxine and TSH levels to exclude hypothyroidism
- Pituitary imaging preferably with MRI.

Table 3: Clinical features of prolactinoma

Caused by prolactin excess

Women

- Oligomenorrhoea/amenorrhoea
- Galactorrhoea
- Infertility
- Hirsutism/acne (less common)
- Osteoporosis

Men

- Reduced libido
- Impotence
- Oligospermia
- Erectile dysfunction
- Galactorrhoea (less common)

Caused by tumor mass (usually in men)

- Headache
- Visual field defects (classically bitemporal hemianopia)
- Cranial nerve palsies
- Temporal lobe seizures
- Unilateral exophthalmos (rare)

Caused by other pituitary hormone deficiency

- Microprolactinoma - Other pituitary functions usually normal
- Macroprolactinoma - Varying degrees of hypopituitarism may be present

Table 4: Causes of hyperprolactinaemia

Physiological

- Pregnancy
- Lactation
- Stress

Drugs

- Anti-emetics (domperidone, prochlorperazine)
- Phenothiazines (chlorpromazine, haloperidol)
- Tricyclic antidepressants

Primary hypothyroidism

Pituitary tumors

- Prolactinoma
- GH secreting (raised prolactin in 30% of acromegalics)

Polycystic ovary syndrome

Uncommon hypothalamic/stalk lesions

- Sarcoidosis
- Langerhan's cell histiocytosis
- Hypothalamic tumors

Chest wall stimulation

- Repeated self-examination of breasts
- Post-herpes zoster

Liver/kidney failure

- Dynamic testing with dopamine receptor antagonist (e.g. domperidone) when prolactin level is not greatly raised.
- Full assessment of pituitary function in patients with clinical or biochemical evidence of hypopituitarism or with a microadenoma.
- Urgent prolactin assay in all patients with visual failure and a large pituitary lesion.

Management

Indications for treatment – Infertility, menstrual disturbance with long-term hypogonadism (osteoporosis risk), troublesome galactorrhoea, enlarging pituitary tumor with pressure effects (particularly visual failure).

Drug therapy – Dopamine receptor agonists – Bromocriptine initially 1.25 mg at bed time, gradually increased to 2.5 mg t.d.s. Cabergoline and quinagolide are longer-acting and better tolerated than bromocriptine.

Surgery and radiotherapy – Patients who are intolerant of dopamine receptor antagonists or who fail to exhibit tumor shrinkage may require transphenoidal surgery and/or pituitary radiotherapy.

NELSON'S SYNDROME

Pituitary tumour develops after bilateral adrenalectomy for Cushing's disease in 10–15% of patients and is associated with markedly raised ACTH and β -lipotrophin levels. Diagnosis suspected from increasing skin and mucosal pigmentation.

PRECOCIOUS PUBERTY

In girls – Most often due to premature secretion of gonadotropins in excess of that appropriate to a person's age resulting in premature development of secondary sex characters and rapid skeletal growth. Treatment – Medroxyprogesterone (Provera) 100 mg of depot preparation every 2 weeks, later increased to 300 mg every 2 weeks.

In boys – Most often pathological lesion exists and must be looked for.

HYPOPITUITARISM

Juvenile onset – (a) Selective gonadotrophic failure – Normal or increased stature, eunuchoid habitus, gonadal and genital underdevelopment; amenorrhoea in females. (b) Selective growth hormone failure with dwarfism. (c) Panhypopituitarism.

Adult panhypopituitarism (Simmond's disease).

Causes – (a) Pituitary tumours. (b) Tumours in region of hypothalamus. (c) Granulomas – Tuberculosis, sarcoidosis, histiocytosis, syphilis. (d) Infarction – Post-partum necrosis (Sheehan's syndrome), pituitary apoplexy. (e) Unknown, especially isolated defect. (f) Miscellaneous – Haemochromatosis, trauma, maternal deprivation, after treatment of pituitary lesion.

Clinical Features

See Table 5 for the Clinical features of pituitary insufficiency.

Investigation: of Hypopituitarism

1. Visual fields – should be charted.
2. Imaging – (a) *Plain skull radiograph* – as initial screening procedure. Enlargement of pituitary fossa, undercutting of anterior clinoid processes and thinning of dorsal sella if large intrasellar tumour. A small pituitary adenoma initially enlarges on one side of the pituitary fossa, in a lateral film this may be seen as a 'double

Table 5: Clinical features of pituitary insufficiency

Deficient hormone	Manifestations
Growth hormone	Wrinkling of skin (crow's feet) Tiredness Lack of muscle bulk and strength
LH/FSH	<i>Women</i> Oligomenorrhoea/amenorrhoea Infertility Dyspareunia Breast atrophy Flushes
	<i>Men</i> Loss of libido, impotence Infertility Flushes Regression of secondary sexual characteristics Loss of body hair Soft testicles Fine wrinkles around the mouth
Adrenocorticotrophic hormone	Fatigue Anorexia Wt. loss Hypoglycaemia Loss of axillary and pubic hair in women
Thyroid stimulating Hormone	Wt. gain Constipation Fatigue Cold intolerance Dry skin
Vasopressin	Polydipsia Polyuria Nocturia

floor'. (b) *CT scan* – if pituitary fossa abnormal on plain radiograph or endocrinological or ophthalmological evidence of pituitary or hypothalamic lesion. A large adenoma can be detected easily in CT scans taken after IV contrast. (c) *MRI* – Advantage: Sagittal view especially useful in identifying relationship between suprasellar and infrasellar structures. Also better than CT scanning in distinguishing optic pathway from the suprasellar component of a tumor. (d) *Angiography* – may be necessary in selected cases, e.g. suspicion of the lesion being an aneurysm.

Laboratory Findings and Tests to Confirm Pituitary Insufficiency

Growth Hormone

- Low insulin-like growth factor I adjusted for sex and age
- Insulin-induced hypoglycaemia test (glucose <40 mg/dL), maximal stimulated growth hormone <3.5 µg/liter, <10 mU/liter (N >10 mU/liter)

Luteinizing Hormone and Follicle-stimulating Hormone

In women

- Reduced oestradiol with normal or reduced basal luteinizing hormone and follicle stimulating hormone

In men

- Reduced testosterone with normal or reduced basal luteinizing hormone and follicle-stimulating hormone
- Normochromic, normocytic anaemia

Thyroid Stimulating Hormone

- Reduced thyroxine or free thyroxine with normal or reduced TSH
- Elevated cholesterol

Adrenocorticotrophic Hormone

- Low or reduced basal cortisol (8–9 am) < 83 nmol/liter, (3 µg/dL), N >83 nmol/L with normal or reduced adrenocorticotropin hormone
- Hypoglycaemia (glucose <40 mg/dL)
- Eosinophilia
- Lymphocytosis
- Insulin-induced hypoglycaemia test (glucose <2.2 mmol/L, 40 mg/dL), maximal stimulated cortisol <550 nmol/L, 20 µg/dL (N >550 nmol/L, 20 µg/dL) (N > 550 nmol/L)

Vasopressin

- Reduced urine osmolality
- Raised serum osmolality and sodium
- Water deprivation test

Treatment

1. Treatment of underlying cause if possible, e.g. surgical removal of pituitary adenoma or craniopharyngioma.
2. Pituitary hormone replacement therapy
See Table 6 for Pituitary hormone replacement therapy.
3. **Radiotherapy** – when radical removal is incomplete.

Table 6: Pituitary hormone replacement therapy

Hormone deficiency	Replacement	Dose
GH	GH	0.27–0.7 mg s.c. in evening
Gonadotropins		
Women	Estradiol Or Conjugated equine Oestrogens plus Progesterone	1–2 mg/d p.o. 0.625–1.25 µg/d p.o. Estradiol 25–100 mg/d i.m.
Men	Testosterone	250 mg i.m. q 2–3 wks Transdermal 5–7.5 mg/24 hr Implant 600–800 mg q 4–6 months
TSH	Thyroxine	75–150 µg/d
Adrenocorticotrophic hormone	Hydrocortisone	10 mg morning 5 mg noon 5 mg evening to 10 mg t.d.s.
Prolactin	Nil	Nil
ADH	Desmopressin	10–40 µg/d intranasal in 2–3 divided doses 300–600 µg/d p.o. in 2–3 divided doses

PITUITARY DWARFISM

Causes

Congenital (and sometimes hereditary) deficiency of the anterior pituitary growth hormone or destructive pituitary lesion in childhood. If gonadotropin output is also affected, sexual development is retarded with production of infantilism.

Clinical Features

Very slow rate of growth and hypoglycaemic attacks in childhood. No mental defect and no disproportion between relative sizes of the body and limbs of the child. Hypogonadism may be superadded. The bones are often thin and centres of ossification delayed in appearance.

Treatment

2 mg or more of human growth hormone IM two or three times weekly for an indefinite period until optimal growth or cessation of response is observed. Thyroid hormone, adrenal corticoids and testosterone or oestrogen are given only if needed.

Causes and Differential Diagnosis of Dwarfism

1. **Familial** – usually one of the parents has a short stature.
2. **Constitutional** – The parents are of normal stature and no abnormality is found on examination of the child. Diagnosis is made by elimination.
3. **Delayed puberty** – Delay in onset of puberty may be familial. It is commoner in boys than in girls.
4. **Low birth weight** – (a) Premature infants. (b) Intra-uterine growth retardation secondary either to maternal disease or poor intra-uterine environment. These children are marasmic at birth with dry skin and wrinkled facies.
5. **Simple caloric deficiency** – without any other nutritional deficiency.
6. **Endocrine disorders**
 - (a) **Growth hormone deficiency** – Selective deficiency of growth hormone. Body dimensions in proper proportion but stunted. Skin normal and hair distribution appropriate for sex.
 - (b) **Hypothyroidism** – Plump but squat and stunted. Thick subcutaneous tissues. Coarse hair. Mental retardation. Typical facies.
7. **Chromosomal abnormality**
Gonadal dysgenesis (Turner's syndrome) – Hypogonadism in females at puberty with sexual underdevelopment, primary amenorrhoea, retardation of growth,

webbing of skin of neck, increase in carrying angle at the elbows and osteoporosis. Buccal smear chromatin negative in 80%.

8. Primary skeletal disorders

Short-limb dwarfism:

- (a) **Achondroplasia** – Most common type. Disproportionate short stature, comparatively long trunk, and rhizomelic shortening of limbs. Large head with prominent or bulging forehead (bossing), midface hypoplasia. Trident hand. Waddling gait due to excessive lumbar lordosis and tilted pelvis.
- (b) **Diastrophic dwarfism** – Low birth weight, radiographic evidence of overlapping joints, dislocation of cervical spine and congenital heart disease.

Short-trunk dwarfism:

- (a) **Spondyloepiphyseal dysplasia tarda** – Progressive abnormalities of spinal and epiphyseal development. Height reduction obvious by adolescence. Secondary degenerative arthritis of hip common.
 - (b) **Spondyloepiphyseal dysplasia congenita** – In newborn, barrel-shaped chest, deep Harrison's groove and pigeon breast. Also flat dish-like facies, cleft palate and widely spaced eyes. In older children, the short neck makes the head appear to rest directly on the shoulders.
9. **Chronic diseases** – retard growth and in these cases the history and examination are usually diagnostic.
 - (i) Vitamin D deficiency rickets.
 - (ii) Renal acidosis – may occur in either generalised renal disease or in specific tubular defect.
 - (iii) Coeliac disease – Stunted retarded child with anorexia, distended abdomen, wasted buttocks, anaemia and steatorrhoea.
 - (iv) Diabetes mellitus (unregulated).
 - (v) Glycogen storage disease.
 - (vi) Idiopathic hypercalcaemia of infancy.
 - (vii) Congenital heart disease.
 - (viii) Pseudohypoparathyroidism – due to unresponsiveness of kidneys and bones to action of parathormone. Dwarfism, epilepsy, mental changes, intracranial calcification in basal ganglia, soft tissue calcification and brachydactyly.
 10. **Storage disorders**
 - (a) **Hurler's syndrome** (MPS IH) – Infant large at birth, but growth rate decreases during early months of life. Coarse facies, flattening of nasal bridge, corneal clouding, hepatosplenomegaly, claw hand deformity and thoracolumbar kyphosis. Macrocephaly, macroglossia, hirsutism. Mental retardation. Severe and multiple skeletal changes on radiography.

(b) *Hunter's syndrome* (MPS II) – (i) Severe form with progressive mental retardation and death before age of 15. (ii) Milder form with survival to adulthood. Coarse facies, joint stiffness and contractures, hepatomegaly, hernia, cardiac complications, hirsutism and deafness. Radiographic features – Enlarged sella turcica, spatulate ribs, beaking of lumbar vertebrae, short and broad long bones – less pronounced than in case of Hurler's syndrome.

(c) *Morquio's syndrome* (MPS IV) – Normal at birth but growth rate restricted by 2 years of age and ceases by 12 years of age. Dwarfism, awkward gait, knock-knee, bulging sternum, flaring of rib cage, flat foot. Discoloured teeth and ligamentous laxity. Aortic regurgitation and atlantoaxial instability which may cause spinal compression and quadriplegia.

11. **Emotional and physical deprivation** – Growth retardation and hormone dysfunction are reversed if the child is removed to a satisfactory emotional and physical environment.
12. **Unclassified** – Progeria – Alopecia, bird-like features, premature senility.

ADIPOSOGENITAL DYSTROPHY (FROHLICH'S SYNDROME)

Cause – of true Frohlich's syndrome is hypothalamic lesion, commonest being craniopharyngioma.

Clinical features

1. Adiposity of buffalo type.
2. Headache, vomiting and visual disturbances if tumor.
3. Sexual infantilism pronounced in males; genital deficiency in girls not evident until puberty.
4. Hands small and fat with tapering fingers; delicate hairless skin.
5. Other symptoms of hypothalamic disturbance may be present – lethargy, polyuria, polydipsia, and sleep disorders.

X-ray skull – Deformity, erosion or compression of sella turcica and anterior clinoid process if tumour.

LAURENCE-MOON-BIEDL SYNDROME

Rare familial disorder characterized by obesity, hypogonadism, diminished body hair, fine-textured skin, dwarfism, polydactyly, retinitis pigmentosa, and mental retardation.

THE POSTERIOR PITUITARY DISORDERS OF VASOPRESSIN SECRETION

DIABETES INSIPIDUS

Diabetes insipidus is characterized by passage of large volume (>3 liters/24 hrs) or 40 mL/kg/24 hrs, urine osmolality <300 mosmol/kg. Three primary pathogenic mechanisms are responsible for the polyuria:

1. Reduced renal response to vasopressin (nephrogenic diabetes insipidus, NDI)
2. Lack (usually partial) of osmoregulated vasopressin (cranial or hypothalamic diabetes insipidus, CDI)
3. Persistent excessive fluid intake (primary polydipsia)

Nephrogenic Diabetes Insipidus

Pathogenesis

In NDI, vasopressin fails to concentrate the urine as a result of three pathogenic mechanisms:

- V_2R defect – Vasopressin's major physiological action is on the renal distal nephron, where it binds to a seven-domain G-protein coupled membrane receptor (V_2R) to generate cyclic AMP, which activates intracellular protein kinases.
- Post- V_2R defect, intracellular or water channel proteins (aquaporin) defect
- Failure to maintain hypertonicity of the renal medullary interstitium

Causes

Causes of Nephrogenic diabetes insipidus are listed in Table 7.

Clinical Features – The X-linked disorder causes profound polyuria, dehydration, vomiting, fever, irritability and failure to thrive in infant boys.

Table 7: Causes of nephrogenic diabetes insipidus

Familial

- X-linked recessive (V_2R gene)
- Autosomal dominant (aquaporin-2 gene)

Acquired

- Metabolic (hypokalaemia, hypercalcaemia)
- Drugs (lithium, demeclocycline)
- Osmotic diuresis (diabetes mellitus)
- Post-obstructive uropathy
- Solute wash-out from renal interstitium

Cranial Diabetes Insipidus

Pathogenesis – Nucleotide deletion of the vasopressin gene has been demonstrated in a number of kindreds; this causes defects in protein folding with subsequent neuronal degeneration.

Causes

See Table 8 for the causes of diabetes insipidus.

Clinical features – Patients present with sudden onset of polyuria, polydipsia and nocturia (see Table 9 for causes of primary polydipsia). Children may develop enuresis. Hypernatraemia occurs if fluid intake is not adequate. Pregnancy can be associated with worsening polyuria or may cause transient CDI as a result of degradation of circulating vasopressin by placental enzyme vasopressinase. In traumatic DI, triphasic response may occur. Initial polyuria, prolonged antidiuresis and final polyuria.

Clinical features – Excessive drinking leads to polydipsia, polyuria, and occasionally nocturia. Patients may drink huge volumes of fluid (> 20 liters/day) which causes transient hyponatraemia because the kidney diluting capacity is exceeded by the large fluid load.

Diagnosis of Diabetes Insipidus

1. **Urine volume** – It is necessary to confirm excessive urine output (> 3 liters/24 hrs).
2. **Blood glucose, serum calcium and potassium** estimation to exclude other causes of polyuria.

3. **Serum uric acid** is elevated in hypothalamic diabetes insipidus.

4. **Fluid deprivation/desmopressin test** (Table 10)

Patient preparation

- Normal fluid overnight
- Avoid caffeine and smoking
- Weigh patient

Fluid deprivation (dehydration) phase

- Obtain blood and urine for osmolality measurements and urine volume at 8 am
- Restrict fluid for upto 8 hours
- Weigh patient every 2 hrs
- Obtain blood and urine for osmolality and urine volume
- Stop test if wt. loss > 5% of starting wt. or intolerable thirst
- Beware of surreptitious drinking

Desmopressin phase

- Inject desmopressin 2 µg IM.
- Patient is allowed to eat and drink upto 2 × volume passed during deprivation phase.
- Obtain blood and urine for osmolality and urine volume at 8 pm and 8 am the next day.

5. **Hypertonic saline infusion test** – Plasma measurements of vasopressin and osmolality during 2-hr infusion of 5% (855 mmol/liter) saline at a rate of 0.04–0.06 mL/kg/minute to confirm diagnosis of CDI.

Table 8: Causes of diabetes insipidus

<i>Familial</i>
• Autosomal dominant
• DIDMOAD syndrome (CDI, DM, optic atrophy, deafness)
<i>Cerebral malformation</i>
• Septo-optic dysplasia
• Laurence-Moon-Biedl syndrome
<i>Acquired</i>
• Trauma (head injury, surgery)
• Tumor (craniopharyngioma, pinealoma, hypothalamic metastasis, pituitary)
• Lymphocytic infiltration of stalk
• Autoantibodies to vasopressin magnocellular neurons
• Granulomas (tuberculosis, sarcoidosis, histiocytosis)
• Vascular (aneurysms, sickle-cell disease, Sheehan's syndrome)
• Infection (meningitis, encephalitis)
• Idiopathic

Table 9: Causes of primary polydipsia

• Compulsive, habitual drinking
• Psychosis
• Drugs (lithium, carbamazepine)
• Head injury
• Granuloma (sarcoidosis)
• Idiopathic

Table 10: Interpretation of fluid deprivation/desmopressin test

After fluid deprivation	After desmopressin	Diagnosis
<300	>750	CDI
<300	<300	NDI
>750	>750	PP
300–750	<750	? Partial CDI
		? Partial NDI
		? Primary PD

Urine osmolality mOsmol/kg

6. **Therapeutic trial of low-dose desmopressin** – 10–20 µg intranasally for 2 weeks is an alternative method of confirming the diagnosis. In case of CDI there is symptomatic improvement, NDI no effect, progressive hyponatraemia in case of primary polydipsia.
7. **Additional investigations** – Once diagnosis of diabetes insipidus is confirmed, the underlying cause must be sought. CDI patients must have pituitary and hypothalamic imaging (preferably MRI) to look for a structural lesion. In CDI, the normal hyperintense signal of the posterior pituitary is lost on T₁-weighted MRI.
6. **Drugs** – (besides diuretics) – antihistamines, carbamazepine, vitamin D excess, demethyl-chlortetracycline. (Also refer to Polyuria in Chapter 8).

ESSENTIAL HYPERNATRAEMIA

Causes: Various types of organic disease affecting pituitary hypothalamic region.

Clinical features – Sustained hypernatraemia, decreased thirst. Some patients show anterior pituitary dysfunction, obesity, hyperlipidaemia and episodic muscle weakness.

Investigations – Normal kidney function, no signs of hypovolaemia and patient can form concentrated urine with dehydration. Vasopressin levels are inappropriately low for the serum osmolality.

Management

NDI – Polyuria from metabolic and blood electrolyte disturbances causing NDI is often reversible once these are corrected. In familial NDI, hydration should be maintained by adequate fluid intake. Urine output can be reduced by upto 50% with a combination of indomethacin and thiazide diuretic. High dose desmopressin may be efficacious in partial NDI.

CDI– Desmopressin is the drug of choice. Daily dose – Oral 50–1200 µg in divided doses, intranasal 5–40 µg by spray in one to three doses, parenteral 1–2 µg i.m. Desmopressin in excess over prolonged period causes hyponatraemia.

Primary polydipsia – Water restriction, with treatment of any associated psychiatric disorder.

Differential Diagnosis

(of Polyuria and Polydipsia)

1. **Diabetes mellitus** – Urine volume rarely exceeds 3 liters per day. Presence of sugar in urine and elevated blood sugar.
2. **Chronic kidney failure** – Urine not in such large quantities, often nocturia. Blood pressure high. Other urinary findings like albuminuria and casts. Polyuria resistant to pitressin. Specific gravity fixed at about 1,010 in chronic kidney failure.
3. **Hypercalcaemia** – High serum calcium. Inability to concentrate urine.
4. **Hypokalemia** – Polyuria may be seen in the presence of decreased values for serum potassium. Symptoms of drowsiness, anorexia, nausea and marked muscular weakness. Electrocardiogram – prolongation of QT interval, T wave inversion and sagging of ST segment. Correction of electrolyte disturbance results in return to normal.
5. **Caffeine idiosyncrasy** – This runs in families. Polyuria ceases if only water is drunk.

SYNDROME OF INAPPROPRIATE ANTIDIURESIS (SIAD)

The syndrome of SIAD is one common cause of dilutional hyponatraemia. The main features are hyponatraemia with corresponding low plasma osmolality, urine osmolality greater than plasma osmolality, persistent urinary excretion of sodium, absence of hypotension and hypovolaemia and of oedema-forming states and normal kidney and adrenal function.

Pathogenesis – Administration of vasopressin and water causes a dilutional hyponatraemia in which the patient remains normovolaemic but becomes hypotonic and usually has persistent excretion of sodium. Urine osmolality is greater than plasma osmolality. The syndrome of inappropriate antidiuresis is the term used for these patients who must also retain normal kidney and adrenal function and must not be hypotensive or hypovolaemic. See Table 11 for the causes of SIADH.

Table 11: Causes of SIADH

Tumors – Carcinoma of bronchus, also of duodenum, pancreas or prostate. Lymphoma, leukemia, thymoma.

Chest disorders – Pneumonia, tuberculosis, emphysema, cystic fibrosis, asthma, pneumothorax, lung abscess, positive pressure ventilation.

CNS disorders – Head injury, meningitis, encephalitis, Guillain-Barre syndrome, brain tumor, brain abscess, cerebral hemorrhage, cavernous sinus thrombosis, hydrocephalus, cerebral or cerebellar atrophy, Shy-Drager syndrome.

Drugs – Thiazide diuretics, vincristine, vinblastine, cyclophosphamide, chlorpropamide, carbamazepine, phenothiazines, tricyclic antidepressants, oxytocin, vasopressin.

Miscellaneous – Idiopathic, acute porphyria, hypothyroidism, glucocorticoid deficiency, acute psychosis.

Diagnostic criteria

1. Dilutional hyponatraemia (plasma osmolality appropriately low compared to plasma sodium).
2. Urine osmolality > plasma osmolality.
3. Persistent renal sodium excretion.
4. Absence of hypotension, hypovolaemia and oedema forming states.
5. Normal renal and adrenal function.

Treatment - (a) Of cause if possible. (b) Restriction of fluid intake to 0.5–1 liter/day. (c) If water restriction poorly tolerated Demeclocycline 1–2 g/day in divided doses but its maximal effect may be delayed for 3–6 weeks. It induces nephrogenic diabetes insipidus. (d) Induction of natriuresis and diuresis with frusemide and sodium chloride supplements. (e) Inhibition of neurohypophyseal vasopressin secretion with phenytoin. (f) Slow infusion of hypertonic saline. Plasma sodium should not be raised faster than 100 mmol/liter/24 hours. (g) The other treatment is to reduce body water by giving an AVP receptor-2 antagonist (vaptan) to block the antidiuretic effect of AVP and increase urine output. One of the vaptans, a combined V2/V1A antagonist (Conivaptan), has been approved for short-term, in-hospital IV treatment of SIADH.

2. OBESITY

Obesity describes a weight of 120% or above. Obesity is often expressed in terms of body mass index (BMI), but pathophysiologically may be considered to be present when sufficient body fat has accumulated to adversely affect health.

BMI is calculated by measuring an individual's weight in kg., and dividing his/her height in meters square (kg/m_2). Table 12 gives WHO classification of obesity.

CAUSES OF OBESITY

Inherited Causes (Table 13)

Environmental causes

High-energy diets - Increased consumption of energy dense foods. Less regular eating patterns, shorter meals and increased snacking may also contribute.

Physical Inactivity

Other causes

Endocrine disease

- (a) **Pituitary** - (i) Frohlich's syndrome. (ii) Puberty adiposity. (iii) Climacteric both males and females. (iv) Pregnancy.

Table 12: WHO classification of overweight

Classification	BMI (kg/m^2)	Associated health risk
Underweight	<18.5	Low (but risk of other clinical problems increased)
Normal	18.5–24.9	Average
Overweight		
Pre-obese	25–29.9	Increased
• Obese class I	30–34.9	Moderately increased
• Obese class II	35–39.9	Severely increased
• Obese class III	≥ 40	Very severely increased

Table 13: Inherited causes of obesity

Condition	Key features	Genetic defect
Prader-Willi syndrome	Short stature, small hands and feet, almond-shaped eyes, learning difficulties, hypogonadism	Paternally imprinted gene, chromosome 15
Bardet-Beidl syndrome	Mental retardation, renal dysplasia, polydactyly, hypogonadism	Several described (chromosomes 4, 11, 15, 16)
Leptin deficiency Leptin receptor mutations Proopiomelanocortin defects Melanocortin-4 receptor defects Prohormone convertase 1 deficiency	Severe hyperphagia, hypogonadism Severe hyperphagia, hypogonadism Moderate obesity, red hair Severe early-onset obesity Failure to process insulin and Proopiomelanocortin	Leptin gene Leptin receptor gene Proopiomelanocortin gene Melanocortin-4 receptor gene Pro-hormone convertase 1 gene

- (b) *Thyroid* – Hypothyroidism.
- (c) *Adrenal cortex* – Cushing’s syndrome.
- (d) *Gonads* – Eunuchoidism sometimes. Polycystic ovary syndrome.
- (e) *Pancreas* – Islet-cell tumors and chronic hypoglycaemia often associated with adiposity.
- (f) *Hypothalamus* – Encephalitis, meningo-encephalitis, craniopharyngioma (including Frohlich’s syndrome). Third ventricle tumors and cerebral injuries may also produce adiposity by involvement of hypothalamus.

Drugs (Table 14).

TYPES OF BODY FAT DISTRIBUTION

Pear type – Fat accumulates mainly around hips and thighs (gynoid distribution) characteristic of females.

Apple type – Fat storage mainly in the abdomen (android distribution), found in both sexes.

MORBID EFFECTS OF OBESITY

See Table 15 for the effects of obesity.

MANAGEMENT OF OBESITY AND OVERWEIGHT

- Exercise** – is useful as a supplement to dieting unless there is a medical contraindication.
- Diet** – Rigid dieting is best treatment. 800 to 900 calories per day. It must contain amounts of all essential

foodstuffs. Bulkiness of food is important as the patient needs to be satiated. People tend to ingest a constant volume of food regardless of caloric or macronutrient content. Adding water or fiber to a food decreases its energy density by increasing weight without affecting caloric content. Examples of foods with low-energy density include soups, fruits, vegetables. *Foods to be avoided* – bread and anything made with flour, cereals, potatoes and other whole root vegetables, foods containing much sugar, all sweets and salt. Fatty foods

Table 15: Effects of obesity

- Endocrine and metabolic diseases**
 - Metabolic and insulin resistance syndrome – Features include insulin resistance with associated hyperinsulinaemia, impaired glucose tolerance, type 2 diabetes mellitus, dyslipidaemia characterised by hypertriglyceridaemia and low serum HDL cholesterol levels.
- Cardiovascular disease**
 - Hypertension
 - Coronary heart disease
 - Cerebrovascular and thromboembolic disease
- Pulmonary disease (Table 16)**
 - Restrictive lung disease
 - Obstructive sleep apnoea
- Musculoskeletal disease**
 - Gout
 - Osteoarthritis
- Neurologic disease**
 - Idiopathic intracranial hypertension (pseudotumour cerebri)
- Cataracts**
- Gastrointestinal, biliary and pancreatic disease**
 - Gastrooesophageal reflux disease
 - Gallstones
 - Pancreatitis
- Liver disease**
 - Nonalcoholic steatohepatitis
- Genitourinary disease in women**
 - Irregular menses
 - Amenorrhoea
 - Infertility
- Pregnancy** – Neural tube defects, perinatal mortality, pre-eclampsia, gestational diabetes, pre-term labour, caesarean sections, deep vein thrombosis.
- Malignancy** – Sex-hormone-sensitive cancers such as cancer of colon, rectum and prostate in men and the breast, ovary, endometrium and cervix in women.
- Skin** – Dermal and sweat rashes.
- Psychosocial** – Psychological and emotional stress appears to be more common.
- Postoperative complications.**

Table 14: Drugs causing obesity

• Anticonvulsants:	Sodium valproate, phenytoin, gabapentin
• Antipsychotics:	Chlorpromazine, risperidone, olanzapine
• Antidepressants:	Citalopram, mirtazapine
• β -blockers	Atenolol
• Corticosteroids	Prednisolone, dexamethasone
• Insulin	All formulations
• Serotonin antagonists	Pizotifen
• Sex steroids	Medroxyprogesterone acetate, progesterone, combined oral contraceptives
• Oral	Glibenclamide, hypoglycaemic gliclazide, repaglinide, pioglitazone
• Protease	Indinavir, ritonavirinhibitors

Table 16: Classification of obesity-related respiratory compromise*Stage 1 - BMI <27 kg/m²*

- Normal forced vital capacity
- Reduced end-expiratory reserve volume
- Low-normal PaCO₂
- Recumbency in sleep may impair ventilation and vascular perfusion
- Impaired exercise capacity

Stage 2 - BMI 27-35 kg/m²

- Restrictive defect, forced vital capacity 80% predicted
- Reduced lung and chest wall compliance
- End-expiratory reserve volume almost equals closing volume
- Ventilation/perfusion mismatch
- Increased alveolar-arterial gradient
- Impaired gas exchange during sleep
- Mild daytime hypercapnia indicative of sleep-disordered breathing
- Dyspnoea on exercise and at rest

Stage 3 - BMI >35 kg/m²

- Pulmonary hypertension and right heart failure
- Hypercapnoea
- Obesity-hypoventilation syndrome
- Obstructive sleep apnoea

like cream, butter, fat. Beans and pork. Fluids not more than 2 pints a day. No restriction of - meat, fish and fowl, all green vegetables, eggs and fruits.

3. **Drugs:** (a) *Sibutramine* - inhibits reuptake of noradrenaline and serotonin, promoting and prolonging satiety. Dose - 10 mg starting, may be increased to 15 mg daily if inadequate wt. loss on 10 mg, or decreased to 5 mg if patient does not tolerate 10 mg dose. Side-effects - Dry mouth, constipation, insomnia, noradrenergic effects of the drug can cause tachycardia and increased blood pressure. Sibutramine should be avoided in patients with arrhythmia or uncontrolled hypertension. (b) *Orlistat* - is an intestinal lipase inhibitor. It generates malabsorption of 30% dietary fat. Dose - 120 mg with each of the main meals, to be taken immediately after a meal or one hour later. Side effects - are related to effect of fat malabsorption such as loose stools, faecal urgency and flatus. The drug should be used only in patients who can adhere to a low-fat diet. (c) *Rimonabant* - is cannabinoid receptor antagonist. Blockade with the drug produces wt. loss and wt.—independent improvement of some cardiovascular risk factors. Dose - 20mg daily. Side effects are minimal. (d) *Lorcaserin* - is a selective 5-HT_{2C} receptor agonist, by activating the 5-HT_{2C} receptor, lorcaserin is thought to decrease food intake through the pro-opiomelanocor-

tin system of neurons. Dose - 10 mg bd. (e) *PHEN/TPM* - is a combination drug that contains a catecholamine releaser (phentermine) and an anticonvulsant (topiramate). Topiramate was found to have weight loss as an unintended effect when used as an anticonvulsant.

4. **Bulk agents** - which provide essential nutrients and produce a feeling of satiation.
5. **Psychotherapy** - Motivation for weight reduction must be cultivated in the patient's mind. Neurotic subjects are known to seek relief from their anxiety by eating.
6. **Liposuction** - Large volume liposuction is possible, however upper limit that can be removed remains to be defined. The removed fat should not be considered as lost weight.
7. **Surgery** -
 - *Laparoscopic adjustable gastric banding* - (a) A laparoscopic implantation of a silastic band around the stomach just below the gastroesophageal junction. (b) This creates an hour-glass effect. Since the outlet is small, food stays in the pouch longer and patient feels satisfied for a longer time. (c) The band can be adjusted by injecting fluid into as an outpatient. (d) It is 100% reversible.
 - *Laparoscopic sleeve gastrectomy* - (a) This is an operation in which approximately 2/3rd of the left side of the stomach is removed. (b) The stomach thus takes the shape of a tube or sleeve. (c) It removes that part of the stomach that contains Ghrelin hormone, hence decreases the appetite. (d) It is irreversible.
 - *Laparoscopic Roux-en-y bypass* (a) A small stomach pouch is created by stapling the stomach. This causes restriction of food intake. (b) Next a "Y-shaped" section of the small intestine is attached to the pouch to allow food to bypass the first part of small intestine by malabsorption. It is reversible.

Advantages

- In restrictive procedures patients have early satiety with small meals thereby restricting total calorie intake.
- (a) In malabsorptive procedures along with small meals the bypassed portion reduces absorption as well. It also causes good hormonal changes leading to resolving morbidities like diabetes, hypertension, sleep apnoea, etc. (b) The band or staples do not cause cancer. (c) Bariatric surgery improves fertility.

Complications

- Bleeding
- Infection
- Leakage

3. THYROID DISEASE

THYROTOXICOSIS

The term *thyrotoxicosis* refers to the clinical syndrome of hypermetabolism and hypersensitivity which result from excessive amount of thyroid hormones. The term *hyperthyroidism* is used to denote sustained increase in thyroid hormone biosynthesis and secretion by the thyroid gland. Thyrotoxicosis can occur without hyperthyroidism when it is caused by thyroiditis or exogenous thyroid hormone administration. See Table 17 for the causes of thyrotoxicosis. Table 18 describes complications of hyperthyroidism in pregnancy.

GRAVES' DISEASE

Graves' disease is an autoimmune disorder in which thyroid stimulating immunoglobulin (TSI) binds to and stimulates thyroid stimulating hormone (TSH) receptor

Table 17: Causes of thyrotoxicosis

Primary hyperthyroidism

- Graves' disease
- Toxic multi-nodular goiter
- Toxic adenoma
- Functioning thyroid carcinoma metastasis
- Activating mutation of TSH receptor
- Struma ovarii
- TSH secreting pituitary adenoma
- Iodine excess (Jod-Basedow phenomenon)
- Activating mutation of Gsa (McCune-Albright syn.)

Thyrotoxicosis without hyperthyroidism

- Subacute thyroiditis
- Silent thyroiditis
- Other causes of thyroid destruction: Amiodarone, radiation, infarction of adenoma
- Ingestion of excess thyroid hormone (thyrotoxicosis factitia)

Secondary hyperthyroidism

- TSH secreting pituitary adenoma
- Thyroid hormone resistance syndrome
- Chronic gonadotropin-secreting tumor
- Gestational thyrotoxicosis
- Thyrotoxicosis factitia

on thyroid cell membrane resulting in excessive synthesis and secretion of thyroid hormone. Table 19 lists potential risk factors for Graves' disease and Table 20 describes its clinical features.

Table 18: Complications of hyperthyroidism in pregnancy

- Increased and recurrent pregnancy loss
- Preterm delivery
- Pre-eclampsia
- Foetal growth restriction
- Foetal thyroid hyperfunction or hypofunction
- Foetal goiter from excessive antithyroid drug therapy
- Neonatal thyrotoxicosis
- Increased perinatal and maternal mortality
- Decreased IQ of offspring due to excessive use of antithyroid drugs

Table 19: Potential risk factors for Graves' disease

1. Genetic susceptibility – Role of hereditary factors is evidenced by increased incidence of other autoimmune disorders in members of patients' families.
2. *Emotional stress.*
3. *Gender* – Females more prone than men (7 to 10:1) ratio.
4. *Pregnancy* – Iodine containing drugs.
5. *Iodine and drugs* – Amiodarone and iodine containing contrast media may precipitate Graves' disease.
6. *Irradiation*, e.g. radioactive iodine for multinodular goiter.

Table 20: Clinical features

Thyrotoxicosis (found in thyrotoxicosis of any cause)

Symptoms

- Weight loss with increased appetite
- Heat intolerance and sweating
- Fatigue and weakness
- Hyperactivity, irritability, dysphoria, insomnia
- Dyspnoea
- Oligomenorrhoea, loss of libido
- Diarrhoea/hyperdefecation
- Polyuria

Signs

- Tremor, hyper-reflexia
- Tachycardia, atrial fibrillation in elderly
- Warm moist skin
- Lid retraction, lid lag (causing a stare)

Contd...

Contd...

<ul style="list-style-type: none"> • Muscle weakness, proximal myopathy • Gynaecomastia
<i>Specific for Graves' disease</i>
<ul style="list-style-type: none"> • Family or personal history of immune disorders (e.g. vitiligo, pernicious anaemia, type 1 diabetes mellitus, coeliac disease, myasthenia gravis) • Ophthalmopathy
Grittiness, increased tear production
Periorbital oedema
Chemosis (conjunctival oedema)
Proptosis (unilateral in 5–10%)
Diplopia caused by extraocular muscle dysfunction
Impaired visual acuity/visual fields (caused by optic nerve compression)
Corneal ulceration
<ul style="list-style-type: none"> • Pretibial myxoedema • Thyroid acropachy (resembling finger clubbing)
Strongly associated with ophthalmopathy suggesting a shared pathogenesis that is most likely the result of fibroblast activation by cytokines from autoreactive T cells.
<i>Thyroid acropachy</i> in Graves' disease. The hypermetabolic state leads to axial bone destruction presumably secondary to enhanced neoclast activity. Acropachy is not to be confused with clubbing which is usually painless.

Laboratory Evaluation of Thyroid Function

Tests for Testing Thyroid Function

- Serum based methods for measuring both total (T4 and T3) and free (T4 and T3) thyroid hormone concentrations (Table 21)
- Measurement of thyroid hormone binding proteins – Thyroid Binding Globulin (TBG), Transthyretin (TTR)/ Prealbumin (TBPA) and Albumin as well as for the pituitary thyroid stimulation. Thyroid stimulating hormone (TSH) and the thyroid hormone precursor protein Thyroglobulin (Tg)
- Tests to determine thyroid antibodies – Thyroid peroxidase antibodies (TPOAb), Thyroglobulin antibodies (TgAb) and TSH receptor antibodies.

Testing for Thyroid Dysfunction

TSH is the first test to be performed since it is the single best test for thyroid function. The most advanced (third generation) chemiluminescent TSH assays can measure values <0.1 mU/L, thus aiding detection of subclinical

Table 21: Values of thyroid function test

Test	Range
TSH	0.5–4.7 m μ /L
T3	0.92–2.78 nmol/L
FT3	0.22–6.78 nmol/L
T4	58–140 nmol/L
FT4	10.3–35 pmol/L

Table 22: Causes of abnormal serum TSH concentrations

TSH below normal	TSH above normal
Primary hyperthyroidism	Primary hypothyroidism
Pituitary/hypothalamic disease with central hypothyroidism thyroid (TSH unreliable)	Pituitary thyrotroph adenoma, pituitary resistance to hormone
Prolonged thyrotroph cell suppression after recent hyperthyroidism in euthyroid or hypothyroid patient	Generalized thyroid hormone resistance
Old age	Thyrotoxicosis from rapid correction of severe hypothyroidism with parenteral T4
Problems with T4 treatment: Overdosage for fatigue or overweight diseases. Altered T4 clearance because of drugs or disease	Old age
Severe systemic illness (Sick euthyroid state)	Drugs, e.g. amiodarone
	Problems with T4 treatment: under dosage, altered GI absorption or altered clearance of T4 because of drugs
	Recovery phase after severe systemic illness

thyrotoxicosis. A normal TSH value is sufficient indicator to stop further thyroid function in most cases. However, in cases suggestive of possible hypothalamic pituitary disease (central), a free T4 level estimation is desirable. See Table 22 for the causes of abnormal serum TSH concentrations.

Indications for TSH Testing

- Patients presenting with suspected goiters
- As screening test for congenital hypothyroidism
- Patients with AF, dyslipidaemia, osteoporosis and infertility
- As screening test for thyroid disorders in patients with unclear diagnosis

Diagnosis

1. **Serum T3, T4** – (Refer)
2. **Thyroid antibodies** – (Refer)
3. **Serum thyroperoxidase (TPO)** – Increased concentrations of TPO antibodies indicate autoimmune thyroid disorder and a raised TSI Graves' disease.
4. **Other laboratory abnormalities** – Hyperglycaemia, hypercalcaemia, elevated alkaline phosphatase, leucocytosis and elevated liver enzymes may occur.
5. **Imaging**
 - Nuclear medicine scanning – Radioactive uptake and scanning. After ingestion of I^{131} , the emitted radiation allows external detection, calculation of fractional uptake and scintigraphy imaging of thyroid gland.
 - Thyroid ultrasound – Can identify thyroid nodule and goiter. Also, Doppler index of blood flow percentage is used to distinguish between Graves' disease and thyrotoxicosis caused by non-hypermetabolic destructive thyrotoxicosis.

Differential Diagnosis:

Toxic nodular goiter (Table 23)

Total T4. In some clinical conditions, Total T3 and T4 may be elevated (Table 24) while in the thyroid functional state free T3 and T4 levels may be normal –

1. Hereditary abnormalities of binding proteins, e.g. TBG deficiency or TBG excess, abnormal albumin and transthyretin levels.
2. Acquired deficiency of binding proteins, e.g. nephrotic syndrome causing protein loss, impaired production of proteins in severe liver disease and therapy with androgens or anabolic steroids.
3. Drug-induced alterations in T4 binding to TBC, e.g. salicylates, phenytoin.
4. Presence of T4 antibodies.
Radioimmunoassay measurements overcome many of these problems.

Table 23: Differences between Graves' disease and toxic nodular goiter

	Graves' disease	Toxic nodular goiter
Age	Younger	Older
Gland	Smooth, diffuse	Nodular, irregular
Eye signs	enlargement	Rare
Cardiac involvement	Common	Common
Pressure symptoms	Uncommon	Common
Autoimmune disease	Uncommon	Uncommon
	Common	

Total T3. Indications for free T3 / total measurements –

1. In patients suspected of having thyrotoxicosis.
2. In patients taking drugs that inhibit peripheral conversion of T4 to T3, e.g. dexamethasone, propranolol, propylthiouracil, amiodarone.

Testing Both TS4 and FT4

Clinical situations

- Optimising the therapy in newly diagnosed patient with hypothyroidism
- Diagnosing and monitoring thyroid disorders in pregnancy
- Monitoring patients with hypothyroidism in early months after treatment
- Diagnosing and monitoring treatment for central hypothyroidism
- Endo-organ thyroid hormone resistance
- Sick euthyroid state
- Women with type 1 diabetes should have their thyroid function including serum TSH, FT4 and thyroid peroxidase antibody test status established preconception at booking when pregnant and at 3 months post-partum.

Thyroid Autoimmunity. Thyroid Specific Autoantibodies

1. **Thyroid peroxidase autoantibodies (TPOAb).** Clinical use – Approximately 70–80% of patients with Graves' disease and virtually all patients with Hashimoto's, atrophic thyroiditis or post-partum thyroiditis have TPOAb detected. A euthyroid patient with detectable TPOAb is at a risk of development of hypothyroidism.
2. **Thyroglobulin autoantibodies (TgAb)** – is primarily an adjunct test for serum Tg estimation.
3. **TSH receptor autoantibodies (TRAb).** Clinical uses – In the differential diagnosis of hyperthyroidism, prediction of foetal and neonatal thyroid dysfunction due to transplacental passage of normal TRAb and prediction

Table 24: Causes of elevated serum thyroxine concentration

- Thyrotoxicosis
Increased serum protein binding
Increased serum thyroxine binding globulin concentrations
- Inherited
Estrogen: Pregnancy, exogenous humoral production
Hepatitis, hepatoma
HIV infection
Psychiatric and medical illness
- Drugs: Heroin, methadone, 5-Fluorouracil, amiodarone, propranolol

of course of Graves' disease treated with antithyroid drugs.

Thyroid Function Tests in Special Situations

1. Patients presenting with AF, hyperlipidaemia, osteoporosis, subfertility.
2. Type 1 diabetes in women raises the likelihood of developing postpartum thyroid dysfunction by three times.
3. Women with past history of postpartum thyroiditis.
4. Patients with diabetes, Type 1 DM - yearly thyroid function tests. Type 2 DM - at diagnosis.
5. Down syndrome and Turner's syndrome. Yearly tests because of high incidence of hypothyroidism.
6. Patients receiving Amiodarone and Lithium. Assessment at beginning of therapy and thereafter every 6–12 months during treatment and till 12 months after cessation of therapy with amiodarone and every 6–12 months during therapy with lithium.
7. Post neck irradiation or surgery - Assessment annually.
8. Destructive treatment of thyrotoxicosis by radioiodine or surgery. Assessment 4–6 weeks after treatment, followed by quarterly and annually thereafter.
9. Treatment with antithyroid drugs. Thyroid function every 1–3 months to determine if stable hormonal concentrations have been reached when antithyroid therapy is started and thereafter if long term treatment is required.
10. Patients on thyroxine therapy, regardless of the cause, TSH annually. In pregnant women, dose may need to be increased by 50 µg/d to maintain TSH level.

Management: of Thyrotoxicosis

1. 'Antithyroid' drugs

Thionamides

Mode of action - Carbimazole and Propylthiouracil inhibit iodine organification by thyroid peroxidase, reducing T_3 and T_4 production. Propylthiouracil also inhibits conversion of T_4 to T_3 in severe thyrotoxicosis. These drugs also reduce TSH receptor-stimulating antibody levels, which probably accounts for sustained remission in 40–50% of patients with Graves' disease.

Indications - (1) All subjects preoperatively. (2) Children and adolescents with first attack of thyrotoxicosis. (3) Thyrocardiacs and thyrocachectics. (4) Patients with small toxic multinodular goiters. (5) Pregnancy with hyperthy-

roidism. (6) Patients who for some reason cannot have surgery, and radioactive iodine is not available or justified because of young age of the patient. (7) Mild cases.

Contraindications - (1) Hypersensitivity. (2) Anaemia or leucopenia. (3) Kidney or liver disease.

Dosage

- (a) Titration regimen - Initial dose: High doses (carbimazole 40–60 mg/day, or propylthiouracil 300–450 mg/day), then gradually reduced every 4–8 weeks based on FT4 levels. When FT4 levels are normal carbimazole 5–15 mg/day or propylthiouracil 50 mg/day. Treatment is usually continued for 18–24 months, with regular checking of FT4 and TSH levels.
- (b) Block-replace regimen - Carbimazole 40 mg/day or propylthiouracil 300 mg/day is maintained throughout and hypothyroidism avoided by addition of T4 100 µg/day. Three to four weeks after starting treatment, T4 dose is subsequently adjusted based on FT4 levels. This regimen can be given for 6 months with a remission rate similar to that of the titration regimen. Patients are reviewed regularly in the year after stopping antithyroid drugs, because 70% of relapses occur during this period.

Duration of therapy - Tr. is continued for 18–24 months, with regular checking of T_4 and TSH levels every 3 months.

Side-effects - Abnormal sense of taste, pruritus, arthralgias and urticaria, hepatitis. The most serious is agranulocytosis related to dose of methimazole (> 30 mg/day).

Other antithyroid drugs - (a) β -blockers (propranolol 60–120 mg/day) relieve symptoms such as tachycardia, tremor and anxiety. β -blockade should be used as primary treatment only in patients with thyrotoxicosis due to thyroiditis. (b) *Dexamethasone* 8mg/day may be used to inhibit conversion of T_4 to T_3 in patients with thyroid storm (the most severe form of thyrotoxicosis). Also to relieve severe anterior neck pain and to restore euthyroidism in patients with painful subacute thyroiditis. (c) *Inorganic iodine* (SSKI or Lugol's solution) decreases synthesis of thyroid hormone and release of hormone from the thyroid in the short term. It is used to reduce thyroid vascularity before thyroidectomy, and in thyroid storm. (d) *Lithium* carbonate inhibits thyroid hormone secretion. Dose: 300–450 mg tds to provide temporary control of thyrotoxicosis in patients who are allergic to thionamides and iodide. Another short term use for lithium has been as an adjunct to radioiodine therapy in that the drug slows release of iodine from the thyroid. (e) *Potassium perchlo-*

rate 500 mg bd inhibits iodine uptake by the thyroid gland by direct inhibition of the sodium iodine supporter. It can be combined with thionamides. Side effects – Aplastic anaemia, nephrotic syndrome with prolonged treatment. Advantages – Particularly useful in patients with iodine-induced thyrotoxicosis as seen in patients with amiodarone induced thyrotoxicosis. (f) *Cholestyramine* decreases reabsorption of thyroid hormones from the enterohepatic circulation. Dose – 4 gm qds in combination with methimazole or PTU.

2. Radioactive iodine

Mode of action – Destruction of functional thyroid cells or inhibition of their ability to replicate.

Indications – (i) In patients over the age of 40 it is the treatment of choice. (ii) Toxicity recurring after previous subtotal thyroidectomy. (iii) Very nervous patients who fear surgery. (iv) Patients with severe thyrotoxic heart disease or other debilitating conditions. (v) Young patients who have relapsed following antithyroid drugs or who have shown sensitivity reactions to them.

Contraindications – (i) Patients under 45 years of age because of high incidence of hypothyroidism (except recurrence of thyrotoxicosis after subtotal thyroidectomy or severe cardiac or other associated disease). (ii) During pregnancy and lactation.

Advantages – (i) Simple procedure. (ii) Patient may be ambulant. (iii) Usually no radiation sickness or initial swelling of the thyroid gland. (iv) No skin changes. (v) Successful in almost all cases. (vi) Cheap. (vii) Useful in uncooperative patients and those with extremely large goiters.

Table 25: Indications of surgery

Table 25: Indications of surgery	
<i>Absolute</i>	
Suspicion of biopsy proven malignant nodules	
Co-morbidity requiring surgery, e.g. hyperparathyroidism	
Pregnancy or lactation	
Young children	
Severe intolerance to antithyroid medications	
Large compressive/obstructive goiter	
<i>Relative</i>	
Severe Graves' ophthalmopathy	
Patients desiring pregnancy within 6–12 months of treatment	
Patients unable to continue close follow-up	
Patients incompletely treated by radioactive iodine ablation	

(viii) Also useful when serious toxic reactions have followed therapy with other compounds. (ix) No mortality.

Disadvantages – (i) High incidence of permanent hypothyroidism. (ii) Optimum benefit does not take place until about 3 months.

Dose – Antithyroid drugs are given and/or shortly after ¹³¹I to prevent thyroid storm. Antithyroid drugs must be stopped for a minimum of 3–5 days before ¹³¹I to allow uptake of the isotope 555 MBq to ablate the thyroid. High doses are used for large goiters in severely thyrotoxic patients.

Side effects – Mild neck pain, anterior neck pain caused by radiation thyroiditis or worsened thyrotoxicosis, owing to leakage of preformed thyroid hormones from the damaged thyroid gland. Graves' ophthalmopathy may develop or worsen after treatment especially in smokers and in patients with severe hyperthyroidism. Graves' ophthalmopathy can be prevented by simultaneous administration of glucocorticoids.

3. Surgery (Subtotal thyroidectomy)

See Table 25 for the indications of surgery.

GRAVES' DISEASE

See Table 26 for the symptoms and signs of thyroid ophthalmopathy.

Table 26: Thyroid ophthalmopathy

Table 26: Thyroid ophthalmopathy	
<i>Symptoms</i>	
Dry eyes	Field loss
Puffy eyelids	Dyschromatopsia
Proptosis	Photopsia on up gaze
Eyelid retraction	Ocular pressure or pain
Diplopia especially at extreme gaze	Lacrimation
Visual loss	
<i>Signs</i>	
Lid signs: Lid lag and lid retraction resulting in a staring look.	
Soft tissue signs – Eyelid oedema, conjunctival erythema and chemosis.	
Proptosis – Combined with lid retraction and inferior rectus restriction leads to corneal exposure and ulceration.	
Restrictive extraocular myopathy. Recti involved in decreasing order of severity and frequency are inferior rectus, superior rectus and lateral rectus.	
Strabismus often represents as hypotropia or esotropia. In patients with thyroid ophthalmopathy and exotropia, possibility of concurrent myasthenia gravis should be considered.	
Optic nerve compression – Compressive thyroid optic neuropathy.	

Contd...

Contd...

Glaucoma may result from decreased episcleral venous flow.

Other eponymous signs

- Vigouroux sign (Eyelid fullness)
- Stellwag's sign (Incomplete and infrequent blinking)
- Graves' sign (Resistance to pulling down the retracted upper lid)
- Joffroy sign (Absent creases on the forehead on superior gaze)
- Mobius sign (Poor convergence)
- Ballet sign (Restriction of one or more extraocular muscles)

Deep glabellar rhytides – Due to hypertrophy of brow depressor muscles compensating for lid retraction

Management

Discomfort

- Artificial tears during the day
- Simple eye ointment at night
- Dark glasses with side frames

Medical therapy: (1) No smoking. (2) Reduction of morning lid oedema by sleeping on a bed with its head slightly raised. (3) Radiotherapy. (4) Glucocorticoids. (5) Antioxidants. (6) Somatostatin analogues. (7) Monoclonal antibody (Rituximab). (8) Immuno-suppressive drugs.

Surgery: (1) Orbital decompression. (2) Strabismus surgery. (3) Lid lengthening. (4) Blepharoplasty.

Contraindication – Patients showing evidence of marked exophthalmos. The likelihood of such patients developing even more severe exophthalmos of the malignant type after surgery is great.

Advantages – (i) Cures a higher percentage of patients. (ii) Cures in a shorter time.

Disadvantages – (i) Greater risk to the patient. (ii) Expense of hospitalization. (iii) Interference with patient's work for a considerable time. (iv) Complications like laryngeal paralysis, tetany and hypoparathyroidism. (v) Permanent hypothyroidism.

Table 27: Precipitating factors of hyperthyroid crisis

- Thyroid surgery
- Radioiodine
- Withdrawal of antithyroid drugs
- Iodinated contrast agents
- Acute illness (e.g. stroke, infection, trauma, diabetic ketoacidosis)

Preparation for surgery – The antithyroid drug is stopped 2 weeks before operation and replaced by pot. iodide 60 mg tds which reduces the size and vascularity of the gland. An alternative method for patients who need surgery within a short period of time is propranolol 80 mg t.d.s. and pot. iodide 60 mg t.d.s. for 10 days prior to surgery.

Management of Strategic Disorders in Thyrotoxicosis

Graves' disease in pregnancy – should not be managed by the block-replace regimen; insufficient thyroxine crosses the placenta to counter the effects of antithyroid drugs, resulting in foetal hypothyroidism. Instead the lowest possible dose of antithyroid drug should be used to maintain euthyroidism. Thyroidectomy is safe in the second trimester of pregnancy. If available, propylthiouracil should be used in early gestation because of the association of rare cases of fetal aplasia cutis and other defects, such as choanal atresia with carbimazole and methimazole. Because of its rare association with hepatotoxicity, propylthiouracil should be limited to the first trimester and then maternal therapy should be converted to methimazole (or carbimazole) at a ratio of 15–20 mg of propylthiouracil to 1 mg of Methimazole.

THYROID EMERGENCIES

Hyperthyroid Crisis (Thyroid Storm)

An uncommon, life-threatening exacerbation of thyrotoxicosis. See Table 27 for precipitating factors and Table 28 for the clinical features of hyperthyroid crisis.

Treatment

- Carbimazole 300 mg or propylthiouracil 600 mg loading dose, then 100 mg or 200 mg 6-hourly
- Stable iodine (e.g. Lugol's iodine or sodium ipodate 500 mg p.o. 1 hr. later)
- Propranolol 60 mg every 6 hours (Caution with complicating cardiac failure) or dexamethasone 8 mg orally od. If β -adrenergic blocking agents labetalol or esmolol are contraindicated, diltiazem may be used to slow the heart.

Table 28: Clinical features of hyperthyroid crisis

- Severe thyrotoxicosis
- Cardiac – Marked tachycardia, conduction disturbances such as AV blocks
- Cerebral: Delirium, seizure, coma
- GI: Vomiting, diarrhoea, abdominal pain, jaundice
- Fever

Table 29: Causes of hypothyroidism

Primary hypothyroidism (95% of cases)	Secondary hypothyroidism (5% of cases)	Other causes
Idiopathic Hashimoto's thyroiditis Irradiation of thyroid subsequent to Graves' disease Surgical removal of the thyroid Late stage invasive fibrous thyroiditis Iodine deficiency	Pituitary or hypothalamic neoplasms Congenital hypothyroidism Pituitary necrosis (Sheehan's syndrome)	Drug therapy (e.g. amiodarone, lithium, interferon) Infiltrative diseases (e.g. sarcoidosis, amyloidosis, scleroderma, hemochromatosis)

- Supportive measures (Dexamethasone, i.v. fluids, cooling)
- Treatment of precipitating cause

HYPOTHYROIDISM

Clinical condition resulting from reduced production of thyroid hormone. When the hypothyroidism is of severe degree and of long-standing, it is seen as myxoedema which is characterised by deposition of mucinous material (hyaluronic acid and mucopolysaccharides) causing swelling of skin and of subcutaneous tissues. The cause may be *primary thyroid disease*, or less commonly, disease of the pituitary or hypothalamus (*secondary hypothyroidism*) (Table 29).

Clinical Features

Onset – Insidious with physical, mental and metabolic processes below normal (Table 30).

A thyroid enlargement is usually made out by its movement on swallowing which will be lost only by a large impacted goiter, or by a rare case of invasive carcinoma or Riedel's thyroiditis.

Investigations

1. *Thyroid function tests* –
 - Reduction in free and total T_4 , and rise in serum TSH (usually more than 15–20 mU/L) indicates primary hypothyroidism.
 - Elevated serum TSH with normal serum T_4 is termed 'subclinical' hypothyroidism.

Note: Measurement of serum free or total T_3 is usually unhelpful, since T_3 may be only slightly reduced, because of increased peripheral conversion of T_4 to T_3 .

- Reduction in free and total T_4 , with TSH level within or below normal range, suggests secondary hypothyroidism.

Table 30: Clinical features of hypothyroidism

<i>General</i>
<ul style="list-style-type: none"> • Tiredness, somnolence • Weight gain • Cold intolerance • Goiter • Hyperlipidaemia
<i>Skin and subcutaneous tissues</i>
<ul style="list-style-type: none"> • Coarse dry skin • Puffiness of face with malar flush • Baggy eyelids • Myxoedema – Swollen oedematous appearance of supraclavicular regions, neck, back of hands and feet • Minimal sweating • Alopecia • Vitiligo • Carotinaemia • Erythema ab igne
<i>Cardiovascular/Respiratory</i>
<ul style="list-style-type: none"> • Bradycardia • Angina • Cardiac failure • Pericardial effusions • Pleural effusions
<i>Psychiatric features</i>
<ul style="list-style-type: none"> • Depression (myxoedema madness) • Psychosis
<i>Neuromuscular</i>
<ul style="list-style-type: none"> • Aches and pains • Carpal tunnel syndrome • Cerebellar ataxia • Myalgia and muscle stiffness • Hoarseness • Deafness of perceptive type • Delayed relaxation of reflexes

Contd...

Contd...

Gastrointestinal –
<ul style="list-style-type: none"> • Constipation • Ileus • Ascites
Hematological –
<ul style="list-style-type: none"> • Iron deficiency anaemia (due to blood loss from menorrhagia). • Macrocytic anaemia (due to associated vitamin B12 deficiency) • Pernicious anaemia • Normochromic, normocytic anaemia (most common) which may respond to thyroxine alone.
Reproductive system –
<ul style="list-style-type: none"> • Infertility • Menorrhagia • Hyperprolactinaemia and galactorrhoea • Impotence
Developmental –
<ul style="list-style-type: none"> • Growth retardation • Mental retardation • Delayed puberty

2. **Serum cholesterol** – Elevated in primary thyroid failure. A fall in serum cholesterol level of more than 50 mg/dL in response to thyroxine treatment is good retrospective evidence of primary thyroid failure.
3. **ECG** – Bradycardia, low voltage complexes and flattened or inverted T waves. Marked improvement occurs with thyroxine treatment.
4. **Thyroid antibodies** – (Refer)

Iodine-deficient hypothyroidism – Most iodine deficient individuals have a goiter but are euthyroid with normal or elevated serum TSH.

Cretinism – Severe maternal iodine deficiency leading to goiter and hypothyroidism is associated with – (a) *Neurological cretinism*: Mental retardation after birth, which is not improved by iodine or thyroid supplementation either in pregnancy or neonatal life. (b) *Myxoedematous cretinism*: Iodine deficiency in late pregnancy results in neonatal hypothyroidism, which predominantly affects somatic development leading to marked growth retardation, and responds to iodine supplementation or thyroxine.

Management

Initiating replacement therapy

Table 31 gives dosages to initiate thyroxine replacement therapy and Table 32 gives conditions requiring increase in thyroxine dosage.

Table 31: Initiating thyroxine replacement therapy

Patient	Thyroxine therapy
Healthy adult patients with hypothyroidism	Thyroxine 1.6 µg/kg/d 1 µg/kg/d may require upto 4 µg/kg/d
Elderly children	Levothyroxine 0.075 mg/d to be titrated against serum TSH levels with small gradual increments
Young patients without risk factors for cardiovascular disease	Thyroid replacement at 0.025 mg/d, gradually increased by 0.025 to 0.50 every 4–6 weeks till TSH levels are normalized
Patients at risk of cardiovascular compromise	

Table 32: Conditions requiring increase in thyroxine dosage

Pregnancy: Foetal requirement for T ₄	
Drugs:	
Increased clearance of T ₄	Rifampicin
	Phenytoin
	Carbamazepine
Decreased absorption of T ₄	Cholestyramine
	Sucralfate
	Aluminium hydroxide
	Ferrous sulphate

Clinical Response

The earliest is usually diuresis and weight loss is usually minimal and late. Other features which improve are appetite, constipation, hoarseness of voice, and much later cold intolerance and fatigue.

Monitoring therapy – The objective of T₄ therapy is to restore serum T₄ and TSH to normal levels. In most patients dose requirements of T₄ do not change but pregnancy and some drugs, e.g. rifampicin, phenytoin, carbamazepine (increased clearance of thyroxine), and cholestyramine, sucralfate, aluminium hydroxide, ferrous sulphate (decreased absorption of thyroxine) may necessitate a dose increase.

Duration of therapy – Mild hypothyroidism occurring within the first 6 months after therapy for hyperthyroidism, or diagnosis of subacute or silent thyroiditis, may be temporary. If symptoms are sufficiently severe, T₄ can be given for 6 months and then stopped for 6 weeks so that serum TSH can be measured. For hypothyroidism in other circumstances T₄ therapy is lifelong.

Special Situations

Ischaemic heart disease – T₄ should be started on a low dose (25 µg daily or on alternate days) to avoid precipitating a worsening angina, or myocardial infarction. The dose can be increased every 4 weeks until euthyroidism is achieved.

'Subclinical' hypothyroidism – Elevated serum TSH with normal T_4 levels is seen in patients treated for hyperthyroidism, and also occurs spontaneously, particularly in the elderly. The slowly progressive nature of thyroid failure in these patients, particularly those who have received radioiodine or who are thyroid antibody-positive, require T_4 .

Pregnancy – In patient on thyroxine replacement therapy, the mean increment in the required daily dose is 50 μg , which is usually by the end of the first trimester though may be delayed as the 6th month in some. The levothyroxine dose may need to be increased by up to 50% during pregnancy, with a goal TSH of less than 2.5 mIU/L during the first trimester and less than 3.0 mIU/L during the second and third trimesters.

Central hypothyroidism – Glucocorticoid replacement should be initiated prior to thyroxine replacement.

Drug interactions – With antacids and iron formulations concurrent use of these may reduce efficacy of Levothyroxine by binding and deleting or preventing absorption of calcium carbonate and ferrous sulphate from insoluble chelate and ferric thyroxine complex respectively. Hence these drugs should be taken at least 4 hours apart from levothyroxine.

Myxoedema coma – Severe life, threatening complication of hypothyroidism typically seen in the elderly and often precipitated by infection, therapy with sedative drugs or inadequate heating in cold weather. Cerebrovascular accidents, CHF, overuse of diuretics.

Cl. Fs. – Although coma does not occur in all patients, depression of the conscious level is common and majority of patients have hypothermia. Other features include hypotension, bradycardia, hyponatraemia and hypoventilation with hypoxia and hypercapnia.

Management

(a) Admission to ICU. (b) Ventilatory support for at least 24–48 hours with frequent measurement of atrial blood gases. (c) Endotracheal tube to be retained till patient fully conscious. (d) If hyponatraemia, fluid restriction and small volume of saline or dextrose saline, usually adequate. If serum sodium falls < 120 mEq/L, hypertonic saline followed by IV frusemide to promote water diuresis may be needed. (e) Warmth should be carried out cautiously or else the resultant peripheral vasodilation may cause hypotension. (f) Hydrocortisone 50–100 μg to tackle the impaired adrenal reserve which may manifest when thyroxine therapy is initiated. (g) Thyroid hormone – T_4 300–500 μg loading dose followed by 50–100 μg q6h for

one or two days. Once patient has an improved sensorium and is accepting orally he/she can be shifted back to oral replacement therapy.

THYROIDITIS

Thyroiditis is a term indicating presence of thyroid inflammation, and thus comprises a large group of diverse inflammatory conditions. Table 33 gives etiological classification of thyroiditis.

Acute Thyroiditis

Clinical features of acute thyroiditis are local pain and tenderness in the affected lobe or entire gland with dysphagia, fever, anterior neck pain. Radioiodine scanning shows "cold" suppurative area. FNab with staining and culture is diagnostic. Appropriate antibiotic therapy and drainage of abscess is the therapy.

Subacute Thyroiditis

Painful subacute thyroiditis often follows viral upper respiratory illness (mumps, coxsackie, influenza and adenovirus) and is the common cause of thyroid pain. Fever, dysphagia, fatigue, anxiety, sweat may occur. Thyroid is very tender, hard, mild to moderately enlarged and often nodular. Pain in neck is constant, after aggravated by neck movements. ESR and CRP are elevated, and thyroglobulin level is high. Doppler study reveals hypoechogenic glands. Subacute thyroiditis is usually self-limiting, euthyroidism is achieved in majority of cases over 6–12 months. *Tr.*

Table 33: Etiological classification

Acute
<ul style="list-style-type: none"> • Infective <ul style="list-style-type: none"> – Bacterial: Staphylo, Strepto, Enterobacter – Fungal: Aspergillus, Candida, Histoplasma, Pneumocystis – Radiation therapy – Drug-induced: Amiodarone
Subacute
<ul style="list-style-type: none"> • Infective <ul style="list-style-type: none"> – Viral or granulomatous thyroiditis – Mycobacterial infection – Silent thyroiditis (including postpartum thyroiditis)
Chronic
<ul style="list-style-type: none"> • Autoimmune: Focal thyroiditis, Hashimoto's thyroiditis, atrophic thyroiditis • Riedel's thyroiditis
<ul style="list-style-type: none"> • Infective <ul style="list-style-type: none"> – Parasitic: Echinococcosis, cysticercosis – Traumatic: After palpation

NSAIDs for mild to moderate pain, in severe cases. Prednisolone upto 40 mg/d. If hypothyroid state is prolonged, thyroxine 50–100 µg daily.

Autoimmune Thyroid Disorder

AITD is the most common organ specific autoimmune disorder comprising Graves' disease, Hashimoto's thyroiditis, (goitrous), atrophic thyroiditis, silent thyroiditis and thyroid associated ophthalmopathy. Middle aged women and men are commonly affected.

Cl. Fs.: Depends upon type and stages of the disease. Hashimoto's thyroiditis presents with small to large firm and painless goiter. Patients slowly develop progressive hypothyroidism, some eventually become hypothyroid. The disease is associated with other autoimmune diseases including pernicious anaemia. Graves' disease has also been mentioned. Thyroid lymphoma is a rare complication of chronic autoimmune thyroiditis.

Diagnosis: CFD is helpful for semiquantitative measurement of blood flow to thyroid gland.

Treatment: (i) Hashimoto's thyroiditis. FNAC is useful, L-thyroxine replacement. (ii) Graves' disease - Antithyroid drugs, propranolol. (iii) Painless postpartum thyroiditis. Thyrotoxic phase can be treated with beta-blockers, during breast feeding. Iodine¹³¹ is contraindicated. By using technetium pertechnate, interruption of breast feeding for only 24 hours.

Drugs: known to provoke autoimmune or destructive inflammatory thyroiditis are lithium, amiodarone, interferon, interleukin-2 and sunitinib.

Post-partum thyroiditis. Painless lymphocytic thyroiditis occurs in up to 10% of women, post-partum. This is an inflammatory autoimmune disorder in which lymphocytic infiltration results in thyroid destruction and leads to transient mild thyrotoxicosis as thyroid hormone stores are released from the damaged thyroid. As the gland becomes depleted of thyroid hormone, progression to hypothyroidism occurs. Thyroid function returns to normal within 12-18 months in majority of cases.

Painful subacute thyroiditis, the most common cause of thyroid pain, is a self-limiting inflammatory disorder of possible viral etiology. Patients typically present with fever and severe neck pain or swelling or both. About half will describe symptoms of thyrotoxicosis. After several weeks, most patients will develop hypothyroidism. Thyroid function eventually returns to normal in almost all patients. ESR and C-reactive protein are elevated in painful subacute thyroiditis.

Riedel's thyroiditis is rare and occurs primarily in middle aged women. The etiology is uncertain and the condition is characterised by fibrosis of thyroid gland and adjacent structures. Symptoms develop insidiously and are due mainly to compression of adjacent structures including trachea, oesophagus and recurrent laryngeal nerve. The thyroid gland is moderately enlarged, stony hard and usually asymmetrical, severe hypothyroidism may occur. Surgery may be necessary to preserve tracheal and oesophageal function. Tamoxifen may also be beneficial. There is an association between Riedel's thyroiditis and IgG4-related systemic disease causing idiopathic fibrosis at other sites (retroperitoneum, mediastinum, biliary tree, lung and orbit).

Hashimoto's thyroiditis - An autoimmune disorder which typically affects middle-aged and elderly women. *Cl. Fs.* - Presentation is with goiter, hypothyroidism or both. *Associated conditions* - include vitiligo, pernicious anaemia, type 1 diabetes mellitus, Addison's disease, and premature ovarian failure. Increased incidence is also found with Down's or Turner's syndrome.

4. THYROID GOITER

A goiter is an enlargement of the thyroid gland, and may be symmetrical, asymmetrical or nodular. See Table 34 for WHO classification of goiter and Table 35 for causes of goiter.

HISTORY

- Long-standing goiter suggests benign disease, unless there has been recent rapid development.
- Ingestion of drugs with goitrogenic action (lithium, antithyroid drugs, iodine).
- Exposure to radiation (particularly in childhood) is a risk for both benign and malignant nodular thyroid disease.

Table 34: WHO classification of goiter

Grade	Description
0	No goiter
1A	Goiter detectable by palpation alone
1B	Goiter palpable and visible only when the neck is fully extended
2	Goiter visible with the neck in normal position
3	Very large goiter visible at 10 meters

Table 35: Causes of goiter**Diffuse goiter**

- Simple, non-toxic
- Grave's disease
- Hashimoto's thyroiditis
- Subacute thyroiditis
- Painless (silent) thyroiditis
- Thyroid lymphoma

Single nodule

- Adenoma
- Carcinoma

Multiple nodules

- Multinodular goiter
- Hashimoto's thyroiditis

- Age of the patient: Thyroid nodules are uncommon in childhood. There may be increased risk of cancer in nodules that develop after the age of 65 years.
- Family history of goiter may suggest autoimmune thyroiditis.
- Pain and tenderness usually suggest subacute thyroiditis or hemorrhage into a cyst.

EXAMINATION

- **Size of the goiter**
- Other features – whether it is diffuse or nodular, firm or hard, tender or painless and its mobility.
- Vascular thrill and systolic bruit suggest hyperthyroidism
- Hoarseness or dyspnoea are more likely to be due to local invasion by malignancy rather than multinodular goiter
- Presence or absence of cervical lymphadenopathy. Table 36 gives the functional status of thyroid goiter.

INVESTIGATIONS**1. Biochemical tests**

Iodine deficiency disorder (IDD) – Severity of IDD can be defined as follows depending on urinary excretion of iodine and prevalence of goiter –

- Mild IDD – Goiter prevalence of 5–20% with mean urinary iodide levels > 50 mg/g of creatinine
- Moderate IDD – Goiter prevalence of 30%, some hypothyroidism and mean urinary iodide levels in the range of 25–50 mg/g of creatinine

Table 36: Functional status of thyroid goiter

<i>Euthyroid goiter</i>	<i>Hypothyroid goiter</i>	<i>Hyperthyroid goiter</i>
Iodine deficiency goiter	Iodine deficiency goiter	Permanent
Autoimmune thyroiditis	Autoimmune thyroiditis	Graves' disease
Subacute thyroiditis	Hashimoto's thyroiditis	Toxic MNG
Postpartum thyroiditis	Subacute thyroiditis	Toxic adenoma
Familial goiter	Postpartum thyroiditis	Iodine induced
Malignancy	Familial (Congenital) goiter	Transient
Goitrogens	(Dyshormonogenesis)	Subacute thyroiditis
Idiopathic	Goitrogens, antithyroid drugs	Postpartum thyroiditis
		Chronic thyroiditis

- Severe IDD – Goiter prevalence > 30%, endemic cretinism (1–10%), and mean urinary iodide levels < 25 µg/g of creatinine
Circulating concentrations of thyroid hormone and TSH – to exclude hyperthyroidism and hypothyroidism.
Serum calcitonin – Calcitonin secretion is increased in medullary thyroid cancer.

2. Immunological tests

- *Circulating thyroid antibodies* (thyroglobulin and thyroid peroxidase) suggest an autoimmune basis for the goiter and are associated with increased risk of future hypothyroidism
- *Serum concentrations of thyroglobulin* are raised in patients with benign or malignant nodules, and is hence of no value in initial assessment of nodular thyroid disease

3. Imaging

- *Thyroid scintiscanning* – Technetium-99m pertechnetate is the most commonly used radionuclide. Pertechnetate ions are trapped by thyroid. Most thyroid malignancies do not concentrate radioisotopes (and thus appear 'cold'), but < 20% of these nodules are caused by cancer, the remaining 80% result from colloid nodules, hemorrhages, cysts or inflammatory lesions (e.g. Hashimoto's thyroiditis). Radionuclide imaging may reveal multifocal abnormalities in patients thought clinically to have a solitary nodule.
- *Ultrasonography* – High resolution ultrasonography can detect lesions of the thyroid as small as 1 mm in diameter. It distinguishes solid from cystic lesions.

- *CT or MRI of neck and thoracic inlet* – for evaluating thyroid size and mediastinal extension of thyroid masses.

4. Fine-needle aspiration biopsy

Obtains thyroid tissue for direct cytological examination and is the optimal initial approach to investigation of a thyroid nodule. Lymphocytic infiltration, obliteration of thyroid follicles, fibrosis and presence of Askanazy cells suggest Hashimoto's thyroiditis; hyperplastic thyroid follicles with fire flare Graves's disease, benign cells adenoma and frankly malignant cells malignancy, lymphoma or metastatic neoplasm.

5. PARATHYROID DISORDERS

HYPOCALCAEMIC DISORDERS

The clinical presentation of hypocalcaemia ranges from an asymptomatic biochemical abnormality to a severe life-threatening condition. Normal serum calcium is 2.15–2.65 mmol/ liter. See Table 37 for the causes of hypocalcaemia.

Table 37: Causes of hypocalcaemia

1. Parathyroid-related disorders

Absence of parathyroid gland or parathyroid hormone

- Congenital
 - DiGeorge syndrome
 - X-linked or autosomal inherited hypoparathyroidism
 - Autoimmune polyglandular syn. type 1
 - PTH gene mutations
- Post-surgical
- Infiltrative disorders
 - Hemochromatosis
 - Wilson's disease
 - Metastases
- After radioactive iodine thyroid ablation
- Impaired secretion of PTH
 - Hypomagnesaemia
 - Pseudohypoparathyroidism

2. Vitamin D-related disorders

- *Vitamin D deficiency*
- Dietary deficiency
- Impaired absorption
- Increased loss

Contd...

- Impaired enterohepatic recirculation
- Anticonvulsant medications
- Impaired 25-hydroxylation
 - Liver disease
 - Isoniazid
- Impaired 1 α -hydroxylation
 - Kidney failure
- Vitamin D-dependent rickets type I
- Oncogenic osteomalacia
- Target organ resistance
 - Vitamin D-dependent rickets type II
 - Phenytoin
- 3. Miscellaneous causes
 - Excessive deposition into the skeleton
 - Osteoblastic malignancies
 - Hungry bone syndrome
 - Chelation
 - Foscarnet
 - Phosphate infusion
 - Citrated blood products infusion
 - Infusion of EDTA-containing contrast reagents
 - Fluoride
 - Neonatal hypocalcaemia
 - Asphyxia
 - Prematurity
 - Diabetic mother
 - Hyperparathyroid mother
 - HIV infection
 - Drug therapy
 - Vitamin D deficiency
 - Hypomagnesaemia
 - Impaired PTH responsiveness
 - Severe illness
 - Pancreatitis
 - Toxic shock syndrome
 - Patients in ICUs

DiGeorge syndrome: It arises from development failure of derivatives of 3rd and 4th pharyngeal pouches, causing agenesis or hypoplasia of thymus (immunodeficiency) and parathyroids (hypocalcaemia), cleft lip and palate, and congenital heart disease.

Contd...

Clinical Features of Hypocalcaemic Neuromuscular Irritability

- Paraesthesia, usually of fingers, toes and circumoral regions.
- Tetany (Table 38), carpopedal spasm, muscle cramps
- Seizures of all types (focal or petit mal, grand mal, or syncope)
- Laryngospasm or grand mal seizures in severe hypocalcaemia during acute falls in serum Ca
- Bronchospasm
- Prolonged QT interval

Latent Tetany

1. *Trousseau's sign* – Carpal spasm produced by compressing the upper arm with a sphygmomanometer cuff to 20 mm Hg above the systolic pressure for 3 minutes.
2. *Chvostek's sign* – Contraction of facial muscles by tapping over the facial nerve in front of the lobe of the ear.
3. *Erb's sign* – Muscles show increased excitability to galvanic stimulation.

Investigations and Diagnosis

Hypoparathyroidism – Serum calcium low, phosphate high and PTH undetectable. Renal function and concentrations of 25-hydroxy and 25-dihydroxy metabolites of vitamin D are normal.

Chronic kidney failure – Low serum calcium, high phosphate, alkaline phosphatase, creatinine and PTH. Normal 25-hydroxyvitamin D₃ and low 1,25-dihydroxyvitamin D₃.

Table 38: Causes of tetany

1. <i>Hypocalcaemia</i>
– Hypoparathyroiditis
– Malabsorption
– Osteomalacia
– Chronic kidney failure
2. <i>Due to alkalosis</i>
– Frequent vomiting (of gastric juice)
– Intake of alkalis
– Hyperventilation
– Primary hyperaldosteronism
3. <i>Due to hypomagnesaemia</i>

Vitamin D-deficiency osteomalacia – Low serum calcium and phosphate, raised alkaline phosphatase and PTH, normal renal function and low 25-hydroxyvitamin D₃.

Management of Acute Hypocalcaemia

Indications

- Symptomatic patients (e.g. with tetany)
- Asymptomatic patients with serum calcium < 1.90 mmol/L, who may be at high risk of developing complications.

Therapy

Calcium gluconate 10ml 10% iv, diluted in 50ml 5% dextrose by slow infusion (> 5 minutes), to be repeated as required to control symptoms.

- For continuing hypocalcaemia – Dilute 10 ampoules of calcium gluconate 10 ml 10% in 1 liter 5% dextrose. Infusion at 50 ml/hour and titrate to maintain serum calcium in the low range. If associated hypomagnesaemia, it must be corrected first. Vitamin D orally if hypocalcaemia is likely to persist.

Management of Persistent Hypocalcaemia

1. Supplemental calcium 10-20 mmol b.d.
2. Vitamin D preparations: (a) Vitamin D₃ (cholecalciferol or vitamin D₂ (ergocalciferol) 25,000-100,000 units (1.25-5 mg/day). (b) Alfacalcidol (1 α -hydroxycalciferol) 0.25-1.0 μ g/day. (c) Calcitriol (1, 25-dihydroxycholecalciferol) 0.25-2.0 μ g/day drug of choice.

CHRONIC HYPOPARATHYROIDISM

Clinical Features

1. *Ectodermal changes* – Nails become brittle, ridges develop and may fall off. Permanent teeth hypoplastic and transversely ridged if disease commences before tenth year. Vesicular or eczematous eruptions may occur on skin. Fissures at angles of mouth. Hair tend to become dry and sparse. Cataracts common. Systemic moniliasis.
2. *Mental symptoms* – Varying from minor disturbances to major psychoses. Electroencephalographic abnormalities may precede development of epilepsy and psychological symptoms.
3. *Diagnostic changes in serum Ca, P and alkaline phosphatase.*

4. *Raised intracranial tension and papilloedema* – may occur, return to normal with correction of hypocalcaemia.
5. *Intracranial calcification* – seen on X-ray in region of basal ganglia as symmetrical punctate opacities.
6. ECG – QT interval prolonged.

Pseudohypoparathyroidism – is characterized by hypocalcaemia caused by PTH resistance. Three major variants are recognised on the basis of biochemical and somatic features – PHP type Ia, PHP type Ib, pseudo- pseudohypoparathyroidism (PPHP) and PHP II.

Patients with PHP Ia exhibit PTH resistance (hypocalcaemia, hyperphosphataemia, elevated serum PTH, absence of increase in serum and urinary cyclic AMP and urinary phosphate after iv PTH infusion). Associated features of Albright's hereditary osteodystrophy (AHO) namely short stature, obesity, subcutaneous calcification, mental retardation, round facies and brachydactyly.

PHP1 β – PTH resistance but no somatic features of AHO.

PPHP – Somatic features of AHO in absence of any evidence of PTH resistance.

PHP-II refers to patients with hypocalcemia and hyperphosphatemia, who have a normal urinary cAMP but an impaired urinary phosphaturic response to PTH.

HYPERCALCAEMIA

See Table 39 for the causes of hypercalcaemia.

Parathyroid-dependent hypercalcaemia – Abnormal parathyroid glands are associated with hypercalcaemia in three distinct settings: (a) Primary hyperparathyroidism. (b) Familial hypercalcaemic hypercalcaemia (FHH) and (c) Lithium-induced hypercalcaemia.

Clinical features: Most patients with primary hyperparathyroidism present with hypercalcaemia, and as the serum calcium increases, the likelihood of clinical symptoms also increases.

1. *Age and Sex* – Parathyroid tumours are 3 times more common in women than in men. Incidence increases with age, most common in post-menopausal women.
2. *Onset* – (i) Usually gradual. Increasing asthenia, bone pains or swelling of bone. (ii) Rarely sudden, e.g. fracture or renal colic.
3. *Hypercalcaemic features* – Muscular weakness, fatigue. Constipation, loss of weight, anorexia, nausea and sometimes vomiting, malaise. Conjunctival flare, irritable eyes. Drowsiness and confusion.

Table 39: Causes of hypercalcaemia

1. Parathyroid dependent hypercalcaemia	
<ul style="list-style-type: none"> • Primary hyperparathyroidism • Tertiary hyperparathyroidism • Familial hypocalciuric hypercalcaemia • Lithium associated hypercalcaemia • Antagonistic antibodies to calcium sensing receptor 	
2. Parathyroid independent hypercalcaemia	
<ul style="list-style-type: none"> • I Neoplasms <ul style="list-style-type: none"> – PTHrP dependent – Other humoral syndromes – Metastases • PTHrP excess (non-neoplastic) • Excess vitamin D <ul style="list-style-type: none"> – Excess ingestion – Granulomatous disease – Williams' syndrome • Thyrotoxicosis • Adrenal insufficiency <ul style="list-style-type: none"> – Kidney failure – AKF – CKF with aplastic bone disease • Immobilization • Drugs <ul style="list-style-type: none"> – Vitamin A intoxication – Milk-alkali syndrome – Thiazide diuretics – Theophylline 	

4. *Renal manifestations* –
 - (a) Due to chemical changes in urine – polydipsia and polyuria.
 - (b) Due to nephrolithiasis – haematuria and renal colic.
 - (c) Due to nephrocalcinosis – chronic nephritis, hypertension.
5. *Skeletal involvement* – is due to generalized increase in osteoblastic bone resorption and increased osteoblastic activity. Radiographic features of hyperparathyroidism are given in Table 40.
6. *Metastatic calcification* – Calcareous deposits in pericardium, myocardium or lungs may produce dyspnoea and tachycardia, and in the muscles pain and tenderness. Corneal calcification may occur.

Table 40: Radiographic features of hyperparathyroidism

• Generalized demineralization of bone with coarsening of the trabecular pattern
• Subperiosteal resorption, most evident in phalanges of the hands
• Bone cysts, usually multiple, tend to occur in central medullary portions of metacarpals, ribs or pelvis and can expand into and disrupt overlying cortex
• Osteoclastomas (brown tumors) found most often in trabecular portions of the jaw, long bones and ribs
• Pathological fractures
• Skull can show a finely mottled 'salt-and-pepper' appearance with loss of definition of inner and outer cortices
• Dental radiographs show erosion or disappearance of lamina due to subperiosteal resorption

Table 41: Biochemical features

Serum	Normal	Hyperparathyroidism
Calcium	Total 9–11 mg. Ionized 5.9–6.5 mg.	More than 11 mg. 6.7–9.5 mg.
Phosphorus	2.5–4.5 mg.	Lowered or normal
Alkaline phosphatase	Females: 5.6 ± 1.8 units Males: 7.6 ± 1.9 units	About 20 units (if associated active bone disease)
PTH	<1 ng/mL	Usually twice normal

Markers of bone formation (e.g. osteocalcin) and bone resorption (e.g. urinary calcium, hydroxypyridinium) in upper range of normal.

- Gastrointestinal features* – Peptic ulceration is common.
- Renal functional abnormalities* – that range from renal concentrating ability to end-stage kidney failure.
- Multiple endocrine neoplasia* – are commonly associated with presence of parathyroid adenoma or hyperplasia. Presence of hypercalcaemia with labile hypertension and neurofibroma are suggestive.
- Unusual presentation* – Occasionally psychosis. Rarely acute pancreatitis.

Diagnosis

- Biochemical features:* (Table 41).
- Radiographs* of bony changes have been already described.
- Hydrocortisone suppression test* – 120 mg. hydrocortisone or 10 mg. prednisolone 8-hourly for 10 days. In patients with primary hyperparathyroidism the plasma calcium level does not usually fall, in most other hypercalcaemic conditions there is marked fall.

Table 42: Differentiation between primary hyperparathyroidism and malignancy-related hypercalcaemia

	Primary	Malignancy-related
Presentation	Typically, as asymptomatic or detected on biochemical screening for other reasons	Diagnosis is made in more advanced stages of underlying disease
Biochemical features	PTH elevated	PTH suppressed Elevated PTHrp (parathyroid hormone-related protein)

Localization of Parathyroid Adenoma

- Scan* – After imaging during successive injections of Thallium-201 (taken up by both thyroid and parathyroid), followed by technetium-99 m (taken up only by thyroid), a computer subtracts one image from the other leaving a parathyroid image if an adenoma is present.
- Ultrasound*– CT scanning is not successful in adenomas less than 0.5 cm in diameter. Ultrasound technique using 10 megahertz waves is more effective.
- Bone mass* – Measured by dual-energy X-ray absorptiometry (DXA) useful in assessing presence or extent of skeletal involvement.

Differential Diagnosis

- Differentiation from other causes of hypercalcaemia**

Primary hyperparathyroidism

- Sporadic (adenoma, hyperplasia or carcinoma)
- Familial
 - Isolated
 - Cystic
 - Multiple endocrine neoplasia type 1 or 2

Malignancy

- Parathyroid hormone - related peptide
- Excess production of 1, 25-dihydroxy vitamin D₃
- Other factors (cytokine, growth factors)

Note: The above two are responsible for 90% of cases

See Table 42 for differences between primary hyperparathyroidism and malignancy-related hypercalcaemia.

- Differential diagnosis of polyuria (and polydipsia).**
- Differentiation from other skeletal diseases** – (a) *Osteoporosis* – Generalized decalcification especially of vertebrae in post-menopausal women, old age, enforced disuse, corticosteroid therapy. Plasma calcium

phosphorus and alkaline phosphatase normal. (b) *Rickets* - Wide and irregular epiphyseal line. Ill-nourished children. (c) *Osteomalacia* - Generalized decalcification in young women on inadequate diet. Plasma calcium and alkaline phosphatase show diagnostic changes. (d) *Osteogenesis imperfecta* - Bones thin, not obviously decalcified. Familial. China-blue sclerotics, otosclerosis, spontaneous fractures. (e) *Paget's disease* - Patchy decalcification with new bone formation. Changes usually confined to skull, spine, pelvis, femurs, and tibiae. (f) *Multiple myeloma* - General decalcification with punched out areas, Bence Jones proteinuria. Myeloma cells in bone marrow. (g) *Metastases* - Patchy distribution, presence of primary growth.

- Milk-Alkali syndrome** - The triad of hypercalcaemia, metabolic alkalosis and kidney failure can result from huge ingestion of calcium and absorbable alkali like calcium carbonate. Immobilization can lead to bone resorption sufficient to cause hypercalcaemia.
- Kidney failure** - Following rhabdomyolysis, during the oliguric phase of kidney failure, severe hypercalcaemia can result from acute hyperphosphataemia and calcium deposition in muscle.
- Williams' syndrome** - in which valvular AS is associated with elfin facies and mental retardation, hypercalcaemia can occur transiently in first four years of life.
- Jansen's metaphyseal chondrodysplasia** - A rare disease in which children present with short stature and hypercalcaemia.

Management

Parathyroid surgery

Indications

- Serum calcium >1 mg/dL above upper limit of normal
- Marked hypercalciuria (>400 mg/day)
- Any overt manifestation of primary hyperparathyroidism (e.g. kidney stones, nephrocalcinosis, osteitis fibrosa cystica, classical neuromuscular disease, symptomatic or life-threatening hypercalcaemia)
- Creatinine clearance <70% of predicted (<60 mL/min)
- Bone mineral density low (T score <2.5 of any site)
- Uncertain prospects for adequate medical monitoring
- Age <50 years

Medical monitoring - (a) Serum calcium should be checked twice yearly, and urinary calcium and bone mass (particularly of the forearm) measured annually. (b) Patient should maintain an active lifestyle and avoid

Table 43: Management of hypercalcaemia

Therapy	Dosage
Rehydration	2-4 L/day normal saline drip
Furosemide	20-40 mg iv after rehydration 12-24 hrly
Pamidronate	60-90 mg iv over 2-4 hr once
Zoledronate	4 mg iv over 15-30 min. once
Calcitonin	4-8 IU/kg SC q 12-24hr
Gallium nitrate	200 mg/m ² iv over 24 hr x 1-5 doses
Plicamycin	15-25 µg/kg iv over 4-6 hr 1-5 doses
Glucocorticoids	200-300 mg hydrocortisone iv over 4-6hr x
Dialysis	3-5 days

any prolonged period of immobilization or dehydration. (c) Dietary calcium should neither be severely restricted nor much promoted. (d) In post-menopausal women, oestrogen therapy to reduce serum calcium by about 0.5 mg/dL and to provide other benefits of hormone replacement. (e) Potent amino-substituted bisphosphonates such as alendronate are useful. (f) Administration of analogues of ligands that activate the calcium-sensing receptor, leading to an increase in parathyroid cell calcium levels and suppression of further PTH production is another approach to medical management.

PARATHYROID CRISIS

Severe hypercalcaemia (Serum calcium >12 mg/dL)

Cl.Fs - Fatigue, weakness, lethargy, confusion, anorexia, nausea, abdominal pain and constipation. Also polyuria, nocturia and polydipsia. Cardiac arrhythmias particularly bradyarrhythmias and heart block.

Management

See Table 43.

6. THE ADRENALS

ADRENOCORTICAL HYPOFUNCTION

Acute Adrenocortical Insufficiency

Causes - May occur in - (a) Adrenalectomized patients. (b) Patients with Addison's disease with inadequate substitution therapy especially with vomiting, diarrhoea, surgical operation, parturition or intercurrent infection. (c) Rarely with meningococcal septicaemia (Waterhouse-Friderichsen syndrome).

Clinical features – Sudden onset with fall of blood pressure, cold and cyanosed extremities, nausea, vomiting and diarrhoea, stupor and terminal coma.

Management – Hydrocortisone 100 mg i.v or i.m is given and a drip started. One liter 0.9% saline is administered in 30–60 min, and several liters of saline, with 5% dextrose if hypoglycaemia. Hydrocortisone 100 mg i.m. is given 6-hourly in the acute phase. Oral medication can be restarted after 24 hours and reduced to maintenance dose over 3–4 days.

ADDISON'S DISEASE

Addison's disease is primary adrenal failure.

Causes

Common

- Autoimmune adrenalitis
- Infections – Tuberculosis. Cytomegalovirus and fungal infections associated with AIDS.
- Tumours – Metastatic disease (notably from breast)
- Inherited disorders – e.g. adrenoleucodystrophies and familial isolated glucocorticoid deficiency.

Rare – Secondary deposits, granulomatous disease, amyloidosis, haemochromatosis, fungal disease (e.g. histoplasmosis); congenital adrenal hyperplasia, meningococcal septicaemia, haemorrhage into adrenals, e.g. in new born or as complication of anticoagulant therapy, adrenal vein thrombosis after trauma or adrenal venography. Drugs, e.g. rifampicin, ethionamide, ketoconazole.

Clinical Features

Onset – usually insidious. Rarely first manifestation may be acute crisis.

1. *Pigmentation of skin and mucous membranes* – Varieties – (a) Bluish black discolouration, or brownish patches or streaks on lips, gums, inside of cheeks and posterior aspect of the palate almost pathognomonic. Rectal and vaginal surfaces also involved. (b) A diffuse tan over the non-exposed as well as exposed portions of the body. (c) Hyperpigmentation of extensor surfaces, pressure points and scars, e.g. face, neck, dorsum of hands and forearms, waist line, knuckles and ankles. Palms and soles escape pigmentation except for the creases at the interphalangeal joints. (d) Multiple black freckles especially on the forehead, face, neck, shoulders and arms. (e) Areas of vitiligo or leukodermic type of pigmentation.
2. *Gastrointestinal symptoms* – Anorexia, often with nausea and vomiting. Constipation with intermittent

diarrhoea. Salt craving. Abdominal pain. Irritation of the diaphragm by tuberculous adrenal may produce shoulder pain.

3. *Cardio-vascular system* – Postural hypotension. Faintness may result on assuming erect position. Sometimes dyspnoea. Heart sounds feeble.
4. *Muscular system* – Muscular weakness, and wasting with creatinuria. Sometimes cramps in muscles.
5. *Mental and nervous* – Lassitude and muscle weakness are invariable and the first symptom to appear in majority of cases. Loss of memory, drowsiness. Sometimes periods of restlessness, irritability and insomnia. Negativism and pessimism in chronic cases.
6. *Genital system* – Impotence and amenorrhoea. Symptoms may be aggravated at the time of menstruation or menopause.
7. *Kidneys* – In a crisis, and to a less extent in subacute phases of the disease, kidney function is severely impaired, the excretion of urine is diminished and it contains granular casts and albumin, and the blood urea and creatinine rise above normal.
8. *Miscellaneous* – Subnormal temperature, anaemia. Loss of body hair (axillary and pubic) in females.
9. *Other autoimmune disease* – Clinical features of other associated autoimmune disease such as vitiligo, thyroiditis, with or without hypothyroidism; pernicious anaemia, hypoparathyroidism, insulin-dependent diabetes mellitus, mucocutaneous candidosis.

Table 44 gives pathogenesis of symptoms of adrenocortical insufficiency.

Addisonian crisis – An acute phase of the disorder in which the patient presents with severe collapse, shock, vomiting, dehydration, hypotension, profound weakness and hypoglycaemia. *Causes* – Usually severe or

Table 44: Pathogenesis of symptoms of adrenocortical insufficiency

1. Increased secretion of ACTH	Pigmentation of skin in areas exposed to light, in oral mucosa, gums
2. Deficiency of adrenal cortisol secretions	
– Cortisol	Asthenia Pigmentation of points of pressure (e.g. elbows and mucus membrane, e.g. genital regions, mouth)
– Aldosterone	Anorexia, nausea
– Androgens	Weight loss Decreased tolerance to stressful situation
	Hypotension, postural syncope
	Diminished axillary and pubic hair growth in females

long-standing hypoadrenalism, or precipitated by intercurrent illness (e.g. pneumonia or other infections), severe diarrhoea, vomiting or major surgery. An intercurrent infection is a predisposing factor but at times there may be no precipitating cause. Extra exertion, anxiety, reduction in dosage of corticosteroids are other causes.

Warning signs - Yawning, hiccough, photophobia, increased sensitivity to cold or actual shivering with the patient curling himself up beneath blankets, and irritability.

SECONDARY ADRENOCORTICAL INSUFFICIENCY

Due to pituitary or hypothalamic diseases such as tumours, infarction, trauma, granuloma or necrosis. It can also be induced by corticosteroid therapy which suppresses corticotrophin releasing hormone (CRH). Symptoms and signs identical to Addison's disease except absence of pigmentation. Features associated with hypotension are unusual since aldosterone secretion is maintained despite absence of ACTH.

Investigations

A. Of Addison's disease

1. Plasma cortisol level - measured at 9 am < 50 nmol/liter confirms diagnosis of adrenocortical insufficiency.
2. Plasma ACTH level - High (> 80 ng/liter).
3. Synacthen tests -
 - (a) *Short Synacthen test* - Following injection of Synacthen 250 mg i.m., cortisol levels are sampled at 30 minutes and 1 hour. If these fail to rise above 550 nmol/liter, or fail to increase by more than 230 nmol/liter, the test is positive for adrenal failure.
 - (b) *Depot Synacthen test* - If Addison's disease is strongly suspected and/or result of short Synacthen test is abnormal or equivocal. Take blood for plasma cortisol (preferably at 9 am), then give 1 mg of Synacthen depot i.m. Take further blood samples at 0, 6 and 24 hours for cortisol estimation. Normal response is a peak at 4-6 hrs (about 900 nmol/L) and little further rise at 24 hrs. In Addison's disease there is no rise, in secondary adrenocortical failure little rise at 4-6 hrs with increased

level at 24 hrs. An alternative is to give depot Synacthen 1 mg i.m. for 3 days and perform short Synacthen test on day 4.

B. Of the cause

1. Radiography - (a) Of abdomen - may reveal calcified adrenals of tuberculous disease. (b) Chest - may show tuberculous lesion or malignancy.
2. Adrenal auto-antibodies - are detected in about 55% of patients. In antibody negative patients, an autoimmune basis for the disease is suggested either by small adrenals on MRI (enlarged with tuberculous Addison's), or presence of other autoimmune diseases.

Differential Diagnosis

1. *Simmond's or Sheehan's disease* - Pigmentation of skin slight and patchy. No pigmentation of mucous membranes. Loss of pubic and axillary hair. Failure of sex function early and essential feature. Response to corticotrophic hormone of pituitary; this is absent in Addison's disease.
2. *Diseases associated with asthenia* - (i) Neurasthenia due to psychogenic factors. (ii) Hyperparathyroidism is often accompanied by extreme lassitude and weakness. Blood chemistry diagnostic. (iii) Myasthenia gravis - progressive weakness.
3. *Anorexia nervosa* - Usually in adolescent females, history of psychic trauma, marked anorexia, no pigmentation. Other psychic manifestations.
4. *Other causes of pigmentation* - (a) *Skin* - Pellagra, gastro intestinal tuberculosis, malabsorption, genetic, familial, malignant disease, liver disease, chronic kidney disease. (b) *Mouth* - pigmentation can be idiopathic or racial, and patchy pigment deposits in the lips are seen in syndrome of small intestinal polyposis. (c) *Other causes of local pigmentation* - include freckles, birthmarks and other pigmented naevi, melanomas, acanthosis nigricans, neurofibromatosis and polyostotic fibrous dysplasia. (d) *Pigments other than melanin* - Iron deposition in haemochromatosis, silver deposits in argyria and haemosiderin in some bleeding diseases.
5. *Intestinal polyposis* - Spots of brown pigmentation may be present on the skin and lips as well as oral mucosa. Intestinal symptoms. Sigmoidoscopy or barium enema confirms diagnosis.
6. *Salt-losing nephritis* - Steroid output in urine normal but of aldosterone high. In Addison's disease both values low.

Management

Chronic hypoadrenalism

Replacement therapy:

- Cortisone (glucocorticoid) substitution – Initial: Hydrocortisone 20 mg (equivalent to 5 mg prednisolone or 0.5 mg delta or betamethasone) thrice daily for 72 hours. Maintenance – 20 mg morning and 10 mg evening. Dose best monitored by measuring series of serum cortisol levels throughout the day. The aim is to mimic the normal circadian rhythm of cortisol levels, with a peak of upto 650 nmol/L after the first dose of the day and an early morning nadir of < 200 nmol/L. Patients should be advised to double the dose and seek medical advice if they feel ill, e.g. respiratory infection with systemic upset, or if they undergo significant stress. Pregnancy may require an increase in hydrocortisone dose by 50% during the last trimester.
- Aldosterone (mineralocorticoid) substitution* – Fludrocortisone 50–200 mg/day.
- Salt* – Patients with curtailed food intake, diarrhoea or profuse sweating should be given an additional 3–6 gms of sodium chloride daily.
- Adrenal androgen-* replacement is an option in patients with lack of energy, despite optimized glucocorticoid and mineralocorticoid replacement. It may also be indicated in women with features of androgen deficiency, including loss of libido. Adrenal androgen replacement can be achieved by once-daily administration of 25–50 mg DHEA.

Table 45: Cause of Cushing's syndrome

<i>ACTH excess –</i>
• Cushing's disease*
<i>Ectopic ACTH secretion</i>
• Carcinoma of lung (especially small cell)
• Carcinoid tumors of thymus or lung
• Medullary carcinoma of thyroid
• Carcinoma of colon
• Pheochromocytoma
<i>Non-ACTH dependent</i>
• Primary unilateral adrenocortical tumors (adenoma or carcinoma)
• McCune-Albright syndrome: Bilateral tumor (Gsa mutation)
• Primary pigmented nodular dysplasia
• ACTH – independent macronodular adrenal hyperplasia
<i>Spontaneous Cushing's syndrome (rare)</i>

*Cushing's disease is the most common cause of spontaneous Cushing's syndrome, occurring in 60-70% of pts. It results from ACTH hypersecretion by a pituitary corticotrophic adenoma.

Emergency management of Addisonian crisis: (a) Fluid resuscitation with normal saline. (b) Hydrocortisone – 100 mg i.v. bolus every 6 hours. Once patient is well enough, hydrocortisone 20 mg t.d.s. orally. This can be stepped down to maintenance over next 2 weeks.

ADRENAL CORTICAL HYPERFUNCTION

CUSHING'S SYNDROME

Cushing's syndrome refers to the clinical manifestations induced by, chronic exposure to excess corticosteroid. See Table 45 for the cause of Cushing's syndrome.

Cushing disease is corticosteroid excess due to pituitary dependent bilateral adrenal hyperplasia. The microadenomas, because of their size do not cause symptoms by local mass effect.

Clinical Features

Clinical features of Cushing's syndrome are listed in Table 46.

Table 46: Clinical features of Cushing's syndrome

Centripetal fat deposition

- Moon face
- Buffalo hump
- Truncal obesity

Protein-wasting effect of excess cortisol

- Striae: Commonly located on abdomen and flanks, purplish-red in colour and more than 1 cm in diameter
- Easy bruising, and slow healing of minor wounds
- Lower limb oedema
- Muscle wasting in upper arms and thighs, with fatiguability
- Osteoporosis particularly of vertebral bodies leading to compression fractures, back pain and loss of height
- Impaired defense against infection, often leading to superficial mucocutaneous infections.

Others

- Hypertension
- Hirsutism in men
- Psychiatric disturbance (e.g. anxiety, increased emotional lability, irritability). Psychosis may occur
- Retarded growth concomitant with weight gain

Electrolyte changes

- Hypokalaemia
- Glucose intolerance
- Mineralocorticoid oversecretion and genetic susceptibility

D.D. - 1. *Simple obesity* - No characteristic fat distribution, thin skin or proximal myopathy as in Cushing's 2. *Polycystic ovary syndrome* - associated with obesity and hirsutism. No other features of cortisol excess, and skin is thick. 3. *Chronic alcoholism* - History and other features of liver disease. High blood ethanol and γ -glutamyl transpeptidase (γ -GT) levels. Macrocytosis.

Diagnosis of Spontaneous Cushing's Syndrome

I. Tests indicating cortisol overproduction

1. *24-hour urinary cortisol excretion* - Increased value ($>90 \mu\text{g/day}$, 280 nmol/day) is diagnostic of hypercortisolism.
2. *Overnight dexamethasone suppression test*
 - Dexamethasone 1 mg p.o. between 11 pm and midnight; plasma cortisol measured next morning.
 - Normal individuals almost totally suppress cortisol production (plasma cortisol $<20 \text{ ng/mL}$, 50 nmol/L)
 - Used for positive diagnosis of Cushing's syndrome
3. *Low-dose dexamethasone suppression test*
 - Dexamethasone 2 mg/day p.o. for 2 days in 8 divided doses
 - Normal individuals almost totally suppress cortisol production (24-hour urinary cortisol excretion $<10 \mu\text{g}$, 50 nmol/L)
 - Used for possible diagnosis of Cushing's syndrome
4. *High-dose dexamethasone suppression test*
 - Dexamethasone 8mg/day for 2 days in 8 divided doses
 - Patients with Cushing's disease exhibit partial suppression of cortisol production (significant decrease in 24-hour urinary 17-hydroxy steroids or cortisol excretion, usually $>50\%$)
 - Patients with other causes of Cushing's syndrome (ectopic ACTH secretion syndrome, adrenal tumors) typically show significant variation in cortisol production
5. *Corticotrophin-releasing hormone test*
 - Synthetic bovine (or less often, human) corticotrophin releasing hormone $100 \mu\text{g}$ or $1 \mu\text{g/kg}$ i.v., plasma ACTH and cortisol measured during the next one hour
 - Patients with Cushing's disease are typically responsive (ACTH and/or cortisol plasma levels increase by $>50\%$ and/or 20%)

- Patients with the ectopic ACTH syndrome or adrenal tumor are typically unresponsive.

II. For establishing the cause of cortisol overproduction

Assessment of Corticotrophin Function

Adrenal tumors - The presence of circulating ACTH coincident with hypercortisolism almost excludes a primary autonomous adrenocortical tumor. Adenomas typically secrete exclusively cortisol, whereas carcinomas secrete precursors and androgens.

Pituitary Disease or Ectopic ACTH

1. *Plasma cortisol and ACTH* - are both markedly elevated in ectopic ACTH secretion due to malignant tumors. A mean plasma ACTH above 400 ng/liter is unlikely to be due to pituitary disease.
2. *High dose dexamethasone suppression test* - In Cushing's disease there is fall in serum cortisol to less than 50% of the basal value.
3. *CRH test* - A pituitary adenoma (i.e. Cushing's disease) responds to pharmacological manipulation using CRH and there is partial suppression by high dose dexamethasone suppression test.

Imaging Techniques

Locate the tumor responsible for spontaneous Cushing's syndrome

1. *Pituitary MRI* - detects a microadenoma in up to 60%.
2. *Chest radiograph* - In ectopic ACTH syndrome, most tumors are located in the thorax: highly aggressive oat-cell carcinomas, or indolent bronchial carcinoids.
3. *CT scan* - Adrenocortical tumors are easily viewed.
4. *Octreoscan* - Scintigraphy with labelled somatostatin analogues is sensitive detecting tool for bronchial carcinoids.

Bilateral Inferior Petrosal Sinus Sampling

Allows collection of blood draining immediately from pituitary gland. In difficult cases, it establishes whether ACTH oversecretion is of pituitary or non-pituitary origin. In patients with Cushing's disease and negative pituitary MRI, it may help to localize the microadenoma before surgery. An increased central/peripheral plasma ACTH ratio >2 at baseline and >3 at 2-5 min after CRH injection is indicative of Cushing's disease.

Management

Cushing's disease – Transsphenoidal pituitary surgery (microadenectomy). If surgery fails hypercortisolism can be controlled with antiadrenocortical drugs Metyrapone and Ketoconazole. If intolerance to these drugs, then Op'DDD which has specific adrenolytic action. Simultaneous radiotherapy is often indicated, allowing the anti-adrenocortical therapy to be discontinued later. In rare cases bilateral adrenalectomy may be necessary.

Ectopic ACTH syndrome – Surgical resection of tumor cures hypercortisolism in patients with more indolent tumors such as bronchial carcinoid. Chemotherapy may reduce ACTH secretion by oat-cell carcinoma of the lung.

ADRENOGENITAL SYNDROME

Clinical features – of excess of adrenal androgens may vary from slight hirsutism in the adult female to adrenocortical virilism. The manifestations depend on the age and sex of the individual – (a) *New-born infants* – When the fetus is exposed to excessive androgens there is pseudoprecocious puberty in the male and pseudohermaphroditism in the female. (b) *Children of either sex* – Precocious puberty of the male type, including muscular development and accelerated epiphyseal maturation. (c) *Adult female* – Virilization with enlargement of clitoris, premature axillary and pubic hair, muscular development and accelerated epiphyseal maturation. Because of inhibitory action of androgen on pituitary, breast development and menses do not occur.

PRIMARY ALDOSTERONISM (CONN'S SYNDROME)

Primary aldosteronism is the most common cause of mineralocorticoid hypertension (Table 47).

- Most cases are secondary to a solitary, small (0.5–2 cm) aldosterone-producing adenoma of adrenal gland. Female to male ratio is 3:1
- One-third cases are caused by bilateral adrenal hyperplasia
- Rarely, glucocorticoid-suppressible hyper-aldosteronism (GSH) is the cause.

Clinical Features

Presentation is usually with hypertension and hypokalaemia. Rare nonspecific symptoms include muscle weakness, nocturia and tetany. Severe hypertension may be associated with kidney and retinal disease.

Table 47: Causes of hyperaldosteronism

Primary aldosteronism
Syndrome of apparent mineralocorticoid excess (SAME)
Cushing syndrome
Glucocorticoid resistance
Adrenocortical carcinoma
Congenital adrenal hyperplasia
Progesterone-induced hypertension
Liddle's syndrome

Diagnosis

- Hypokalaemia – Spontaneous hypokalaemia (< 3.5 nmol/L) is uncommon in untreated hypertension. When found in a patient taking diuretics, these should be withdrawn, potassium stores replenished, and serum potassium remeasured after 2 weeks.
- Elevated plasma aldosterone levels
- Suppressed plasma renin activity

The accepted screening test is concurrent measurement of plasma renin and aldosterone with subsequent calculation of the aldosterone-renin ratio (ARR); serum potassium needs to be normalized prior to testing.

ARR screening is positive if the ratio is >750 pmol/L per ng/mL per hour, with a concurrently high normal or increased aldosterone. If one relies on the ARR only, the likelihood of a false positive ARR becomes greater when renin levels are very low.

Saline infusion test – which involves the IV administration of 2 L of physiologic saline over a 4-h period. Failure of aldosterone to suppress below 140 pmol/L (5 ng/dL) is indicative of autonomous mineralocorticoid excess

- Abdominal CT or MRI to differentiate if possible hyperplasia from adenoma

Secondary hyperaldosteronism results from excess renin causing angiotensin stimulation of zona glomerulosa.

Causes – Accelerated hypertension, renal artery stenosis. Conditions associated with normal BP include heart failure and cirrhosis, where sodium retention results from excess aldosterone production.

DD of Adrenal Adenoma, Hyperplasia and GSH

1. *Effect of posture on aldosterone level* – In adrenal hyperplasia, erect posture increases plasma aldosterone.
2. *Administration of ACTH* – No effect on plasma aldosterone in adrenal hyperplasia, and small effect in adenoma, but marked rise in patients with GSH.

3. *Measurement of intermediary glucocorticoid metabolites* (e.g. 18-hydroxy cortisol or 18-oxocortisol/corticosterone) in plasma or urine. Levels are lowest in hyperplasia, higher in adenoma and much higher in GSH.
4. *Imaging* – Adrenal CT or MRI when biochemical tests have confirmed the diagnosis.

Differential Diagnosis – of Hypertension and Hypokalaemia

1. *Essential hypertension with* – (a) Vomiting and diarrhoea. (b) Diuretic therapy. (c) Oral contraceptives or oestrogen therapy. (d) Steroid therapy.
2. *Kidney disease* – (a) Accelerated or malignant hypertension. (b) Renovascular hypertension. (c) Potassium-losing nephropathies, e.g. chronic pyelonephritis. (d) Renin-secreting renal tumour.
3. *Adrenocortical dysfunction* – (a) Primary aldosteronism. (b) Cushing's syndrome and ectopic ACTH syndrome. (c) Endogenous mineralocorticoid excess (some adrenocortical tumours). (d) Exogenous administration of mineralocorticoid.
4. *Pseudo-aldosteronism* – (excessive liquorice ingestion).
Treatment – (a) *Adenoma* – should be removed. Spironolactone 300–400 mg/day for 3–4 weeks should be given as preparation for surgery. (b) *Bilateral hyperplasia* – Adrenalectomy contraindicated. Spironolactone 50–400 mg/day, or if not tolerated Amiloride 10–40 mg/day. Dexamethasone if GSH.

HYPERADRENALISM PHEOCHROMOCYTOMA

Pheochromocytoma is a catecholamine secreting tumour that arises from the chromaffin cells of the sympathoadrenal system. Ninety percent of all cases arise from the adrenal medulla. Extra-adrenal pheochromocytoma (paraganglioma) is usually encountered intra-abdominally. Ninety percent arise in the wall of urinary bladder. Intrathoracic origin is rare and is located in relation to paravertebral sympathetic chains.

Known associations – Neurofibromatosis, medullary carcinoma of thyroid and with hyperthyroidism (multiple endocrine adenomatosis).

Clinical Features

Hypertension – cardinal feature

- (a) Paroxysmal – Attacks of paroxysmal hypertension arise suddenly lasting for minutes or hours. Usually brought

on by emotional strain, or palpation of abdomen, or sudden change in posture such as lying on one or other side in bed at night. Symptoms are often paroxysmal

- Headache
 - Sweating
 - Palpitations
 - Pallor (Patients with pheochromocytoma do not flush)
 - Nausea
 - Tremor
 - Weakness
 - Anxiety
 - Epigastric pain
 - Chest pain and dyspnoea
 - Constipation
- (b) Sustained hypertension – Some tumours secrete adrenaline and/or nor-adrenaline constantly causing persistent hypertension. Suspicion is aroused if signs of hyperthyroidism, intermittent glycosuria or frank diabetes.

Diagnosis

1. Biochemical test – Increased excretion of free catecholamines or their metabolites in urine – Vanilmandelic acid (VMA), normal 25 μmol (7 mg)/24 hr or metanephrines, normal 5.5 μmol (1.0 mg)/24 hr, or total catecholamines normal 0.36 μmol /24 hr (60 μg /24 hr).
2. Localization – Tumours are localized by CT or MRI scanning of abdomen or scintigraphy with ^{131}I -meta-iodobenzyl-guanidine (MIBG). If a tumour is not found in the adrenals, CT scan can be extended to include the rest of the abdomen, pelvis, chest and neck.

Management

Surgical removal of tumour. Pre-operative therapy to minimize risk of precipitous hypertension during surgery: α -blockade (phenoxybenzamine 20 mg t.d.s., increased to 240 mg/day if required) and β -blockade (propranolol 40 mg t.d.s., increasing to 240 mg/day if required) for minimum of 2–3 weeks before surgery.

7. PANCREAS

DIABETES MELLITUS

Diabetes mellitus is a group of metabolic diseases characterized by hyperglycaemia resulting from defects in insulin secretion, insulin action or both. Table 48 shows

Table 48: Etiologic classification of diabetes mellitus and impaired glucose tolerance

I. Type I DM (β -cell destruction, absolute insulin deficiency). Insulin dependent diabetes mellitus (IDDM)	
(a) Autoimmune	
(b) Idiopathic	
II. Type II DM – Non-insulin dependent (NIDDM)	
III. Maturity onset diabetes in young (MODY 1-6) Genetic defects in β -cell function have the following mutations:	
a. MODY 1 - Hepatocyte Nuclear Transcription factor (HNF) 4 α	
b. MODY 2 - Glucokinase	
c. MODY 3 - HNF - 1 α	
d. MODY 4 - Insulin promotor factor-1 (IPF1)	
e. MODY 5 - INF - 1 β	
f. MODY 6 - Neurogenic differentiation1, (Neuro D1)	
IV. Secondary causes	
1. Pancreatic disease	
Cystic fibrosis	
Trauma/pancreatopathy	
Hemochromatosis	
Pancreatitis	
Fibrocalcific pancreatic diabetes (FCPD)	
Carcinoma of pancreas	
2. Endocrine disorders	
Acromegaly	Conn's syn.
Cushing's syn.	Pheochromocytoma
Glucagonoma	Hyperthyroidism
3. Drug-induced	
Glucocorticoids	Phenytoin
Diazoxide	Pentamidine
Thiazides	α -interferon
β -adrenergic agonists	Thyroid hormone
4. Infections	
Congenital rubella	Coxsackie B virus
Cytomegalovirus	
5. Insulin receptor defects	
Anti-insulin receptor antibodies (Stiffman syn.)	
Lipoatrophic diabetes	
6. Other genetic syndromes (sometimes associated with DM)	
Down's syndrome	
Turner's syndrome	
Wolfram's syndrome	
Prader-Willi syndrome	
Klinefelter's syndrome	

Contd...

Contd...

Laurence-Moon-Biedl syndrome
Myotonic dystrophy
Friedreich's ataxia
Huntington's chorea
Porphyria

V. Gestational diabetes

VI. Impaired glucose tolerance (Borderline diabetes)

- a. Primary: Obese, non-obese
- b. Secondary: All conditions mentioned under secondary DM, cirrhosis of liver, kidney failure, chronic undernutrition, hypokalaemia, stress, e.g. myocardial infarction.

etiologic classification of diabetes mellitus and impaired glucose tolerance.

Pathogenesis

Type 1 diabetes – Due to a combination of genetic, auto-immune and environmental factors, there is destruction of pancreatic β cells.

1. **Genetic factors** – (a) Twin studies: Among monozygotic twins, the concordance rate is 30–70%, i.e. if one twin gets DM, the chances of second twin getting are 30–70%. (b) Major Histocompatibility Complex (MHC). Genes on the short arm of chromosome 6 encodes for Human Leucocyte Antigens (HLA). There is a strong association with Type I DM and HLA-DRD and HLA-DR4.
2. **Autoimmunity** Humoral and cell mediated immunity leads to lymphocytic infiltration of the islets of Langerhans called insulinitis. β cells are more susceptible to destruction by cytokines like TNF- α , TNF- γ , IL-1.

Autoimmune basis is also suggested by association with other autoimmune diseases like Graves' disease, Coeliac disease, pernicious anaemia. Addison's disease, polyglandular autoimmune syndrome I and II.

3. **Environmental factors**

- (a) **Viruses:** Congenital rubella, mumps, coxsackie B, rotavirus.
- (b) **Chemical:** Nitrosourea compounds, Rodenticide, Pentamidine are associated with increased risk.
- (c) **Diet:** (i) Cow's milk (bovine milk proteins) may stimulate immune response against β cells. (ii) Wheat proteins (gluten). Gluten-sensitive enteropathy (coeliac disease) in 5–10% cases.
- (d) **Stress** in early life

Type 2 Diabetes (NIDDM)

Aetiopathogenesis

Type 2 DM is disorder characterized by insulin resistance and impaired insulin secretion. Hyperglycaemia develops due to (i) Peripheral resistance to action of insulin. (ii) Increased hepatic glucose output. (iii) Impaired pancreatic β cell secretion of insulin.

- Genetic factors:** Type 2 DM has very strong genetic predisposition.
 - Twin studies - Concordance in monozygotic twins is 70–90%. If both parents are diabetic, their offspring has 90% chance of developing type 2 DM.
 - Polygenic factors - Type 2 DM is a polygenic multifactorial disease, in majority of cases. No consistent major genetic genes has yet been implicated.
 - Monogenic forms are rare, e.g. Wolfram syndrome, MODY types 1–6, MELAS (mitochondrial myopathy, encephalopathy, lactic acidosis, stroke).
- Obesity lipotoxicity, nutrition.**
 - Obesity and central fat distribution. The cut offs for BMI are 23 kg/m² and waist circumference for men at 90 cm and for women 80 cm.
 - Lipotoxicity. Adipose tissue can secrete a large number of 'adipokines' which can impair insulin secretion and action by an endocrine effect, e.g. leptin or increase in insulin resistance, e.g. TNF- α , Resistin, Adinopectin (low levels contribute to insulin resistance). Free fatty acids inhibit glucose uptake and increase hepatic glucose output.

- Environmental factors**
 - Nutrition: Generous dietary intake
 - Physical inactivity
 - Vitamins and trace elements - Low levels of Vitamin D, zinc, copper, chromium.
- Insulin resistance.** It is a state in which a given concentration of insulin gives a subnormal biological response on patients target tissue e.g. skeletal muscle, adipose tissue and liver. There is resistance to exogenous and endogenous insulin. There are overt diabetics who do not respond to conventional and supraphysiological levels of insulin, but at the end are commonly seen in individuals with mild glucose intolerance. It is also called metabolic syndrome. Deadly quartet-CHAOS (CAD, HT, Obesity, Adult onset diabetes and Stroke). See Table 49 for the criteria of insulin resistance.
- The 'thrifty phenotype' hypothesis** - Individuals with low birth weight appear to have higher risk of NIDDM, particularly if they become obese in later life. This hypothesis suggests that intra uterine malnutrition leads to defective pancreatic development. Such individuals may become susceptible to diabetes, hypertension and heart disease in later life.

Table 50 gives distinguishing features between IDDM and NIDDM.

Table 51 enlists risk factors for type 2 diabetes.

Endothelial Dysfunction in Diabetes

Atherosclerosis is the leading cause of death in diabetic patients. It is an early abnormality and may play a key role in the micro and macrovascular disease condition associated with the disease. Several measures have been shown to cause improvement in endothelial dysfunction including exercise and wt. loss, lipid lowering, ACE inhibitors, antioxidants, reducing homocysteine levels, reducing

Table 49: Criteria for diagnosis of IR (WHO).

- Central obesity (BML, WHR)
- Low Tg (>150 mg/L, high LDL)
- Low HDL (< 40–50 mg/dL)
- High BP (>130/85 mm Hg)
- FBS >100 mg/dL

Table 50: Distinguishing features between IDDM and NIDDM

	IDDM (Type 1 DM)	NIDDM (Type 2 DM)
Body habitus	Normal or thin	Obese
Acute complication	Ketoacidosis	Hyperosmolar coma
Plasma insulin	Low to absent	Normal to high
Auto-antibodies	Present	Absent
Sulphonyl therapy	Unresponsive	Responsive
Insulin therapy	Responsive	Responsive to resistant
Family h/o diabetes	No	Yes
Age at onset	<40	>40

Table 51: Risk factors for type 2 diabetes

- Age \pm 45 years
- Overweight (BMI \geq 25 kg/m²)
- Family history of diabetes (parents or siblings with diabetes)
- Habitual physical inactivity
- Previously identified IFG or IGT
- History of GDM or deliver of a baby >9 lbs
- Hypertension (\geq 140/90 mm Hg in adults)
- HDL cholesterol \geq 35 mg/dL (0.9 mmol/L) and/or triglyceride level \geq 250 mg/dL (2.82 mmol/L)
- Polycystic ovary syndrome
- History of vascular disease

hyperglycaemia and nitric oxide co-factors like tetrahydrobiopterin and modulation of insulin resistance.

Latent diabetics – are those with normal glucose tolerance test who have had abnormal tests in certain forms of beta-cell stress, e.g. during pregnancy or infection, when obese, or during treatment with drugs such as corticosteroids.

Clinical Features

Onset – Usually gradual in adults, but acute in children.

Modes of presentation –

- Presence of osmotic symptoms (polyuria, polyphagia, polydipsia)
- Weight loss, fatigue and lassitude
- Pruritus vulvae in females or balanitis in males
- Loss of libido or erectile dysfunction
- Blurring of vision
- Accidental discovery or asymptomatic glycosuria (e.g. during life insurance examination)
- Symptoms due to diabetes - related complications e.g. abdominal pain in ketoacidosis (Table 52)

Convulsions – Fits should be considered hypoglycaemic until proved otherwise, especially in children. EEG abnormalities are common in insulin-treated patients, especially those with recurrent hypoglycaemia. Day time attacks suggest epilepsy, while nocturnal attacks are often hypoglycaemic.

Laboratory Investigations in Diabetes

1. Blood glucose estimation

In non-diabetes, blood glucose levels are 70-100 mg/dl.

Table 52: Abdominal pain in diabetes:

1. Gastric dilatation
(a) Acute – Ketoacidosis.
(b) Chronic – Autonomic neuropathy.
2. Pancreatitis
(a) Acute following development of type IV hyperlipidaemia.
(b) Chronic – precedes development of diabetes.
3. Infarction
(a) Mesenteric.
(b) Myocardial (Painless in autonomic neuropathy).
4. Genitourinary
(a) UTI.
(b) Bladder retention.
5. Hepatobiliary
(a) Cholecystitis.
(b) Fatty infiltration of liver causing hepatic capsular distension.
(c) Thoracolumbar radiculopathy.

(a) *Random blood glucose* is done at any time in the day, irrespective of meals. If <140 mg normal, >200 mg indicates DM and between 140–200 mg, GTT is required.

(b) *Fasting blood glucose* is measured after 12 hr fast. Normal <100 mg, diabetes if >126 mg and impaired fasting glucose 101–125 mg (pre-diabetics).

(c) *Post-prandial blood glucose* is measured 2 hr after a meal. Normal <140 mg, Diabetes >200 mg Impaired glucose tolerance 140–199 mg.

2. Oral glucose tolerance test (OGTT)

Pre-diabetes also known as impaired glucose tolerance is a condition with no symptoms but these pts. can develop more serious type DM. Hence individuals with family history of DM type 2, women who had gestational diabetes or had a baby weighing > 9 pounds, the obese with much belly fat and the elderly should undergo the test. In OGTT the first sample is taken after an overnight fast of 8 hrs following which patient is given glucose 1 g/kg body wt. Blood is then collected at 30, 60, 120 and 180 minutes. In diminished glucose tolerance, level of blood glucose is highly raised at 180 minutes.

Factor affecting GTT

1. Age – GTT decreases in patient > 60 years of age
2. Obesity
3. Surgery – Due to stress of surgery, there is increase in cortisol and catecholamine secretion.
4. Drugs – Thiazides, phenytoin, oral contraceptives, thyroxine, corticosteroids.

Urine glucose – Normally about 100 mg/d is excreted and can be estimated by tests for reducing sugar e.g. Benedict's tests or clinistix method. Those measurements are now not recommended.

3. Glycosylated haemoglobin (GHb)

It is used to measure long-term glycaemic control. Hb in the blood is glycated by glucose. Glucose combines with protein residues on Hb chains by slow 'Non-enzymatic glycation'. This results in formation of Hemoglobin A1c proportionate to amount of blood glucose (Table 53). Since life span of RBCs is 21 days, the HbA1c will reflect blood glucose levels over last 2–3 months. Table 54 gives clinical value of glycohaemoglobin assays.

Advantages - No relation to meals, physical activity, crash diets or modes of therapy.

Disadvantages - (a) Cannot be used to change daily diseases of drugs or insulin. (b) Values are unreliable in hemolytic anaemias and haemoglobinopathies because of reduced life span of RBCs. (c) In iron deficiency anaemia,

Table 53: Correlation between HbA1c and mean blood glucose levels

HbA1c	Mean blood glucose (mg/dL)
5	100
6	135
7	170
8	205
9	240
10	275
11	310
12	345

values are higher, lower values in pregnancy, Vitamin C, E deficiency.

Self-monitoring of Blood Glucose

- Type I diabetes 4–6 times a day depending on the insulin regimens.
 - Type II diabetics on oral hypoglycaemic drugs need to monitor 1–2 times/d.
 - During pregnancy more frequent monitoring.
 - During acute complications or illness 2-hourly.
3. **Microalbumin.** Pts with microalbuminuria have a greater risk of developing kidney failure, and cardiovascular damage. Reference is 0–1.7 mg/dl in spot random sample, upto 20 mg/L in 24 hr urine volume.
 4. **Urine protein/creatinine ratio** gives information about proteinuria in pts with diabetic nephropathy. Higher the ratio, greater the damage.
 5. **Serum creatinine.** In diabetics with nephropathy a doubling of creatinine suggests a 50% reduction in GFR.
 6. **Insulin levels.** Elevated blood glucose levels with low insulin levels indicate insufficient insulin for adequate control of blood glucose. Similarly high insulin levels with low blood glucose indicate a change in dosage of drugs.
 7. **C-peptide** is used to monitor beta cell activity and capability over time and help in deciding when to start insulin therapy. C-peptide in conjunction with insulin and glucose levels can be used to diagnose cause of hypoglycaemia and monitor its treatment.
 8. **Insulin antibody test**– Quantitative determination of antibodies against insulin in serum.
 9. **GAD-65 antibody** is an enzyme produced primarily by pancreatic islet cells. GAD-65 antibodies are common in newly diagnosed diabetic patients and often appear years before clinical onset of the disease.

Table 54: Clinical value of glycohaemoglobin assays

- Estimates average blood glucose level over previous 2–3 months
- Identifies patients that may require intensification of treatment
- Assesses impact of treatment changes during previous 1–2 months
- Predicts pregnancy outcome and foetal macrosomia
- Predicts risk of long-term complications over 3–10 years
- Allows comparison of glucose control among different populations
- Unaffected by short-term (hours) changes in glucose concentration
- Self-monitoring of blood glucose by patients at home

Table 55: Markers of IDDM

1. Genetic markers
2. Islet cell antibodies (ICA)
3. Insulin autoantibodies (IAA)
4. Elevated proinsulin levels
5. Circulating adhesion molecules
6. Antiglutamic acid decarboxylase (64K anti-GAD).

Presence of the antibody – (a) Is a strong predictive marker for onset of type 1 DM. (b) Helps differentiate between Type 1 and Type 2 diabetes. (c) Aids in prediction, diagnosis and management of DM. (d) Indicates need for progression to insulin therapy in Type 2 DM. (e) To determine the cause of hypoglycaemia. (f) To monitor recovery after removal of an insulin-producing tumor of the pancreas.

Early detection of IDDM – Some of the markers that can predict the development are given in Table 55.

PREGNANCY AND DIABETES

Pregnancy predisposes to diabetes by three mechanisms.

1. Antagonization of peripheral actions of insulin due to raised levels of oestrogens, progesterone, corticosteroids, human chorionic somatomammotropin and human placental lactogen.
2. Rapid insulin destruction due to high insulinase activity of placenta.
3. Depletion of β cell insulin reserve. Increased utilization of stored nutrients and glucose to feed the foetus leads to fasting hypoglycaemia, ketonaemia and elevated free acids which leads to insulin release and ultimately depletion of beta cell insulin reserve.

See Table 56 for the adverse effects of diabetes on pregnancy and Tables 57 and 58 for effects on foetus.

Management of diabetes in pregnancy

1. Diet high protein intake. Restriction of salt if oedema.
2. Exercise.

Table 56: Adverse effects of diabetes on pregnancy

• Polyhydramnios
• Pre-eclampsia, eclampsia
• Recurrent abortions
• Premature labour
• Prolonged labour
• Abnormal presentations
• UTI
• Monilial vaginitis
• Hypoglycaemia (first trimester)
• Hyperglycaemia (third trimester)
• Postpartum hemorrhage
• Puerperal sepsis
• Retinopathy
• Nephropathy
• Gastropathy
<i>Adverse effect on foetus</i>
• Macrosomia (large babies) because of foetus/hyperinsulinaemia causing excessive fat deposition and visceromegaly.
• Prematurity.
• Post-partum hypoglycaemia from persisting insulin secretion after birth in absence of glucose supplied via placenta.
• Intra-uterine death more common after 37th week, hence early termination of pregnancy is advisable especially if she has vascular complications.

3. Insulin therapy is essential. In first half of pregnancy requirement may be reduced due to morning sickness. Constant glucose utilization through the placenta and absence of antagonists to maternal glucose utilization. Post-partum insulin dosage must be readjusted as insulin requirements fall due to removal of placental lactogen.
4. Oral hypoglycaemic agents should be avoided except metformin which is effective in women with PCOD to aid conception.

Foetal monitoring in GDM for foetal anomalies

- (a) USG at 18–22 wks for malformations.
- (b) Foetal echo at 20–24 wks.
- (c) Serum α -fetoproteins.
- (d) Chromosomal studies if required.

For foetal well-being

- (a) Maternal records of foetal movements.
- (b) Foetal heart rate patterns (cardiotomography).
- (c) USG. Non-stress test, contraction.
- (d) Lecithin: Sphingomyelin ratio (for lungs).

Renal glycosuria is a rare condition in which sugar is eliminated in urine despite a normal or low blood sugar. This is due to improper functioning of renal tubules. When glucose in blood increases beyond 180 mg/dL, it is excreted in urine. This point is known as renal threshold for glucose (RTG).

SPECIAL CATEGORIES OF DM

1. Late-onset Autoimmune Diabetes of Adults (LADA) – A variation of type 2 DM, patients have autoantibodies such as anti-islet cell and anti-glutamic acid (GAD)

Table 57: Effects of diabetes on fetus

First trimester	Second trimester	Third trimester
Foetal malformation	Hypertrophic cardiomyopathy	Hypoglycaemia
Growth retardation	Resp. distress	Hypocalcaemia
Foetal loss	Foetal loss	Hypomagnesaemia
Placental	Low IQ	Polycythaemia
Macrosomia		Intra-uterine death
insufficiency		

Table 58: Malformations due to diabetes in fetus

Cardiac	Neurological	Renal	Skeletal	GI tract	Endocrine
VSD	Sacral agenesis	Renal agenesis	Sacral agenesis	Anorectal atresia	Pseudo-hermaphroditism
Conus arteriosus	Caudal regression syn.	Ureteric duplication	Cleft lip/cleft palate		
Dextrocardia	Anencephaly		Arthrogryposis		
	Myelocele				
	Hydrocephalus				

antibodies. Insulin levels are low. However, they progress gradually and present in non-obese young adults and may respond to OHAs. Eventually they become insulin dependent.

2. Maturity onset Diabetes of the Young (MODY2) is inherited genetic defect in β -cell glucokinase function defect. Patients are detected during routine screening or during pregnancy. The hyperglycaemia is minimal. MODY 1,3,4,5,6 present in early adulthood, are symptomatic, have severe hyperglycaemia and are prone to develop complications.
3. Fibro Calculous Pancreatic Diabetes (FCPD). See later.
4. Brittle diabetes - Here patients have wide fluctuations in blood sugar and recurrent episodes of ketoacidosis in spite of adequate doses of insulin. It usually occurs in young females with psychiatric problems and menstrual irregularities.

Management of Diabetes Mellitus

See Table 59 for the goals in management of diabetes.

Diet

- Restoration of normal blood glucose and optimal lipid levels.
- Maintenance of blood glucose level as near to physiologic levels to prevent onset or progression of complications.
- Maintenance of normal growth rate in children and adolescents as well as attainment and maintenance of reasonable body weight in adolescents and adults.
- Provision of adequate nutrition for pregnant women, the fetus and during lactation.
- Consistency in timing of meals and snacks to prevent inordinate swings in blood glucose levels.
- Motivation to have small frequent meals.

Table 59: Goals in the management of diabetes

• Elimination of the catabolic state and its symptoms
• Elimination of glycosuria
• Achievement of preprandial and post-prandial euglycaemia as indicated by normal HbA _{1c}
• To prevent or retard the progression of complications associated with diabetes
• Prevent metabolic crises like ketoacidosis and hypoglycaemia
• Maintain normal growth and body weight
• Encourage self-reliance and self-care
• Ensure optimum quality of life

- Determination of a meal plan appropriate for individual's lifestyle and based on dietary history to have good compliance.
- Management of weight reduction for obese individuals with NIDDM.
- Improvement in the overall health of patients with diabetes through optimal nutrition.

Total calories -

Requirements are determined by the patient's activity (Table 60).

Overweight NIDDM should be encouraged to establish their weight within a desirable range. A reduction of approximately 500 kcal/day can result in loss of 1-2 kg/month.

Carbohydrates - should comprise 55-60% of the calories, with the form and amount to be determined by individual eating habits and blood glucose and lipid responses. Unrefined carbohydrates should be substituted by refined carbohydrates to the extent possible.

Proteins - Recommended dietary allowance of 0.85 g/kg body weight for adult is an appropriate guide. If kidney dysfunction, reduce intake to 0.6 g/kg.

Fat - should comprise $\leq 30\%$ of total calories and all components should be reduced proportionately. Replacement of saturated with polyunsaturated fat is desirable to reduce cardiovascular risk. Cholesterol intake should be < 300 mg/day.

Fibre - Increased consumption of dietary fibre especially soluble fibre are associated with lower levels of blood glucose and serum lipids. The water insoluble fibres such as cellulose, lignin and most hemicelluloses found in whole grain breads, cereals and wheat bran affect gastrointestinal transit time and faecal bulk with little impact on plasma glucose. However highly viscous water soluble fibres such as pectins, gums and storage polysaccharide found in fruits, legumes, lentils roots, tubers, oat and oat bran, when eaten in purified form, reduce serum levels of glucose and insulin. Ideal recommended amount of fibre in patient's diet is 35-40 g/day.

Table 60: Caloric requirements

Nutritional status	Types of activity		
	Sedentary	Light work	Heavy
Calories per kg body weight			
Obese	25	30	35
Normal	30	35	40
Lean	35	40	45

Alternative sweeteners – Both nutritive and non-nutritive sweeteners are acceptable in diabetes management.

Sodium – Should be restricted to 1000 mg/1000 kcal, not to exceed 3000 mg/d to minimize symptoms of hypertension.

Alcohol – in moderation and may need to be restricted entirely by person with diabetes and insulin-induced hypoglycaemia, neuropathy, poor control of glucose and lipids, or obesity.

Vitamins, minerals and antioxidants – intake should be encouraged.

- (a) **Forbidden foods** – Sugar, jam, jellies, honey, jaggery, tinned fruits and juices, sweets, chocolate, ice creams, pastries, glucose drinks, foods made with sugar, pudding, sauces.
- (b) **Foods allowed in moderation** – Bread of all kinds and chapattis made from wheat or millets, plain biscuits, all fresh fruits, baked beans, breakfast cereals.
- (c) **Free foods** – All meat, fish, eggs (not fried), clear soup or meat extracts; tea or coffee; vegetables such as cabbage, cauliflower, spinach, pumpkin, brinjal, lady's finger, turnip, French beans, cucumber, lettuce, tomato, spring onions, radish, asparagus. Spices, salt, pepper and mustard; butter and margarine. Sugar substitutes for sweetening.

Exercise

See Table 61 for the potential risks and benefits of exercises.

Medical evaluation prior to formulating exercise programme

- History and physical examination
- Review of diet and medication
- Fundoscopy
- Foot evaluation

Neurological evaluation – (a) Sensory/motor. (b) Autonomic –

- Cardiovascular risk-factor profile
- Stress test assessment of glucose control

Exercise prescription

Type – Must be adjusted to patient's preference and existing medical condition. Aerobic exercise is preferred (swimming, cycling, walking, running). Addition of moderate resistance should be considered.

Duration – 20–45 mins. per session.

Frequency – 3–4 sessions per week is required to observe beneficial metabolic effects. 4–5 sessions per week for weight reduction.

Table 61: Risks and benefits of exercises

Potential benefits of exercises

- Maintenance of desirable body weight
- Improved sense of wellbeing and enhanced social interactions
- Enhanced insulin sensitivity
- Improved glucose control
- Decreases triglycerides and increases HDL-cholesterol levels
- Improved fibrinolysis
- Improved cardiac performance

Potential risks of exercises

- *Cardiovascular* – Myocardial ischaemia or infarction, dysrhythmias. Hypertensive response to exercise.
- *Microvascular* – Retinal haemorrhage, proteinuria, accelerated microvascular disease.
- *Metabolic* – Hypoglycaemia, hyperglycaemia, ketosis.
- *General* – Muscle strains/sprains, foot injury, joint injury, degenerative arthritis, poor dietary compliance.

ADA recommends 150 min/week (distributed over at least 3 days) of moderate aerobic physical activity with no gaps longer than 2 days.

Intensity – Patient's maximal pulse rate is estimated by subtracting patient's age from 220. Patient can be started at 40 to 50% of their maximal pulse rate with gradual increments to 60–70% over 6–8 weeks.

Programme

- Stretching (5–10 mins)
- Warm up (5–10 mins)
- Exercise (20–45 mins)
- Warm down (10 mins at 30% of full exercise intensity)

Exercise should be avoided when plasma glucose concentration is >250 to 300 mg/dL and/or presence of ketones in urine.

Oral Antidiabetic Drugs (OADs)

Insulin Secretagogues

Sulphonylureas – Lower blood glucose levels and are effective orally. See Table 62 for the characteristics of commonly used sulphonylureas Table 63 for response to sulphonylureas.

Mode of action – The sulphonylureas bind to a specific sulphonylurea receptor on pancreatic beta cells and exert their insulinotropic effects by closing adenosine triphosphate (ATP)-dependent potassium channels. This in turn, causes depolarization of the beta cells, which promotes influx of calcium and stimulation of insulin secretion.

Table 62: Characteristics of commonly used sulphonylureas

Drug	Initial daily dose (mg)	Doses/day	Comments
First generation			
Acetohexamide	250 mg	1–2	Has diuretic and uricosuric activity
Chlorpropamide	100 mg	1–2	Can potentiate ADH Disulfiram-like action with alcohol in 1/3rd of pts. Has diuretic activity
Tolazamide	100 mg	1–2	
Second generation			
Glibenclamide	2.5–20 mg	1–2	Hypoglycaemia can be severe
Gliclazide	40–320 mg	1–2	Metabolism/excretion by liver/kidney
Glipizide	5 mg	1–2	Mild diuretic activity
Glyburide	2.5 mg	1–2	Highest risk of hypoglycaemia
Glimepiride	1 mg	1	Excreted in urine and bile

Table 63: Diabetics likely to respond to sulphonylureas

- Onset of diabetes after 30 years of age
- Short duration of diabetes (5 years)
- Residual beta cell function
- Absence of GAD and islet cell antibodies
- Normal weight or moderately obese
- Fasting glucose <250 mg/dL

Sulphonylureas also probably exert extra-pancreatic effects on both the liver and peripheral muscle tissues.

First generation sulphonylureas have greater incidence of hypoglycaemia and more chances of drug interactions. Hence, second generation drugs are preferred. In patients with significant kidney disease is advisable to use Tolazamide, as it is exclusively metabolized by the liver.

Timing – Sulphonylureas should be taken 30 mins. prior to meals initially, because acute release of insulin results in lower postprandial plasma glucose excursion than when the drug is taken together with the meal. However, after several months, the acute insulin response wanes and the need to take the drug prior to meal becomes less evident.

In symptomatic patient with fasting blood sugar >250–300 mg/dL, or urinary ketones positive, therapy should be initiated with insulin.

Approximately, 20 to 25% of diabetics fail to respond to sulphonylureas. (primary failure). Those who respond initially to oral hypoglycaemic agents and then as the duration of diabetes increases glycaemic control deteriorates (secondary failure). The rate of secondary failure is about 4-5% per year (Table 64).

Table 65 gives contraindications and adverse effects and Table 66 drug interactions of sulphonylureas.

Table 64: Causes of secondary sulphonylurea failure

<i>Natural history of NIDDM</i>
• Progressive β cell failure: genetic
• Progressive insulin resistance: genetic
<i>Patient-related</i>
• Dietary non-compliance/weight gain
• Poor compliance with medication
• Lack of exercise
• Stress, intercurrent illness
<i>Therapy-related factors</i>
• Glucose-toxicity
• Inadequate doses
• Simultaneous use of diabetogenic drugs.

Insulin Sensitizers

Biguanides: Metformin – a guanidine derivative, effective and safe for control of hyperglycaemia (Table 67). Table 68 lists contraindications for the use of metformin.

Proposed mechanism of action

- Causes anorexia
- Decreases intestinal absorption of glucose
- Increases muscle and adipose tissue glucose uptake
- Decreases hepatic insulin resistance and thereby gluconeogenesis and glucose production.

Indications

NIDDM patients, obese or normal weight as monotherapy or in combination with sulphonylurea or insulin.

Dosage: 1.5 g to 2.5 g/day in 3 divided doses after meals

Side effects – Metallic taste, anorexia, nausea, abdominal discomfort and diarrhoea. These are mild, transient and self-limiting, subsiding after first 2 to 3 weeks

Table 65: Contraindications and adverse effects of sulphonylureas*Contraindications*

- Type 1 diabetes mellitus
- Pancreatic diabetes
- Gestational diabetes
- Allergy to sulphonylureas
- Severe infection, stress, trauma
- Major surgery
- Kidney and liver dysfunction

Adverse effects of sulphonylureas

- Hypoglycaemia
- Allergic reactions
- Skin rash
- Haematological abnormalities
 - Haemolytic anaemia
 - Thrombocytopenia
 - Agranulocytosis
- Facial flushing – (antabuse effect of chlorpropamide)

Table 67: Beneficial effects of metformin

- Decreases blood glucose:
 - Decreases fasting glucose by 60-70 mg/dl
 - Decreases the increment in plasma glucose after meals
- Does not increase plasma insulin levels
- Induces weight loss
- Improves plasma lipid profile:
 - Decreases LDL cholesterol and triglycerides
 - Decreases postprandial hyperlipidaemia

of therapy. Small initial doses and administration with meals minimizes side effects. Lactic acidosis if contraindications are not observed before starting metformin.

Malabsorption of vitamin B₁₂ in about 30% of patients

Underweight patients – or those whose control remains poor despite weight reduction are often markedly insulin deficient (severe lethargy, polyuria, persistently elevated HbA_{1c} values, rapid weight loss, ketonuria) should be treated with insulin. When there is uncertainty about residual insulin secretion, estimation of endogenous insulin secretion by glucagon stimulations test may be useful. Basal blood sampling for glucose and c-peptide

Table 66: Sulphonylureas and drug interactions*Deterioration of glycaemic control*

- Drugs that increase sulphonylurea metabolism (Rifampicin, barbiturates)
- Inhibitors of insulin secretion. (Thiazides and loop diuretics, β adrenergic blockers, phenytoin)
- Inhibitors of insulin action (steroids, growth hormone)

Increase in hypoglycaemia

- Drugs that displace sulphonylurea from albumin binding sites (Aspirin, fibrates, trimethoprim)
- Competitive inhibitors of sulphonylurea metabolism (H₂ blockers, alcohol)
- Inhibitors of renal excretion (probenecid, allopurinol)
- Antagonist of counter regulatory hormones (sympatholytic drugs, β adrenergic blockers)
- Concomitant use of drugs with hypoglycaemic action (Alcohol, aspirin)

Table 68: Contraindications of metformin

- Renal insufficiency (creatinine >1.5 mg/dl or GFR < 60 mL/min)
- Hepatic failure
- Severe cardiac disease
- Severe pulmonary disease with hypoxaemia
- Severe trauma, systemic infection or shock
- Pregnancy

is carried out after overnight fast. Glucagon 1 mg bolus is given i.v., blood sampling is done at 5 minutes for glucose and c-peptide.

Moderately obese patient – Full doses of metformin are started on combined therapy with a sulphonylurea, with gradual dose increments until blood sugar levels fall, or maximum doses of both the drugs are reached. Younger patients or older patients with symptomatic hyperglycaemia if poorly controlled, on combined therapy need insulin therapy.

Thiazolidinediones

Mode of action. Selective action for nuclear peroxisome proliferator activated receptor gamma (PPAR- γ), followed by activation of insulin responsive genes that regulate carbohydrate and lipid metabolism. The drug primarily reduces insulin resistance in peripheral tissues and also longer glucose production by the liver.

Contraindications – (a) type 1 DM. (b) Liver dysfunction. (c) Class III or IV cardiac disease.

Dose: 15–48 mg bd can be combined with sulphonylurea metformin.

Side effects - (a) Peripheral oedema (b) precipitation of cardiac failure (c) worsening of diabetic macular oedema.

Alpha-glucosidase Inhibitors

Acarbose/Voglibose. Its major action is to lower post-prandial plasma glucose levels, while causing a modest reduction in fasting plasma glucose concentration. See Table 69 for the indications and contraindications of alpha-glucosidase inhibitors.

Mode of action - Inhibition of breakdown of complex carbohydrates within the intestine, thus resulting in delayed absorption of glucose within small bowel and a consequent reduction in post-prandial glucose levels. Acarbose inhibits enzymes known as alpha-glucosidase. These enzymes cleave oligo- and disaccharides into monosaccharides, which then are rapidly absorbed from GI-tract. There are several intestinal alpha-glucosidase including glucoamylase, sucrase, maltase, isomaltase and lactase. The inhibitory effect on various alpha glucosidase are variable.

Dose - Acarbose 25–100 mg t.d.s. Voglibose 0.2–5 mg t.d.s. It is taken orally three main meals. In combination with metformin 500 mg for increased efficacy.

Side effects - Bloating, abdominal discomfort, diarrhoea and flatulence. These tend to diminish with continued use of the drug.

Insulin Secretagogues (Glinides, Meglitinides) (Repaglinide, Nateglinide)

Mechanism of action - closely resembles that of sulphonylurea. The meglitinides stimulate release of insulin from pancreatic β cells and their action is mediated through a

different binding site on the sulphonylurea receptors of the β cells. They have a very short onset of action and short half-life (about 1 hour). They are useful in decreasing PPG and have a low risk of hypoglycaemia, especially Nateglinide. Elevation of liver enzymes has been reported with repaglinide.

Doses

Repaglinide - 0.5 mg three times a day to a maximum of 4 mg per dose and 16 mg/per day.

Nateglinide - 60–120 mg t.d.s to be taken 30 minutes prior to meals.

Combination therapy of two drugs is often required to achieve good blood glucose control. If glycaemic control cannot be achieved, insulin therapy is preferred to addition of a third drug.

DPP-4 Inhibitor

(Vildagliptin, Saxagliptin)

Mode of action - inhibit degradation of native GLP-1 and thus enhance the incretin effect. Improve islet cell function by increasing α and β cell responsiveness to glucose.

Dosage

Vildagliptin 50–100 mg daily in 2 divided doses with meals. Saxagliptin 2.5–5 mg od

Reduced doses should be given to patients with renal insufficiency.

Human Glucagon-like Peptide-1 (GLP-1) Analogue Liraglutide, Exenatide

Mode of action - The drug supplements the body's own GLP-1 to trigger the secretion of insulin into the blood. It acts also stops the liver from releasing too much sugar into the blood. It acts when it is needed, when sugar levels are elevated after a meal.

Both the analogues are associated with reduced risk of hypoglycaemic episodes, including nocturnal hypoglycaemia to half the level seen with NPH.

The potential advantage of insulin detemir is low risk of hypoglycaemia when compared with insulin glargine. Also it has weight-sparing effect when compared with NPH insulin and insulin glargine.

Side effects - Nausea is the most common adverse effect leading to withdrawal.

Amylin Agonist

Patients who are insulin deficient are also amylin deficient, an analogue of amylin (pramlintide) was created and found to reduce postprandial glycemic excursions in

Table 69: Indications and contraindications of alpha-glucosidase inhibitors

Indications

- Monotherapy in patients with mild to moderate hyperglycaemia.
- Adjunctive therapy in patients on sulphonylurea but who have suboptimal glycaemic control.

Contraindications

- Underlying disorder of GI-tract including inflammatory bowel disease, colonic ulceration.
- Pregnancy and lactation.
- Serum creatinine >2.5 mg/dL.
- Cirrhosis of liver.

Table 70: Insulin preparations

Insulin preparation	Onset (Hrs)	Peak (Hrs)	Duration (Hrs)
<i>Rapid acting</i>			
Regular	½–1	2–4	6–8
Lispro (analogue)	¼–½	1–2	3–5
<i>Intermediate acting</i>			
NPH (isophane)	1–4	8–10	12–20
Lente (insulin zinc suspension)	2–4	8–12	12–20
<i>Long acting</i>			
Ultralente (extended insulin zinc suspension)	3–5	10–16	18–24

Table 71: Indications of insulin

• Type 1 diabetes
• Gestational diabetes
• Hyperglycaemia despite maximum doses of oral agents
• Decompensation due to intercurrent events such as infection, acute injury or stress
• Development of severe hyperglycaemia with ketosis
• Perioperative in patients undergoing surgery
• Kidney or hepatic disease

See Table 70 for the insulin preparations and Table 71 for the indications.

type 1 and type 2 diabetic patients taking insulin. Pramlintide slows gastric emptying and reduces glucagon secretion. It is used as subcutaneous injection.

Side effects are nausea and vomiting. Because pramlintide slows gastric emptying, it may influence absorption of other medications and should not be used in combination with other drugs that slow GI motility.

Sodium-Glucose Co-Transporter 2 Inhibitors (SLGT2)

Mode of action - Lower the blood glucose by selectively inhibiting this co-transporter, which is expressed almost exclusively in the proximal convoluted tubule in the kidney. This inhibits glucose reabsorption, lowers the renal threshold for glucose and leads to increased urinary glucose excretion. Thus, the glucose-lowering effect is insulin independent and not related to changes in insulin sensitivity or secretion.

Side effect - Due to the increased urinary glucose, urinary or vaginal infections are more common and the diuretic effect can lead to reduced intravascular volume.

Example - Canagliflozin, dapagliflozin and empagliflozin

Insulin

Early intensive treatment of new onset DM aimed at high glucose control reduces the risk of microvascular complications and probably also macrovascular disease. “Metabolic memory” and legacy effect are terms that have been used to describe the fact that glucose control early in diabetes profoundly influences the prognosis later on in life. Most patients with Type 2 DM ultimately require insulin to attain glycaemic targets.

Types of insulin

Species of origin - Bovine, Porcine, recombinant DNA technology - Human.

Treatment Strategies

1. *Single dose regimen* - Daily injection of intermediate acting insulin given before breakfast. The starting dose 0.3 to 0.4 U/kg/day; increased gradually to obtain glucose values in acceptable range. Regular insulin can be added to decrease the glucose level that follows breakfast.
2. *Twice daily regimen* - Combination of regular and intermediate acting insulin b.d., i.e. before breakfast and before dinner (“Split mix” regimen).
3. *Multiple daily injections* - For achievement of more tight control of blood glucose which requires administration of at least 3 injections per day. These can be given with use of mixture of intermediate and short-acting insulins (pre-mixed insulin) in the morning before breakfast, with regular insulin before supper and intermediate acting at bedtime; or again a combination of regular and intermediate acting before dinner. Divide the total daily into 2 equal doses (following 1:1 transfer from basal insulin. Give half before breakfast and other half before dinner. The largest meal will require larger proportion of insulin. Reduce total dose by 20% if patient experiences recurrent hypoglycaemia.
4. *Insulin concentrations* - The insulins are available in many concentration. In India the commonly used is 40 U/mL. In United States, the insulin used is of concentration 100 U/mL. Worldwide insulin is available in a wider range of concentrations including U-40, U-80, U-100, U-500.
5. *Insulin purity* - The impurities which may be contained are proinsulin, insulin intermediates and contaminating proteins from islet tissue or exocrine pancreas such as glucagon, somatostatin and pancreatic polypeptides. Standard insulins currently have only 10 to 20 PPM of proinsulin and purified monocomponent insulins less than 1 PPM.

6. *Sites of injection* – The best sites are subcutaneous fat on abdomen, buttock, anterior thigh and dorsal area of arm. Insulin is rapidly absorbed if the extremity is subsequently exercised or with massage of local area, or increased local skin temperature.

Insulin Delivery Systems

Insulin Pens

A very important barrier in the use of conventional insulin delivery process which is time-consuming, inconvenient and painful. Insulin dosing via syringe is associated with a high risk of dosage errors. The pen devices have various advantages. The ease of insulin pens and the flexibility of incorporating insulin injections into the lifestyle can improve diabetic control with much less effect while maintaining the quality of life. It is also simpler for specific population to use (e.g. older adults, children and adolescents and pregnant women).

Types of Insulin Pens

1. *Reusable pens.* An insulin cartridge (called prefills), is inserted into the pen delivery chamber. This allows greater flexibility (i.e. changing types of insulin without the need to buy another pen, if prescription changes). Also they are designed for longer duration of use.
2. *Prefilled pens* contain a built-in single use insulin cartridge, hence requires no loading by the patients and is easy to use. These portable, durable and light weight delivery systems are particularly helpful for patients who have been handling the cartridges in reusable pens or those with busy schedules. The new generation flex pen have less injection force and an easy needle attachment with 'just twist' mechanism.

Continuous Insulin Infusion Systems in Type 2 Diabetes

Insulin pumps can be useful to mimic the physiological insulin secretion (Table 72). Pumps have the benefits of continuous subcutaneous insulin infusion (GSI) in selective patients with continuous glucose monitoring system (CGM) is a therapeutic option enabling diabetic patients

Table 72: Indications for use of infusion pumps

High HbA1c levels despite multiple daily injections
Brittle diabetes
Frequent episodes of severe hypoglycaemia
Chronic kidney disease requiring kidney replacement
Elderly subject
Frequent travelers with varied food habits

to restructure life styles based on glycaemic pattern. Table 73 compares insulin pumps with pens.

Complications – of Insulin Therapy

- *Hypoglycaemia* – frequently encountered problem because of mismatch between timing of insulin, meals and exercise.
- *The counter-regulatory hormones* – Glucagon and epinephrine are of primary importance in the response to insulin-induced hypoglycaemia. Patients with diabetes progressively lose their counter regulatory hormone responses to hypoglycaemia. The first hormone to be lost is glucagon which is lost by 5 years of IDDM.
- *Nocturnal hypoglycaemia*
Dawn phenomenon – Early morning glucose production by the liver is increased and sensitivity to action of insulin is decreased. Thus higher levels of insulin are required to maintain euglycaemia in early morning hours. This has been attributed to growth hormone surge which increases insulin resistance transiently.
Somogyi effect – Increase in blood glucose value because of transient hypoglycaemia. It is mediated by increases in levels of circulating counter regulatory hormones.
(See also later)
- *Insulin oedema* – The oedema may be present on feet and ankles or generalized anasarca. Insulin may act directly on kidneys reducing excretion of sodium and increasing retention of water.
- *Lipoatrophy and lipohypertrophy* – Seen with animal insulins. Lipoatrophy is localized loss or absence of subcutaneous fat at sites of frequent injections. The cause seems to be local immunologic reaction to impurities in insulin.

Table 73: Comparison of insulin pens vs insulin pumps

Insulin pens	Insulin pumps
Cheap	Very expensive
Easy to use and learn	Difficult to use and learn
Need to change cartridge and needle based on usage pattern	Need to change infusion set once in 3 days
Frequency of shot is more	Only one shot once in 3 days
Can incorporate any insulin (human, analogue, etc.)	Incorporates only fast-acting human insulin or rapid-acting analogue insulin
Bolus administration requires additional insulin shots	Any number of bolus doses can be delivered without pain of injection
	Risk of infection if infusion set not changed once in 3 days
	Overeating and frequent bolus insulin injection can lead to weight gain

Lipohypertrophy – is swelling of the subcutaneous fat. It is probably a direct effect of insulin on local tissue lipogenesis. Use of purified insulins prevents this occurrence.

- **Insulin allergy** – can be localized at site of injection or generalized. (a) Localized allergy – Patches of swelling and redness at site of injection, usually pruritic and often painful. (b) Generalized – Urticaria, pruritus, angioedema, rash, flushing, palpitations and bronchospasm. Acute anaphylaxis can occur but is extremely rare.
- **Obesity and weight gain** – Most of early weight gain following initiation of insulin therapy is due to rehydration and correction of catabolic state of poorly controlled diabetes, but subsequent chronic weight gain is two-third due to fat and one-third due to lean body mass.

Insulin Analogues

These modern insulins have been developed with an objective of overcoming the problems with conventional insulins. In general, they are considered more physiological, predictable and safe insulin preparations.

Modern Insulins

Rapid-acting

- Insulin lispro
- Insulin aspart
- Insulin glulisine

Long-acting

- Insulin glargine
- Insulin detemir

Premix

Biphasic insulin lispro

Clinical Efficacy of Rapid Acting Modern Insulins as Compared to RHI

- Better postprandial glucose control
- Good HbA1c control
- Less chances of hypoglycaemia
- Meal time flexibility

Use of Short-acting Modern Insulin in Special Situations

1. **Critical care** – Improved glycaemic control is associated with improved hospital outcome.
2. **Diabetic ketoacidosis** – Use of Aspart every 1–2 hr is safe and effective alternative to use of iv regular insulin.

Long-term efficacy – Treatment with rapid acting insulin analogue has shown an improvement in PPG and a reduction in the risk of CV events.

Kidney failure – Unaltered pharmacokinetics and safety profile in patients with various degrees of kidney dysfunction.

Gestational diabetes mellitus – Better control of PPG due rapid onset, more flexible regimen because it can be given pre-prandial as well as post-prandial, less hypoglycaemia and safe for both mother and fetus.

Analogues in insulin pumps – Replicating endogenous insulin production is the goal of treatment for DM. The two main methods of achieving this goal are continuous subcutaneous infusion (CSI) and multiple daily injections (MDIs) comprising basal and prandial injections. It has been shown that Lispro when used with external pump improves glycaemic control and stability with much lower doses than of insulin and dose increase frequency of hypoglycaemic episodes.

See Table 74 for Summary comparison of rapid acting insulin analogues.

Table 75 gives causes of recurrent hypoglycaemia in IDDM.

COMPLICATIONS

Metabolic Complications

Diabetic Ketoacidosis

Is a state of acidaemia induced by excess production of ketoacids. Dehydration and hyperglycaemia are the rule, lactic acidosis may also be present. See Table 76 for the precipitating causes of diabetic ketoacidosis.

Pathophysiology – Diabetic ketoacidosis is caused by severe insulin deficiency and is accentuated by excessive glucagon secretion. This leads to major clinical and laboratory abnormalities seen in diabetic ketoacidosis, which includes excess mobilization of free acids from adipose tissue, increased glucose production from the liver and impaired glucose uptake and utilization by muscle (Fig. 2).

The two major effects of uncontrolled diabetes are:

- Increased glucose production which causes hyperglycaemia, osmotic diuresis, electrolyte depletion and dehydration
- Increased ketogenesis, resulting in metabolic acidosis.

Diagnosis – The cardinal features are:

- Acidosis (arterial pH \leq 7.3)
- Plasma anion gap (\geq 16 mmol/liter)

Table 74: Summary comparison of rapid acting insulin analogues

Diameter	Glulisine	Lispro	Aspart
Meal time flexibility	Pre as well as post-prandial administration	Pre as well as post-prandial administration	Pre as well as post-prandial administration
Blood glucose control	Similar control in comparison with Lispro	Similar to Glulisine	More than 10 mg/dl reduction as compared to Lispro
Hypoglycaemia	Maximum reduction in nocturnal hypoglycaemia upto 60% vs HI	Maximum reduction in nocturnal hypoglycaemia upto 68% vs HI	Maximum reduction in nocturnal hypoglycaemia upto 72% vs HI
Renal impairment	Conc. increases with moderate to severe renal dysfunction - upto 40%	Dose reduction required	Remains unaffected
Storage Shelf-life	Temp. 30°C 24 months	Up to 30°C 27 months	Up to 30°C 30 months

Table 75: Recurrent hypoglycaemia in IDDM

1. Excessive or inappropriate dosage schedule.
2. Low renal threshold (renal glycosuria – dose monitoring with urine analysis).
3. Coexisting hypoadrenalism or hypopituitarism.
4. GI disease – Coeliac disease, diabetic gastroparesis.
5. Alcohol abuse.

Table 76: Precipitating causes of diabetic ketoacidosis

1. Acute infection viral or bacterial single most common cause.
2. Omission of insulin or inadequate dosage.
3. Vomiting.
4. Diarrhoea.
5. Prolonged neglect of diabetes.
6. Indiscretions in diet.
7. Surgical operations.
8. Trauma.
9. Myocardial infarction.
10. Pregnancy.
11. Thyrotoxicosis.
12. Resistance to insulin.
13. Unnoticed interruption of insulin delivery in diabetics treated with continuous subcutaneous insulin infusion.

**Fig. 2:** Metabolic effects of severe insulin deficiency

- Serum ketone is positive
 - Serum bicarbonate ≥ 15 mmol/liter
 - Hyperglycaemia (plasma glucose ≥ 11.1 mmol/liter)
- Differential Diagnoses of Comas in Diabetes: See Tables 77, 78 and 79.

Investigations

Blood glucose, urea and electrolytes (especially potassium), full blood count and blood gases. ECG should be monitored continuously for signs of hypokalaemia.

Management

See Table 80 for the management of diabetic ketoacidosis.

Complications of DKA

Iatrogenic complications

1. **Osmotic and volume disturbances**—Administration of insulin without sufficient fluids causes shift of water from extracellular space; further shrinking of extracellular fluid volume impairs blood flow to critical vascular beds, or precipitates vascular collapse. Similarly insufficient saline administration may also result in hypotension.
2. **Potassium disturbances** – Premature (before insulin has begun to act) and inappropriate potassium administration may cause fatal hyperkalaemia (cardiotoxicity) in early course of management. Glucose, insulin, and volume expansion with normal saline are potential modalities for lowering serum potassium;

Table 77: Differential diagnosis of coma in diabetes

Types of coma		Blood glucose	Ketosis	Acidosis	Dehydration
1.	Ketoacidotic hyperglycaemia	+++	+++	+++	+++
2.	Hyperosmolar hyperglycaemia state	+++	0	0	+++
3.	Lactic acidosis	- to +++	0 to +	+++	0
4.	Hypoglycaemic (see later)	Low	0	0	0
5.	Kidney failure	+ to +++	0	++	0

Table 78: Differential diagnosis of ketoacidaemia from hypoglycaemic coma

	Diabetic ketoacidosis	Hypoglycaemic coma
<i>History</i>		
Precipitating cause	Infection, trauma, too little insulin	Undue exercise, missed meal, too much insulin or oral hypoglycaemic drug like glibenclamide.
Rate of onset	Slow, over a period of hours or days	Abrupt, minutes
<i>Signs</i>	Absent	Usually marked
Sweating	Marked	Nil
Dehydration	Rapid and deep (air hunger)	Stertorous
Respirations	Patient usually arousable (except in advanced case)	Coma often deep
Depth of coma		
<i>CNS signs</i>	Diminished	Usually brisk, extensor plantars
Reflexes	Absent	Common
Muscular twitchings	Absent	May occur
Convulsions	Yes	No
Acetone in breath		

Table 79: Differential diagnosis of diabetic ketoacidosis (DKA) and hyperosmolar non-ketotic coma

	DKA	HONK
Age and type of diabetes	Mostly in young Type 1, can occur in Type 2	Usually Type 2, > 40 yrs
Causes	Relative or absolute insulin deficiency	Multifactorial
Blood glucose (mg/dl)	>250	>600
Serum Na (mEq/L)	Normal or low	Usually high
Blood/urine ketones	++++	or trace (+)
Blood pH	<7.0	>7.3
Serum bicarbonate (mEq/L)	<15	>20
Serum osmolality	Variable	≥ 20 mosm/kg
Mortality	5–10%	30–50%
Subsequent course	Nearly always insulin dependent	Often controlled on diet alone Rarely need insulin

Table 80: Management of diabetic ketoacidosis

Admission
<ul style="list-style-type: none"> • Diagnosis suspected and confirmed immediately by blood glucose and ketone measurements • Initial assessment of magnitude of dehydration, hyperosmolality, and acidosis • Fluid loss measured by subtracting admission weight from last recently known stable weight • Effective serum osmolality = $2 \times [\text{serum Na}^+ (\text{mmol/liter}) + \text{serum K}^+ (\text{mmol/liter})] + \text{serum glucose (mmol/liter)} + \text{urea (mmol/liter)}$ • Initial assessment of serum potassium and kidney function.

Contd...

<ul style="list-style-type: none"> • Evaluate patient for sepsis and/or precipitating illness
<i>Hour 1</i>
<ul style="list-style-type: none"> • <i>Fluid administration</i> <ul style="list-style-type: none"> – If strikingly hypovolaemic with low blood pressure and relative or absolute anuria, fluid administration should be normal saline and, if necessary, colloids; rate of administration should be that necessary to restore circulatory function – When blood pressure is normal and urine output adequate: fluid administration should be normal saline; rate of administration 1000 mL/hour • <i>Insulin</i>

Contd...

Contd...

Contd...

<ul style="list-style-type: none"> - Continuous intravenous infusion of regular insulin 5–10 units/hour or intramuscular regular insulin (20 units loading dose and 5 units/hour)
<ul style="list-style-type: none"> • Potassium
<ul style="list-style-type: none"> - Start intravenous potassium at 10–40 mmol/hour at initiation of insulin therapy if serum potassium is not > 5 mmol/liter and renal output is good. If patient is hyperkalaemic, temporarily delay intravenous potassium
<ul style="list-style-type: none"> • Alkali
<ul style="list-style-type: none"> - Sodium bicarbonate intravenously is seldom indicated, except in severe acidosis (pH < 7.0) with incipient circulatory collapse. Dose, if given, is 50–100 mmol/liter sodium bicarbonate given in 0.45% saline over 30–60 minutes. Additional K⁺ must be given with bicarbonate therapy
<p>Hour 2</p>
<ul style="list-style-type: none"> • Fluid administration
<ul style="list-style-type: none"> - Continue normal saline at 500 mL/hour. Maintain calculated plasma osmolality > 285 mOsmol/liter throughout the first 12 hours. If serum Na⁺ > 150 mmol/liter switch to 0.45% saline.
<ul style="list-style-type: none"> • Insulin
<ul style="list-style-type: none"> - Check blood glucose and adjust insulin dose to maintain a fall of about 5 mmol/liter/hour. Do not allow blood glucose to fall below 11.1–14.0 mmol/liter. Anion gap should be decreasing and blood pH increasing
<ul style="list-style-type: none"> • Potassium
<ul style="list-style-type: none"> - Maintain serum potassium at 4.0–5.0 mmol/liter by continued addition of potassium to intravenous fluids
<p>Hours 3–4</p>
<p>Continue as for hour 2</p>
<p>Observe for cognitive or neurological symptoms and continue to do so for 12 hours</p>
<p>Hours 5–8</p>
<ul style="list-style-type: none"> • Fluid administration
<ul style="list-style-type: none"> - Normal saline 250 mL/hour. When blood glucose reaches 11.1–14.0 mmol/liter, change intravenous fluid to 500 mL/hour normal saline with 5% glucose
<ul style="list-style-type: none"> • Insulin
<ul style="list-style-type: none"> - Continue insulin at maintenance dose until ketoacidosis has cleared (blood pH > 7.35, serum ketones negative)
<ul style="list-style-type: none"> • Potassium
<ul style="list-style-type: none"> - Continue at 10–40 mmol/hour until ketoacidosis has cleared
<ul style="list-style-type: none"> • Phosphate
<ul style="list-style-type: none"> - Consider phosphate replacement at 6 hours if serum phosphate is < 2.0 mg/dL
<p>Hours 8–24</p>
<ul style="list-style-type: none"> • Fluid administration
<ul style="list-style-type: none"> - Continue intravenous repletion with 0.45% saline with or without 2.5% or 5.0% glucose as needed
<ul style="list-style-type: none"> • Insulin
<ul style="list-style-type: none"> - After ketoacidosis has cleared (blood pH > 7.35, serum ketones negative) switch to subcutaneous insulin and then stop intravenous or intramuscular insulin

hence, failure to administer potassium in later stages may cause fatal hypokalaemia in potassium-depleted patients.

3. **Hypoglycaemia and reappearance of ketosis** – During therapy of DKA, normalization of blood glucose is usually achieved sooner than reversal of ketoacidotic state. Because insulin therapy must be continued, hypoglycaemia develops unless glucose is given. Fingerstick glucose measurements should be done hourly for 4h, 2 hourly for next 4h, and 4 hourly till pt. improves. Glucose generally falls at rate of 50–100 mg/dL/h. Failure to maintain glucose and insulin treatment until ketones have been cleared and depleted glycogen stores restored, results in recurrence of ketosis.
4. **Cerebral oedema** – may rarely occur in children but is even rarer in adults. The condition should be suspected when a pt. with ketoacidosis begins to deteriorate 3 to 10 hours into treatment with increasing stupor or coma coupled with signs of raised intracranial pressure; an unexpected fever may also be an early sign. Osmotic disequilibrium between intracellular and extracellular fluids probably plays a role. Tr. – Mannitol 20% iv 1.5–2 mL/kg body wt. over 15 minutes and dexamethasone 10 mg iv followed by 4mg in q6h. Clinical response will be seen in 12–24 h.
5. **Hypocalcaemia** – may develop during phosphate replacement.

Non-iatrogenic complications

1. **Infection** – Although leucocytosis may occur in DKA in absence of infection, fever generally indicates infection and demands careful search for pneumonia, pyelonephritis and septicaemia. A rare ketoacidosis-associated infection is mucormycosis of paranasal sinuses with facial pain, bloody nasal discharge, orbital swelling, blurred vision and impaired consciousness. Tr. – Broad spectrum antibiotics. Blood, urine and throat cultures should be taken prior to giving antibiotic.
2. **Vascular thrombosis** – Combination of volume contraction, low cardiac output, increased blood viscosity, underlying atherosclerosis, direct endothelial damage due to hyperosmolar milieu, and changes in clotting factors and platelet function predispose to thrombosis.
3. **Respiratory distress syndrome** – Hypoxia and ARDS may develop in course of therapy of DKA hyperosmolar coma. Clinical picture is characterized by unexplained hypoxaemia and dyspnoea in absence of any underlying pulmonary/cardiac disease.
4. **Pancreatitis** – Acute abdominal pain is a common presentation of DKA, and resolves rapidly on therapy.

Specific etiologies can be gastroparesis, ischaemic bowel, and cholecystitis. Raised serum amylase is observed in 80% of cases. It may represent pancreatic damage (hypertonicity and hyperperfusion); in some instances, it is subclinical.

5. *Myocardial infarction* – can precipitate or complicate DKA, it is a major cause of morbidity.
6. *Hyperlipidaemia* – Severe hypertriglyceridaemia (triglycerides > 1000 mg/dl) is seen in about 10% which on follow-up resolve in 70% of cases. The abnormality is related to acute metabolic changes in DKA.

Hyperosmolar Hyperglycaemic State

Generally occurs in elderly often in non-insulin dependent or new diabetic. Precipitating factors – include infection, myocardial infarction and treatment with drugs such as thiazides, steroids and diphenylhydantoin. The situation may be exaggerated by drinking large quantities sugar containing fluids from excessive thirst.

Clinical features – It is characterised by severe dehydration, hyperglycaemia and absence of ketoacidosis.

- **Laboratory findings** – Blood glucose >50 mmol/liter (900 mg/mL), plasma urea > 120 mg/100 mL and often raised plasma osmolality (often more than 360 mOsm/kg).
- **Management- IV fluids:** Start 1 L 0.9% NaCl/hr initially. Hypovolaemic shock – 0.9% NaCl (1 L/h) and/or plasma expanders
 - Mild hypotension – Evaluate serum Na⁺
 - High: 0.45% NaCl (4–14 mL/kg/h) depending on state of hydration
 - Low: 0.9% NaCl (4–14 mL/kg/h) depending on state of hydration

When serum glucose reaches 300 mg/dL, change to 5% dextrose with 0.45% NaCl and decrease insulin to 0.05–0.1 U/kg/h to maintain serum glucose between 250–300 mg/dL until plasma osmolality is \geq 315 mOsm/kg and patient is mentally alert.

Insulin

Regular 0.15 U/kg as iv bolus followed by 0.1 U/kg/h iv infusion

Check serum glucose hrly. If it does not fall by 50 mg/dL in first hr, then double the insulin dose hrly until glucose falls at a steady hrly rate of 50–70 mg/dL

Check electrolytes, BUN, creatinine and glucose every 2–4 h until stable. If patient is NPO, continue iv insulin and supplement with sc regular insulin as needed. When patient can eat, initiate sc insulin or previous treatment regimen and assess control.

Potassium

If initial serum K is < 3.3 mEq/L, hold insulin and give 40 mEq K (2/3 as KCl and 1/3 as KPO₄) until K \geq 3.3 mEq/L.

If initial serum K \geq 5, do not give K but check potassium every 2 hrs.

If initial serum K \geq 3.3 but < 5 mEq/L, give 20–30 mEq in each liter of iv fluid to keep serum K at 4–5 mEq/L.

Lactic acidosis – Rare cause of severe metabolic acidosis. Caused by excess lactate production and/or inadequate utilization. It may be precipitated by metformin, or another systemic disorder, e.g. diabetes, liver or renal failure, pancreatitis or leukaemia. Evidence of cardiovascular collapse is usually evident.

Management – is mainly supportive. Large doses of soda bicarb are required to maintain normal pH, until the primary cause is removed. Peritoneal or hemodialysis may be necessary to remove excess sodium. Blood transfusion may be helpful if severe hypotension.

Hypoglycaemic Coma (Refer)

Non-metabolic Complications

The ‘triopathy’ (retinopathy, neuropathy and nephropathy) are the classical late complications of diabetes mellitus.

Diabetic Retinopathy

1. Background diabetic retinopathy – includes hemorrhages and microaneurysms in retina, together with exudates. Visual acuity is normal.
2. Pre-proliferative retinopathy – is a development of background retinopathy. Capillary closure occurs leading to retinal ischaemia.
3. Proliferative retinopathy – is characterised by growth of new vessels on optic disc and iris. Hemorrhage occurs initially in subhyaloid space but progresses to involve the vitreous gel, leading to poor vision. Untreated disease may result in traction retinal detachment.
4. Proliferative disease – of the iris (rubeosis iridis) may occur.
5. Maculopathy – due to hemorrhage, oedema of macula, ischaemia and proliferation of macula.

Prevention – American Diabetes Association (ADA) recommends the following = ophthalmologic examination schedule: (1) individuals with type 1 DM should have an initial eye examination within 5 Years of diagnosis (2) individuals with type 2 DM should have an initial eye examination at the time of diabetes diagnosis, (3) women with DM who are; pregnant or contemplating pregnancy

should have an eye examination prior to conception and during the first trimester and (4) if eye exam is normal, repeat examination in 2–3 years is appropriate.

Tr. (a) Proliferative retinopathy – Panretinal photocoagulation. (b) End-stage proliferative retinopathy – Pars plano vitrectomy. (c) Rubeosis iridis – Photocoagulation. (d) Maculopathy – Grid treatment to areas of thickening. If advanced macular oedema generalised grid therapy, with photocoagulation applied to macula.

Diabetic Nephropathy

Major cause of premature death, principally from end-stage kidney disease and cardiovascular disease (Table 81). See Table 82 for the risk factors and Table 83 for the staging of diabetic nephropathy.

Pregnancy and Proteinuria in Diabetes

Development of microalbuminuria or macroalbuminuria in a diabetic woman carries the risk of pre-eclampsia.

Nephropathy in Type 2 DM – is largely disease of older age, with associated obesity, hypertension and dyslipidaemia and high rates of cardiovascular disease that restrict manifestations of diabetic kidney disease.

Renal medullary necrosis results from ischaemia to the medulla and papilla. Patient has flank pain, hematuria and fever. Urinalysis shows red and white blood cells, bacteria and papillary fragments.

Renal tubular acidosis manifests as hyperkalaemic and hyperchloraemic metabolic acidosis.

Nephropathy in type 2 Diabetes has more similarities than differences in T1DM. Hyperfiltration is less common. Microalbuminuria might not be as specific for diabetic kidney disease.

Tr. – ACE inhibitors reduce the rate of progress from micro- to macroalbuminuria and can slow the decline in GFR in patients with microalbuminuria. In addition ACEIs tend to reduce severe CVD (cardiac infarction, stroke). ARBs have a smaller magnitude of rise in potassium com-

pared to ACEIs. In patients unable to tolerate ACE inhibitor and/or ARBs, use of non-DCCBs, β -blockers or diuretics can be considered for control of BP.

Diabetic Foot

Risk factors: (a) Evidence of neuropathy. (b) Evidence of ischaemia. (c) Foot deformities. (d) Callus at pressure areas. (e) Previous history of foot ulcers. (f) Impairment of sight (when attempting self-care). (g) Elderly.

See Table 84 for the grading of diabetic foot ulcers.

Tr. – High risk patients should be advised to wash and inspect the feet daily, use creams or lotions to prevent dry skin/callus formation, avoid walking barefoot and avoid thermal injuries, seek medical attention for any injury/discomfort, and avoid self-treatment of corns, calluses or other disorders.

Diabetic Neuropathy

See Table 85 for the types of diabetic neuropathy.

(a) **Sensorimotor neuropathy** – 1. Acute – Neuropathy is symmetrical and predominantly sensory. Symptoms Pain, stabbing or burning, particularly on soles of feet and shins. (a) Hyperaesthesia. (b) Paraesthesiae and feeling of numbness. 2. Chronic – may take years to develop, and nerve function in most cases unlikely to improve. Treatment – Tricyclic antidepressants e.g. Amitriptyline 25–50 mg at bedtime may provide relief from pain.

(b) **Autonomic neuropathy.**

See Table 86 for the clinical manifestations of autonomic neuropathy.

(c) **Diabetic mononeuropathy** – (a) Entrapment neuropathy (median carpal tunnel syndrome, usually bilateral, or of lateral cutaneous nerve of thigh). (b) Spontaneous mononeuropathy – Cranial nerves 3rd and 6th are most often involved. Onset is sudden but recovery occurs in most patients after weeks or months. (c) External pressure palsies – e.g. of radial, ulnar and peroneal nerves.

Table 81: Definitions of abnormalities in albumin excretion

Category	24-h urinary albumin excretion rate	Overnight urinary albumin excretion rate	Albumin: creatinine ratio
Normal albuminuria	<30 mg/day	<20 μ g/min	<2.5 mg/mmol (for men) <3.5 mg/mmol (for women)
Microalbuminuria	30–300 mg/day	20–200 μ g/min	2.5–25 mg/mmol (for men) 3.5–25 mg/mmol (for women)
Macroalbuminuria (overt nephropathy)	>300 mg/day	>200 μ g/min	>25 mg/mmol

Table 82: Risk factors for diabetic nephropathy

- Hyperglycaemia
- Hypertension
- Baseline urinary albumin excretion
- Increasing age
- Duration of diabetes
- Presence of retinopathy
- Smoking
- Raised cholesterol and triglyceride
- Male gender

Table 84: Grading of diabetic foot ulcers

Grade 0	High-risk foot, no ulcers
Grade 1	Superficial ulcer, skin deep
Grade 2	Deeper ulcer, usually with infection/cellulitis, no bone involvement
Grade 3	Osteomyelitis and foot ulceration
Grade 4	Localised gangrene (toes, forefoot or heel)
Grade 5	Gangrene of entire foot

(d) Proximal motor neuropathy (Diabetic amyotrophy)

– Cl. Fs. – Acute onset in type 2 poorly controlled diabetes with markedly elevated HbA1c. (a) Presents with severe pain, paraesthesia, hyperpathia in upper legs, and weakness and muscle wasting, especially of quadriceps. (b) Skin tenderness over anterior aspects of the thighs and weakness of hip flexion in one or both legs. (c) Knee jerks may be absent. (d) Often complicated by development of contralateral pelvic girdle weakness, wasting, weight loss, incontinence and impotence. (e) Occasionally associated with extensor plantar response and/or elevated CSF protein. (f) Excellent long-term prognosis, at least partial recovery within 1–2 years, but recurrence not uncommon.

Skin Disorders

1. *Diabetic dermopathy* (skin spots, pigmented pretibial patches). Bilateral multiple hyperpigmented macules in pretibial areas. Lesions may also appear on forearm, and anterior surface of lower thigh. Lesions ultimately evolve into shallow pigmented scars.
2. *Vascular abnormalities*. Small arterial involvement may lead to slow healing leg ulcers.
3. *Nerve-related problems*. Motor nerve damage leads to risk of ulcers on feet.
4. *Infections*. Cutaneous manifestations may be due to vascular, nutritional or metabolic disturbances –

Table 83: Stages of Nephropathy in type 1 DM

- *Stage 1:* Hyperinflation is associated with increased GFR.
- *Stage 2:* Silent stage. Absence of any kidney dysfunction clinically.
- *Stage 3:* Microalbuminuria or stage of incipient nephropathy. Urinary albumin excretion rate in range of 30 to 300 mg/24 hrs. Concomitant increase in systolic and diastolic BP.
- *Stage 4:* Macroalbuminuria. Urinary albumin excretion > 300 mg/24 hrs. If left untreated, BP continues to rise, accelerating decline in GFR.
- *Stage 5:* Uremia and end stage kidney disease.

Table 85: Diabetic neuropathy

- (a) Sensorimotor neuropathy
 - Acute
 - Chronic
- (b) Autonomic neuropathy
- (c) Diabetic mononeuropathy
- (d) Proximal motor neuropathy (Diabetic amyotrophy)

Table 86: Clinical manifestations of diabetic autonomic neuropathy*Cardiovascular*

- Painless myocardial infarction
- Orthostatic hypotension
- Tachycardia

Gastrointestinal

- Constipation
- Diarrhoea
- Oesophageal dysfunction
- Faecal incontinence

Gastroparesis

- Genitourinary
- Erectile dysfunction
- Neurogenic bladder
- Retrograde ejaculation
- Cystopathy

Metabolic

- Hypoglycaemia unawareness
- Hypoglycaemia unresponsiveness
- Argyll Robertson pupil
- Sweating disturbances
- Areas of asymmetrical anhidrosis
- Gustatory sweating
- Heat intolerance

- (a) Bacterial - Folliculitis, furuncle, carbuncle, styes, paronychia, cellulitis
- (b) Fungal - Vulvovaginitis, balanitis, intertrigo
- (c) Viral - Herpes zoster.
- Necrobiosis lipoidica diabetorum (NLD)* is one of the best cutaneous markers for DM. It presents with well-circumscribed erythematous papules, which develop into large irregularly delineated plaques, with a waxy, yellow centre. Also the epidermis becomes thin and transparent, allowing underlying vasculature to become visible.
 - Insulin resistant disorders.* (a) Acanthosis nigricans. A close association exists between AN, obesity, and insulin resistance. Presence of AN on neck and medial thigh is more commonly associated with obesity. Conversely in nonobese patients, lesions may occur in axillary region. (b) *Bullosis diabeticorum.* Bullae appear spontaneously, usually on feet and toes, and occasionally on hands and fingers. They often occur in patients with diabetic neuropathy.
 - Atherosclerosis.* It causes the skin of legs to become hairless, thin and shiny. Toenails thicken and discolour.
 - Eruptive xanthomatosis.* The condition is caused by long-term high blood glucose levels. It consists of firm, yellow, pea-like lesions. Each lesion has a red halo and may itch. Like blisters of DM, lesions usually disappear when blood glucose and cholesterol levels are in a healthy range.
 - Digital sclerosis* occurs more commonly in type 1 DM. Skin on the back of the hands becomes tight and thick. Sometimes skin on toes and forehead also becomes thick. Finger joints can also become stiff, so that patient is unable to approximate palmar surfaces of fingers and palms - 'Prayer sign' (Fig. 3).
 - Granuloma annulare.* Most common form is localized annulare. The generalized form is more prevalent and presents in the form of annular or arciform plaques, that begin as red or reddish-brown papules symmetrically spread across upper trunk, neck, arms, and occasionally legs.
 - Allergic skin reactions* can occur in response to drugs.
 - Dry skin.* Rough, dry and scaly skin affects most individuals over 60. It can be found on the legs, feet, hands and or face. In more serious cases the skin loses its suppleness, and can crack and become inflamed.

Charcot's neuroarthropathy is a rare and disabling condition affecting the joints and bones of the feet. Features

Fig. 3: Positive prayer sign

for development of this condition are together with autonomic dysfunction with increased flow of blood flow to the foot. A unilateral swollen hot foot with neuropathy must be considered to be Charcot's foot until proved otherwise.

Endothelial Dysfunction in Diabetes

Endothelial dysfunction is believed to be the earliest functional abnormality in blood vessels in diabetes. Several therapies have been shown to ameliorate this, namely exercise and weight loss, lipid lowering, anti-oxidants, PPAR-X and agonists reducing homocysteine levels, aspirin reducing hyperglycaemia and more recently nitric oxide co-factors such as tetrahydrobiopetrin and modulation of insulin resistance.

Microvascular Complications in Diabetes

Hypercoagulable state as indicated by decreased fibrinolysis and increased coagulability is responsible factor for their developments.

Gastroparesis in DM - Delayed gastric emptying in absence of gastric outflow obstruction. It can lead to worsening of glycaemic control and malnourishment.

Table 87 gives proposed mechanisms by which hyperinsulinaemia contributes to hypertension.

Carotid Intima-media Thickness in Type-2 DM

CIMT measurements is an effective, noninvasive technique which can assist in identifying patients with diabetes who are at higher risk of developing microvascular and macrovascular complications.

Somogyi phenomenon. (Post-hypoglycaemic hyperglycaemia) refers to rebound hyperglycaemia after an episode of hypoglycaemia as a result of counter regulatory hormone release. It manifests as morning fasting hyperglycaemia in response to undetected nocturnal hypoglycaemia. The subtle clinical signs of which are mild nocturnal sweating, morning headache and hypothermia. The significance of this phenomenon is that correction of morning hypoglycaemia depends on reducing and not increasing the evening dose of intermediate-acting insulin.

Dawn phenomenon. In this, there is fasting hyperglycaemia but no hypoglycaemia. This is likely to be due to nocturnal surge for GH release or increased clearance of insulin in the morning. It can be confirmed and differentiated from Somogyi phenomenon by observing hyperglycaemia at 3am and in morning fasting state. The aim is to demonstrate that correcting of fasting hyperglycaemia is by increasing and not decreasing the dose of insulin.

FIBROCALCULOUS PANCREATIC DIABETES

FCPD is a type of diabetes secondary to Tropical Chronic Pancreatitis (TCP). TCP is a juvenile form of non-alcoholic chronic calcific pancreatitis peculiar to tropical countries.

Etiology - Age - Majority between 10-40 years. Sex-Males predominate.

Clinical Features

1. *Abdominal pain* usually occurs several years before onset of diabetes and usually disappears by the time that diabetes is manifest. Pain usually severe, epigastric and with periods of remission and exacerbation. It radiates to back on either side and is relieved by stooping forward or lying in a prone position.
2. *Diabetes* is usually severe and most patients require insulin.
3. *Steatorrhoea* may occur.
4. *Others* - Extreme emaciation, peculiar cyanotic hue of lips, bilateral parotid enlargement and abdominal distension.

Table 87: Proposed mechanisms by which hyperinsulinaemia contributes to hypertension

Vasodilation
Increased sympathetic activity directly and from vasodilatation
Increased renal sodium/hydrogen exchange
Lower free acids stimulating aldosterone secretion
Vascular smooth muscle proliferation
Atherosclerosis increasing vascular rigidity

Investigations

1. *Plain X-ray of abdomen* - Presence of pancreatic calculi, mostly to right of first and second lumbar vertebrae, may occasionally overlap the spine.
2. *Ultrasonography* - Pancreas appears hyperechoic with irregular margins, the duct is irregularly dilated and shows stones in the lumen.
3. *CT scan* - Pancreatic mass is preserved in early stages, varying degree of atrophy in more advanced disease. In extreme cases little pancreatic parenchyma is visible, its place being taken by a 'bag of stones'. Pancreatic duct appears irregularly filled with stones in the lumen.
4. *Pancreatic function tests* - abnormal.

Treatment

(a) *Of diabetes* - Insulin is required in more than 80% of cases. Upto 20% respond to oral hypoglycaemic agents (usually sulphonylureas). (b) *Oral pancreatic enzymes* - for steatorrhoea (c) *Surgery* - if severe and intractable pain - Lateral pancreateo jejunostomy. Pancreatectomy might be needed.

8. HYPOGLYCAEMIA

A deviation below normal fasting range of blood sugar (2.5 mmol/liter). It may be asymptomatic, mild (recognised and corrected by the patient), severe, or may present as coma. See Table 88 for the Clinical classification of hypoglycaemia.

HYPOGLYCAEMIA WITHOUT HYPERINSULINAEMIA

1. Postprandial.
2. Alcohol ingestion.
3. Starvation, prolonged exercise, infection (e.g. *P. falciparum*).
4. Non-islet cell tumors (release IGF-II) - e.g. Hepatoma, adrenal carcinoma, mesothelioma, fibrosarcoma.
5. Iatrogenic - Oral hypoglycaemic drug, postpolygastrectomy (late dumping), salicylism (in children), propranolol (inhibits hepatic glycogenolysis).

Insulin-induced hypoglycaemia - After 10 years or more of diabetes, in some patients the adrenergic features become less marked, and neuroglycopenic symptoms are more prominent. Beta-blockers like propranolol can impair warning symptoms as also switch over from animal to human insulin.

Table 88: Clinical classification of hypoglycaemia

1. Postprandial (reactive) hypoglycaemia –	
<i>Endogenous hyperinsulinism</i>	
<ul style="list-style-type: none"> – Insulin antibodies – Noninsulinoma pancreatogenous hypoglycaemia 	
<i>Congenital deficiencies of enzymes of carbohydrate metabolism</i>	
<ul style="list-style-type: none"> – Hereditary fructose intolerance – Galactosaemia 	
<i>Others</i>	
<ul style="list-style-type: none"> – Alimentary hypoglycaemia – Idiopathic (functional) postprandial hypoglycaemia 	
2. Postabsorptive (Fasting) hypoglycaemia*	
<i>Drugs</i>	
<ul style="list-style-type: none"> – Insulin or insulin secretagogues – Sulfonylureas – Quinine – Pentamidine – Salicylates, sulfonamides (rarely) 	
<i>Critical illness</i>	
<ul style="list-style-type: none"> – Hepatic, kidney or cardiac failure – Sepsis – Malaria – Inanition 	
<i>Hormonal deficiencies</i>	
<ul style="list-style-type: none"> – Cortisol or growth hormone or both – Glucagon and epinephrine (in insulin dependent DM) 	
<i>Endogenous hyperinsulinism</i>	
<ul style="list-style-type: none"> – Insulinoma – Noninsulinoma – Autoimmune hypoglycaemia – Antibodies to insulin – Antibodies to insulin receptor 	
<i>Others</i>	
<ul style="list-style-type: none"> – Non-beta-cell tumors – Hypoglycaemia of infancy and childhood 	

*Precipitated by deprivation of food for few hours or longer. Fasting hypoglycaemia indicates an identifiable underlying disease, while reactive post-prandial hypoglycaemia occurs in absence of organic disease.

SYMPTOMS

Sympathoadrenal symptoms are caused by increased activity of the autonomic nervous system and may be triggered by a rapid fall in glucose concentration. *Neuroglucopaenic*

Table 89: Symptoms of hypoglycaemia

<i>Autonomic</i>	<i>Neuroglucopaenic</i>
<ul style="list-style-type: none"> • Sympathetic <ul style="list-style-type: none"> – Tremor – Sweating – Palpitation – Anxiety – Nausea – Warmness – Shivering • Parasympathetic <ul style="list-style-type: none"> – Pallor – Paraesthesia – Hunger – Sweating 	<ul style="list-style-type: none"> Dizziness Confusion Tiredness Difficulty in speaking Inability to concentrate Headache Amnesia Shivering Drowsiness Blurred vision Drowsiness Seizures Coma

symptoms are caused by cerebral glucose deficiency and require an absolutely low level of glucose (Table 89).

Large doses of glucose should be avoided in NIDDM to avoid possibility of a resultant hypoglycaemia stimulating a further insulin response.

Sequelae – Prognosis for recovery of cerebral function deteriorates with increasing duration of coma. Prolonged severe or recurrent hypoglycaemia usually leads to permanent cerebral damage or dementia.

DIAGNOSIS

A. Of Hypoglycaemia state

1. Suggestive history.
2. Dramatic response to IV glucose during attack.
3. Low plasma glucose level during attack (<94 mg/dL).
4. C-peptide concentrations >200 pml/L

B. Of the cause

Fasting attacks:

- (a) *Clinical* – Exclude hypopituitarism, Addison's disease, liver cirrhosis or failure, sarcoma (radiograph of chest and abdomen), alcohol ingestion after fasting, self-administration of insulin or sulphonylurea.
- (b) *Investigations for insulinomas* – (i) Overnight fasting plasma glucose and insulin measurements – will demonstrate spontaneous hypoglycaemia and raised plasma insulin (Normal range 3–13 mU/liter at normal fasting plasma glucose concentration). (ii) Plasma C-peptide measurements – Low plasma C-peptide with high plasma insulin. (iii) Plasma proinsulin measurements – High fasting plasma pro-insulin.

Localization - Insulinomas tend to be small. CT scan can detect 70-80 and MRI about 85%. Transabdominal ultrasound identifies many insulinomas and endoscopic ultrasound has sensitivity of about 90%. Selective pancreatic arterial calcium injections, with end point of sharp increase in hepatic venous insulin levels but is an invasive procedure. Intraoperative pancreatic ultrasonography invariably localizes insulinomas that are not palpable by the surgeon.

Tr. - Surgical resection is curative. Medical therapy for unresectable insulinomas includes administration of diazoxide or octreotide.

- (c) *Self-administration of insulin* - (i) Insulin antibodies. (ii) During spontaneous hypoglycaemia low plasma C-peptide with high plasma insulin.
- (d) *Sarcoma* - Spontaneous hypoglycaemia with low plasma insulin and no ketosis.

MANAGEMENT

1. *Acute attack* - Administration of rapidly absorbable carbohydrate. (a) In mild reaction - orange juice (100 mL) or corn syrup or candy taken orally sufficient. (b) *In unconscious or uncooperative patients* 50 mL of 50% glucose i.v. If vein not available Glucagon 1 mg s.c. or i.m. will cause sufficient increase in blood sugar to allow the patient to become rational and cooperative. The hyperglycaemic effect is however transient and supplementary carbohydrate must be given to prevent relapse. It is ineffective in hypoglycaemia induced by alcohol. When recovery is slow, e.g. after overdose of insulin or sulphonylurea therapy, constant infusion of 10-20% dextrose is given to maintain the blood sugar.
2. *Conservative treatment and prevention of acute attacks* (a) Diet - carbohydrate not more than 150 gms in slowly absorbable form like cereals, bread, fruits and vegetables. Liberal protein because glucose derived from it is liberated slowly; fat to make up calories. In hepatogenic type bed-time meal to prevent early morning hypoglycaemia. (b) Restriction of physical exercise.
3. *Surgical measures* - Removal of islet cell tumors, or partial resection of pancreas in: (a) fulminating cases where convulsions are not controlled by glucose. (b) Severe chronic cases not controlled by diet. (c) Patients with marked, neuropsychiatric symptoms.
4. *Drugs* - (a) Glucagon - The efficacy depends on size of hepatic glycogen stores. The drug has little effect on blood glucose in patients who have been fasting or are hypoglycaemic for long periods. Diazoxide and Octreotide may be used to control symptoms while the patient is awaiting surgery or when the patient is not a candidate for surgery.

9. MULTIPLE ENDOCRINE NEOPLASIA MEN

MEN is characterised by occurrence of tumors involving two or more endocrine glands in a single patient. The MEN syndromes are inherited as autosomal dominant disorders, first degree relatives have about 50% risk of developing the disease.

FORMS OF MEN

There are two major forms: MEN type I and type II. Each form is characterized by development of tumors within specific endocrine glands. Clinical manifestations are related to the sites of tumors and to their products of secretion (Table 90).

MTC-ONLY - In this variant, medullary thyroid carcinoma is the sole manifestation of the syndrome.

Genetic testing - Identifies the 50% of family members who do not have inherited the mutation and who do not have to undergo further screening, for family members who have inherited the mutation and are at a high risk of developing tumors, there are two clinical approaches -

- (a) Continued testing of calcitonin release following pentagastrin stimulation. This usually delays total thyroidectomy until 10-13 years of age.
- (b) Total thyroidectomy is advised on the sole basis of the abnormal genetic test, at the age of 5 years; the earliest age at which metastasis in MEN2 α has been reported and total thyroidectomy at an earlier age has been recommended.

10. CARCINOID SYNDROME

Carcinoid syndrome is a constellation of symptoms, most obviously flushing and diarrhoea, caused by the release of hormones and other substances from a carcinoid tumor, a type of neuroendocrine tumor (Table 91).

Diagnosis - (a) Estimation of 24-hour urinary excretion or 5-HIAA, the breakdown product of serotonin. Circulating chromogranin A levels are also raised. (b) Routine imaging (chest radiography/CT and hepatic ultrasonography or CT/MRI) reveals presence of hepatic secondaries and bronchial primaries (Fig. 4). (c) Isotope imaging using somatostatin may clarify the distribution of the disease particularly hepatic deposits (nodal disease). Radio-labelled MIBG is actively metabolized by some tumors and may also show their distribution.

Management - (a) Drug therapy - Injections of somatostatin reduce tumor size in a small proportion of patients.

Table 90: Multiple endocrine neoplasia syndromes		
Type	Tumors	Biochemical features
MEN1	Parathyroids	Hypercalcaemia and ↑ PTH
	Pancreatic islets Gastrinoma Insulinoma Glucagonoma VIPoma PPoma	↑ Gastrin and ↑ basal gastric acid output Hypoglycaemia and ↑ insulin Glucose intolerance and ↑ glucagon ↑ VIP and WDHA ↑ Pancreatic polypeptide
	Ant. Pituitary Prolactinoma GH-secreting ACTH-secreting	Hyperprolactinaemia ↑ GH Hypercortisolaemia and ↑ ACTH
	Associated tumours Adrenal cortical Carcinoid Lipoma	Hypercortisolaemia or primary hyperaldosteronism ↑ 5-HIAA Nil
MEN2a	Medullary thyroid carcinoma Pheochromocytoma Parathyroid	Hypercalcaemia ↑ Catecholamines Hypercalcaemia and ↑ PTH
MEN2b	Medullary thyroid carcinoma Pheochromocytoma Associated abnormalities Mucosal neuromas Marfanoid habitus Medullated corneal nerve fibres Megacolon	Hypercalcaemia ↑ Catecholamines

PTH: parathyroid hormone. VIP: Vasoactive intestinal peptide. WADHA: Watery diarrhoea, hypokalaemia and achlorhydria. 5-HIAA: 5-hydroxyindoleacetic acid.

Fig. 4: Right bronchial carcinoid (arrow)

Octreotide is given thrice daily s.c. or in long-acting depot preparations. (b) Non-surgical debulking – (i) Transarterial embolization (cutting off the arterial blood supply on which the secondary deposits depend) can be performed

Table 91: Clinical features of carcinoid syndrome
• Flushing
• Diarrhoea
• Hepatomegaly
• Abdominal pain
• Bowel obstruction

– Wheeze
– Sweating
– Palpitations

when the portal circulation remains intact. Prophylaxis with high octreotide and antibiotics is necessary. (ii) Radioisotope therapy (iodine-labelled or Yttrium-labelled) somatostatin can be targeted to extensive tumor deposits if initial investigations show that the tumor accumulates the isotope.

Table 92: Causes of precocious puberty*True precocious puberty**Gonadotropin-releasing hormone dependent*

- Idiopathic
- Secondary
 - Cerebral palsy/hydrocephalus
 - Tumor masses in hypothalamic region
 - Head trauma
 - Chronic inflammatory conditions
 - Radiotherapy
 - Sexual abuse
 - Adoption-related

Gonadotropin-releasing hormone independent

- McCune-Albright syndrome
- Testotoxicosis

Precocious breast development

- Premature thelarche
- Thelarche variant
- Hypothyroidism

Virilization (Pubic, axillary hair development)

- Adrenarche
- Congenital adrenal hyperplasia
- Cushing's disease
- Adrenal tumors

Others

- Gonadotropin-secreting or sexsteroid secreting tumors
- Exogenous steroids

Table 93: Endocrine causes of hypertension*Mineralocorticoid excess states*

- Low renin, high aldosterone
- Primary aldosteronism

Low renin, low aldosterone

- Congenital adrenal hyperplasia
- Liddle's syndrome
- Apparent mineralocorticoid excess
- Licorice or carbenoxolone ingestion

Mineralocorticoid/glucocorticoid excess states:

- Cushing's syndrome (particularly ectopic adrenocorticotropin syndrome)
- Steroid therapy (glucocorticoid/mineralocorticoid activity)

Pheochromocytoma*Miscellaneous*

- Acromegaly
- Primary hyperparathyroidism

11. MISCELLANEOUS**PANCREATIC TRANSPLANTATION**

Indications – (a) Patients who have Type-1 DM with kidney failure and who are therefore candidates for kidney transplantation. (b) Failure of standard therapy and episodes of hypoglycaemia unawareness.

Relative contraindications – Age >55 and significant atherosclerotic cardiovascular disease. Cell and islet can be cryopreserved to optimize timing of transplantation.

Pancreatic islet cell transplantation is less invasive and islets can be cryopreserved to optimize timing of transplantation.

Neurology

1. INVESTIGATIONS IN NEUROLOGY

NEURORADIOLOGY

Skull X-ray

CT scanners and MRI produce bone images much superior to plain radiographs. Still plain X-rays can be used for conditions listed in Table 1.

Spine X-ray

- Antero-posterior view* – Pedicle erosion with or without paraspinal mass suggests malignant extradural tumour. Osteosclerotic myeloma and POEMS syndrome (Polyneuropathy, Organomegaly, Endocrinopathy, M protein, Skin Changes) associated with demyelinating neuropathy similar to CIDP (Chronic Inflammatory Demyelinating Polyradiculopathy).
- Lateral view* – (i) Collapse of vertebral body suggests malignant infiltration. (ii) ‘Scalloping’ of posterior surface of vertebral body indicates longstanding intradural lesion. (iii) Narrow disc space, narrow canal and hypertrophic facet joints disc disease or lumbar spinal canal stenosis. If disc space is destroyed infection is more likely.
- Oblique views* – (i) Expansion of intervertebral foramina suggests neurofibroma. (ii) Narrowing from osteophytic encroachment indicates possible root compression.

Table 1: Utility of plain X-ray of skull

- Fractures* – in head injury patients.
- Bone erosion* – (a) Focal, e.g. pituitary fossa. (b) Generalized, e.g. Multiple myeloma.
- Bone hyperostosis* – (a) Focal, e.g. Meningioma. (b) Generalized, e.g. Paget’s disease.
- Abnormal calcification* – (a) Tumors, e.g. meningioma, craniopharyngioma. (b) Aneurysm wall.
- Midline shift* – if pineal calcified.
- Signs of increased intracranial pressure* – Erosion of posterior clinoids.
- Configuration* – Platybasia, basilar impression.

CT Scanning

Brain – Abnormalities are inferred from alterations in tissue density and displacement of normal structures (Fig. 1).

CT with contrast media – Contrast media are used to highlight regions with breakdown of blood barrier which leads to enhancement (demyelination, encephalitis, granuloma, abscess, tumour, metastasis). The extent of enhancement also reflects relative cerebral vascularity, which is increased in some lesions (e.g. A-V malformations) and reduced in areas of acute infarction. Intrathecal contrast medium is used for CT myelography or cisternography. CT is more sensitive than MRI to intracranial calcification and better at showing fractures, bone erosion and acute intracranial hemorrhage. Acute hematomas are denser than brain and hence appear white.

Ultra-fast scanning – Sequences which allow images to be produced in less than 1 second can be used to perform dynamic scanning which can be used to monitor bolus injections of gadolinium so that cerebral blood volumes and regional blood-flow maps can be produced. This may be useful when investigating acute stroke.

Fig. 1: CT scan coronal view showing extradural haematoma

Spine – CT scan is appropriate where the lesion can be localised to a particular area, e.g. lumbar disc disease.

Advantages

- CT is safer after recent trauma and in very ill patients
- More sensitive to intracranial calcification than MRI and better at showing fractures, bone erosion and acute intracranial hemorrhage (particularly subarachnoid hemorrhage)
- Acute hematomas are denser and hence appear white.

MRI

MRI is now the modality of choice for investigating most neurological diseases. Different tissues contain different amounts of hydrogen in various molecular environments; the appearance of the image depends principally on the concentration and molecular environment of the perturbed hydrogen protons and the applied radio frequency pulse.

The appearance can be changed by manipulating the radiofrequency pulse, using electronic protocols (sequences). The parameters measured are termed 'T₁' and 'T₂' relaxation times.

Images relying principally on contrast produced by T₁ relaxation are termed 'T₁-weighted' (T₁W) and show CSF darker than brain. They show gross anatomical detail of the brain and spinal cord. T₁W imaging is more sensitive to subacute hemorrhage and fat-containing structures.

Water (and therefore CSF) appear white on T₂-weighted (T₂W) images which are very sensitive to increase in cerebral water (as in most inflammatory and neoplastic diseases of CNS). T₂W images are more sensitive than T₁W images to edema, demyelination, infarction and chronic haemorrhage.

Hydrogen protons in bone or in areas of calcification return little signal and therefore appear dark on both T₁W and T₂W sequences.

After hemorrhage, haemoglobin liberated from RBCs degrades to methaemoglobin and then hemosiderin.

Methaemoglobin in subacute hematoma returns high signal on T₁W sequences. Hemosiderin in chronic hematoma returns low signal on both T₁W and T₂W sequences and therefore appears similar to bone.

Fluid attenuated inversion recovery (Flair) is a useful pulse sequence that produces T₂W images in which the normally high signal intensity of CSF is suppressed. Flair images are more sensitive than standard spin echo images for any water-containing lesions or edema.

Differential Diagnosis on MRI

Differential diagnosis on MRI is given in Table 2.

Table 2: Differential diagnosis on MRI

• Multifocal white matter (high-signal) lesions on T ₁ weighted sequences:
– Posterior reversible encephalopathy syndrome (PRES) – Accelerated hypertension, pregnancy (toxaemia), acute GN, cyclosporine HUS, TTP
– Multiple sclerosis
– Infection – progressive multifocal leucoencephalopathy, Lyme disease, opportunistic infections
– Inflammatory – acute disseminated encephalomyelitis, sarcoidosis
– Cerebrovascular disease – migraine, toxaemia of pregnancy, subacute atherosclerotic encephalomyelitis
– Vasculitis – granulomatous, systemic necrotizing, rheumatoid
– Neoplasm – metastasis
– Toxic – pontine myelinolysis, post-radiation change
• Materials returning high-signal on T ₁ weighted sequences:
– Fat (including fat-containing tumour products)
– Subacute hematoma (methaemoglobin) (Fig. 2)
– Melanoma (melanin is paramagnetic)
– Flowing blood (on some sequences)
– Paramagnetic contrast agents (e.g. gadolinium)
– White matter
– Manganese in acquired liver disease and total parenteral nutrition
– Metastasis from melanoma
– Wilson disease (in globus pallidus), copper overload (Fig. 3)
– Lesions in areas containing fat (e.g. the orbit for optic neuritis)
– Functional MRI - Blood oxygen level dependent (BOLD)

Fat suppression sequences – Fat appears bright on standard T₁W and T₂W sequences. Sequences that suppress the fat signal are used to investigate suspected fat-containing tumors and lesions in areas containing fat (e.g. the orbit).

Other Magnetic Resonance Techniques

- Magnetic resonance spectroscopy – can be used to measure cerebral metabolites. It has been used in some clinical situations (e.g. to distinguish radionecrosis from recurrent neoplasms) and to assay cerebral levels of drugs.

Clinical MRI - The patient is given specific tasks to perform (motor, language, visual, etc.) while MRI sequences are being performed. These EPI sequences are able to detect increased O₂ delivery and blood flow to areas of the brain that are responsible for these, which are shown in colour on the MRI images.

Fig. 2: MRI T2 flair image axial view showing subdural haematoma

Fig. 3: MRI in Wilson's disease-panda sign

Fig. 4: CT angio MIP image - (maximum in ten sity projection) in MCA infarct showing occlusion beyond M2

Fig. 5: MRI axial view postcontrast flair images in meningitis

High resolution MRI - Use of high resolution sequences allows appreciation of cyst and scolex appearance in neurocysticercosis.

MR angiography (MRA) - Because moving hydrogen atoms in flowing blood return different signals from those in static tissue, sequences are designed to demonstrate vessels (Fig. 4). Two sequences are in clinical use - 'time of-flight' and phase-contrast. Both rely on post-processing of images by the scan computer to produce the angiogram. They can selectively demonstrate arteries or veins, based on the velocities and direction of blood flow, and can be used to demonstrate patency of blood vessels. No injection contrast is needed, but MRA can be performed after injection of gadolinium to show vascular distortions caused by intracranial mass lesions or AV malformation.

Contrast enhancement - Following i.v. injection of a paramagnetic agent (e.g. gadolinium), areas of blood-brain barrier breakdown are enhanced. Contrast agents are used for detection, preoperative assessment and follow-up imaging of intracranial tumours, inflammatory disease (especially meningeal) (Fig. 5) and in patients presenting with cranial nerve palsies.

MRI sequences - CSF signal suppressing sequences - Lesions in the paraventricular brain (e.g. multiple sclerosis) may be difficult to detect because of high signal returned by the adjacent CSF. Special sequences can be used (e.g. Flair), which produces a scan with dark CSF that increases the conspicuousness of periventricular plaques.

MRV - In suspected CVT. Contrast MRV to differentiate between slow flow and occlusion.

ANGIOGRAPHY

Cerebral angiography is usually performed by selective catheterization of the carotid or vertebral arteries.

Passage of the contrast bolus through the cranium from artery to vein is recorded by a series of radiographic exposures timed to show maximum opacification of each component of the vascular tree. Subtraction of each digitized image from a baseline image (obtained before the arrival of intravascular contrast) is performed electronically. This process removes details of the baseline image (bone) from subsequent images, so they show only the opacified vessels.

Digital Subtraction Angiography

Because digitized systems are sensitive to lower concentrations of contrast medium, images can be obtained following both intravenous (IV-DSA) and intra-arterial (IA-DSA) injection. IV-DSA has the advantage of a lower risk of complications of causing stroke. MRI can provide images of a quality similar to those obtained by IV-DSA without exposing patients to the risk of ionizing radiation and radiographic contrast agents. Thus IA-DSA is reserved for specific situations in which very high-resolution imaging is required (e.g. suspected intracranial aneurysm).

Although the role of cerebral angiography is declining, its use in therapy is increasing as endovascular therapies for treatment of brain AV malformations and aneurysms become more widely available.

Uses

1. To demonstrate source of subarachnoid or other intracranial hemorrhage. Multiple views are necessary to demonstrate configuration of an aneurysm prior to surgical intervention, and detailed angiography is performed to demonstrate vessels feeding and draining an angiomatous malformation.
2. To demonstrate displacements and vascularity due to an intracranial tumour.
3. To demonstrate vessel occlusion, stenosis or plaque formation.
4. To identify A-V malformation.

RADIONUCLIDE SCANNING

Metabolism and blood flow can be evaluated using the techniques of positron emission tomography (PET) and single-photon emission computed tomography (SPECT).

Both techniques measure cerebral blood flow, but PET provides unique information about cerebral metabolism of oxygen and glucose using oxygen-15 and fluorine-18 respectively. Interictal PET localize the lesion in focal epilepsy.

^{99m}Tc HMPOA is used in SPECT. This is lipophilic and crosses the intact blood-brain barrier to bind to unspecified receptors. Its distribution reflects cerebral blood flow and remains stable for about 1 hour, during which scanning is performed.

Uses - Investigation of patients with seizure disorders, dementia, neoplasms and ischemic disease. Both are used to complement and validate MRI data. Ictal SPECT to localize seizure onset zone in focal epilepsy.

ULTRASONOGRAPHY

Ultrasonography is useful in CNS only when performed through a bone defect (e.g. an open fontanelle or after laminectomy). Duplex ultrasound combines high resolution real-time imaging with Doppler flow analysis and is used to evaluate the cervical carotid arteries. **Uses** - To evaluate hydrocephalus and neonatal hemorrhage in young children. Duplex scanning has replaced angiography for screening patients with suspected carotid bifurcation stenosis.

CLINICAL NEUROPHYSIOLOGY

The ability to generate and propagate electrical potentials is a fundamental property of nerve and muscle cells. For the recording of such activity and the information it can provide about brain and neuromuscular disorders, three techniques are used -

Electroencephalography

EEG is the study of the electrical activity of the brain as detected by 8-16 pairs of electrodes attached to the scalp in standard positions. The wave forms are classified according to their frequency - delta <4 Hz (Stage III and IV sleep). Theta 4 to 8 Hz (drowsiness), Alpha 8 to <13 Hz (relaxed wakefulness in posterior region), Beta >13 Hz (frontocentral region).

- (a) **The probability of detecting epileptiform activity increases with repeated EEG records in 90% of patients with epilepsy. An epileptiform activity will be detected after four 20 minutes routine EEG records.**
- (b) **Detection of ictal discharges during a clinical attack** - Ictal discharges usually comprise of focal or lateralized rhythmic delta-theta or alpha-beta activity in

focal seizures (Temporal, occipital, parietal or frontal). Generalized spike and wave activity and fast activity is seen in generalized seizures, (absence, myoclonic, tonic-clonic seizures). In photosensitive epilepsies like juvenile myoclonic epilepsy (JME), photic stimulation evokes epileptiform discharges (photoparoxysmal response).

- (c) **Presurgical evaluation** – Special intracranial electrodes are placed over the cortex (subdural grid, or in the brain parenchyma (depth electrodes) close to the suspected epileptic focus. Ictal discharges are then studied during prolonged video EEG monitoring to localize the seizure onset zone as part of presurgical evaluation of epilepsy. The epileptogenic zone is then resected as a surgical treatment for refractory epilepsy. In herpes encephalitis periodic lateralized epileptiform discharges (PLEDs) are seen.

Periodic patterns on EEG – (a) Periodic Sharp Wave Complexes (PSWC) of frequency 0.5 to 2 Hz in Prion diseases, e.g. Creutzfeldt-Jakob disease. (b) Triphasic waves in hepatic encephalopathy but may be seen in other metabolic encephalopathies like uraemia. (c) Periodic complexes of subacute sclerosing encephalitis consist of sharp and slow waves accompanied by myoclonus occurring at interval of 5–15 secs. (d) Generalized periodic pattern is seen in coma due to severe brain injury caused by hypoxia, cardio-respiratory arrest and suggests a poor prognosis.

Uses

Epilepsy

- (a) *Detection of epileptiform activity between seizures* (interictal epileptiform discharges, IEDs) supports a clinical diagnosis of epilepsy. IEDs include localized (non-physiological) or generalized spike or sharp waves, with or without slow waves, occurring singly or in bursts and not accompanied by any clinical changes.
- (b) *Detection of ictal discharges during a clinical attack* – confirms that the attack is of epileptic origin. Ictal discharges usually comprise bursts of sharp or spike and slow waves, or rhythmic activity at various frequencies. In absence epilepsy, overbreathing commonly evokes absence attacks accompanied by typical generalized 3 Hz spike and slow wave discharges. In photosensitivity, photic stimulation evokes epileptiform discharges.
- (c) *Classification of epilepsy* – Focal IEDs or generalized IEDs starting focally are consistent with partial epilepsy; generalized symmetrical IEDs are associated with generalized epilepsies.

- (d) *Underlying cause* – Focal delta activity suggests a localized structural lesion while diffuse encephalopathies (toxic, metabolic, degenerative) produce generalized slow waves.

- (e) *Assessment of treatment in epilepsy* – In status epilepticus and childhood absence epilepsy, improvement in clinical attacks correlates closely with a reduction in discharges. Persistence of generalized IEDs increases the risk of seizure recurrence in children.

- (f) *Presurgical evaluation* – Special intracranial electrodes are placed close to the temporal lobes extra- or intracerebrally and ictal discharges studied during prolonged monitoring to localize the epileptogenic zone before surgical resection.

Encephalitis and other encephalopathies

- In encephalitis EEG shows a diffuse, slow wave abnormality which, if associated with periodic sharp wave discharges in the temporal region, is strongly suggestive of herpes simplex encephalitis.
- Short-interval (0.5-4 seconds) periodic discharges or triphasic waves in Creutzfeldt-Jakob disease and metabolic encephalopathies.
- Long interval (> 4 seconds) periodic discharges in subacute sclerosing panencephalitis.

Evoked Potentials

The electrical responses of CNS structures to sensory input are usually indiscernible against the background of an ongoing EEG, or over the spinal cord. However, electronic averaging of the small responses to discrete repeated stimuli enables identification of these so-called evoked potentials. The modalities are:

- (a) *Visual evoked potentials (VEPs)* – are averaged potentials evoked by visual stimuli and detected by scalp electrodes placed over the occiput. In multiple sclerosis, VEPs demonstrate abnormality when MRI is normal, because the optic nerves are involved early; however a similar response pattern may occur in patients with ischemic or compressive lesions. (i) In multiple sclerosis there is delayed p100 response. (ii) In spondylosis myelopathy there is delayed central conduction at the level of cervical spinal cord. (iii) Denervating disorders – Spontaneous potentials like positive sharp waves and fibrillations are due to active denervation. The MUAPs in denervating disorders like anterior horn cell diseases are large (amplitude), wide (long duration) and due to expansion of motor unit (reinnervation). (iv) Primary myopathy – The MUAPs are small in amplitude and polyphasic due to breakdown of muscular fibre and small size of motor

unit. This is typically seen in muscular dystrophies (LGMD, DMD, BMD).

- (b) Brainstem auditory evoked potentials (BSAEPs) – (a) To determine deafness in neonates and very young children. (b) Suspected acoustic neuroma. (c) Comatose patient. (d) Multiple sclerosis.
- (c) Somatosensory evoked potentials (SEPs) – (a) Distinguish between peripheral, spinal cord and central lesions. (b) For identifying brachial plexus lesions (since peripheral nerve conduction measurements are inappropriate).

Electromyography and Nerve Conduction Studies

Electromyography (EMG)

Electromyography is performed using a needle electrode which records the electrical potential generated by about ten muscle fibres in the vicinity of the needle tip. In normal muscle, no electrical activity occurs with the muscle at rest. During slight voluntary contraction, a few motor axons discharge at rates of about 10–20/second, each axon activating the muscle fibres it innervates. The summated electrical response from the muscle fibres is referred to as the motor unit action potential (MUAP).

Denervating disorders – In conditions causing degeneration of motor neurons (e.g. axonal peripheral neuropathy, motor neuron disease), muscle fibres losing their nerve supply depolarize spontaneously. The resulting small potentials recorded from muscles at rest are termed ‘fibrillations’ and ‘positive sharp waves’. Fibrillation potentials become less prominent during re-innervation. In motor neuron disease, neuromyotonia and radiation nerve damage, spontaneous discharges of motor units produce fasciculation potentials in resting muscles. These are similar to MUAPs in appearance.

Primary myopathy – Shrinkage of muscle fibres in muscle disease if uniform, MUAPs have normal outlines but are smaller in number, if non-uniform, MUAPs become small but more complex. The number of motor neurons is usually normal, so a maximum contraction, though weak, produces a full interference pattern. The picture is seen in most metabolic myopathies and in some muscular dystrophies. In Duchenne and Becker muscular dystrophies and acquired inflammatory myopathy, muscle fibres necrosis probably causes disconnection of part of muscle fibres from their nerve supply. This functional denervation produces fibrillation potentials, and collateral reinnervation with compensatory muscle hypertrophy gives rise to long-duration, unstable polyphasic MUAPs, which may have

high altitude components. In myotonic dystrophies, needle insertion provokes bursts of muscle action potentials of diminishing frequency and amplitude, giving rise to a characteristic dive bomber sound when modified through a loudspeaker.

Radiculopathy – In severe cases the finding of retained sensory action potentials in an anaesthetic area indicates a lesion proximal to the dorsal root ganglia.

Quantitative EMG – Using a computer, the interference pattern can be decomposed into constituent MUAPs, allowing parameters such as duration, amplitude and polyphasicity to be quantified.

Nerve Conduction Studies

Measures conduction in response to electrical stimulus.

Distal latency, i.e. latency from stimulus to recording electrodes, amplitude of the response and conduction velocity provide information of motor and sensory nerve function, i.e. measurement of conduction distance allows calculation of the maximal motor or sensory conduction velocities. These are normally in the range of 50–60 m/second in the arm and 40–50 m/second in the leg. The most easily studied nerves are the median, ulnar and radial nerves in the arm, and common peroneal, tibial and sural nerves in the leg.

- (a) *Peripheral neuropathy* – Electrophysiology (EMS and NCS) differentiates between demyelinating and axonal neuropathies and narrows the differential diagnosis of peripheral neuropathies.
- (b) *Radiculopathy* – A normal sensory nerve action potential (SNAP) in presence of impaired sensation indicates a lesion proximal to dorsal root ganglia like in radiculopathy.
- (c) *Demyelinating neuropathies* – Delayed distal latencies, prolonged conduction velocity, conduction block, delayed F wave (a late response recorded from muscle as a result of propagation of nerve impulse to motor neuron cell and back again) in case of proximal demyelination (GBS).
- (d) *Axonal neuropathies* – There is reduction in number of nerve fibres in a nerve. There is reduction in amplitude or absent CMAPs (compound muscle action potential) and SNAPs. The conduction velocity, latency is normal. Denervating potentials are seen on needle EMG.
- (e) *Entrapment neuropathy* – Disorders such as carpal tunnel syndrome, neuropathy at the elbow and peroneal palsy at the knee cause selective demyelination with focal slowing of conduction velocity or block, which is used to localize the lesion. The degree of conduction abnormality may indicate the severity and longevity of the nerve lesion.

Table 3: Indications for nerve conduction studies and electromyography

Clinical presentation	Differential diagnosis	Neurophysiological findings
Localized weakness and sensory symptoms	Peripheral nerve lesion	Nerve conduction and EMG changes limited to distribution of one nerve.
	Radiculopathy	Sensory nerve potential retained in area of numbness. EMG changes, confined to one myotome
Generalized weakness and sensory symptoms	Peripheral neuropathy	Slow motor and sensory conduction velocities in demyelinating neuropathy. Reduced response amplitudes and EMG signs of denervation in axonal neuropathy Combination of the above common
	Polyradiculopathy and sp. cord lesions	Normal motor and sensory conduction
Weakness without sensory symptoms	Motor neuron disease	Retained sensory nerve conduction, widespread fasciculation potentials and EMG signs of denervation/re-innervation
	Motor neuropathies	Slowing of motor conduction velocity; may have conduction block, retained sensory responses
	Neuromuscular transmission disorders	Myasthenia gravis – may exhibit muscle action potential decrement on repetitive nerve stimulation, abnormal 'jitter' or single-fibre EMG Lambert-Eaton myasthenic syn. – low resting compound muscle action potential amplitude, increasing after maximal voluntary activation or tetanic nerve stimulation
	Primary myopathy	Usually normal nerve conduction; EMG may show fibrillation potentials caused by muscle fibre necrosis, myotonia, low-amplitude polyphasic motor action potentials, full 'interference pattern' of electrical activity despite weak contraction

(f) *Myasthenic disorders* – In *myasthenia gravis* there is decremental response on RNS (repetitive nerve stimulation) on slow frequency. In Lambert Eaton syndrome there is incremental response on high frequency RNS. Indications for nerve conduction studies and electromyography.

See Table 3 for the Indications for nerve conduction studies and electromyography and findings in the studies.

Immunochemistry studies for muscular dystrophies like Duchenne, Becker, limb girdle muscular dystrophies (e.g. sarcoglycanopathies). Congenital muscular dystrophies, congenital myopathies (central core, nemaline).

MUSCLE BIOPSY

Diagnostic value of muscle and nerve biopsy is given in Tables 4 and 5.

LUMBAR PUNCTURE AND CSF EXAMINATION

Lumbar puncture (LP) allows access to CSF. The volume of CSF is about 150 mL produced at a rate of 300–500 ml/day.

Table 4: Diagnostic value of muscle biopsy

1. Polymyositis/dermatomyositis.
2. Myotonic dystrophy.
3. Metabolic muscle disease, e.g. glycogen storage disease.
4. Trichinosis, toxoplasmosis.
5. Polyarteritis.

Table 5: Diagnostic value of nerve biopsy

1. Differentiating between axonal and demyelinating neuropathies (of prognostic significance).
2. Demonstrating infiltration of peripheral nerves, e.g. amyloidosis, sarcoidosis, leprosy, carcinoma, vasculitis.
3. Diagnosis of congenital hypertrophic neuropathies.
4. Giant axonal neuropathy.

Functions of CSF:

- Provide a protective cushioning effect for the brain and sp. cord
- Preserves a stable chemical environment
- Removes waste products of cerebral metabolism

Indications for LP

1. *Diagnostic:*

- (a) *Infection* – Bacterial meningitis. Changes in CSF in non-bacterial meningitis and encephalitis are often nonspecific and more detailed testing may be required.
- (b) *Subarachnoid hemorrhage* – LP should be performed only in those cases of SAH that are negative on CT scan, and ideally should be delayed for 6 hrs after onset of hemorrhage to allow blood to reach lumbar region. Xanthochromia, a yellow discoloration caused by pigments released from degenerated RBCs, is found after 24 hours and may last up to 7 days.
- (c) *Inflammatory disorders* – Inflammatory neuropathies (including Guillain-Barre syndrome), SLE, sarcoidosis and Behcet's syndrome with neurological involvement may all result in nonspecific CSF abnormalities.
- (d) *Demyelination* – Analysis of paired CSF and serum for oligoclonal IgG forms part of laboratory supportive criteria for multiple sclerosis, but local synthesis of IgG also occurs in inflammatory and infectious disorders.
- (e) *Malignant disease and other disorders* – Neurological symptoms arising from carcinomatosis, lymphoma, leukaemia, paraneoplastic disorders, hepatic encephalopathy and septic cerebral emboli may be an indication for CSF analysis.

2. *Therapeutic:*

- *Drug instillation* – Cytotoxic drugs for lymphoma or leukaemia treatment may require intrathecal administration. Also antibiotics and antifungal agents, pump systems are used to deliver intrathecal baclofen for resistant spinal spasticity, and also to administer analgesia for post-operative pain relief.
- *Reducing volume* – Benign intracranial hypertension may require repeated removal of large volumes of CSF to reduce CSF pressure rapidly.

Contraindications

1. *Raised CSF pressure* – Symptoms suggestive of raised pressure, focal neurological signs and a fluctuating conscious level all require a CT scan before LP because of risk of herniation of brain substance through foramen magnum.
2. *Spinal block* – LP may precipitate a sudden deterioration if there is a spinal block.

3. *Coagulopathies* – because of increased risk of epidural hemorrhage. Value of information gained from the procedure must be weighed against the risk, and replacement therapy must be available.
4. *Local suppuration* – Infection can be introduced into CSF and subsequently meningitis, if there is skin infection at lumbar puncture site.

Technique

1. *Position* – The patient is placed on his side at the edge of the bed with the knees drawn up and the head bent forward to get maximum flexion of the spine. 2. *Site* – The skin and fascia over the lumbar space selected are sterilised (usually between the spines of the 3rd and 4th lumbar vertebrae), this space being a plane passing through the highest points of both iliac crests) and infiltrated with a small amount of 1% lignocaine. 3. *Puncture* – The lumbar puncture needle is inserted through the anaesthetised skin in the mid-line and passed forwards and slightly upward till it reaches the tough spinous ligament. This is pierced. A sudden “give” or cessation of resistance indicates that the needle has passed through the dura and entered the intrathecal space. The stylet is then removed and the fluid should flow out at once. It should be withdrawn slowly, if the tension is high.

Difficulties that may be encountered

- *CSF does not flow* – The position of the needle should be adjusted slightly or the stylet re-inserted to dislodge anything that may have blocked the lumen.
- *Blood stained fluid* – may be due to subarachnoid hemorrhage or puncture of a vessel. To differentiate 2-3 mL CSF should be collected in 3 bottles. In SAH, fluid will be uniformly stained, in traumatic tap CSF clears in the third bottle.
- *Dry-tap* – usually results from poor technique, but may be caused by anatomical anomalies, previous surgery, or infections causing arachnoiditis.

Complications of Lumbar Puncture

1. *Headache* – is probably caused by subsequent leakage of CSF through the dural hole. Risk of headache may be reduced if patient sits up for a few hours after the procedure. Dural leakage can be minimized using a fine spinal needle, with its bevel in the spinal axis.
2. *Herniation of the brain or spinal cord* – can be avoided by excluding intracranial lesions before and undertaking LP. If consciousness deteriorates or respiration fails, immediate surgical decompression is required. Meanwhile the raised intracranial pressure should be reduced by 20% mannitol, 1 g/kg body weight by rapid iv infusion.

3. Other complications

- Meningitis or epidural abscess, caused by poor asepsis
- Intracranial bleeding, spinal or intracerebral subdural hematomas
- Damage or infection of the intervertebral disc
- Intraspinal dermoid cyst

Components of Normal CSF

Components of normal CSF are given in Table 6.

Physical Characters

1. Pressure - Normal in horizontal position 50-180 mm. of water; in sitting position 200-250 mm. Increased tension - intracranial tumour or haemorrhage or intracranial sinus thrombosis, meningitis, meningism, hydrocephalus, benign intracranial hypertension, uraemia and fulminant hepatic failure and sometimes encephalitis. Decreased tension - subdural hematoma, spinal subarachnoid block or block in region of foramen magnum, repeated lumbar punctures. CSF leak causing intracranial hypotension.
2. Appearance -
 - (a) *Normal* - Clear and colourless.

Table 6: Components of normal CSF

• pH	7.3
• Osmolality	295 mOsmol/L
• Total protein	0.1–0.45 g/L
- Pre-albumin	2–8%
- Albumin	45–75%
- γ -globulin	1–10%
• Glucose	2.22–3.89 mmol/L
• Cells	$1-4 \times 10^5/l$
• Sodium	135–148 mmol/L
• Potassium	2.5–3.3 mmol/L
• Chloride	116–128 mmol/L
• Bicarbonate	23–30 mmol/L
• Lactate	1.1–1.9 mmol/L

- (b) *Turbid* - in meningitis. Fibrin clot “cobweb” usually in tuberculous meningitis. A pellicle may also develop in other forms of meningitis, poliomyelitis, intraspinal tumour, general paresis and epidemic encephalitis.
- (c) *Blood-stained* - Intracerebral haemorrhage, subarachnoid haemorrhage, leakage of blood from cerebral tumour, haemorrhagic form of encephalitis, trauma of spinal cord, trauma of needle, haemorrhagic diathesis (including anti-coagulants, bleeding from angioma or from A-V malformation).
- (d) *Xanthochromia* (yellow tinting) - (i) Recent subarachnoid bleeding. (ii) Spinal block. (iii) Guillain-Barre syndrome. (iv) Acoustic neuroma. (v) Subdural haematoma. (vi) Purulent meningitis. (vii) Rifampicin.

Differentiating features between traumatic tap and subarachnoid haemorrhage are given in Table 7.

CSF in Meningitis

CSF findings in different causes of meningitis are given in Table 8.

Chemical Composition

1. Protein - Normal <0.45 g/litre. *Increased* - in purulent meningitis, encephalitis, poliomyelitis, multiple sclerosis and neurosyphilis, spinal cord compression;

Table 7: Differentiating features between traumatic tap and subarachnoid haemorrhage

	<i>Traumatic tap</i>	<i>Subarachnoid haemorrhage</i>
Xanthochromia	Absent	Present after centrifugation
Clotting	May occur	Absent
Blood staining	Varies from tube to tube	Usually uniform in all tubes
Pressure	Usually normal	Elevated
Repeat puncture at higher interspace	Often clear	Similar to initial tap

Table 8: CSF findings in different causes of meningitis

Type	Appearance	Cells (μ l)	Protein (g/L)	Blood glucose (mmol/L)
Bacterial	Purulent	>1000 (>60% neutro)	>0.8	>50% level, may be absent
Tuberculous	Viscous, may clot on standing	5–400 (>80% lympho)	0.8–4	>50% level, may be absent
Viral	Clear or cloudy	10–1000 (>80% lympho)	<0.6	>50% level, may be low in measles
Fungal	Clear or cloudy	<400, mixed inflammatory cells	<1.2	<50% level
Malignant	Clear or cloudy	<200 mixed inflammatory and malignant cells	<1.5	<50% level

intracranial tumour and cerebral arteriosclerosis. Also amyloidosis, alcoholism, diabetes, acoustic neuroma, cerebral toxoplasmosis.

Increase of cells and protein without alteration of sugar and chloride values – Virus encephalitis, brain abscess, subarachnoid haemorrhage, tumour, lead poisoning, aseptic meningeal reaction as in sinus thrombosis, lymphocytic choriomeningitis.

Protein-albumin cytological dissociation in GBS (elevated protein with normal cells).

Immunoglobulin (IgG) – Normal 0.5–4.5 mg/litre. Rises in demyelination and with neurosyphilis, primary lateral sclerosis, viral encephalitis, fungal meningitis, myelopathy due to vitamin B₁₂ deficiency and subacute sclerosing encephalitis.

2. Chlorides – Diminished in purulent meningitis, and meningism, marked reduction in tuberculous meningitis. Also systemic disorders accompanied by hypochloraemia.
3. Glucose – *Reduced* – or absent in pyogenic meningitis, moderately decreased in tuberculous meningitis, in some viral meningitis like mumps, LCMV, measles. *Raised* – slightly in encephalitis, diabetes mellitus, carcinomatosis of meninges. *Normal* – in aseptic meningeal reaction, syphilitic meningitis.
4. Acetone – normally absent, its presence is of grave significance.

Cytological

Cell count – Normal 0–5 cells, lymphocytes. Between 10 and 100 per c.mm. – neurosyphilis, encephalitis, poliomyelitis, epilepsy, uraemia. 100 to 500 – tuberculous or syphilitic or aseptic meningitis, lymphocytic choriomeningitis and poliomyelitis. Over 500 – purulent meningitis.

Lymphocytosis – (a) Meningitis – Tuberculous, viral, spirochaetal, protozoal, rickettsial, carcinomatous, brucellar, chemical (e.g. after myelography), partially treated bacterial. (b) Parameningeal infections. (c) Poliomyelitis, herpes zoster. (d) Encephalitis. (e) Cerebral abscess. (f) Cerebral tumour. (g) Sinus thrombosis. (h) Following cerebrovascular accidents and subarachnoid haemorrhage. (i) Multiple sclerosis. (j) Post-traumatic. (k) Lead poisoning.

Polymorphonuclear leucocytosis – Pyogenic or fungal meningitis, acute syphilitic meningitis, early stage of poliomyelitis.

Mixed – Cerebral abscess, early stage of poliomyelitis, syphilitic meningitis, infection of bones of skull in neighbourhood of meninges and many cases of tuberculous meningitis.

Eosinophils – Pathognomonic of cerebral or spinal cysticercosis, primary amoebic meningoencephalitis, gnathostomiasis.

Plasma cells – in neurosyphilis, also peculiar large iron-containing cells (Hortega cells).

Malignant cells – in malignant growth of brain or spinal cord leukemic meningeal metastasis, primary CNS lymphoma, angiocentric lymphoma.

Bacteria and Parasites

1. Pyogenic organisms on smear and culture in purulent meningitis.
2. Tubercle bacilli in TB meningitis.
3. Leptospira in meningeal type of Leptospira icterohaemorrhagica infection.
4. Flagellated trypanosomes in sleeping sickness more easily seen in CSF than in blood.
5. Trichinella larvae in cerebral type of trichinosis.
6. Echinococci, cysticerci, yeasts (torula), fungi and actinomycotic granules in infection of the nervous system with these organisms.
7. Free living, motile amoebas in primary amoebic meningoencephalitis.

Serological

CSF is abnormal in most untreated patients of neurosyphilis with positive VDRL, FTA and TPHA tests.

2. DISORDERS OF SPEECH

Common terminologies in speech disorders are given in Table 9.

APHASIA

Control of speech in the cerebral cortex – Many sensory and motor activities are concerned in the four major language modalities – speech production, speech comprehension, reading and writing. The formulation of language is primarily a sensory function and demands the integration of auditory, visual and sensory events. It takes place in the cerebral hemisphere where predominant hand area (handedness) is situated and is called the dominant hemisphere. The left cerebral hemisphere is responsible for language function in more than 90% of normal right handed individuals and about 70% of normal left-handers.

Table 9: Common speech disorders

<i>Aphasia or dysphasia</i>	A disorder of language with impaired comprehension and/or expression of spoken and/or written language.
<i>Alexia</i>	Inability to read. Other language functions like comprehension and expression being normal.
<i>Agraphia</i>	Inability to write. Other language functions are normal in pure agraphia.
<i>Alexia with agraphia</i>	Inability to read and write.
<i>Alexia without agraphia</i>	Inability to read, but writing is normal.
<i>Dysarthria</i>	Disorder of articulation, normal language function in pure dysarthria.
<i>Aphonia and dysphonia</i>	Disorder of voice (sound) production. Articulation and language functions are normal.
<i>Broca or motor aphasia</i>	Speech is nonfluent and effortful. May be meaningful. Phonemic (similar sounding) paraphasias (penail for pencil, tan for fan). Repetition is impaired and reading comprehension may be impaired. Associated right hemiparesis common.
<i>Wernicke or sensory aphasia</i>	Speech is meaningless. Fluent and effortless. Semantic (similar meaning) paraphasias (pencil for pen). Repetition is impaired. Associated right hemianopia is common. Aetiology is usually an embolic stroke.
<i>Global aphasia</i>	Speech comprehension as well as expression is severely impaired. Associated right hemianopia common. Recovery is to a Broca's aphasia as comprehension improves.
<i>Anomic (nominal) aphasia</i>	Localization is anywhere in the dominant hemisphere.

1. *Broca's area* – Once language is formed, the formulated language must be transmitted anteriorly by means of subcortical association fibres to the cortical area of expression just anterior to the motor cortex.
2. *Receptive area* – Here the spoken word is understood and appropriate reply or action initiated. The temporal lobe receptive area lies close to the auditory cortex of transverse gyrus of temporal lobe, and the parietal lobe area within angular gyrus.
3. *Arcuate fasciculus* – is a link between receptive and expressive areas in order to integrate function.
4. *Naming* – Difficulty in naming is useful in establishing dysphasia, though it does not help to localise the lesion further as it occurs in varying degrees in all forms of dysphasia.
5. *Reading and writing* – Disturbances of reading (alexia) and writing (agraphia) are usually part of a more generalised aphasia. Alexia with agraphia is due to damage to left angular gyrus. Pure agraphia with little or no speech defect occurs with left parietal lesion. Co-existence of dysgraphia, dyscalculia, finger agnosia, and right-left disorientation indicates a lesion of left angular gyrus.

CLINICAL ASSESSMENT OF DYSPHASIA

1. *History* – Patient's native language and handedness and educational status.
2. *Conversational testing* – Spontaneous speech: (a) Nonfluent aphasia: Here there is decreased output to 10 or less words per minute accompanied by increased effort in production of words, dysarthria, and short phrase length. The lesion is anterior to fissure of Rolando. (b) Fluent aphasia. Here the output of words may reach 200 words per minute. Effortless speech with no dysarthria, but accompanied by paraphasia. Paraphasia is a substitution within a language which may be literal (replacement of syllable), verbal (replacement of word), or substitution of a meaningless nonsense word (neologism). Patient with fluent aphasia is unaware of the substitutions.
3. *Repetition of spoken language* – Repetition is disproportionately poor in conduction dysphasia. In the uncommon transcortical dysphasias repetition is excellent despite other language defects.

APHASIC SYNDROMES

Various aphasic syndromes are listed in Table 10.

Major Aphasic Syndromes

1. *Broca or motor aphasia* – results from damage to posterior part of inferior frontal gyrus. Speech is slow, laboured, poorly articulated and reduced to a few words (telegraphic). Comprehension is little impaired.
2. *Wernicke or sensory aphasia* – Posterior lesions of superior temporal gyrus. It differs from Broca's aphasia in that comprehension is severely impaired. Speech is effortless and fluent but with frequent paraphasias (inappropriate words or words with inappropriate syllables) and neologisms (non-existent words). An embolus to the inferior division of the middle cerebral artery, to the posterior temporal or angular branches in particular.

Table 10: Aphasic syndromes

1. Major aphasic syndromes

- Broca aphasia
- Wernicke aphasia
- Global aphasia
- Anomic aphasia

2. Minor or disconnected syndromes

- Conduction aphasia
- Transcortical aphasias (motor and sensory)
- Restricted and transient 'mini-Broca'
- Modality specific aphasias:
 - Pure word blindness
 - Pure word deafness
 - Pure word mutism (aphemia)
 - Agraphia.

3. Global aphasia – is the commonest variety of aphasia and occurs with large peri-Sylvian lesions. The expressive disturbance characteristic of Broca's aphasia is combined with loss of comprehension of equal severity. Speech is non-fluent. This may persist after large cerebral infarcts. With less extensive lesions there may be some recovery towards one of the former categories; usually because comprehension improves.
4. Anomic (nominal) aphasia – The term denotes certain language disorders that result from lesions that interrupt association pathways. Here the main defect is in naming objects. There are also pauses in speech, groping for words, and substitution of another word, phrase or gesture to convey the meaning. Lesion is deep in the basal portion of posterior temporal lobe, in frontal lobe and in angular gyrus. It may be a manifestation of early Alzheimer's disease or of confusional states. It may also be the only residual abnormality after recovery from Wernicke, conduction or transcortical aphasia.

Disconnection (Dissociative) Language Syndromes

The term denotes certain language disorders resulting not from lesions of the cortical language areas themselves but presumably from lesions that interrupt association pathways.

Conduction aphasia – Patient comprehends spoken and written language with only minor mistakes, but is unable to repeat what is heard or read. Spontaneous speech is fluent but paraphasic. Common cause is infarction in the angular gyrus.

Transcortical aphasia – Due to ischemic damage in the region between major vascular territories (watershed), the motor-sensory language areas may be isolated from the surrounding cortex. In the *sensory type*, disorder of language is much like Wernicke aphasia except for preservation of repetition. In the *motor type*, patient spontaneously produces a few grunts and syllables, can faultlessly repeat phrases or even sentences that are heard or read. The lesion is subcortical in frontal lobe, or partially recovered Broca aphasia.

Other modality-specific aphasias – (a) *Pure word mutism* (aphemia) – Patient loses capacity to speak, but is able to write and to understand spoken words. (b) *Pure word deafness* – Patient can hear but cannot understand spoken language. Expressive speech remains normal. The lesions in the dominant temporal lobe (Heschl gyri).

DYSARTHRIA

Peripheral neuromuscular control of speech – There are two essential processes for the conversion of the thought conceived in the cerebral cortex into the spoken word, by means of the voluntary musculature – (a) phonation or the production of sound and (b) articulation.

Types and Causes of Dysarthria

1. *Spastic* – due to bilateral pyramidal lesion – e.g. pseudobulbar palsy, motor neuron disease, upper brainstem tumours. Speech slurred, monotonous, high-pitched indistinct 'hot potato' speech, some disturbance of swallowing, jaw jerk exaggerated. Rarely with unilateral lesion especially in thalamus.
2. *Rigid (Parkinsonian)* – due to extrapyramidal lesion – (a) Speech slow, laboured, intermittent and jerky – monotonous or festinate speech, or it may be hesitant with sudden outpouring of rapid speech (explosive speech).
3. *Ataxic* – Two types – (a) Defect in articulation itself in the form of slurring of consonants. (b) Disorder of rhythm of speech, i.e. disturbance of normal co-ordination between speech and respiratory movements. Speech is slurred, drunken. The rhythm is irregular, at times explosive staccato or scanning. *Causes* – cerebellar diseases, hereditary ataxias, multiple sclerosis, anticonvulsant drug toxicity.
4. *Flaccid* – due to lower motor neuron lesions – (a) *Facial paralysis* – causes difficulty with labials resulting in slurred speech. (b) *Tongue paralysis* – Guttural speech. (c) *Palatal paralysis* – Nasal speech.

5. *Choreic and myoclonic* – Speech is interrupted by abnormal movements.
6. *Myasthenic* – Early stage – speech slurred with nasal twang occurring only when patient has been speaking for long. Later – persistent dysarthria and aphonia.

With pure disorders of articulation, language functions are intact. The only exception occurs with a restricted left frontal lesion and ‘mini-Broca’ aphasia, with recovery from mutism, elements of both aphasia and dysarthria can be recognised.

3. THE CRANIAL NERVES

OLFACTORY NERVE

Affection of olfactory nerves causes anosmia. Table 11 lists various causes of anosmia.

OPTIC NERVE

Anatomy – The visual system is composed of peripheral reception in retina, central pathway and cortical centres (Fig. 6).

Visual field defects tend to fall into patterns of one quarter or one-half of visual fields. Blindness in one quarter of a field is called *quadrantanopia* (quadrants = 1/4, an = without, optic = vision). Blindness in one half of a field is called *hemianopia*. When corresponding quadrants or halves of the fields, e.g. the right halves are affected, the defect is termed *homonymous*, and described as right or left. Patterns of visual field loss and causes are enumerated in Table 12.

III, IV AND VI. CRANIAL NERVES

Oculomotor – Paralysis causes – 1. Diplopia. 2. External paralytic squint (divergent squint). 3. Inability to move eye upwards, directly downwards or directly inwards. 4. Ptosis due to paralysis of levator palpebrae. 5. Pupil dilated and not reacting to light or accommodation.

Trochlear – 1. Diplopia on looking in direction of action of superior oblique, i.e. downwards and inwards. 2. Head inclined forwards and towards shoulder on sound side to avoid giddiness when looking downwards.

Abducent – 1. Diplopia on looking outwards. 2. Convergent squint. 3. Paralysis of external rectus with inability to turn the eye outwards beyond midpoint (Internal paralytic squint). 4. Head turned towards affected side.

Table 11: Causes of anosmia

1. Head injury (fracture of cribriform plate).
2. Viral infection.
3. Tumours (usually meningioma).
4. Drugs – Penicillamine.
5. Endocrinal – Addison’s disease, thyrotoxicosis.
6. Aneurysm of circle of Willis.
7. Tabes.
8. Refsum’s disease.
9. Increased intracranial pressure (rare).

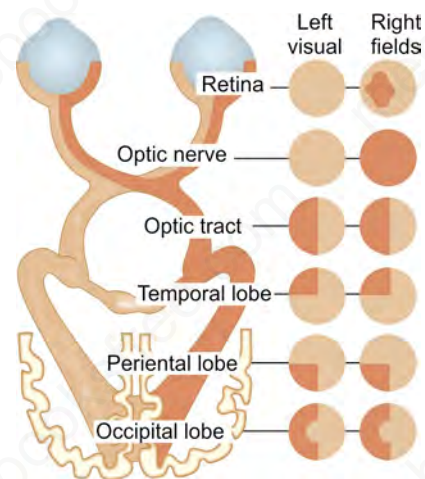

Fig. 6: Visual pathways showing various sites of interruptions and the field defects thus produced

Causes

1. *Within brainstem* (Nuclear and fascicular lesions) – Neoplasms, vascular lesions, encephalitis, syringobulbia, tuberculoma.
2. *At base of brain* – Meningeal affections: Tuberculous, bacterial and fungal meningitis, carcinomatous infiltration of meninges, meningovascular syphilis. Direct neoplastic invasion from sinuses and nasopharynx, Guillain-Barre syndrome, sarcoid and herpes zoster.
3. *Lesions at petrous tip* – Mastoiditis or otitis media may cause diffuse inflammation of petrous bone with combination of 6th, 7th and 8th nerve palsies.
4. *Lesions in region of cavernous sinus* – Cavernous sinus thrombosis (6th nerve most vulnerable), intrasellar tumours such as chromophobe adenomas (3rd nerve). Aneurysmal dilatation of intracavernous portion of carotid artery, carotid-cavernous fistula.

Table 12: Patterns of visual field loss and causes

Site of lesion	Field defect	Causes
Optic nerve	Monocular scotoma or blindness	MS, optic nerve glioma, ischemic optic neuropathy, compression by tumour, Leber hereditary optic atrophy
Optic nerve and chiasma	Heteronymous defect (field defects that differ in the two eyes)	Craniopharyngioma and other suprasellar tumours
Optic chiasma	Bitemporal hemianopia	Pituitary tumour, meningioma of tuberculum sellae, craniopharyngioma, aneurysm
Optic tract	Homonymous hemianopia	Tumour, rarely demyelinative
Lateral geniculate	Homonymous hemianopia	Post cerebral artery occlusion, tumour
Geniculocalcarine pathway	Homonymous hemianopia	Infarction, mass lesion, demyelinative
Superior temporal lobe	Inferior quadrantanopia or noncongruent homonymous hemianopia	Temporoparietal infarction, mass lesion
Occipital lobe and calcarine cortex	Homonymous hemianopia, congruent; central homonymous hemianopic scotoma, homonymous altitudinal hemianopia loss of vision in corresponding upper or lower visual fields, blindness with retained pupillary reflexes	Post cerebral artery occlusion, infarction of one occipital pole Infarction above or below calcarine sulcus Bilateral infarction; central scotoma, if only occipital lobes affected

5. *Lesions at superior orbital fissure and orbital apex* – Neoplasms such as meningiomas.
6. Tolosa Hunt syndrome – is idiopathic inflammatory granulomatosis of superior orbital fissure causing III, IV, VI and V nerve first division involvement. Clinically it is indistinguishable from anterior cavernous syndrome. Table 13 lists the causes of painful ophthalmoplegias.

Impaired vertical gaze

1. Parinaud's syndrome.
2. Richardson-Steele syndrome (Progressive supranuclear palsy)
3. Grave's disease.
4. Thalamic hemorrhage.

Isolated IV nerve palsy

Cerebral peduncle lesion.

Oculogyric crisis (Oculogyric spasm). Sudden paroxysmal, tonic, upward deviation of both eyeballs for seconds or minutes may be observed in post-encephalitic Parkinsonism, petit mal epilepsy, Millard Gubler syndrome or may be drug-induced, e.g. Phenothiazine.

Nystagmus

Nystagmus is a rhythmic repetitive oscillation of the eyes. It is initiated by a slow eye movement that drives the eye

Table 13: Painful ophthalmoplegic syndromes

A. III nerve palsy:
1. Diabetes mellitus, vasculitis.
2. Intracranial aneurysms – Posterior communicating artery, internal carotid artery.
3. Ophthalmoplegic migraine.
B. VI nerve palsy:
1. Tolosa-Hunt syndrome.
2. Gradenigo's syndrome.
3. Carcinoma of nasopharynx.
4. Internal carotid artery aneurysm (intraclinoid).
C. Total ophthalmoplegia:
Superior orbital fissure syndrome.

off target followed by a fast (jerk nystagmus) or another slow (pendular nystagmus) corrective eye movement in the opposite direction. Some of the types and causes of nystagmus are listed in Table 14.

Causes

1. Ocular lesions.
2. Labyrinthine disease.
3. Brainstem and cerebellar disease.

Degrees of nystagmus – Nystagmus present with eyes deviated less than 30% from the midline is abnormal.

Table 14: Causes and types of nystagmus

Cause	Type of nystagmus
• Retinal or ocular	
• Congenital cataract	Rapid pendular
• Congenital macular defect	Increased on looking to the sides
Albinism	Present throughout life
<i>Labyrinthine (Vestibular)</i>	
(a) Physiological	Nystagmus in plane of rotation Horizontal nystagmus on caloric testing
(b) Pathological	Slow phase to side of lesion, quick phase to normal side
Damage to labyrinth or vestibular nerve, e.g. Meniere's disease	Turning eyes away from side of lesion increases amplitude but does not change direction of nystagmus
Vestibular neuritis	Vertigo
Ischemia	Tinnitus and hearing loss often
CNS nystagmus	
Vascular disease. Demyelination Neoplasm. Wernicke's encephalopathy Drug toxicity, e.g. phenytoin	Horizontal, vertical, rotatory or dissociate Vertigo seldom. Signs of brainstem involvement

1st degree – Nystagmus with eyes deviated to one side.

2nd degree – Nystagmus with eyes deviated to one side and in midline position also.

3rd degree – Nystagmus in all directions of gaze.

Types of Nystagmus

- Optokinetic nystagmus (OKN) – Impaired horizontal OKN in parietooccipital infarcts. Impaired vertical OKN in PSP (downward jerks impaired when drum rotated upwards).
- Pendular – Congenital or acquired, Multiple sclerosis, monocular vertical in case of visual loss. Oculopalatal myoclonus, oculomasticatory monorhythmia. Associated with oscillopsia, if acquired.
- Jerk – Vestibular or neural lesion.
 - Horizontal* – (i) Peripheral – Greatest amplitude away from side of lesion, with fast component always in the same direction. Lesion in labyrinth. (ii) Central – Greatest amplitude towards the lesion. Fast component in direction of gaze. Occurs with brainstem, vestibular nuclei or cerebellar lesions.
 - Vertical* – Downbeat (first phase downwards in primary position, in cervicomedullary lesions, vestibulocerebellar lesions). Upbeat in midbrain, medulla and vermian lesions (Wernicke encephalopathy).
 - Periodic alternating nystagmus* – Each cycle lasts 2–3 minutes. Lesions at cervicomedullar junction, medulla, nodule, uvula, MS.
 - Rebound* – Cerebellum, medulla.
 - Jerk nystagmus* – Slow drift of the target followed by a fast corrective saccade. Jerk nystagmus can be downbeat, upbeat, horizontal (left or right), and torsional
 - Gaze evoked* – Most common type, in the direction of gaze. Impaired gaze holding. Causes – sedatives, anticonvulsants, brainstem and cerebellar lesions.
 - Vestibular nystagmus* – Pure form in brainstem, vestibulocerebellar lesions. Mixed form in peripheral vestibular diseases.
 - Convergence retraction nystagmus* – Bilateral adduction causing convergence and retraction of both eyes on looking upwards in Parinaud's syndrome, midbrain posterior commissure lesion.
 - Ocular bobbing* – Conjugate eye movements with fast downward movement and slow drift back to the midline. Massive pontine lesions in comatose patients.
 - Ocular flutter* – Intermittent bursts of back to back horizontal saccades without any intersaccadic interval. No vertical component.
 - Opsoclonus* – Back to back saccades in multiple directions (horizontal, vertical). Associated with facial twitching, myoclonus, ataxia (dancing eyes and dancing feet). Cerebellitis, posterior fossa tumors, neuroblastoma, paraneoplastic, lithium, phenytoin.

TRIGEMINAL NERVE

Motor – (a) *Peripheral lesions* (between pons and Gasserian ganglion). All three divisions may be affected giving rise to: Weakness and wasting of muscles of mastication on affected side with deviation of jaw towards the affected muscles.

Causes – (i) Between pons and trigeminal ganglion: Inflammatory lesions such as meningitis, compression by tumour or aneurysm, degeneration as in tabes. (ii) Trigeminal ganglion – Tumours, e.g. meningioma, acoustic neuroma, fracture of middle cranial fossa, Gradenigo's syndrome (with 6th nerve), herpes zoster. (iii) After leaving the ganglion – Cavernous sinus or superior orbital fissure lesions, fracture of bones of face. (iv) Motor neuropathy in metastasis at skull base.

(b) *Central lesions* – Weakness of muscles of mastication with paralysis of external rectus and of face on affected side.

Causes – Tumours, syringobulbia, and vascular lesions involving pons, and uppermost cervical segments of spinal cord.

Sensory – 1. Impaired or absent corneal reflex. 2. Loss of sensation of half of face and scalp to light touch, pain and temperature but not to deep pressure pain. Also of palate and nose. Sensation of broken cup when patient drinks. 3. Taste may be impaired on anterior two-thirds of tongue. 4. Diminished secretion of tears and saliva on affected side. 5. Excessive furring of tongue on affected side.

Trigeminal Neuralgia (Tic Douloureux)

A disorder characterised by paroxysmal attacks of neuralgic pain with affection of one or more divisions of the trigeminal nerve. The pain involves the first and second divisions equally, and rarely the first. It rarely occurs bilaterally.

Aetiology

Age – usually after middle age. *Sex* – more in females. *Cause* – unknown. May entail a fault in the mechanism that insulates neurones from each other. Vascular compression of nerve root by an aberrant blood vessel.

Exciting causes – Spontaneous, or following exposure to cold wind, blow on face, or chewing, or eating, or drinking hot or cold fluid or talking, or washing the face.

Symptoms

During the attack

1. Pain – (i) Usually II and III division together. (ii) Severe in intensity. (iii) Sharp, shooting lasts less than 30 secs.

(a) *Site* – Unilateral, more commonly confined to one of the three divisions of the nerve. Common points of origin are just external to alae nasi, infra orbital foramen or mental foramen below the canine tooth. Pain sometimes confined to one branch of a division. Tendency for pain to commence locally and subsequently spread in each attack, thus invading a larger area. (b) *Character* – sharp and paroxysmal, sudden in onset and cessation. Short lightning flashes of pain or “red hot needles”. (c) *Duration* – only a few seconds. Rarely half a minute or longer due to series of short sharp stabs of pain, interrupted by brief intervals. The pain usually resolves after a few weeks but eventually recurs.

2. Associated symptoms – (i) During the attacks, the face is often thrown into a strong involuntary tonic spasm on the affected side. (ii) Flushing of face. (iii) Dilatation of pupil. (iv) Excessive lacrimation and (v) sometimes secretion of nasal mucus and saliva may occur on the side of pain.

In between the attacks

1. *Trigger zones* – Certain localised hyperaesthetic spots on face, gums or tongue, a slight stimulus of which sets off an attack.
2. *Dull continuous pain* – follows paroxysmal pains if severe. Usually of a boring character. Skin over affected region is sore and tender after a paroxysm.
3. *Sensory changes* – none except for hyperaesthesia.
4. *Skin and hair* – After repeated attacks skin becomes shiny and hair in the area may become grey or rubbed away.
5. *Loss of weight and depression* – due to interference with food intake and recurrence of pain over a prolonged period.

Differential Diagnosis of Facial Pain

1. **Symptomatic trigeminal neuralgia** – (a) Neuralgia indistinguishable from the idiopathic variety may occur as a result of compression of trigeminal root or ganglion, e.g. meningioma, acoustic neuroma, aneurysm of basilar artery, arteriovenous malformations, basilar invagination, epidermoid cholesteatomas in the cerebellopontine angle, as a result of Paget's disease or osteomalacia. (b) Paratrigeminal neuralgia (Raeder's syndrome) – Severe pain in and around one eye accompanied by Horner's syndrome on the affected side. It is continuous and progressive and is usually caused by a structural lesion, often malignant, in the base of the skull involving the paratrigeminal

region. (c) Multiple sclerosis - Diagnosis of multiple sclerosis should always be suspected in a young patient with trigeminal neuralgia. (d) Syringobulbia. (e) Painful superior orbital fissure syndrome (Tolosa-Hunt syndrome) - caused by granulomatous tissue involving nerves III, IV and VI. Pain with development of ocular palsies and loss of first division trigeminal sensation.

2. **Referred pain** - Paranasal sinuses, toothache, aural infection. Temporomandibular joint dysfunction (Costen's syndrome) - abnormality of bite and aggravated by chewing.
3. **Vascular pain** - (a) *Migraine* - Episodes of severe and continuous pain, often burning in character in or behind one eye, or in cheek, forehead and temple. Often suffusion of conjunctiva and blocking of nostril on that side. (b) *Temporal arteritis* - Pain of dull, throbbing nature with associated scalp tenderness. Thickened temporal arteries with reduced or absent pulsations.
4. **Other neuralgias** - (a) *Post-herpetic neuralgia* - Pain continuous in nature. Vesicles and scars of herpetic infection. (b) *Glossopharyngeal neuralgia* - Pain in tonsillar fossa, back of throat and larynx; may radiate to ear on affected side. Swallowing is the stimulus most likely to produce pain.
5. **Atypical facial pain** - Intermittent but long-lasting pain of aching character which affects the cheek and upper jaw, often bilateral and occurs almost exclusively in young and middle-aged women. Generally believed to be a manifestation of depression or anxiety.
6. **Miscellaneous** - (a) *Clonic facial spasm* - Sometimes painful, usually associated with intermittent twitching of eyelid and face on one side. Platysma usually involved in twitching. (b) *Neuralgic pain* - occasionally associated with facial hemiatrophy. (c) *Idiopathic trigeminal neuropathy* - Commonly associated with muscle wasting of masseter.

Management

1. Elimination of all possible sources of infection.
2. Drugs:
 - (a) *Analgesics* - Potent analgesics must be used with caution because of danger of habituation.
 - (b) *Carbamazepine* - Effective in relieving symptoms in majority of patients within 24 hours. Initial dose 100 mg t.d.s. gradually increased to 200 mg qds. or more. Side effects - dizziness and drowsiness common. Dryness of mouth, nausea and vomiting

and erythematous rashes may occur but disappear within 48 hours after stopping treatment. Rarely depression of bone marrow. *Oxcarbamazepine* - alternative with equal efficacy and better side effect profile with less chances of bone marrow toxicity.

- (c) *Phenytoin sodium* - 0.1 gm t.d.s. when carbamazepine cannot be tolerated or
 - (d) *Gabapentin* - 300 mg bd can be increased to 1,800 mg/day.
 - (e) *Pregabalin* - 25 mg bd can be increased to 300 mg/day.
3. Injection of alcohol - into affected nerve, or the Gasserian ganglion, if more than one division is affected. Inject about 10 minims of 90% alcohol after local anaesthesia with 2-3 drops 2% procaine. Relief seldom lasts more than 6 months.

Undesirable effects - Neuropathic keratitis, paresis of muscles of mastication lasting a few months, numbness or deadness in the skin of the face. Useful in those in whom on account of age or for some other reason surgery is contraindicated.
 4. Microvascular decompression - Separation of blood vessels in contact with trigeminal nerve roots and insertion of nonabsorbable sponge gives relief from pain in most patients.
 5. Radiofrequency thermocoagulation - of trigger spot or site of pain origin localised by electrical stimulation of needle inserted into trigeminal ganglion produces permanent relief.
 6. Surgery - Selective or complete pre-ganglionic section of the trigeminal root. Indications - (i) Failure of repeated injections to give relief. (ii) Patient going abroad. (iii) To avoid necessity for repeated injections. Permanent relief from pain but disadvantages are permanent dysaesthesiae in most cases. A better technique is percutaneous electrocoagulation of the preganglionic rootlets corresponding to the trigger zone, the temperature of the probe being so regulated as to coagulate the small thinly myelinated pain fibres but preserving the more heavily myelinated touch fibres.

VII. FACIAL NERVE

Facial Weakness

General characteristics - Facial palsy can be due to upper or lower motor neurone involvement. Table 15 gives the differentiating features between the two.

Lesions, Causes and Localization

Supranuclear

1. Corticospinal lesion –

Causes – Tumour, abscess, haemorrhage or thrombosis. Signs – (a) Lesions in region of cerebrum, cerebral peduncles and upper pons – Facial palsy associated with paralysis of ipsilateral limbs.

(b) Lesions in region of lower pons, prenuclear lesions – Facial palsy with crossed paralysis of limbs.

- Mimic paralysis – Weakness or abolition of emotional movements of face with retention of voluntary movements due to lesions of anterior part of frontal lobe or lesions in neighbourhood of optic thalamus.

Nuclear and Infranuclear Lesions

Causes and features of nuclear and infranuclear facial palsy are given in Table 16.

Bilateral Lower Motor Neuron Facial Palsy

Causes of bilateral lower motor neuron facial palsy are given in Table 17.

Table 15: Differentiating features between upper and lower motor neuron facial palsy

Upper motor neuron	Lower motor neuron
Affect mainly muscles of lower part of face	Whole face affected
Never complete palsy	Complete palsy
Seldom isolated palsy	Isolated emotional movement
Loss of emotional movement	Emotional movement preserved
No muscle contracture	Marked muscle contracture may occur
No reaction of degeneration	Reaction of degeneration present
EMG and nerve conduction normal	Evidence of lower motor neuron lesion on EMG

Table 16: Causes and features of nuclear and infranuclear facial palsy

Site of lesion	Possible causes	Associated features
Pons [Fig. 7(1)]	Vascular lesions, tumour, multiple sclerosis, encephalitis, syringobulbia motor neuron disease,	5th nerve involvement – Sensory loss on opposite side and often paralysis of ipsilateral jaw muscles or 6th nerve involvement – Facial palsy with contralateral limb weakness
Cerebellopontine Angle [Fig. 7(2)]	Tumour in cerebellopontine angle, e.g. acoustic neuroma, Meningioma	Nerve deafness, tinnitus, vertigo, cerebellar signs, loss of corneal reflex CSF changes
Temporal bone lesion		
Region of geniculate ganglion [Fig. 7(3)]	Trauma, herpes zoster of geniculate ganglion (Ramsay Hunt syndrome). Spread of infection from middle ear or mastoid	Variable deafness, vertigo Defective lacrimation Loss of taste on anterior 2/3 of tongue
Between geniculate ganglion and nerve to stapedius [Fig. 7(4a)]	Spread of infection from middle ear	Loss of taste on anterior 2/3 of tongue Hyperacusis Impaired salivary secretion
Between branching of nerve to stapedius and chorda tympani nerve [Fig. 7(4b)]		Facial motor paralysis Loss of taste on the anterior 2/3rd of the tongue Hearing is spared (no hyperacusis)
Within stylomastoid foramen (distal to branching of chorda tympani nerve) [Fig. 7(4c)]	Bell's palsy, suppurating glands, encephalitis, tetanus, acute inflammatory polyneuropathy, otitis media, mastoidectomy	Facial paralysis only
Peripheral nerve [Fig. 7(5)]	Tumour or inflammation of parotid gland, Sarcoidosis, Trauma, Parotid operation	Paralysis of some facial muscles only

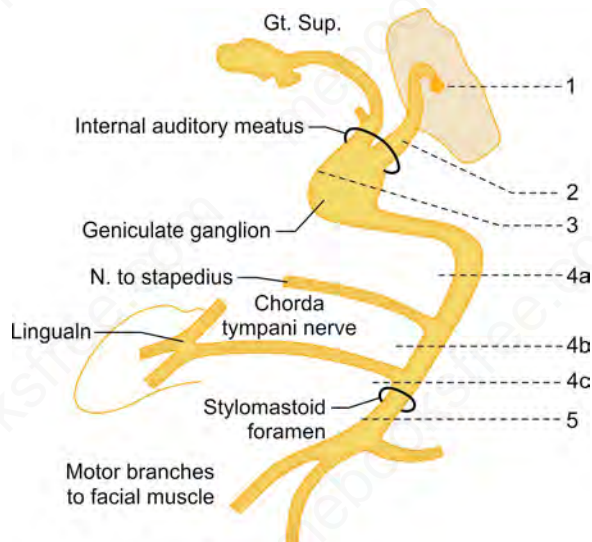

Fig. 7: Components of the facial nerve

Signs - Flattening of all normal folds, sagging of corners of mouth, fixed expression-less mask like face, no voluntary movements of facial muscles. Whites of eyes seen when patient attempts to close them. Patient talks as if he had severe stomatitis.

Bell's Palsy

Bell's palsy is an acute, apparently isolated, lower motor neuron facial palsy for which no cause can be found. Presumed to be viral due to HSV 1 (viral genomic sequences detected).

Aetiology

(a) *Associated known clinical conditions* - Diabetes, severe hypertension, last trimester of pregnancy, dental anaesthesia. (b) *Causes* - (i) Exposure to cold; oedema and subsequent compression of nerve trunk within the rigid Fallopian canal causes circulatory disturbance. (ii) Other important causes of acute facial palsy include suppurative otitis media, herpes zoster, head injury, Guillain-Barre syndrome, sarcoidosis and multiple sclerosis.

Symptoms

Sudden, following exposure to chill or without any apparent precipitating cause, maximum paralysis in 24 hours. Postauricular pain is common and may precede paralysis by 2 days. There may be spontaneous complaints of loss of sense of taste, hyperacusis and watering of the eye. Sweating less on affected side.

Table 17: Causes of bilateral lower motor neuron facial palsy

1. <i>Bilateral infranuclear lesions:</i>
- Guillain-Barre syndrome
- Leprosy
- Leukaemia
- Syphilitic or meningococcal meningitis
- Double otitis media
- Presumed to be viral due to HSV 1 genomic
- Post-diphtheritic
- Bell's palsy
- Uveoparotid paralysis.
2. <i>Muscle disease</i> - Myasthenia gravis/myotonic dystrophy, facioscapulohumeral dystrophy.

Signs

1. Forehead cannot be wrinkled; frowning lost (frontalis).
2. Eye cannot be closed (orbicularis oculi, sphincter of palpebral fissure). On attempting closure, eyeball turns upwards and outwards (Bell's phenomena).
3. On showing the teeth, the lips do not separate on affected side. Whistling not possible. Articulation of labial components difficult. Nasolabial fold flattened out. Angle of mouth on affected side droops with dribbling of saliva (Orbicularis oris, sphincter of oral fissure).
4. Cheek puffs out with expiration because of buccinator paralysis. Food collects between teeth and paralysed cheek. Fluid runs out while drinking (buccinator).
5. Base of tongue lowered (stylohyoid and posterior belly of digastric).
6. Vesicles within the external auditory meatus and ear drum in Ramsay Hunt syndrome. Pain may precede facial weakness. Deafness may result.

Investigation

Electromyography - of prognostic importance: (a) If signs of denervation after 10 days - Axonal degeneration, recovery incomplete or delayed. (b) If incomplete denervation in less than 7 days - Good prognosis. (c.) Fibrillation potential after 2 weeks suggests Wallerian degeneration.

Management

1. *Local heat* - Infra-red or moist heat, or short wave diathermy over face or parotid region or both, if there is tenderness of nerve trunk.

2. **Local treatment of muscles** - (a) The patient should massage the facial muscles with bland oil twice daily for 5 minutes. The massaging movements should start from the chin and lower lip and be directed upwards. With return of function the patient should practise movements of various muscles of face before a mirror. (b) Prevention of facial sagging - application of strips of adhesive tape to lift up the angle of the mouth. The tape is attached to the temple and extends down in a V shaped fashion to the upper and lower lips.
3. **Protection of eye** - with dark glasses or eye patch. The eye should be washed twice daily with mild zinc-boric solution to prevent conjunctivitis.
4. **Corticosteroids** - if seen within a week of the onset. Help by reducing secondary oedema. Prednisolone 40 mg daily for 4 days, reduced over next 6 days.
5. **Antivirals** - like acyclovir, valacyclovir or famciclovir in combination with steroids, if started within 3 days of onset.
6. **Surgery** - Decompression of facial nerve in second or third week cannot influence favourably natural course of Bell's palsy. In cases which fail to recover after 9 months anastomosis of facial with accessory or preferably hypoglossal nerve may be considered, or plastic surgery in cases of total paralysis with atrophy of musculature.
7. **Treatment of sequelae** - (a) Residual severe weakness - plastic surgery. (b) Faulty reinnervation resulting tears pouring from affected side on chewing (syndrome of crocodile tears) - cutting of tympanic nerve which normally conveys the glossopharyngeal salivary fibres.

VIII. AUDITORY NERVE

Cochlear Branch

1. Tinnitus. 2. Nerve deafness. Causes - (a) *At cochlear level* - Otosclerosis, Meniere's syndrome, drugs such as salicylates, streptomycin, quinine, prolonged exposure to noise. (b) *In nerve trunk* - Old age, inflammatory or toxic lesions, cerebellopontine angle tumours. (c) *In brainstem* - Pontine vascular lesions, severe demyelination, rarely tumours.

Tests of Function

- (i) **Whispered or spoken voice** - The distance at which spoken or whispered voice is determined. The distance being noted, the examiner compares the patient acuity of hearing with his own.

Table 18: Rinne and Weber test

Test	Normal	Conduction	Sensory neural deafness deafness
Rinne	AC > BC	BC > AC	AC > BC (both are reduced)
Weber	Not lateralized	Localized to poorer ear	Lateralized to better ear

- (ii) **Tuning fork tests** - Rinne and Weber tests are useful in differentiating between conduction and sensorineural deafness (Table 18).

Vestibular Branch

1. Vertigo.
2. Nystagmus.
3. General symptoms such as sweating, nausea, vomiting.

Tests of Function

- Stance and gait. In presence of unilateral disturbance of vestibular function, patient tends to reel towards the affected side
- Positional testing for nystagmus. Patient will complain of vertigo and develop nystagmus within 10 seconds of head movement in presence of disorder of the labyrinth or its vestibular connections.
- Caloric tests allow one to investigate labyrinthine function in each ear based on the fact that the cupola can be deflected by currents setup in the semicircular canals if they are heated or cooled. Nystagmus - cold opposite, warm same (cows). The test can be performed on the opposite side after an interval. The test is particularly valuable in unconscious patients and must be performed in every case of coma.
- Stepping test involves marching for 50 steps at normal walking speed. If there has been more than 30° in body rotation or more than 1 meter of displacement from the starting point, it is suggestive of vestibular dysfunction.
- Past-pointing (Refer cerebellar disorders).

Tinnitus. Patient complains of subjective sensation of noises in the year (ringing, whistling, buzzing, roaring). It is usually accompanied by deafness. Causes: (a) Local: Peripheral impairment of function of conducting apparatus of the ear, e.g. wax in the year, catarrh of Eustachian tube, acute labyrinthitis. (b) Systemic: Drugs like quinine, salicylates; fever, severe anemia, AR. (c) Central auditory nerve tumour, aura of epilepsy, temporal lobe or brainstem lesions.

IX, X. GLOSSOPHARYNGEAL AND VAGUS NERVE

Disorders

1. *Paralysis of palate* - (a) Unilateral paralysis: No symptoms. Positive 'Ah' test. (b) Bilateral paralysis - Nasal regurgitation, nasal twang, no elevation of palate on phonation.
2. *Posterior Pharyngeal wall weakness* - (a) Unilateral - Pharyngeal wall droops on affected side. (b) Bilateral - Marked dysphagia.
3. *Pharyngeal gag reflex* is tested by stimulating the back of the throat. The afferent arc of the reflex is the 9th Cr. nerve, the efferent arc 10th Cr. Nerve. If there is no elevation of the palate when patient says 'ah' but there is elevation, during the gag reflex, there is an UMN lesion. If both volitional and reflex activities are absent, there is likely to be LMN lesion or muscle lesion.
4. *Movement of Larynx* - whilst patient is made to swallow some water, the force of upward movement of the larynx is assessed digitally.
5. *Voice and ability to cough* - Paralysis of one vocal cord (the cord lying in the midline) leads to hoarseness, low tone voice and inability to cough explosively (bovine or gander cough).
6. *Vocal cords* may be examined with a laryngoscopic mirror. The vocal cord on the affected side lies immobile midway between abduction and adduction.

CAUSES of laryngeal paralysis - (a) Nuclear lesions - Syringobulbia, posterior inferior cerebellar artery thrombosis, encephalitis, progressive bulbar paralysis, diphtheria. (b) Tumours, meningovascular syphilis, extension of infection from middle ear. (c) Trunk - Penetrating wounds and tumours. (d) Recurrent laryngeal nerve - Aortic aneurysm, enlarged left atrium, mediastinal mass or glands, enlarged thyroid, carcinoma of oesophagus.

XI. ACCESSORY NERVE

Cranial portion - Same as nuclear lesions of vagus - paralysis of palate, pharynx and larynx.

Spinal branch - Paralysis of sternomastoid (weakness of rotation to opposite side) and of upper fibres of trapezius (lowering of shoulder, winging of scapula). The supranuclear connections act on the ipsilateral sternomastoid (turning the head to contralateral side) and on contralateral trapezius. This results in head turning away from the relevant hemisphere during a seizure, and turning towards the relevant hemisphere with cerebral infarct.

Causes - (a) *Nuclear lesions* - Poliomyelitis, motor neuron disease, syringomyelia, cervical spinal cord tumours. (b) *Lesions of nerve trunk* - (i) Within posterior fossa - Tumours near jugular foramen, granulomatous meningitis or basal carcinoma (usually with 9th, 10th, and 12th nerves). (ii) After exit from the skull - Compression by enlarged deep cervical glands, or injury by penetrating wounds or during operations in cervical region.

XII. HYPOGLOSSAL NERVE

1. Unilateral paralysis - Wasting of tongue. Tongue becomes sickle shaped with concavity on paralysed side. Deviation towards paralysed side on protrusion.
2. Bilateral paralysis - Marked wasting, protrusion not possible. Fasciculations if progressive bulbar paralysis. Dysarthria. In pseudobulbar palsy tongue is somewhat smaller than normal owing to spastic contraction of the muscles.

Causes

- (a) *Unilateral lower motor neuron lesions* - (i) Hypoglossal nucleus or fibres of the nerve in the course through medulla - Poliomyelitis, syringobulbia, thrombosis of median branches of vertebral artery. (ii) Between medulla and hypoglossal canal - Glomus tumour, meningioma or aneurysm of vertebral artery, granulomatous or carcinomatous meningitis. Congenital anomalies in neighbourhood of foramen magnum, e.g. basilar impression. Periostitis of hypoglossal canal. Rarely head injury.
- (b) *Bilateral lower motor neuron lesion* - Progressive bulbar paralysis.
- (c) *Bilateral upper neuron paralysis* - Pseudobulbar palsy due to double hemiplegia, multiple sclerosis, motor neuron disease, tumours of brainstem.

4. PUPILLARY DISORDERS

Pathway of pupillary constriction and light reflex (Parasympathetic).

Afferent impulse - such as bright light shone in one eye carries it through the optic nerve to midbrain and from here to Edinger Westphal nucleus on same and opposite side, through the posterior commissure.

Efferent fibres - leave in oculomotor nerve, pass to ciliary ganglion and then to short ciliary nerve, to the constrictor fibres of sphincter pupillae. Shining a light in one eye will constrict both pupils to an equal degree provided all pathways are intact.

Pathway of pupillary dilatation – (Sympathetic) –

Fibres descend from the hypothalamus through lateral portion of brainstem into the spinal cord. Pupillary fibres pass out in anterior roots of C8, T1, enter the sympathetic chain and in the superior cervical ganglion give rise to postganglionic fibres which enter the cranium along the wall of the internal carotid artery. The fibres then pass through the ciliary ganglion to the iris or join the cranial nerves III, IV, V and VI running to the eye and iris.

PUPILLARY ABNORMALITIES

- Position** – may be congenitally eccentric. Sometimes ectopic pupil in midbrain lesions.
- Irregularity** – Slight irregularity (anisocoria) may occur in (i) healthy subjects, (ii) coloboma, operative procedures, synechiae or acute glaucoma, (iii) neurosyphilis.
- Inequality** – (i) Encephalitis sometimes. (ii) Intracranial haemorrhage. (iii) Aneurysm of aorta. (iv) GPI. (v) Third nerve lesions. The abnormal pupil will be smaller when it is dilated and larger when it is constricted.
- Dilatation** (Mydriasis) –
 - III N lesion* – Refer.
 - Drugs*–Mydriatic drops, amphetamine, glutethimide, atropine, cocaine, dhatura poisoning.
 - Tonic pupil* (Holmes-Adie syndrome) – Benign condition usually occurring in young women. Unilateral dilated pupil, reacts promptly to mydriatics and miotics, but very slowly to light and accommodation, the larger pupil becoming smaller than its fellow. When the pupil is associated with sluggish or absent tendon reflexes, it is called Holmes-Adie syndrome. Cause is unknown.
 - Optic atrophy* – producing blindness.
 - Asphyxia and deep anaesthesia*.
 - Parinaud's syndrome* – Dilated fixed pupil with loss of upward gaze.
- Constriction** (Miosis) –
 - Horner's syndrome – (i) Miosis – Affected pupil smaller than opposite pupil. (ii) Ptosis – Drooping of eyelid (less marked than with III N palsy). (iv) Enophthalmos. (v) Absence of sweating (if lesion proximal to fibre separation along internal and external carotid arteries).

Causes – Sympathetic damage at sites listed in Table 19.

Table 19: Sympathetic damage at various sites and causes

1. Preganglionic	Tumour (glioma) Vascular lesion - Lateral medullary syn. Syringobulbia
2. Cervical cord	Tumour Syringomyelia
3. Ant. roots C8, T1	Tumour, e.g. neurofibroma Lower brachial plexus palsy
4. Cervical sympathetic chain	Pancoast tumour
5. Post-ganglionic	Int. carotid occlusion, dissection Middle fossa lesions (tumour, granuloma)

Raeder's paratrigeminal syndrome – Painful Horner's syndrome with involvement of one or more cranial nerves (II to VI) and orbital sympathetic supply, usually pain in V nerve distribution.

- Argyll-robertson pupil – (i) Miosis, generally bilateral. (ii) Irregular. (iii) Does not react to light either directly or consensually. (iv) Reaction to accommodation is instantaneous. (v) Reacts slowly and unevenly to atropine or homatropine. (vi) Stroma of iris may show loss of pigment or actual atrophy. (vii) Failure of pupils to dilate to painful stimuli.

Causes – (i) Neurosyphilis especially tabes dorsalis. (ii) Brainstem encephalitis. (iii) Multiple sclerosis. (iv) Cerebral tumour in region of third ventricle, aqueduct of Sylvius or corpora quadrigemina. (v) Syringomyelia. (vi) Chronic alcoholism. (vii) Diabetes. (viii) Following infectious mononucleosis.
- Failure of accommodation** – (i) Selective impairment in lesions of third nerve or ciliary ganglion, or diphtheria. (ii) Parkinson's disease. (iii) Brainstem lesions such as tumours or encephalitis.
- Absent light reflex** – Third nerve lesions, AR pupil, glaucoma, iritis, cataract.
- Wernicke's pupil reaction** – Absence of pupillary contraction when a ray of light is thrown on the blind side of the retina, whilst illumination of the seeing half of each retina still evokes a normal light reflex. It signifies a lesion in the visual path in the optic tract.
- Marcus Gunn pupil** (pupillary escape). On stimulation of normal eye by bright light there is no abnormality; when affected eye is stimulated reaction is slower, less complete and very brief so that the pupil may start dilating again (pupillary escape phenomena). Seen particularly in optic nerve damage due to multiple sclerosis.

10. **Pupillary abnormalities in unconscious patient** – Refer Coma.
11. **Other light-near dissociation syndromes** – Pupils do not react to light, react on accommodation. Pupils of normal size, vision intact. Causes – Neurosyphilis, diabetes, high midbrain lesions, pinealoma, multiple sclerosis. Bilateral optic atrophy.
12. **Miscellaneous pupillary reactions**
- Hippus** – Rhythmic contractions of the iris, regular in periodicity and visible to the naked eye, causing the pupils to alternately dilate and contract. Causes – (i) Normal in some. (ii) Rheumatic chorea. (iii) Multiple sclerosis. (iv) Brain tumour sometimes. (v) Alcoholic subjects. (vi) Unilateral in paralysis of IIIrd nerve.
 - Paradoxical pupillary reaction** – Pupils dilate instead of contracting on exposure to light. Not uncommon in tabes.
 - Cilio-spinal reflex** – Reaction of pupil to painful stimulus of skin of neck causing the pupil to dilate; it is often absent in the early stages of tabes and in cervical sympathetic palsy.

5. SENSORY IMPAIRMENT

CONDUCTION OF SENSORY AFFERENT IMPULSES

All forms of sensation – travel via a peripheral nerve and a sensory root to the spinal cord, or the brainstem (Fig. 8).

Fig. 8: Diagram showing course of sensory paths to the thalamus and from there to the cerebral cortex

Touch – Fibres carrying sense of light touch ascend the posterior columns on the same side as they enter, up to nuclei gracilis and cuneatus. Further fibres then cross the midline to ascend the brainstem in the medial fillet, being here joined by touch fibres from the face. They then pass to the thalamus and on to the post-Rolandic cortex. Other elements of touch on entering the cord ascend several segments, and then cross to the opposite side, enter the lateral spinothalamic tract, ascend this tract and end in the posterolateral ventral nucleus of the thalamus.

Pain and temperature – are transmitted only through short posterior root fibres which terminate in posterior horn at the level of root entry and 2 to 4 segments higher. Neurones of the second order cross to the opposite side, enter the lateral spinothalamic tract, ascend this tract and end in the posterolateral ventral nucleus of the thalamus. From the thalamus, sensory impulses pass through the posterior limb of the internal capsule and the thalamoparietal radiations to the post-Rolandic cortex. However lesions at cortical level cause little disturbance of pain and temperature.

Deep sensibility (appreciation of position and movement) – is conveyed centrally by way of long posterior root fibres which ascend in the ipsilateral posterior column. These fibres terminate about cell bodies in the gracile and cuneate nuclei, the fibres of which pass across the median plane and ascend in the medial lemniscus to the posterolateral ventral nucleus of the thalamus. A relay from the thalamus extends to the post-central gyrus of the parietal lobe.

Lesions confined to purely cutaneous nerves do not alter deep sensibility because in the peripheral nervous system the fibres subserving deep sensibility pass only in the nerves that supply muscles.

Localization of lesion – of disturbances of sensation.

SENSORY CORTEX LESIONS

- Extreme variability of response to sensory stimuli.
- Impairment of appreciation of posture and passive movement, light touch, and discrimination of two compass points.
- Affection of appreciation of size, shape, form, roughness and texture of objects (astereognosis), ability to distinguish between different weights (barognosis) and ability to recognise symbols written on the body, usually palms (graphaesthesia).
- Qualitative recognition of pain, heat and cold preserved but in dealing with thermal stimuli, e.g., heat, it may be difficult to say which of the two is hotter.
- Difficulty in appreciating intensity of stimuli.

SUBCORTICAL LESIONS

1. Hemianaesthesia affecting the contralateral face, upper and lower limbs.
2. Sensory loss severe and extensive.
3. No variability of response and threshold as in cortical lesions.
4. No alteration in appreciation of qualitative pain, heat and cold.
5. Astereognosis and loss of appreciation of position, passive movement, and tactile localization.

THALAMIC LESIONS

1. Gross impairment of all forms of sensation on opposite side of body if lesion extensive.
2. Loss of appreciation of posture, passive movement, and often of light touch.
3. Threshold for pain raised with exaggerated response to painful stimuli (hyperpathia).

BRAINSTEM LESIONS

1. *Lateral* – Hemianalgesia and thermoanaesthesia on opposite side of body. Intact postural sense, appreciation of passive movement and tactile discrimination.
2. *Lesions of medulla* – affecting the descending root of Vth nerve, and ascending spinothalamic tract from the rest of the body, e.g. posterior inferior cerebellar artery thrombosis – Loss of pain and temperature on one side of face and opposite side of body.

SPINAL CORD LESIONS

1. *Total cord lesion* – Bilateral loss of all forms of sensation below a definite level. The upper level of the lesion may be indicated by a zone of hyperaesthesia.
2. *Hemisection of spinal cord (Brown-Sequard syndrome)* – Common causes are compression of cord, intramedullary neoplasms, sometimes due to stab in the back, bullet-wounds, vertebral fractures or caries, vascular causes, arachnoiditis. *Cl. Fs.* – Contralateral loss of pain and temperature, ipsilateral loss of proprioception. At the highest level on the side of lesion there is a band of analgesia due to involvement of the root entry zone.
3. *Central (intrinsic) cord lesions* – e.g. syringomyelia or intramedullary tumours. Dissociated anaesthesia, i.e. loss of pain and temperature and preservation of proprioception and ‘discriminatory’ sensation.

4. *Dorsal column lesions* – e.g. subacute combined degeneration. (a) Loss of proprioception and vibration sense leading to ataxia. (b) Loss of deep pain (loss of tenderness of tendo-Achilles). (c) Positive Rombergism (ataxia occurs with eyes closed but not when they are open). (d) Hypotonicity (many spinocerebellar fibres travel in the posterior columns before entering the spinocerebellar tract).
5. *Posterior root entry zone* – e.g. tabes dorsalis. Severe sensory ataxia, impaired tactile discrimination, and impairment of deep pressure sensation, and of position, joint and vibration sense.
6. *Conus medullaris* – There is loss of sensation in the saddle area – upper and inner thigh and perianally. Involvement of the roots of cauda equina produces loss of sensation along the roots involved along with involvement of deep reflexes. The plantar is never extensor in conus medullaris or cauda equina lesions.

PERIPHERAL NERVE LESIONS

1. *Polyneuropathy* – Peripheral loss of sensation affecting both hands and feet (glove and stocking anaesthesia).
2. *Lesion of sensory root* – Loss of all forms of sensation over a clearly defined dermatome in one part of body only.
Hysterical – Anaesthesia of “glove and stocking” distribution of the limbs. Unlike polyneuropathy, there is an abrupt line of demarcation between the area of complete sensory loss and that where all sensation is normal. Areas of spurious sensory loss may be found elsewhere, e.g. over one-half of the skull. Reflexes are not diminished.

6. THE REFLEXES

DEEP REFLEXES

Figure 9 shows components of the spinal reflex mechanism of the quadriceps reflex (knee jerk). Table 20 gives causes of absent deep reflexes

A – afferent path;

B – efferent path;

C – pathway of cerebral inhibition.

Causes of exaggeration – Organic lesion of pyramidal tract, tetanus, strychnine poisoning, fright, anxiety.

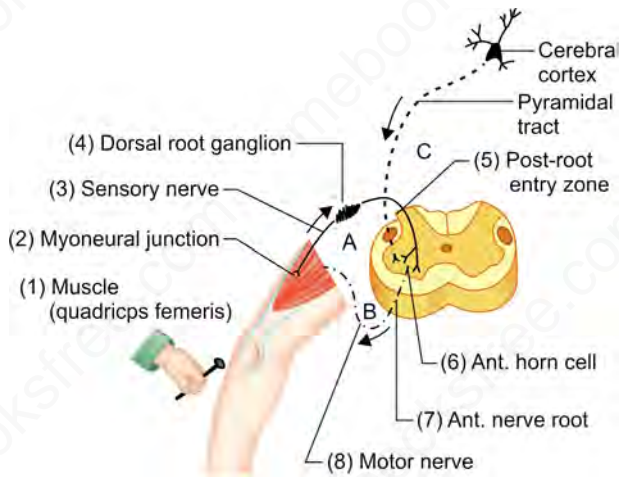

Fig. 9: Components of the spinal reflex mechanism of the quadriceps reflex (knee jerk)

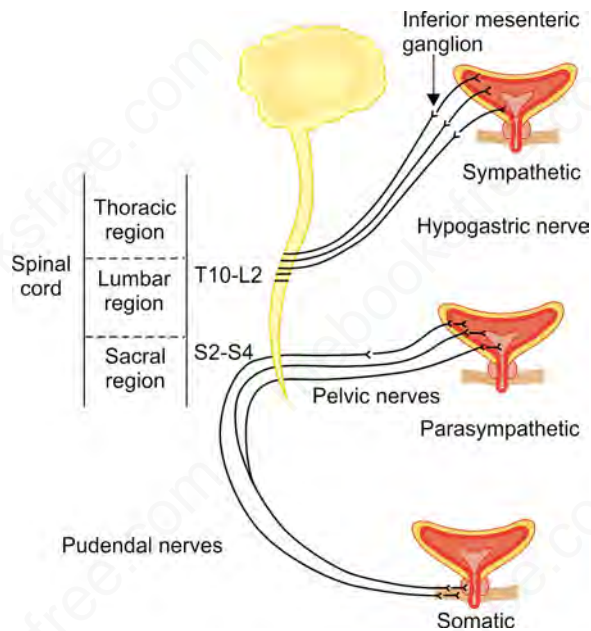

Fig. 10: Innervation of the lower urinary tract

7. NEUROLOGICAL DISTURBANCES OF BLADDER AND BOWEL

BLADDER DISORDERS

The two functions of the bladder are storage and voiding. Normal bladder control requires intact spinal connections between the pontine micturition centre and the sacral spinal cord (S2, S3, S4) (Fig. 10). The pontine centre receives input from higher centres, particularly the medial aspects of the frontal lobe. Disruption of spinobulbosacral

Table 20: Causes of absent deep reflexes

A. Focal lesions within reflex

1. Muscles – Myopathies, periodic paralysis.
2. Sensory nerves – Sensory polyneuritis, e.g. diabetes.
3. Posterior root ganglion – Herpes zoster of 3rd or 4th lumbar segment.
4. Posterior root entry zone – Tabes, subacute combined degeneration.
5. Anterior horn cells – Poliomyelitis, progressive muscular atrophy.
6. Anterior nerve root – e.g. tumour, spondylitis, radiculopathy.
7. Peripheral motor nerve – e.g. diphtheria, trauma.

B. Lesions outside the spinal reflex

1. State of cerebral or spinal 'shock' which occurs immediately after a severe cerebral catastrophe or spinal injury.
2. Muscle contracture – will produce depression in deep reflexes.
3. Normal individuals unable to relax.

Table 21: Neurological causes of voiding dysfunction

Suprapontine causes

- Cortical causes
 - Frontal lobe lesions
 - Normal-pressure hydrocephalus (NPH)
 - Cerebrovascular accident (ACA territory)
- Frontal tumors
- Dementia

Infrapontine causes

- Spinal cord injury
- Multiple sclerosis
- Neoplasms (metastatic, primary)
- Tropical spastic paraparesis (HTLV-I)
- A-V malformations
- Cervical myelopathy
- Myelitis

Subsacral causes

- Tethered cord
- Spina bifida
- L4-L5 central disc prolapse
- Cauda equina lesions – ependymoma, neurofibroma

Others

- Multiple system atrophy

micturition reflex pathway results in impaired storage and/or voiding. Neurological causes of voiding dysfunction are listed in Table 21.

TYPES OF BLADDER DISTURBANCES (NEUROGENIC BLADDER)

- I. *Upper motor neuron lesion* (Spastic neurogenic bladder). Bladder capacity is reduced and there are involuntary detrusor contractions. Infantile type of reaction with urgency. Detrusor sphincter dyssynergia. Detrusor instability:
- Cerebral lesions (Cortical bladder)* – (a) Patient voids in inappropriate places (frontal lobe incontinence, uninhibited bladder). (b) Associated mental deficiency. Usually patient is not aware of having soiled his clothes. Infection is common. There is complete emptying of bladder.
 - Spinal cord lesion (Spinal bladder)*:
 - Acute transection of spinal cord* – (i) Flaccid paralysis of bladder (denervated bladder). Bladder rapidly becomes distended and there is retention with overflow incontinence. (ii) Later as spasticity develops (as also spasticity in the legs), the bladder becomes spastic and contracted. Distension produced by accumulated urine provokes reflex contraction (automatic or reflex bladder). The bladder can be emptied by manual pressure. But contrary to cortical bladder emptying is incomplete.
 - Incomplete lesion of cord* – e.g. compression, multiple sclerosis, trauma. (i) Weak voluntary control remains. (ii) Urgency and precipitancy of micturition and difficulty in both initiating and inhibiting bladder action. (iii) Sensation of bladder filling and distension may or may not be present depending on whether or not sensory tracts are interrupted.
- II. *Lower motor neuron lesions* (Atonic or autonomous neurogenic bladder) – Lesion in micturition centre of

cord, cauda equina, sacral roots, or interrupting sacral reflex arc. (i) Continuous dribbling incontinence. (ii) Micturition can be initiated by suprapubic pressure. (iii) High infection risk.

- Posterior root lesions* (Sensory bladder) – e.g. tabes dorsalis, subacute combined degeneration, diabetes. Break of reflex arc on afferent side. (i) Bladder both insensitive and hypotonic, and overfills without patient being aware of it. (ii) Urine can be voided by considerable straining but evacuation is incomplete. (iii) Patient can initiate micturition as motor component is normal.
- Anterior root lesions* – Herniated disc or sacral cord lesions – e.g. spina bifida, tumour. Break of reflex arc on efferent side. Bladder partially paralysed (paralytic bladder) and hypotonic. There is painful distension of bladder but inability to initiate or continue micturition. In later stages there is compensatory distension of bladder and overflow incontinence.

Table 22 shows main types of bladder neurogenic dysfunction.

INVESTIGATIONS

(a) *Post-micturition residue estimation* – using ultrasonography or catheterization; a residue of more than 100 ml is most likely to contribute to bladder dysfunction. (b) Dynamic tests involving assessment of lower urinary tract for assessing detrusor behaviour. The tests involve measuring pressure-volume relationship during bladder filling and micturition using cystometry and a voiding study. (c) Patients at risk of upper tract disease should be assessed by *iv urography* and, if indicated follow-up *isotope renography*.

Table 22: Types of bladder neurogenic dysfunction

	<i>Uninhibited bladder</i>	<i>Spinal bladder</i>	<i>Cauda equina lesions</i>	<i>Sensory bladder</i>
Lesion	Higher cerebral centres in frontal lobe	Spinal cord above sacral	Cauda, pelvic nerves	Posterior columns, posterior roots involving sacral segments
Sensation	Normal	Normal	Pain, paraesthesiae in low back. Sacral, perineal	None
Residual urine	Nil	>100 mL	+	+++
Bladder capacity	Normal	Reduced	Bladder large	Large bladder
Voiding evacuation	Sudden uncontrollable inappropriate urge incontinence	Sudden and uncontrollable reflex, urgency and frequency Urgent incontinence incomplete emptying	Straining or dribbling Stress incontinence	Straining and dribbling

MANAGEMENT

Impaired emptying – A permanent indwelling catheter can be used, or patient taught to perform intermittent self-catheterization.

Impaired storage – Oxybutynin hydrochloride has both anticholinergic and musculotropic actions. Dosage: initial 2.5 mg b.d. with gradual increase.

Other treatment – Desmopressin 20 µg intranasally has antidiuretic effect and hence circumvents the problem of volume-determined detrusor hyper-reflexia.

Faecal incontinence – may be caused by loss of voluntary control over the pelvic floor. Cauda equina or a more selective injury may lead to pelvic floor weakness. Surgery may be required for sphincter or post-anal repair. Symptomatic treatment with constipating agent (e.g. loperamide) helps if no cause is found.

8. INVOLUNTARY MOVEMENTS

EPILEPSY AND CONVULSIVE MOVEMENTS

1. **Fits or convulsions** – are motor manifestations of epileptic seizure. Epileptic seizure is a sudden abnormal, excessive paroxysmal discharge arising from repetitive neuronal firing in the cortex – Grand mal, petit mal, focal cerebral seizures, etc (See Epilepsy).

Table 23: Causes of myoclonus

Physiological myoclonus – A phenomenon occurring at onset of sleep (Hypnic jerks).

Pathological myoclonus:

a. *Myoclonus occurring in epilepsy*

- Myoclonic static epilepsy
- LG syndrome
- Juvenile myoclonic epilepsy

b. *Progressive myoclonus*

- Familial disorders – Tay-Sachs disease, Lafora body disease, Gaucher's disease, Ramsay Hunt syndrome, benign polymyoclonus.
- Subacute sclerosing encephalitis
- Creutzfeldt-Jakob disease
- Alzheimer's disease.

c. *Metabolic disorders*

- Renal, hypoxic or hepatic encephalopathy
- Hyponatremia
- Hypocalcemia
- Alcohol and drug withdrawal.

2. **Myoclonus** – Sudden, brief, shock-like jerks. Muscles of face and limb are mainly affected. Movements may be stimulated by visual, auditory or tactile stimuli.

Types of myoclonus

Focal myoclonus – These myoclonic jerks may arise from the cerebral cortex, brainstem, spinal cord or peripheral ns. Cortical myoclonus is a form of focal motor seizure. If repetitive and regular, it is synonymous with epilepsia partialis continua. Brainstem myoclonus (palatal myoclonus) is a regular, slow, rhythmic movements of the palate and sometimes ocular, facial and diaphragmatic muscles.

Multifocal or generalized myoclonus – usually arises from the brainstem and may be stimulus sensitive, especially to sound. Table 23 gives causes of myoclonus.

Management – treatment of underlying condition. Drugs can be used are GABAergic Valproic acid, Clonazepam, Levetiracetam, Primidone, Piracetam.

3. **Opisthotonus** – Extreme hyperextension of neck and spine varying from arching of spine to a state of rigidity so marked that only heels and vertex touch the bed.

Causes – (i) Meningeal irritation, usually in children, (ii) extreme extrapyramidal rigidity, e.g. late stages of subacute encephalitis, (iii) tetanus, (iv) pontine hemorrhage secondary to tentorial pressure coning, (v) brainstem encephalitis, (vi) drugs – Dopamine blockers, (vii) hysteria.

MOVEMENT DISORDERS

1. **Chorea** – Involuntary, irregular random nonstereotype, purposeless, nonrhythmic, abrupt, rapid, unsustained, jerky movements that flow from one part to the other. Table 24 for the causes of chorea.

Table 24: Causes of chorea

Hereditary neurological disorders

- Huntington's disease
- Benign familial chorea
- Paroxysmal choreoathetosis
- Wilson's disease
- Neuroacanthocytosis

Other causes

- Kernicterus
- Levodopa
- Phenytoin, carbamazepine toxicity
- Infections – Tuberculoma, toxoplasma in HIV
- Antiphospholipid antibody syndrome
- Cerebrovascular – Basal ganglia (caudate, thalamus) infarct/hemorrhage

Table 25: Types of dystonia

1. Single part of body.
2. Segmental – Two or more contiguous parts of body, e.g. cranial dystonia (Meige syndrome) with blepharospasm, oromandibular dystonia and sometimes cervical dystonia.
3. Generalized dystonia – Segmental plus other areas (leg plus trunk).
4. Multifocal – Two or more noncontiguous parts of body.
5. Hemidystonic – affecting one half of the body.

2. **Dystonia** – Movements that are sustained, frequently twisting, repetitive patterned causing abnormal posturing due to contraction of agonist and antagonist muscles. Progress from action induced and specific to occurrence at rest and generalized. May be slow or shock like (myoclonic dystonia).

Table 25 for the types and Table 26 for the causes of dystonia.

Diagnosis and investigation – When focal brain lesions are identified, the basal ganglia particularly the putamen or rostral midbrain is usually involved. The most common cause is primary torsion dystonia (PTD). Dopa-responsive dystonia (DRD) and some secondary dystonias (e.g. Wilson's disease) are treatable and must be excluded.

Management – BOTOX (Botulinum toxin) injection into affected muscles under EMG guidance every 3 months provides symptomatic relief useful in focal dystonia. Wilson's disease should be ruled out in young patients. High dose central anti-cholinergic (trihexphenidyl: 20–120 mg/day) useful in children. Tetrabenazine 25–75 mg can be used with low dose titration.

3. **Ballismus** – Wild, rapid, flinging movements usually affecting the proximal joints of one arm, occurring constantly or with short remissions. Absent during sleep. Movement may be confined to one limb (monoballismus), one side (hemiballismus), or all the limbs.

Cause – The most common cause is a partial lesion (infarct or hemorrhage) in the STN, but cases can also be seen with lesions in the putamen, thalamus and parietal cortex. Structural lesions like granulomas

Treatment – Hemiballismus (hemichorea) may be controlled by therapy with tetrabenazine 25 mg bd or haloperidol 1.5–3 mg tds.

4. **Tremors** – Most common disorder is a rhythmic and regular movement that affects one or more body parts like limbs, neck, tongue, chin or vocal cords due to alternate or simultaneous contractions of agonists and antagonists. Two main types based on phenomenology are rest and action tremors. Table 27 gives classification of tremors:

Table 26: Causes of dystonia

1. **Primary (idiopathic) dystonia** – Pure dystonia.
2. **Dystonia plus syndromes**
 - Neurochemical disorders (dopamine responsive dystonia, myoclonus dystonia, dystonia plus Parkinsonism)
 - Huntington's disease
 - Wilson's disease
 - Corticobasal degeneration.
3. **Secondary dystonia** – due to structural brain damage.
 - Perinatal cerebral injury
 - Kernicterus
 - Encephalitis
 - Head trauma
 - Thalamic lesions
 - Antiphospholipid syndrome
 - Focal cerebrovascular lesions/stroke
 - AVM
 - Hypoxic injury
 - MS
 - Posterior fossa tumors
 - Cervical cord lesions, syringomyelia
 - Toxins – Mn, Co, methanol
 - Hypoparathyroidism
4. **Heredodegenerative diseases** (never pure dystonia)
 - X-linked recessive: Lubag
 - X-linked dominant – Rett syndrome
 - AD – Juvenile Parkinsonism
 - HD (usually chorea)
 - DRPLA
 - SCA 3
 - AR – Wilson's disease (with tremor, Parkinsonism)
 - MLD
 - Lesch Nyhan syndrome
 - Ataxia telangiectasia
 - Friedreich ataxia
 - Neuroacanthocytosis
 - HSP with dystonia
 - Juvenile neuronal ceroid lipofuscinosis
 - Niemann-Pick type (dystonic lipidosis)
 - Homocystinuria
 - Hartnup disease
 - Glutaric acidemia
 - Neurodegeneration with brain iron accumulation (PKAN)

Contd...

Contd...

Mitochondrial diseases
Leigh disease
Leber disease
With parkinsonian syndromes
Idiopathic Parkinson's disease, PSP, PP, LBD
CBGD

- A. Physiological – Fine, of a part of the body occurring under stress (usually hand and feet).
- B. Pathological tremors – Selective distribution, e.g. proximal or distal limb muscles groups, trunk or face, slower rate and disappearance during sleep.
- (a) *Tremor at rest* – Parkinson's disease, Parkinson's syndrome (drug-induced, post-encephalitic, CO poisoning); multiple sclerosis, trauma.
- (b) *Postural tremor* – Tremor that is most obvious on maintaining a position as in holding the arms outstretched – (i) Exaggerated physiological tremor – Anxiety, thyrotoxicosis, alcohol, caffeine, drugs, e.g. bronchodilators, tricyclic antidepressants, lithium, heavy metals (e.g. mercury). (ii) Structural brain disease – Wilson's disease, severe cerebellar disease, neurosyphilis, multiple sclerosis. (iii) Benign essential familial tremor.
- (c) *Intention or action tremor* – Brainstem or cerebellar dysfunction – Multiple sclerosis, spinocerebellar degeneration, drugs (e.g. phenytoin), stroke, tumour (e.g. medulloblastoma), alcohol, developmental (e.g. Arnold-Chiari malformation), non-metastatic paramalignant syndrome, trauma.

Clinical types

Benign essential (familial) tremor – Characteristically seen in the hands and sometimes the head and often precipitated by using the hands. It is frequently familial and aggravated by anxiety, tiredness, anger, fear. Alcohol may briefly alleviate the tremor. Drug therapy with propranolol or primidone may help.

Cerebellar tremor – (a) *Static tremor* – develops, if patient attempts to maintain a limb in a fixed posture. (b) *Action or intention tremor* – A disorder of co-ordination becomes evident in the distal part of the limb approaching its objective, e.g. in the finger nose test when there is a marked terminal wobble as the finger nears its object. Most frequently seen in multiple sclerosis.

Table 27: Classification of tremors

(a) <i>Rest tremors</i> – 3 to 6 Hz, with patient sitting or lying in repose.
(b) <i>Action tremor</i> – 8 to 10 Hz, while writing or pouring water.
(c) <i>Postural tremor</i> – 8 to 10 Hz, a type of action tremor with arms or legs.
(d) <i>Intention tremor</i> – A type of action tremor, bringing the finger to touch the nose.
(e) <i>Task-specific action tremor</i> – while writing only is primary writing tremor.
(f) <i>Orthostatic tremor</i> – 11 to 20 Hz, fast tremor while standing only. Responds to clonazepam.
(g) <i>Dystonic tremors</i> – Tremors associated with abnormal posturing (dystonia).
(h) <i>Rubral or midbrain tremors</i> – Combination of rest tremor worse with posture and action.
(i) <i>Slow tremors</i> – 1 to 3 Hz. Myorhythmia in brainstem pathologies, Whipple's disease.
(j) <i>Position specific tremor</i> – while holding a specific position like wing beating position.
(k) <i>Palatal tremor</i> – also referred to as palatal myoclonus resulting from lesions in Guillain-Mollaret triangle (formed by dentate nucleus, red nucleus, inferior olive via central tegmental tract).
(l) <i>Neuropathic tremor</i> – in HMSN, paraproteinemia associated neuropathies, reflex sympathetic dystrophy (usually postural tremors).
(m) <i>Fasciculatory tremor</i> – Irregular tremor caused by fasciculations of distal muscles across joints in MND and monomelic amyotrophy.
(n) <i>Cortical tremors</i> – A form of cortical myoclonus.
(o) <i>Psychogenic tremor</i> – Abrupt onset, spontaneous remission, various combinations of rest, postural and kinetic tremors, changing variable amplitude and frequency, increase with attention and less with distractibility, respond to placebo and psychotherapy.
(p) <i>Hereditary chin tremor</i> – AD inheritance.

Parkinsonian tremor – Usually begins in one upper limb and later involves lower limb on same side, the other side being affected in the same order after a further interval. Increased by emotional excitement and disappearing during sleep.

Flapping tremor (Asterixis) – detected at the wrists and fingers when the hands are outstretched. Seen in hepatic precoma, may occur in uraemia, barbiturate intoxication, CO₂ narcosis and respiratory failure.

Task-specific tremor – e.g. primary writing tremor, has the task specificity of dystonia, but the appearance of a localized essential tremor.

Orthostatic tremor – affects the legs and trunk and occurs only on standing still. The tremor may resemble essential tremor or be faster. It responds to clonazepam.

Wing beating tremor – A characteristic of Wilson's disease.

Pendular tremor (Red nucleus tremor) – Most violent form of tremor almost invariably seen in multiple sclerosis. Tremor often present at rest causing jerky extension movements of head, and inarticulate speech. Slightest attempt to move the arm is followed by severe wide amplitude tremor.

Neuropathic tremor – Tremor is unusual in peripheral neuropathy, but can occur in association with chronic relapsing inflammatory polyneuropathy, hereditary motor and sensory neuropathy and benign IgM paraproteinaemic neuropathy.

Searching movements – with eyes closed when afferent input is affected as in posterior column or parietal lobe lesion.

Infantile tremor syndrome – Rapid tremors usually affecting the whole body. Of unknown aetiology. An open mouth, vacant expression, light coloured sparse hair, pallor and puffiness of face may be other characteristics.

Hysterical tremor – A fine tremor localized to one limb or generalized, and a coarse irregular shaking intensified by involuntary movements.

5. **Tics:** are abnormal movements (motor tics) or abnormal sounds (phonic vocal tics). They can be simple or complex and occur abruptly. They are preceded by an inner urge (like akathisia) that is relieved by carrying out the movement. They are intermittent, repetitive, stereotypic. They can be voluntarily suppressed and are exacerbated with stress, boredom, fatigue. May persist in sleep:

- Simple motor tics – Shoulder shrug, head jerk, blink, twitch of nose.
- Complex motor tics – are coordinated patterns of sequential movements – touching the nose, kicking.
- Simple phonic tics – Sniffing, throat clearing, grunting, coughing, sucking sounds.
- Complex phonic tics – Shouting obscenities, profanities (coprolalia), repeating someone else's words (echolalia).

Causes – (i) Primary like Tourette syndrome, adult onset ticks, primary dystonia, HD, WD, neuroacanthocytosis. (ii) Secondary – encephalitis, drugs, e.g. levodopa, carbamazepine, phenytoin, dopamine blocking drugs. Toxins like CO. Mental retardation, Down syndrome, fragile X syndrome, head injury, stroke.

Writer's cramp – is a task specific focal dystonia usually of adult onset or childhood onset.

LOCALIZED INVOLUNTARY MOVEMENTS

Involuntary Movements of Face and Neck

- Spasmodic torticollis** – Tonic or tonic-clonic movements resulting in deviation of head to same particular direction.
Causes – Lenticular disease, arthritis of cervical joints, painful tooth, glandular swelling, acute dystonic reaction to neuroleptic drugs, or idiopathic.
Treatment – Anticholinergic drug may help. In some cases injection of botulinum toxin, or surgical division of spinal accessory nerve and upper cervical posterior primary rami may help.
- Titubation** – A vertical oscillation of the head seen when patient sits up or stands and disappearing on lying down. *Causes* – Disease of cerebellar connections, most commonly seen in multiple sclerosis, old age.
- Hemifacial spasms** – Twitching of muscles supplied by the facial nerve, usually a sporadic disease, clonic, tonic or paroxysm of clonic. MRI may show a vascular loop compressing the facial nerve root entry zone. Demyelination of facial nerve. A condition of varied aetiology in adults manifesting itself by clonic spasms of facial muscles and platysma on one side of face. Degree of affliction varies from slight and occasional twitching around mouth or eye to a constant severe spasm which screws up the eye and distorts angle of mouth. Spasm is both precipitated and exaggerated by excitement and tension.

Movements Limited to Muscles

- Fasciculations** – Visible spontaneous contractions of groups of muscle fibres supplied by a single anterior horn cell (single motor unit) indicate degeneration of anterior horn cells, or irritation of the anterior root. (Produced by denervation hyper-sensitivity to existing acetyl choline.) Table 28 lists the causes of fasciculations.
- Myokimia** – (a) Fine, rapid rippling of muscle fibres most commonly seen in orbicularis oculi usually due to fatigue, common in psychoneurosis. (b) Coarser contraction of bundles of muscle fibres both visible and palpable commonly in outer aspect of thigh, arms, pectorals and intercostals, common in fatigue and neurasthenic states. (c) Facial myokimia – Continuous movements likened to a 'writhing bag of worms'. The condition may occur in attacks and is usually associated with structural disease of the brainstem (pontine glioma) in particular with multiple sclerosis and intrinsic brainstem tumour, or in Guillain-Barre syndrome.

Table 28: Causes of fasciculations

• Benign or physiological following exertion
• Anterior horn cell diseases
– Motor neuron disease
– Syringomyelia
– Hereditary spinal muscular atrophies
– Acute phase of poliomyelitis
– Spinal cord tumour or ischemia.
• Poisoning
– Organophosphorus poisoning
– Nerve agent exposure

3. **Writer's cramp** (Craft) – A specific complaint of inability to write (or type) may occur as a presenting feature of a psychological disturbance or a variety of diseases such as joint disease, carpal tunnel syndrome, Parkinson's disease, spastic or ataxic hand, benign essential tremor and torsion dystonia. Task specific dystonia.
4. **Focal dystonia** – Dystonia, particularly when it begins in adult life, often takes the form of a localised involuntary movement affecting one part of the body.
5. **Flexor-extensor spasms** – in paraplegic patients.
6. **Blepharospasm** – Intermittent spasms of contraction of orbicularis oculi sometimes seen in Parkinson's disease or torsion dystonia, or provoked by neuroleptic drugs. May occur as isolated phenomenon and without apparent cause in middle-aged or elderly patients. It is a focal dystonia.
7. **Orofacial dyskinesia** – Spontaneous movements of mouth, lips and tongue in elderly and chronic psychiatric patients. Most commonly seen as a result of prolonged treatment with neuroleptic drugs. May occur in Huntington's chorea or torsion dystonia, or rarely spontaneously (levodopa therapy).
8. **Palatal myoclonus** – Regular, rhythmic contraction of soft palate, causing the uvula to bob up and down, and speech to be tremulous. Usually appears acutely following vascular lesion in region of red nucleus, olive or dentate nucleus; may occur with tumours in the same region.
9. **Shivering** – Rapid regular movement of the whole muscle due to cold or nervousness.
10. **Akathisia** – is a state of extreme restlessness with and inner urge to move about and is seen most often as a side effect of neuroleptic drugs, i.e. as a symptom of tardive dyskinesia.

11. **Startle** – is a natural defensive reaction, which may be excessive in some families and insuppressible (hyper-reflexia). It is also a prominent feature, with myoclonus, of the spongiform encephalopathies.

Drug-induced involuntary movements – (i) *Tremor* – bronchodilators, tricyclics, valproate, lithium. (ii) *Pseudo-parkinsonism* – Phenothiazines, butyrophenones like haloperidol, reserpine, tetrabenazine. (iii) *Acute dystonias* – Phenothiazines, butyrophenones, metoclopramide, diazoxide. (iv) *Akathisia* (inability to sit still) – Phenothiazines, butyrophenones. (v) *Tardive dyskinesia* – Phenothiazines, butyrophenones.

9. GAITS

DIAGNOSTIC IMPORTANCE IN NEUROLOGY

Unilateral Defect

1. **Hemiplegic (circumduction) gait** – Active forward projection of paralysed limb difficult; front of foot, especially the lateral part of the sole against the ground.
2. **Unilateral high-stepping gait** – of flaccid type in compression of external popliteal nerve or damaged anterior horn cells as in polio. Hip and knee lifted too high in order to clear the drop foot from the ground, and brought loosely down.
3. **Limping gait** (Antalgic gait) – in sciatica. Patient limps with short steps, keeping the painful limb semiflexed and dropping the pelvis, towards the painful side.
4. **Hysterical gait.** (i) **Forward gait** – unilateral dragging gait with scraping of the inner border of the foot, as opposed to the outer border in organic hemiplegia; or the whole foot is dragged along the ground. (ii) **Side gait** – In hysterical hemiplegia, side gait impaired on both sides. In organic hemiplegia the patient moves sideway towards the paralysed side well, but badly towards the healthy side.

Bilateral Defect

1. **Spastic gait** – In spastic paraplegia patient moves swiftly along with abnormally short steps, the front part of the foot clinging to the ground, produced by bilateral circumduction of the legs. In severe cases, tendency to ankle clonus causes a trepidation of the whole body from tremors of the feet.
2. **Scissor gait** – A form of spastic gait with legs crossing alternately in front of each other, producing the cross-legged or "Scissor" gait in congenital cerebral diplegia.

3. *Ataxic gait* - (a) *Cerebellar* - Gait is of two types - (i) Ataxia of legs (Reeling gait). Broad based, walks like a drunkard - The patient tends to reel in several sideways steps towards the side of lesion. (ii) Ataxia of trunk - Patient is grossly unstable and reels in any direction. This is seen in midline posterior fossa lesion including tumours of vermis and foramen magnum abnormalities. (b) *Titubant ataxia* - Ataxia with vertical oscillation of head, trunk and arm in multiple sclerosis.
4. *Reeling or tottering gait* - in severe vertigo, diplopia or alcoholic intoxication. Unsteadiness especially marked on sudden turning.
5. *Vestibular gait* - Tilts to same side when walking forwards and to the opposite side when walking backwards.
6. *Bilateral high steppage (equine) gait* - Patient lifts the leg too high flinging the ankle up (slapping gait) due to foot drop. This type of gait when bilateral is seen in polyneuritis, muscular dystrophies, peroneal muscular atrophy and sometimes lesions of cauda equina.
7. *Stamping gait* - seen in tabes dorsalis where the patient walks on a broad base, lifts the legs unduly suddenly and violently, raising them too high and then bringing them down forcibly stamping the heels on the ground (stamping gait). May also occur in carcinomatous neuro-myopathy or compressive lesions of posterior columns.
8. *Festinant or shuffling gait* - (Small step gait). Movement in a series of small shuffles either due to rigidity of extrapyramidal disease or combined rigidity, instability and lack of confidence in cerebral arteriosclerosis.
9. *Waddling or duck-like gait (myopathic gait)* - The pelvis is rotated through an abnormally large arc, accompanied by compensatory movements of the upper trunk and associated with marked lordosis. Usual causes are progressive muscular dystrophy and other myopathies, chronic forms of spinal muscular atrophy and congenital dislocation of the hips.
10. *Jaunting gait* - in chorea. Sometimes one foot seems to be momentarily entangled by an invisible obstacle which holds the child back for an instant, or his knee may give way suddenly causing him to fall.
11. *Toppling gait* - is characterised by tottering and sudden lurches, resulting in a hesitant and uncertain gait and unexpected falls, in the absence of weakness, ataxia, or loss of deep sensation. It is observed in progressive supranuclear palsy, advanced stages of Parkinson's disease and some cases of inferior cerebellar infarction (toppling to one side only).
12. *Frontal lobe disorders of gait* - Posture is fixed, the base somewhat widened, the gait slow, steps small, marches at the place (slipping clutch sign), hesitant and eventually shuffling (*marche de petit pas, magnetic foot*). Seen in diffuse cerebrovascular disease. Final stages are associated with dementia, oppositional resistance (*genenhalten*) and rigid flexed posture (cerebral paraplegia in flexion).
13. *Gait of normal pressure hydrocephalus* - In absence of significant weakness, tremor, rigidity or ataxia, the base becomes widened, the gait is slowed, the height and length of each step are diminished, with a tendency to shuffle. Difficulty with initiation of gait and tendency to fall backwards are late signs.
14. *Hysterical gait* - A bizarre gait not resembling any known pattern of organic disease. Absence of neurological signs.
15. *Spastic springing gait* - In lathyrism - at first patient walks on tip toe, the body is raised high before the toes leave the ground, giving rise to up and down movements of the shoulder, and progression is effected by tilting the pelvis and circumducting the legs. The legs are crossed scissorwise. Later patient uses one or two long sticks.
16. *"Frog" like gait* - In later stages of muscular dystrophy when the power of standing erect is lost. The patient crawls on hands and toes.
17. *Violent contortions* - of spinal column when walking in torsion dystonia.
18. *Transient dyscrasias* - e.g. intermittent arterial claudication. Normal walk at start, but after going some distance, patient stands still or sits down to rest till the spasm relaxes and then starts off again.
19. *Gait in myotonia congenita* - As soon as the patient starts to walk, the first steps are like those of a man dragging out of a deep mud-hole but as the patient perseveres, the muscles become active and the gait normal.
20. *Dromedary or camel back gait* - with protrusion of buttocks in facioscapulohumeral dystrophy.
21. *Toe-walking gait (Tip-toe gait)* - Tight heel cords limit dorsiflexion of the foot makes patient stride on the balls of his feet, without a definite heel strike. Such a gait occurs in Duchenne's muscular dystrophy, dermatomyositis, in spastic diplegia and in autistic or retarded children.
22. *Nocturnal flipping hand gait* - In carpal tunnel syndrome, patient may get up in the night and walk about the room flipping or shaking his hand in an effort to gain some relief.

23. *Dancing bear gait* - The effort to walk after trying to rise from the chair, may result in stepping on the same spot, as if trying to free the feet, from sticky mud.
24. *Charlie Chaplin gait* - In homocystinuria most patients have to out gait, with bilateral hip flexion contractures patient adopts this gait with both buttocks prominent.

10. HEADACHE

CAUSES

I. Intracranial and local extracranial

1. *Trauma* - Contusional or post-traumatic headache.
2. *Intracranial inflammations* - Meningitis, encephalitis, cerebral abscess.
3. *Vascular headaches* - Hypertension, cerebral or subarachnoid haemorrhage, intracranial aneurysm, vasodilator drugs like nitrites and histamine, adrenaline. Menopausal. Alcohol hangover or withdrawal, coffee withdrawal. Giant cell arteritis (temporal arteritis), thrombosis of intracranial venous sinus.
4. *Traction headache* - Pain produced by intracranial arterial displacement and distortion of the dura, usually caused by space occupying lesions or raised intracranial pressure or low intracranial pressure (intracranial hypotension).
5. *Post-lumbar puncture headache* - Low CSF pressure headache.
6. *Cough headache* - A benign syndrome of severe headache which accompanies coughing, straining or sneezing can be due to posterior fossa tumour.

II. Cranial neuritis and neuralgias

Of sensory nerves of scalp, e.g. orbital neuralgia, or neuralgia of auriculotemporal, posterior auricular or great occipital nerves, herpes of Gasserian ganglion.

III. General or systemic causes

1. *Anoxaemia* - Anaemia, carbon monoxide or carbon dioxide poisoning.
2. *Toxic* - Fevers, uraemia, eclampsia, metallic poisoning, "alcoholic" hangover, post-convulsive, drugs like quinine, tobacco, cocaine, morphine, sulphonamides. Pelvic or gall bladder disease, constipation, intestinal stasis. Nervous exhaustion.
3. *Metabolic factors* - Hypoglycemia, alkalosis or acidosis.
4. *Haemopoietic factors* - Essential polycythemia, thrombasthenia.

IV. Referred pain

1. *Eyes* - Errors of refraction, glaucoma, iritis, etc.
2. *Ears* - Otitis, mastoiditis, vestibular nerve lesions, Eustachian tube block, tumours of middle and inner ear.
3. *Teeth* - impacted teeth, infected tooth sockets and dental roots.
4. *Paranasal sinuses* - Infection of paranasal sinuses may cause localised pain.
5. *Neck* - Diseases of upper cervical spine may be associated with both occipital and frontal pain.

V. Psychogenic

Common cause of headache in depression.

VI. Tension (muscle contraction) headache

Pain resulting from sustained contraction of skeletal muscles of the neck, frontalis, occipital muscles due to emotional tension.

VII. Exertional headache

Headache may come on during exertion and persist for few hours afterwards.

VIII. Other primary headaches

- (i) Hypnic headache syndrome is a late onset disorder and usually wakes up the patient from sleep at around the same time every night. The headache is usually treatable with flunarizine and lithium.
- (ii) Exploding head syndrome can occur any time during day or night.

INVESTIGATION OF A CASE OF HEADACHE

History

1. *Incidence* - Anxiety headaches, migraine, and those due to fevers, sinus disease and eyes most common.
2. *Age* - (a) *Children* (3-16 years) - Migraine, fatigue / psychogenic, post-traumatic, rarely tumour (post-fossa). (b) *Adults* (17-65 years) - Tension, migraine, cluster, post-traumatic, tumour/subdural hematoma. (c) *Elderly* (above 65) - cervicogenic, chronic tension, cranial arteritis, continuing migraine, tumour/subdural hematoma, glaucoma, cluster, Paget's disease of skull.
3. Onset and duration of headache -
 - (i) *Acute headache* - Trauma, spontaneous intracranial hemorrhage, hydrocephalus, tonsillar impaction or acute meningeal irritation (SAH or meningitis). Acute tension headache or migraine.

Thunder clap headache - Acute severe intensity headache in SAH, reversible vasospasm.

- (ii) *Recurrent or chronic headache* - Migraine, migraine plus tension headache (mixed headache) or daily continuous headache (tension headache), are the three common headache syndromes.
4. *Character* - (a) *Pulsating or throbbing* in fever, migraine and arterial hypertension. Sense of tightness or external pressure in brain tumour and meningitis. (b) *Most intense headache* usually in subarachnoid hemorrhage, migraine, fever, meningitis, hypertension, acute cerebral venous thrombosis and terminal phase of brain tumour. (c) *Paroxysmal* in neuralgia. (d) *Psychogenic headache* is often described in over-elaborate terms. (e) *Pain with intracranial tumour* is usually deep, nonthrobbing, dull aching, on waking up, intermittent and lasts from few minutes to hours. (f) *Tension headache* usually bilateral and described as band or cap-like pressure, or constant headache with sharp jabs of pain. Pain usually worse in evenings. (g) *Traction headache* has a bursting quality, typically wakes the patient but disappears soon after rising. (h) *Headache of raised ICP* - Dull ache, worse in morning, worse on coughing, straining, bending. (i) *Cluster headache* - pain is deep, usually retroorbital, often excruciating in intensity, nonfluctuating and explosive in quality. A core feature of cluster headache is periodicity (j) *Paroxysmal hemicrania (PH)* is characterized by frequent unilateral, severe short-lasting episodes of headache. (k) *Short lasting unilateral neurologic headache attacks syndrome* has manifestations of an overlap between cluster headaches and trigeminal neuralgias. (l) *Drug-rebound headache* when offending drug is withdrawn, the prophylactics which were not effective start working and frequency of headaches comes down.
 5. *Site and distribution* - Pain with local distribution suggests organic cause. Psychogenic headache usually diffuse, though first evident in neck and occiput. Headaches due to hypertension, cerebral tumour, toxic, infective and reflex headaches also usually diffuse. A unilateral headache in one or other temple may be due to temporal arteritis or intracranial causes such as inflammation or compression. Sinus headache in front of head at onset. Headache bizarre in quality and varying in location usually of psychogenic origin. Posterior headaches extending into the nuchal region or even the shoulder muscles are almost always due to muscle tension.
 6. *Provoking and aggravating causes* - Migraine made worse by assuming horizontal position or by jolting. Lying down position may at first make the headache

of sinusitis more intense but subsequently it subsides. Sudden change of position or head jolt may aggravate headache of intracranial tumour. Muscle contraction headache usually reduced by movements of head and neck. Psychogenic headache likely to be increased by emotional stress and mental fatigue. Vascular or inflammatory headaches of intracranial origin are accentuated by coughing or other forms of brief straining.

7. *Associated symptoms* - (a) *Nausea, anorexia and vomiting* most common in migraine, vomiting without nausea in brain tumours. (b) *No vomits* in headache of sinus or eye disease. (c) *Visual disturbances* usually precede headache in migraine. When visual defects outlast the headache, likelihood of cerebral vascular accident or brain tumour. (d) *Depression or anxiety* in psychic headache. (e) *Symptoms of nasal obstruction*, or discharge, or pharyngeal discharge in sinusitis. (f) *With facial pain syndromes* - Tension headache, migraine, raised intracranial pressure, benign paroxysmal headache, trigeminal neuralgia, atypical facial pain, post-herpetic neuralgia. Visual obscuration in elevated intracranial pressure.
8. *Sleep* - Long periods of insomnia because of headache most likely due to anxiety. Meningeal headaches may produce loss of sleep.
9. *Family history* - of migraine.

Physical Examination

1. Of the whole body including neurologic examination.
2. Tenderness - of muscles of head and neck in myositis, of scalp in tension headache. Muscle spasm in meningitis. Local tenderness at site of periostitis of bone. Tenderness of scalp after head injuries. Tenderness over temporal arteries in temporal arteritis.
3. Palpation of skull - may reveal the engorged and strongly pulsatile scalp artery of a migraine headache or tenderness and localised erythema of temporal or other cranial arteries.
4. Blood pressure - Accelerated hypertension.
5. Auscultation of mastoid region, and of eyes with the lids gently closed for a bruit.
6. Fundus examination - Papilloedema.
7. Examination of sinuses - Sinus tenderness.

Psychiatric Evaluation

For depression, repressed hostility, aberrant personality problems, most patients with emotion-induced headache.

IV. Investigations

1. X-rays – (a) Of paranasal sinuses. (b) Of skull for evidence of increased intracranial tension or pineal shift. (c) Of cervical spine – for cervical spondylosis.
2. CSF – for evidence of meningitis, cerebral abscess or subarachnoid hemorrhage. CSF pressure manometry for pseudotumour cerebri.
3. Complete blood count – Leucocytosis in meningitis, sinusitis, cerebral abscess. Evidence of anaemia, dyscrasias, leukaemia.
4. Serological tests – for neurosyphilis.
5. Urine – Chronic urinary infection.
6. Fasting blood sugar – Hypoglycemia.
7. Serum creatinine – Uraemia.
8. ESR – Raised in temporal arteritis and infections.
9. EEG – High incidence of abnormality in patients with vascular headaches.
10. CT scan – for diagnosis of intracranial tumours especially fast growing neoplasms such as pituitary tumours, acoustic neuroma, craniopharyngioma.
11. Cerebral angiography – for tumour, berry aneurysm or angiomatous malformation.
12. MRI – is particularly useful for delineating and identifying tumours at the base of the skull, and for demonstrating metastatic lesions. Magnetic resonance imaging is more sensitive in the brain than CT scan, but sometimes less specific.
13. MRV – for venous sinus thrombosis.

Biopsy of Affected Artery

(usually temporal) in giant cell arteritis.

Response to Treatment

Tension headache may be relieved with tranquillizers or infiltration with 10 to 20 mL. One percent procaine solution, if localised areas of tenderness can be outlined. Sumatriptan relieves migraine. Sinus puncture or antibiotics relieve headache of sinusitis.

MIGRAINE

Recurrent attacks of headache, varied in intensity, frequency and duration; commonly unilateral in onset, and usually associated with anorexia and sometimes with nausea and vomiting. Some are associated with conspicuous sensory, motor and mood disturbances.

Aetiology

(i) *Age* – The onset may be in childhood with cyclical vomiting; typical migraine appears in adolescence and continues at intervals until the sixth decade, when the attacks may cease apart from occasional teichopsias. (ii) *Sex* – More common in women. (iii) *Hereditary influences* – the transmitted factor being an abnormal response of cranial and other vasculature to certain external or endogenous stimuli. (iv) *Precipitating causes* – Prolonged fasting, prolonged exposure to bright light. Particular foods, especially cheese, chocolates, citrus fruits, bananas, coffee. Mild associated head injury, e.g. heading a football. Changes in the degree of stress. (v) *Conditions associated with migraine* – Tension headache, the periodic syndrome (recurrent bilious attacks of childhood), epilepsy, allergy.

Mechanisms: Familial tendency towards enhanced vascular contractility in migraine patients produces a sequence of constriction and dilatation. Stimuli which normally produce a healthy flush may produce an incoordinated circulatory response in migraine patients resulting in constriction of small vessels and dilatation of arteries and veins. Serotonin released from platelets produces vasoconstriction. Serotonin then gets adsorbed into vessel wall and in combination with locally released heparin and neurokinin produces pain. Fall of plasma serotonin results in overaction of dilator substances like histamine, bradykinin and prostaglandin E. Serotonin release from platelets is increased by free fatty acids and IgG aggregate.

Classical Migraine

Prodrome – Vague, yawning, euphoria, excessive energy or depression and lethargy.

Aura – usually visual. Flashing lights, zigzag castellations, balls or filaments of light may start peripherally and centrally. Fragmentation, jigsaw appearance (teichopsia), with or without central scotomata, micropsia and metamorphosis are common. The aura typically lasts half hour and is succeeded by headache.

Headache – May be hemicranial or soon becomes generalised. Starts as vague pain and builds up to a throbbing intensity, over the temporal or frontal region associated with pallor, anorexia, nausea, vomiting and photophobia. It may last for several hours and after vomiting has occurred, may decrease in intensity and be followed by sleep. In some headache persists for 48 hours or more. During the headache the superficial temporal artery may be congested and pulsating.

Simplified Diagnostic Criteria for Migraine

Repeated attacks of headaches lasting 4–72 hours that have features listed in Table 29.

Migraine Variants

Common migraine - More common than classical migraine, it is less often unilateral and not preceded by aura. Attacks are more often related to factors such as menstruation and relaxation after stress.

Vertebrobasilar migraine - Due to spasm of vertebrobasilar artery. Usually starts in third decade and differs in symptomatology from classical migraine - Aura may include ataxia, bilateral paraesthesiae, vertigo, diplopia or even transient loss of consciousness. Headache is commonly occipital.

Hemiplegic migraine - Often familial. Headache is followed by contralateral hemiparesis or hemiplegia which may last up to 10 days. Patient may have several attacks affecting one side of the body, whereas the next attacks may affect the opposite side.

Migrainous neuralgia (Cluster headache) - occur mainly in men. (i) *Episodic* - (a) Severe unilateral supra-orbital and/or temporal pain lasting 15–180 minutes, if untreated. (b) Headache associated with at least one of the following on the painful side namely conjunctival injection, lacrimation, nasal congestion, rhinorrhoea, forehead and facial flushing, miosis, ptosis, eyelid oedema. (c) Incidence of attacks range from one attack on alternate days to eight attacks/day. (ii) *Chronic* - Attacks occur for more than one year without remission, or with remission lasting less than 14 days. Occur in clusters with headache free period.

Treatment - Oral or rectal ergotamine 1–2 mg should be given at onset of headache. Not more than 12 mg/week,

or sumatriptan 100 mg p.o. or 6 mg s.c. given in anticipation of attack; or with methysergide 1–2 mg t.d.s. or verapamil 40–80 mg t.d.s., for the duration of cluster. Oxygen 6–8 litres/min, often affords relief within 10 mins. In more refractory cases Prednisolone 40 mg/day reducing over 3–6 weeks and lithium carbonate 250–1500 mg/day may be beneficial.

Post-traumatic migraine - A minor head injury or heading the ball in soccer players (footballer's migraine) may result in a migrainous type of headache, accompanied by vertigo and occasionally vomiting.

Ophthalmoplegic migraine - Headache is commonly around the eye and is accompanied by weakness of movement of one eye (usually III nerve) which may outlast the headache by some days. Children are more commonly affected.

Facial migraine - Unilateral episodic facial pain associated with symptoms suggestive of either migraine or cluster headache. It can be distinguished from migrainous neuralgia by longer duration of pain, lack of clustering, and more frequent episodes of nausea and vomiting.

Abdominal migraine - typically occurs in children, paroxysmal mid-abdominal pain with nausea and vomiting, flushing or pallor.

Retinal migraine - Loss of vision limited to one eye.

Complicated migraine - Patient is left with a persistent neurological deficit after a migraine attack. This occurs most commonly after hemiplegic migraine. CT scan has revealed this to be a much more common occurrence than previously believed, and the pathological basis is presumably infarction after ischemia.

Symptomatic migraine - The term is used when symptoms suggest diagnosis of migraine but where a structural lesion is found such as angiomatic malformation usually in occipital lobe.

Vestibular migraine - Migraine can present with vertigo.

Childhood migraine - Children with migraine may present with transient neurologic, autonomic, GI or visual symptoms and headache may not be the primary symptom. The duration is short. Pain may be unilateral or bilateral (bifrontal or bitemporal).

Menstrual migraine - develops most frequently in the second decade of life and can be a part of premenstrual syndrome usually without aura, and resolves with onset of menstruation.

Migraine equivalents - Prodromal symptoms occur without headache or vomiting.

Table 29: Criteria for migraine

A. Normal physical examination
B. No other reasonable cause for the headache
C. At least two of:
- Unilateral pain
- Throbbing pain
- Aggravation of pain by movement
- Moderate or severe intensity
D. At least one of:
- Nausea or vomiting
- Photophobia and phonophobia

Management

During Attack

1. *Analgesics* - NSAIDs, e.g. diclofenac can be given p.o. or i.m. and is particularly useful when severe vomiting is a feature.

Sublingual Piroxicam has significant analgesic effects in acute migraine without aura with excellent tolerability

2. *Ergotamine* - (a) Ergotamine tartrate 0.25 to 0.5 mg i.m. or orally 1-2 mg. tablet preferably in combination with 100 mg caffeine - 2 tablets at onset followed by 1 tablet after 30 minutes, if necessary, or (b) Dihydroergotamine 1 mg i.m., or 1-2 mg by mouth. Whichever preparation is used, a high dose often causes nausea and vomiting. These may be prevented by giving cyclizine 50 mg. or chlorpromazine 25 mg. Contraindications to ergotamine - Septic or infectious states, peripheral vascular disease, coronary disease, pregnancy, thyrotoxicosis.
3. *5-HT₁ agonists* - are thought to modulate central pain mechanisms by reducing levels of the transmitter substance calcitonin gene related peptide.

Sumatriptan 6 mg s.c. gives relief from headache in 60 minutes, with corresponding improvement in nausea, vomiting and photophobia. Oral dose of 100 mg provides relief within 2 hours. Headaches recur within 48 hrs in little less than half the patients. Contraindications - IHD, Prinzmetal's angina and arrhythmias.

Rizatriptan given orally acts faster than sumatriptan. Rizatriptan wafers may be helpful in cases of nausea with migraine, as they can be taken without fluids, reducing the likelihood of vomiting. Side effects include chest pain and paraesthesia. Naratriptan 1mg or 2.5 mg has less rebound and is more effective.

Zolmitriptan nasal spray 5 mg gives relief in 5 minutes.

4. *General* - Lying in a darkened and quiet room and ice pack to the head may help.

Reducing Frequency and Severity of Subsequent Attacks

1. Elimination of trigger factors - e.g. Sleeping late, irregular and hurried meals, certain foods, especially chocolate and fried food, or missing of meals, psychological stress, contraceptive pills. Treatment of cervical spondylosis.
2. Relaxation exercises - which may include biofeedback from a temporalis electromyogram. Yoga, Pranayama.

3. *Drugs:*

- (a) *Serotonin (5-HT) inhibitors* - (i) *Calcium antagonists* - such as Flunarizine 10 mg/day (ii) *Cyproheptadine* 4 mg t.d.s. (can cause sedation and wt. gain). (iii) *Pizotifen* 0.5 mg t.d.s. or 1.5 mg nocte. (iv) *Methysergide* 1-2 mg t.d.s. is the most effective drug in this group but should be used under supervision in courses not exceeding 3-4 months. Pleural, pericardial and retroperitoneal fibrosis are serious side effects.
- (b) *Topiramate* - an antiepileptic drug used in prophylaxis of migraine, Dose: 2.5 to 5 mg b.d. Side effects - Paraesthesia, renal calculi and wt. loss, fatigue, anorexia.
- (c) *Divalproex (valproic acid)* 200 mg b.d. Side effects - weight gain, tremor, hepatotoxicity.
- (d) *Tricyclic agents* - e.g. Amitriptyline 25 mg tds may be effective irrespective of the presence of depression.
- (e) *Ergotamine tartrate* - for histamine cephalgia 1 mg. by mouth or 0.25 mg by self-administered injection or by suppository used regularly last thing at night can be continued for many weeks without harmful effects, 2 days being left without treatment each week.
- (f) *Hormones* - Progesterone given for last eight days may be useful for migraine occurring in the immediate premenstrual period or at beginning of catamenia. When migraine begins or becomes worse at the time of menopause, oestrin, given in small doses as continuous therapy sometimes helpful.
- (g) *Schedule* - (a) Propranolol 40-160 mg/day or flunarizine 5-10 mg/day as first line of therapy. (b) In patients with episodic and chronic migraine Topiramate 50-100 mg/day. (c) In patients with episodic migraine Divalproex 250-750 mg/day (d) For mixed migraine and tension type headache - Amitriptyline 10-25 mg/day. After 6-12 months of prophylaxis gradual withdrawal should be considered.

11. EPILEPSY

Epilepsy - It is a tendency for recurrent unprovoked seizures, usually two or more seizures. Characterized by recurrent episodes primarily of cerebral origin, in which there is a disturbance of movement, sensation, behaviour or consciousness. These episodes begin suddenly and have a tendency to disappear spontaneously.

Causes: Almost all disorders involving the grey matter can cause epilepsy.

Type of seizure – An epileptic seizure is an abnormal paroxysmal discharge of cerebral neurons sufficient to cause events that are apparent to the subject, an observer or both.

- Partial seizures begin locally in the cortex. Such seizures may spread and become generalized, involving the whole of the cortex.
- Generalized seizures in contrast, involve much of the cortex bilaterally from the outset, and always cause immediate loss of consciousness.

GENERALIZED SEIZURES

Generalized tonic-clonic seizure, following a partial seizure or occurring spontaneously, may be heralded by a cry, followed by loss of consciousness, falling to the ground with spasm of the limbs and deepening cyanosis in the tonic phase; the subsequent clonic phase is marked by stertorous breathing, and jerky limb convulsions of increasing amplitude and decreasing frequency. The tongue may be bitten. Incontinence of urine and faeces may occur. The seizure is typically followed by coma with an ascending consciousness level, then by confusion, headache, aching limbs and a desire to sleep, before complete recovery.

Epileptic myoclonic jerks (usually a sudden flexion movement of the arms) are also generalized seizures and occur in various syndromes. They are usually not associated with loss of consciousness, unless accompanied by absences.

Absences are generalized seizures, and may be simply a sudden brief cessation or slowing of activity, with rapid return to normality without loss of posture. It manifests as subtle motor activities like rapid blinking, chewing movements or movement of hands. Typical absences are accompanied by characteristic 3 Hz spike-and-wave EEG activity. Atypical absences show slower or poorly formed spike-wave EEG activity (frequency ≤ 2.5 Hz); they may be more prolonged than typical absences.

Atonic seizures – characterized by sudden loss of postural muscle tone with brief loss of consciousness without postictal confusion.

Partial seizures (Focal seizures) – Occur in wide variety of forms. Consciousness is not impaired in simple partial seizures. Complex partial seizures are defined by impairment of consciousness, which may occur from the outset or may evolve from a simple partial seizure, automatism may also occur.

Temporal lobe seizures – are partial complex seizures associated with abnormal experiences of smell or feelings of unreality (*jamais vu*) or undue familiarity (*déjà vu*). Visual hallucinations may be seen and absence attacks or vertigo or rising epigastric sensation may occur.

Automatisms (semi-purposeful release phenomena) can occur in complex partial seizures or prolonged absences. Clinical features include lip-smacking, swallowing, fidgeting with the hands and more complex behaviours including vocalization, speech and wandering.

Status epilepticus – Recurrent seizures without gap of consciousness. The duration is usually 60–120 secs. Seizures lasting more than 30 minutes is established status. Treatment should be initiated, if seizures lasts more than 5 min (early status).

Any seizure type may occur, usually in patients known to have epilepsy.

- Generalized tonic-clonic status epilepticus is the most dramatic; the most common causes are anti-epileptic drug withdrawal or non-compliance, meningitis, encephalitis (Figs. 11 and 12) or abscess (particularly frontal) and alcohol withdrawal.
- Complex partial status epilepticus may manifest with prolonged periods of confusion and disorientation, associated with automatic activity for which there is amnesia.
- Absence status epilepticus often occurs in the context of learning disability or *de novo* in older individuals, and may be associated with confusion, disorientation or cognitive slowing.
- Epilepsia partialis continua is focal (usually motor) status epilepticus, often reflects underlying structural abnormalities, and may be unremitting for months or years despite treatment with anti-epileptic drugs. (Rasmussen's encephalitis).

Table 30 gives classification of epilepsy (abbreviated ILAE).

DIAGNOSIS OF EPILEPSY

1. **History**– (a) *Age of onset* – (i) *Infancy* – Metabolic disturbance associated with febrile illness, birth asphyxia, congenital diplegia, congenital hemiplegia and cerebral damage resulting from birth injury. Occasional sequel of meningitis. Rare degenerative disease such as amaurotic family idiocy. (ii) *Early childhood* – Any of the congenital or acquired lesions above mentioned. Idiopathic epilepsy, encephalitis. (iii) *Late childhood and adolescence* – Idiopathic, following previous

Fig. 11: MRI axial Flair image showing hyperintensity in white matter of corona radiata in a case of focal encephalitic

Fig. 12: MRI SWI shows multiple foci of blooming suggestive of hemorrhages in hemorrhagic encephalitis

Table 30: Classification of epilepsy (abbreviated ILAE) generalized epilepsies and syndromes

Idiopathic with age-related onset

- Benign neonatal familial convulsions
- Benign neonatal convulsions
- Benign neonatal epilepsy in infancy
- Childhood absence epilepsy
- Juvenile myoclonic epilepsy
- Epilepsy with generalized tonic-clonic seizures on awakening

Symptomatic or cryptogenic

- West syndrome
- Lennox-Gastaut syndrome
- Epilepsy with myoclonic-astatic seizures
- Epilepsy with myoclonic absences

Symptomatic

- Early myoclonic encephalopathy
- Early infantile myoclonic epilepsy with burst suppression
- Others

Localization-related epilepsies and syndromes

Idiopathic with age-related onset

- Benign childhood epilepsy with centrotemporal spikes
- Childhood epilepsy with occipital paroxysms
- Primary reading epilepsy

Symptomatic

- Epilepsy with simple partial, complex partial or secondarily generalized seizures arising from frontal, parietal, temporal or occipital lobes, or of unknown lobe of onset

Contd...

Contd...

- Epilepsia partialis continua
- Syndromes characterized by specific modes of activation

Unknown whether idiopathic or symptomatic

Epilepsies and syndromes undetermined (focal or generalized)

- Severe myoclonic epilepsy in infancy
- Epilepsy with continuous spike-and-wave activity in sleep
- Acquired epileptic aphasia

Special syndromes

trauma, infections. (iv) Adult life – Idiopathic epilepsy rarely begins after age of 25. Penetrating head injury involving meninges, intracranial tumour, cysticercosis. (v) Later life – Epilepsy most often due to cerebral arteriosclerosis. (b) *Aura or other prodromata* – and sensations experienced before attack. (c) *Description of fit from witness or family*. (d) *Circumstances under which fit occurs*. (e) *Associated features* – such as mental retardation. (f) *Family history* – Fits which cause sudden loss of consciousness with falling, followed by some confusion should be classified as grand mal. (g) *History of febrile convulsions in childhood*.

2. **Examination** – Presence of neurological signs (e.g. hemiparesis, dysphasia, field defect, may lateralize or localize a structural lesion. Dysmorphism and learning disability may suggest a chromosomal disorder, and progressive features (e.g. dementia, ataxia, worsening myoclonus) suggest a neurodegenerative disease. Cutaneous stigmata of the neurocutaneous disorder must be sought. A cardiovascular examination is

essential. The pupils may dilate during a seizure; other features may help lateralize the focus (dysphasia indicates dominant hemisphere onset, and unilateral automatisms are ipsilateral and unilateral dystonia contralateral to a temporal lobe focus).

3. Investigations –

Confirming the diagnosis:

EEG – is of value in establishing the diagnosis of epilepsy and an aid in determining the type of seizure. (a) Normal – Series of small alpha waves about 10 per second and occasionally smaller beta waves. (b) During attack an abnormal rhythm develops – (i) Idiopathic generalized epilepsy – Generalized 3 Hz spikes/wave. Grand mal and Jacksonian epileptic attacks – series of sharp spikes. (ii) Absences – alternating large dome-shaped waves and sharp spikes (dart and dome rhythm). (c) Between the attacks 3 Hz 5w interictal epileptiform activity – Abnormal in about 50%. Intermittent irregular slow waves especially in grand mal. Normal EEG does not rule out epilepsy.

EEG telemetry – in the form of ambulatory recording or videotelemetry, may be necessary, if diagnosis is in doubt despite apparently frequent seizures. If necessary presurgical investigations (e.g. intracarotid sodium amytal testing to determine lateralized memory function and language dominance, intracranial EEG to determine the seizure focus).

Further investigations – may be necessary. Hypoglycemia needs to be ruled out, particularly in patients with early morning seizures. Echocardiography, ambulatory EEG, urinalysis for catecholamine metabolites and porphyrin determination may be required.

Investigating the cause: MRI provides reliable diagnosis of hippocampal sclerosis (demonstrated as loss of volume on a T₁-weighted volumetric sequence and increased signal on a T₂-weighted sequence), cortical dysgenesis and small lesions. It also detects focal lesions like tumor, AV malformations, mesial temporal lobe sclerosis.

Non-epileptic attack disorder – Nonepileptic attacks commonly comprise either prolonged motionlessness with preserved background EEG rhythms, or prominent, often waxing and waning movements including asynchronous limb flinging, pelvic thrusting and opisthotonus. There is no hypoxia but salivation, incontinence and injury may occur. These patients usually have underlying psychological or psychiatric problems.

Diagnosis – (a) Prolactin levels rise immediately after generalized tonic-clonic seizures and some complex partial seizures, and return to baseline within 50 minutes. This

- Meniere's disease
- Episodic ataxias
- Movement and sleep disorders

Metabolic or endocrine

- Hypoglycemia
- Pheochromocytoma
- Carcinoid syndrome
- Porphyria

Psychological or psychiatric

- Hyperventilation
- Panic attacks
- Non-epileptic attack disorder
- Episodic dyscontrol syndrome
- Malingering
- Munchausen's syndrome

does not occur after absence seizures. Serum prolactin levels do not generally rise significantly after non-epileptic attacks. (b) Ictal EEG monitoring does not show the typical changes that may precede or succeed epileptic seizures in nonepileptic seizures.

Differential diagnosis of epilepsy is given Table 31.

Table 34 gives factors which influence recurrence of seizures.

MANAGEMENT

1. General hygiene and diet – Avoiding physical exertion, regular habits of eating and sleeping, adequate diet. Avoid alcohol.

Table 32: Hysterical fit (Pseudoseizures)

Hysterical fit	Epileptic fit
Induced by emotional excitement	Fairly constant periodicity
No incontinence	Incontinence common
Patient not hurt	Tongue biting. At times injury from fall
Usually in presence of people	Can occur anywhere
Movements spectacular. No clonic or tonic sequences	Tonic and clonic phases
Plantar response down going	Extensor plantar response
Corneal reflex present	Corneal reflexes absent during attack
Pupils remain unchanged	Pupils dilate
No turning of head and eyes, eyeballs roll upwards, if eyes forcibly opened	Conjugate deviation of head and eyes
Attacks may be prolonged to impress spectators	Attacks of short duration
Recovery after attack sudden	Gradual recovery
EEG – normal	EEG – epileptiform abnormalities

Table 34: Factors which influence recurrence of seizures

• Cause of seizure
• Seizure type
• EEG findings
• Family history of seizures
• History of febrile seizure
• Todd's paresis (transient postictal focal defect)
• Abnormal neurological findings

2. Drugs – Principles: (i) Adequate therapy, aim being cessation of attacks. (ii) Dosage adjusted to particular patient, small initial doses. (iii) Combination of drugs, if necessary. (iv) Continuity of treatment. Abrupt discontinuation of drugs dangerous. (v) Drug should be continued for 2 years after the last fit.

Choice of drug – depends on seizure type. (a) In localization related epilepsy, first-line prophylactics are lamotrigine, carbamazepine (slow-release), oxcarbamazepine, levetiracetam. (b) In primary generalized, symptomatic generalized and unclassified epilepsies, initial therapy should be lamotrigine or valproate (broad spectrum agents). Valproic acid is useful in absences and benzodiazepines in myoclonic jerks. Patients with refractory generalized epilepsy may benefit from adjunctive treatment

Table 33: Syncope

	Tonic-clonic seizure	Vaso-vagal syncope
Precipitant	Unusual	Emotional, painful or stressful event
Circumstances	Any	Usually upright posture, crowded or hot environment
Onset	Usually abrupt	Usually gradual with feeling of faintness, nausea, sweating, greying of vision
Motor phenomenon	Often characteristic tonic-clonic	Usually flaccid without movement
Skin colour	Pale or flushed	Pale
Breathing	Stertorous, foaming	Shallow
Incontinence	Common	Unusual
Tongue biting	Common	Unusual
Vomiting	Unusual	Common
Injury	Common	Unusual
Postictal	Drowsy, confused, headache, sleep	Rapid recovery
Duration of unconsciousness	Minutes	Seconds

with topiramate or levetiracetam, zonisamide, clonazepam, pregabalin. Antiepileptic drugs are summarized in Table 35.

Plan of Management

(a) *Initial regimen* – The drug selected must be used in monotherapy. The drug should be introduced in small doses, since rapid introduction may cause side effects (particularly carbamazepine).

(b) *Maintenance treatment* – The aim should be to find the lowest dose which achieves complete seizure control without side effects which may be either idiosyncratic, or due to intoxication, or chronic. Serum anticonvulsant levels are a useful guide to therapy – phenytoin (40–80), carbamazepine (20–50), phenobarbitone (40–170), ethosuximide (200–600). Valproate 300–600, oxcarbamazepine 50–125, lamotrigine 4–60 mmol/litre. If the optimum level of a single, first line drug does not control seizures, or if side-effects develop, the initial drug should be substituted with another first line anticonvulsant. If the second drug also fails to control seizures monotherapy with a third anticonvulsant, or combination therapy with two first line drugs should be tried.

If a combination of two first-line drugs is unsuccessful, one of the second-line drugs may be considered.

Table 35: Anti-epileptic drugs

Drug	Indications	Dosage	Side-effects/comments
Carbamazepine	Localization-related	200 mg/d increased by 200 mg at 2wks intervals	Ataxia, rash, conduction defects, neutropenia, SIAHS
Oxcarbamazepine	Localization-related	300 mg/d increased by q3d (max 1200/d)	Side effects less common
Sodium valproate	Localization-related Idiopathic generalized	200 mg bd increased by 200 mg q2 wks	Tremor, obesity, hair loss, menstrual changes, thrombocytopenia
Divalproex sodium	Progressive myoclonic		
Phenytoin	Localization-related	200 mg/d increments of 25–50 mg as per therapeutic monitoring 750–1000 mg o.d.	Gum hypertrophy, acne, hirsutism, facial coarsening, ataxia
Lamotrigine	Localization – related Idiopathic generalized	25 mg/d, in pts on valproate 10 mg/day increases by 25 mg/d q2 wks	Rash, multisystem allergic disorder
Ethosuximide	Absences only	250 mg/d increased by 25 mg q2 wks	GI upset, ataxia Cognitive slowing, mood and behaviour changes, habituation
Barbiturates	Status only		
Clobazam	Localization-related Idiopathic generalized	10–20 mg bd for 1–3 days short-term	Sedation, disinhibition (in children and those with learning disability). It may prevent postictal psychosis.
Clonazepam	Myoclonus only	0.5 mg maximum initially nocte	– – –
Gabapentin	Localization-related	300–400 mg/d increased 400 q/wks Max. 1200 mg tds.	Ataxia, nightmares Wt. loss, slowing, speech difficulties, paraesthesia. Useful in those at risk to interactions
Topiramate	Localization-related Idiopathic generalized	25 mg/d increased by 25 mg q2 wk to 100 mg bd.	Anxiety, tremor, speech difficulties
Tiagabine	Localization-related	35–40 mg/d in divided doses increase 5 mg q1 wk,	Mood changes, psychosis, visual field defects
Levetiracetam	Localization-related Generalized myoclonic seizures	250 mg/d increased to 2–3 g/d	Irritability, somnolence, dizziness
Zonisamide	Localization-related Myoclonic seizures	50 mg/d increased to 300–400 mg/d in bd doses	Dizziness. Renal calculi
Lacosamide	Adjuvant in uncontrolled partial seizures	400–600 mg/d	GI irritation, prolonged interval
Rufinamide	Lennox-Gastaut syndrome	3200 mg/day	Leukopenia, QT shortening

Note: Any drug may cause headaches, diplopia, unsteadiness, nausea, lethargy, sedation, dizziness and unpredictable responses. Vigabatrin therapy may be associated with loss of peripheral visual fields as a result of retinal toxicity and is not recommended.

Drug withdrawal – should take place slowly over 2 to 3 months. If patient is receiving more than one drug, each one should be withdrawn individually.

Pregnancy – No antiepileptic drug can be considered safe in pregnancy; valproate may be more teratogenic than others. The risk may be higher in women who have previous history of foetal malformations. Doses should be kept at the minimum required in the first trimester. Measurement of drug levels helps guide dose increases to achieve a level that previously controlled seizures, if these recur. Postnatally, doses must be reduced again over

weeks to prevent toxicity. Supplemental folate 5 mg/day may reduce risk of malformation.

All women treated with enzyme-inducing drugs (and possibly all other antiepileptic drugs) should be given vitamin K1, during last month of pregnancy, and the newborn 1 mg i.m. to prevent vit. K deficiency bleeding.

Breast-feeding – Lamotrigine, benzodiazepines and barbiturates reach significant levels in breast milk.

Elderly – Incidence of onset of epilepsy shows a second peak in the elderly. Only lower doses of drugs can be tolerated, and interactions with concomitant medications

are common. Carbamazepine and valproate are preferred drugs.

Electrocorticography surgery – Electrodes are placed in affected area of the brain to study how it functions or malfunctions. Using this imaging, surgeons get a precise mapping of the affected part of the brain and operate accordingly.

Social and psychological management – Attention to doubts and fears of the patient. No imposition of unnecessary restrictions. Education of the patient and his relatives about the nature of the illness, its precipitating factors and its consequences.

Surgical Treatment

It is considered in patients refractory to medical treatment. It includes temporal lobectomy in mesial temporal lobe sclerosis. For focal seizures arising from extratemporal region lesionectomy done. In these cases localization of focus is important, done with help of video-EEG, high resolution MRI study, SPECT, PET study.

Deep brain stimulation, Vagal nerve stimulation and laser thermoablation are newer alternatives to surgical treatment in refractory cases.

Status epilepticus – is the repeated occurrence of seizures without recovery in between. Status may be generalized convulsive tonic-clonic, partial motor (epilepsia partialis continua), non-convulsive or absence. Except for absence status, these conditions are medical emergencies.

Clinical features: SE can be divided into four stages depending on the duration for which seizures continue.

1. *Prodromal phase* – In patients with established epilepsy, tonic-clonic SE seldom develops without warning. There is usually a prodromal stage in which seizures become more frequent.
2. *Early status* – Once SE has developed the first 30 minutes comprise of the early stage.
3. *Established status* – is status which has continued for 30 minutes in spite of early stage treatment.
4. *Refractory status* – The stage is reached, if seizures continue for 60–90 minutes after initiation of therapy.

Management

General Measures

- Avoid hypoxia: Protect patient from injury. Semi-prone, head down position. Maintain airway. Administer O₂.
- Monitor ECG, blood pressure, oximetry and temperature.

- Establish intravenous access in large veins. Take blood for electrolytes, glucose, calcium, magnesium, full blood count, anti-epileptic drug levels, alcohol and toxicology screen, and cultures as appropriate. Urea and electrolytes, blood glucose, calcium and phenytoin levels are obtained urgently.
- Check glucose and immediately correct any hypoglycaemia with 50% glucose, up to 50 mL i.v. over, 1–2 minutes into a large vein.
- If poor nutrition or alcohol abuse is suspected, administer thiamine 250 mg (10 mL) i.v. over 10 minutes.
- Check blood gases.

Important

- Investigate the cause of status.
- Reinstate any recently withdrawn anti-epileptic drug.
- Continue existing anti-epileptic drugs.
- Start maintenance therapy promptly.

Note

- 25% of patients with so-called refractory status epilepticus referred to specialist units have pseudostatus epilepticus.
- EEG is useful in the diagnosis of status and pseudostatus.
- The iatrogenic complications of inappropriate treatment are significant.

Specific Drug Therapy

- Lorazepam 4 mg IV over 2–3 minutes or IV Diazepam 5 mg IV. Repeat dose, if necessary. If IV access not possible give Midazolam 10 mg intranasally or IM.
 - Give IV phenytoin 15–20 mg/kg or IV Fosphenytoin 20 mg/kg in infusion at rate of less than 50 mg/min (phenytoin).
 - Alternatives to IV phenytoin are Valproate 500–1000 mg IV bolus or Levetiracetam 1gm bolus.
- Refractory status* - If seizures continue (more than 20 minutes), then intubate and give one of the following:
- (a) Midazolam drip IV. Load with 0.2 mg/kg and infuse at rate of 0.03–0.2 mg/kg/hr or
 - (b) Propofol IV. Load 1–2 mg/kg repeat every 5 mts till seizures stop, followed by IV infusion 2–10 mg/hr. Propofol is a short acting anaesthetic agent with a rapid metabolic clearance and less pronounced hypotensive effect compared to thiopentone or
 - (c) Phenobarbitone IV bolus 6–8 mg/kg at a rate not more than 60 mg/min.
- Partial (local) minor SE* consists of frequent seizures involving an extremity or facial muscles with preservation of consciousness and no tendency for generalisation. *Tr.*

– Phenytoin po during an 8–12 hour period followed by maintenance dose of 300–400 mg/day.

Non-convulsive SE is essentially a behavioural manifestation without significant motor involvement.

12. CEREBROVASCULAR DISEASES

The term cerebrovascular disease embraces:

1. Disease of the cerebral arteries (atheroma being the commonest cause) and of the major neck vessels supplying the brain.
2. Diseases of the heart which may adversely affect blood supply to the brain by changes in blood pressure or as a source of emboli.
3. Disorders of the blood which may lead to impaired clotting, causing hemorrhage, hyperviscosity or hypercoagulable states, which increase tendency for cerebral thrombosis.

Stroke is defined as an acute focal neurological deficit resulting from cerebrovascular disease and lasting more than 24 hours (or causing earlier death). Stroke is not a diagnosis, but a clinical syndrome with numerous causes: Mainly:

- Cerebral infarction
- Intracerebral hemorrhage
- Subarachnoid hemorrhage
- Cerebral venous thrombosis

Table 36 lists the main risk factors for stroke.

ISCHEMIC STROKE

Transient Ischemic Attacks (TIAs)

Refer to an episode of acute neurological deficit. MRI must not show evidence of acute ischemia irrespective of the time period of recovery, occurring as a result of reduced flow to a vessel from fall in perfusion pressure (e.g. cardiac arrhythmia associated with localized stenotic cerebrovascular disease), or blockage of passage of flow by embolism arising from plaques in aortic arch, or extracranial vessels or from heart. If flow is restored within the critical period, ischemic symptoms reverse themselves, otherwise infarction may occur. Since there is no serious persisting disability, the term reversible ischemic neurological deficit (RIND) is used in such cases.

Cardiac embolism from thrombus in left atrium or ventricle.

Table 36: Risk factors for stroke

Major risk factors

- Hypertension
- Cardiac disease – Ischemic heart disease, atrial fibrillation
- Transient ischemic attacks
- Cigarette smoking
- Alcohol
- Hyperlipidemia – elevated LDL cholesterol
- Oral contraceptives
- Obesity
- Sedentary life
- Diabetes mellitus

Associated risk factors

- Diabetes mellitus
- Previous stroke
- Raised haematocrit
- High plasma fibrinogen
- Antiphospholipid antibodies (APLA)
- Asymptomatic carotid arterial lesions (carotid bruits)

Large Artery Disease

Atherosclerosis of the major vessels supplying the brain is the other main source of cerebral embolism. The emboli are usually platelet aggregates or thrombus formed on atherosclerotic plaques, but occasionally comprise cholesterol and other atherosclerotic debris.

Dissection of vertebral or carotid artery can occur spontaneously or following neck trauma. Fibromuscular dysplasia may predispose to dissection.

Major vessel occlusion may be asymptomatic or may cause embolic TIA, or minor or major stroke. It can also result in a stepwise progression of symptoms from propagation of thrombus, for example, vertebral artery occlusion may initially cause only a TIA, but if the thrombus spreads to the basilar artery the patient may develop a major brainstem stroke a few hours or days later.

Middle cerebral artery occlusion is usually the result of cerebral embolism, but can result from localized intracranial atherosclerosis (Fig. 13).

Small Vessel Disease (Lacunar Infarcts)

Occlusion of small penetrating arterioles, usually secondary to hypertension or diabetes mellitus, (microatheroma and hypohyalinosis) leads to small infarcts in subcortical white matter, internal capsule, basal ganglia and pons, termed ‘lacunar infarcts’ (infarcts < 1 cm in diameter)

CL. Fs. All on ipsilateral side – (a) Motor stroke symptoms develop in step-wise fashion (stuttering). Hemiparesis or hemiplegia at times only arm and leg weakness without face. Motor aphasia, if lesion in genu and anterior limb of internal capsule. (b) Ataxic hemiparesis – (cerebellar symptoms with weakness more of leg than arm). (c) Sensory stroke due to thalamic lesion and posterior internal capsule lesion – numbness and tingling on one side of body, less often pain or burning sensation. (d) Mixed stroke – Hemiparesis or hemiplegia with diminished sensations. Dysarthria and a clumsy hand or arm due to infarction in the ventral pons or in the genu of the internal capsule

Figure 14 and Table 37 give arterial territories and neurological deficits.

Figure 14 shows the origin of the great vessels from the aortic arch, the circle of Willis and its branches, the areas of the brain supplied by the major intracerebral arteries.

Fig. 13: MRI ADC image showing hypointensity in left MCA territory suggestive of acute infarct

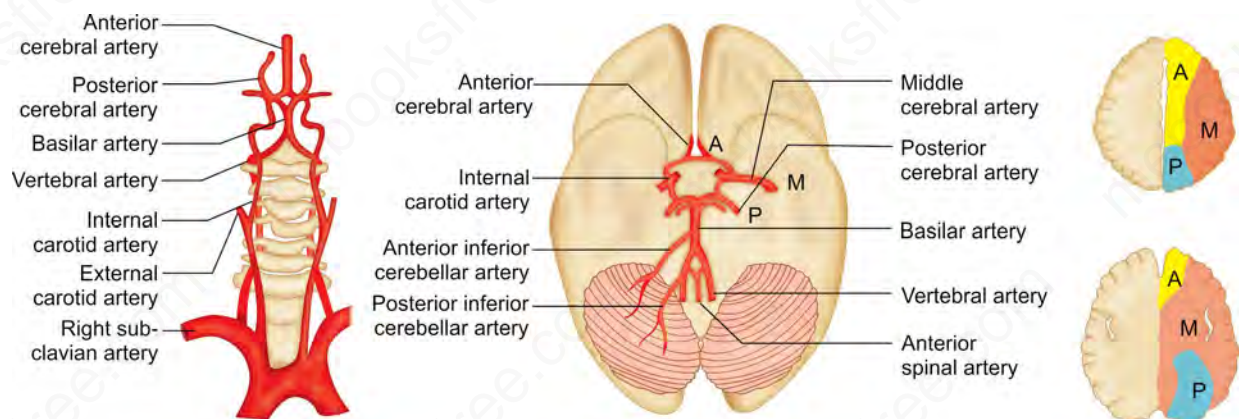

Fig. 14: Cerebral circulation

The distribution of anterior (A), middle (M) and posterior (P) cerebral areas are shown.

Table 38 gives pathophysiology of strokes.

Less common Causes of Stroke

Haematological abnormalities – that promote thrombosis, e.g. polycythemia and thrombocythemia. Anticardiolipin antibodies may cause acquired abnormalities of thrombolysis and are associated with stroke in younger patients. Thrombophilia may cause cerebral venous thrombosis. Low dose oestrogen-containing oral contraceptives do not increase risk of stroke significantly in healthy women, but may do so in those with other vascular risk factors. Sickle cell anemia is common cause of stroke in children.

Subclavian steal – is an uncommon cause of hemodynamic symptoms. If the subclavian artery is occluded or stenosed before the origin of the vertebral artery, arm exercise may cause retrograde flow down the vertebral artery at the expense of the vertebrobasilar circulation, resulting in brainstem TIA.

Migraine – is a rare cause of cerebral infarction. Headache is common in ischemic stroke and may be caused by collateral vasodilatation or carotid dissection.

Vasculitis – is a rare cause of both haemorrhagic and ischemic stroke. Systemic features of the underlying vasculitis usually suggest the diagnosis in SLE, polyarteritis nodosa and giant cell arteritis, but absent in isolated or granulomatous angiitis of the CNS. Cardiac embolism from endocarditis and acquired thrombophilia with anticardiolipin antibodies are other possible causes of stroke in SLE.

Table 37: Arterial territories and neurological deficits

Arterial territory and area supplied	Syndrome if total territory involvement
Internal carotid	
Ophthalmic artery: Retina	Amaurosis fugax, altitudinal field defects in one eye, uniocular blindness
Middle cerebral artery: (Fig. 15) Parietal lobe, frontal lobe, sup. Temporal lobe	Contralateral UMN facial weakness, hemiplegia (arm>leg), hemianopia, aphasia (dominant hemisphere) or visuospatial disorientation (non-dominant hemisphere)
Anterior cerebral artery: Anterior and superior medial frontal lobe	Contralateral foot and leg weakness or hemiplegia (leg>arm), grasp reflexes, incontinence, abulia, apathy, akinetic mutism
Vertebrobasilar territory	
Posterior cerebral artery: (Figs. 16 and 17) Occipital lobe, inferior temporal lobe part of thalamus	Contralateral hemianopia Cortical blindness, if bilateral Amnesia (especially, if bilateral ischemia). Contralateral sensory loss. Thalamic pain, thalamic aphasia.
Posterior inferior cerebellar artery: Lateral medulla, inferior cerebellum	Vertigo and vomiting, dysphagia. Ipsilateral palatal weakness Ipsilateral facial sensory loss (variable) with contralateral hemisensory loss below neck Ipsilateral Horner's syndrome Ipsilateral cerebellar signs
Vertebral and basilar artery: Brainstem and cerebellum	Diplopia, ophthalmoplegia or gaze palsies Nystagmus, vertigo, vomiting Dysarthria, dysphagia, bulbar cranial nerve weakness Ipsilateral facial numbness and weakness (LMN) Hiccups and resp. failure Coma Contralateral hemiparesis or tetraparesis Contralateral or bilateral sensory loss. Normal consciousness, cognitive function and visual fields.
Small vessel (lacunar) syndromes (small stroke)	
Pure motor stroke: Internal capsule or pons	Hemiparesis (face and arm with/without leg) Dysarthria and dysphagia.
Pure sensory stroke: Thalamus, internal capsule	Hemisensory impairment Thalamic pain.
Sensorimotor stroke: Basal ganglia and internal capsule	Combination of above
Ataxic hemiparesis: Internal capsule or pons	Hemiparesis, ipsilateral limb ataxia, dysarthria, clumsy hand, gait ataxia.
Movement disorders: Basal ganglia	Hemichorea, hemiballismus, gait ataxia.

Watershed infarction – During transient circulatory arrest or profound anoxia, infarction can occur at border zone of arterial territories, particularly in parietooccipital region which is the watershed between middle, anterior and posterior cerebral arteries. Usual picture is of visual disorientation or cortical blindness, often associated with visual field defect and sensory impairment.

Multi-infarct dementia – A succession of minor vascular events can lead to dementia. Vascular dementia may also result from diffuse small vessel disease which leads to ischemia of deep white matter and basal ganglia

(Binswanger's disease or 'subcortical arteriosclerotic encephalopathy'). There may not be a clear history of stroke, but dementia is usually marked by step-wise deterioration with periods of improvement. CT or MRI shows patchy or diffuse abnormalities in the periventricular regions (leukoaraiosis).

Silent cerebral infarction – Many middle-aged and elderly patients with hypertension without a history of stroke or TIA have small lacunar infarcts or patchy ischemic periventricular imaging abnormalities (leukoaraiosis) on CT or MRI.

Fig. 15: MRI SWI image showing acute infarct with haemorrhagic transformation in MCA territory

COMPLICATIONS OF STROKE

Cerebral oedema – should be suspected, if a patient with a large infarct or haemorrhage experiences a lucid interval of 24–48 hours and then shows a decline in consciousness. Swelling of infarcted tissue compresses surrounding tissues and blood vessels, and may compress the brainstem leading to coma and death.

Haemorrhagic transformation – of an infarct may occur as a result of spontaneous or therapeutic thrombolysis, but does not necessarily result in clinical deterioration (Figs. 18 and 19).

Pneumonia – may occur due to aspiration from swallowing difficulties.

Oedema of – weak limbs is common, and has a partially autonomic basis.

Fig. 16: PCA territory infarct MRI axial view T2 image

Fig. 17: PCA territory infarct MRI DW image

Table 38: Pathophysiology of stroke

Causes	Common	Less common
Cerebral embolism		
Carotid, vertebral or basilar arteries	Atherosclerotic stenosis and ulceration, atherothromboembolism	Dissection Fibromuscular dysplasia Trauma
Left ventricle	Myocardial infarction	Cardiomyopathy
Aortic or mitral valves	Rheumatic heart disease Mitral valve prolapse Infective endocarditis	Prosthetic valves
Left atrium	Atrial fibrillation	Sino-atrial disease Myxoma Aneurysm

Contd...

Contd...

Causes	Common	Less common
Deep vein thrombosis (paradoxical embolism)		Cong. septal defects Patent foramen ovale
Trauma		Fat or air emboli
Iatrogenic		Cardiac surgery Cardiac catheterization Cerebral angiography
Vasospasm	Subarachnoid hemorrhage	Migraine
Vasculitis		Giant cell arteritis SLE, PAN Other causes of vasculitis Radiation, granulomatous angiitis, TAO, Moyamoya disease Takayasu's disease
Hemodynamic	Carotid occlusion	Severe hypotension Cardiac arrest
Cerebral venous thrombosis	Dehydration Intracranial sepsis	Hypercoagulable states Invasion by tumours
Local arterial thrombosis		
Major arteries	Atherosclerosis	Dissection, fibromuscular dysplasia
Small vessels	Hypertension Arteriosclerosis Diabetes mellitus	
Hypercoagulable states causing arterial and venous stroke	Congestive heart failure Malignancy Polycythemia Thrombocythemia Smoking	Pregnancy Oral contraceptives Protein C deficiency Protein S deficiency Antithrombin III deficiency Sickle cell disease Homocystinuria
Intracranial hemorrhage		
Subarachnoid haemorrhage	Saccular aneurysm A-V malformation Trauma	Haematological abnormalities 'Border zone' infarction Subclavian steal Migraine Vasculitis
Intracerebral haemorrhage	Hypertension Aneurysm A-V malformation Anticoagulant therapy Thrombolytic therapy	Bleeding disorders Vascular tumors Vasculitis Amyloid angiopathy Moyamoya disease

Shoulder pain – may develop as a result of poor posture and spasticity.

Cognitive Effects of Stroke

- *Dysphasia, dysgraphia, dyslexia and dyscalculia* lead to communication difficulties in dominant left hemisphere lesions.
- *Neglect* leads to patients ignoring the environment and their limbs on the hemiparetic side, particularly in non-dominant right hemisphere lesions.
- *Aprosody* (failure to understand or express meaning conveyed by variations in tone, rhythm and accent of speech) may result from non-dominant right hemisphere lesions.
- *Spatial disorientation* may lead to the patient becoming lost, particularly in unfamiliar surroundings.
- *Memory impairment* leads to confusion and disorientation.
- *Anxiety and depression* are common reactions to stroke, but depression may also have an organic basis related to frontal or limbic system.
- *Emotional lability* is common and often leads to tears (or occasionally laughter) precipitated by minor emotional stimuli.

Fig. 18: Acute infarct MCA territory MRI axial view T2 image

Fig. 19: Acute infarct MCA territory MRI DW image

Differential Diagnosis

TIA

Focal epilepsy – causes transient symptoms, which are usually positive (tingling or jerking) in contrast to the negative symptoms in TIA (numbness or paralysis).

Migraine – Isolated focal visual or sensory migraine aura without headache may mimic TIA, but the focal symptoms of migraine progress over 10–30 minutes.

Meniere's disease and benign positional vertigo – TIA should only be diagnosed, if the vertigo is accompanied by other brainstem symptoms (e.g. diplopia, dysarthria), dysphagia, limb weakness.

Hypoglycemia – may cause hemiparesis for about one hour after hypoglycemia has resolved.

Multiple sclerosis – may cause paroxysmal visual blurring or limb symptoms.

Stroke

Space-occupying lesion – About 5% of patients presenting with stroke-like symptoms have a subdural hematoma, tumour or cerebral abscess, granuloma (neurocysticercosis, tuberculoma). The diagnosis is made only on CT or MRI.

Multiple sclerosis – may present with hemiplegia, sensory impairment or brainstem symptoms that mimic stroke. Usually symptoms occur over a few days. Abnormal visual evoked potentials, characteristic MRI appearance and oligoclonal immunoglobulins in CSF may elucidate the diagnosis.

Hysteria – seldom presents with stroke-like symptoms but should be considered, if there are marked fluctuations and signs inconsistent with organic disease.

Table 39: Causes of hemiplegia

A. Sudden onset:

1. Vascular causes.
2. Intracranial infection – encephalitis, meningitis.
3. Trauma – depressed fracture.
4. Hypertensive encephalopathy.
5. Post-epileptic paralysis (Todd's palsy).
6. Multiple sclerosis.
7. Uraemia.
8. Hysterical.

B. Slow onset:

1. Cerebral tumour.
2. Cerebral abscess.
3. Internal carotid artery occlusion sometimes.
4. Chronic subdural haematoma.
5. Meningitis, encephalitis.
6. Chorea.
7. General paralysis of insane.
8. Congenital defects – diffuse sclerosis, cerebral agenesis.

HEMIPLEGIA

Causes of hemiplegia are listed in Table 39.

Determination of the Side of Hemiplegia in an Unconscious Patient

Away from the paralysed side – Conjugate deviation of eyes.

On the hemiplegic side – (1) Cheek puffs out during respiration. (2) Nasolabial fold obliterated. (3) Corneal reflex diminished. (4) Pain stimulation less effective. (5) More

absolute flaccidity of limbs (dropping tests). (6) Paralyzed leg extended and assumes position of external rotation while healthy one tends to be semiflexed. (7) Pupil large on side of haemorrhage. (8) Eyelid release test - Eyelid slides down slowly after both the eyelids are pulled up and released simultaneously. (9) Temperature of paralyzed side usually higher.

Investigation and Diagnosis of a Case of Cerebrovascular Accident

I. History

1. *Age* - In a young patient consider:
 - Cardiac disease - Infective endocarditis, atrial fibrillation, mitral valve stenosis or prolapse.
 - Vascular disease - Severe hypertension, hypercoagulable state, vasculitis, e.g. SLE, arteritis of intracranial vessels - T.B., syphilis, pyogenic.
 - A-V malformation/Aneurysm.
 - Intracranial space occupying lesion
 - Encephalitis, e.g. HSV type 1.
 - Post-ictal.
 - Migraine (classical).
 - Hysteria.
 - Hyperventilation (may simulate TIA).
2. *History of previous minor episodes* - may suggest disease of caroticovertebral system, of embolic disease from these arteries or from the heart, of progressive cerebral arteriosclerosis or effects of hypertension. History of migraine or epilepsy in young patient may suggest intracranial A-V malformation. History of ischemic heart disease, intermittent claudication, bleeding tendency, diabetes or of symptoms suggesting intracranial tumour should be elicited.
3. *History of head injury* - Depressed fracture and subdural haematoma.
4. *History of drugs* - e.g. contraceptive pills, hypotensive drugs, anticoagulants.
5. *Family history* - History of strokes and an early age of onset may suggest familial trait to early atherosclerosis.
6. *Past history* - of diabetes, hypertension or cardiac disease, or of anaemia or fluid loss which may serve as precipitating factors.
7. *Symptoms* -
 - (a) *Mode of onset* - Catastrophic in haemorrhage, progressive in thrombosis, instantaneous in embolism (maximum at onset).

Table 40: Causes of transient hemiplegia

• Transient cerebral ischaemia (TIA)
• Embolism from the heart
• Migraine
• Epilepsy
• Structural intracranial disorders such as tumour, chronic subdural haematoma, giant aneurysm or angioma
• Polycythemia, thrombocythemia or sickle cell disease
• Anaemia
• Hyperviscosity syndromes
• Hypoglycemia
• Hypertensive encephalopathy
• Hysterical hyperventilation
• Multiple sclerosis
• Congestive attacks of GPI.

- (b) *Transient hemiplegia* - or transient focal neurological disturbance may be due to conditions listed in Table 40.
- (c) *Headache* - In cerebral haemorrhage the headache is intense with accompanying stiffness of neck, in carotid insufficiency the headache is temporal and usually on the side of the ischaemia, in basilar artery insufficiency the headache is occipital or suboccipital. Severe headache is felt in subarachnoid haemorrhage at the onset. Headache and vomiting may occur in cerebral tumour or abscess and subdural haematoma. Vomiting preceding a stroke favours a diagnosis of haemorrhage.
- (d) *Chest pain* - suggests associated myocardial infarction.
- (e) *Symptoms suggestive of hysterical hemiplegia* - (i) Onset after emotional shock. (ii) Hysterical type of rigidity. (iii) Plantars never extensor. (iv) Hoover's contralateral leg sign - when patient attempts to raise the paralyzed leg, the opposite heel does not make counter pressure backwards on the palm of the examiner's hand as in organic hemiplegia. (v) Contraction of platysma present on affected side. (vi) Hysterical gait.
- (f) *Coma* - Sudden or rapid loss of consciousness at onset common in subarachnoid hemorrhage, intra-cerebral hemorrhage and brainstem strokes. In subdural hematoma increasing drowsiness and spontaneous variations in coma, the patient may pass from consciousness into coma and back again in a few hours.

- (g) *Seizures* – in tumour.
- (h) *Fever* – in meningitis, encephalitis and cerebral abscess.
- (i) *Involuntary movements* – in encephalitis and chorea. In chorea usually upper limb alone is paretic.
- (j) *Mental symptoms* – encephalitis and sometimes tumour.
- (k) *Abdominal pain and melena* – suggest gastrointestinal bleeding as the precipitating cause.

II. Physical examination

A. Neurologic

1. *State of consciousness* – may vary from full alertness to lethargy, stupor, semiconsciousness or coma.
2. *Speech* – should be evaluated to differentiate between slurred dysarthric speech and dysphasic speech. The former is more likely to be found in diseases of brainstem, the latter in involvement of dominant cerebral hemisphere.
3. *Neck rigidity* – subarachnoid hemorrhage, and meningitis.
4. *Eyes* – (a) *Movements* – Most spontaneous nystagmus and unusual eye movements are due to brainstem disease, but eye deviation away from the side of hemiparesis is common with recent infarction in middle cerebral artery territory. Eyes deviated to side of hemiplegia suggests pontine lesion. (b) *Pupils* – Ipsilateral Horner's syndrome may be found in acute carotid thrombosis but may also indicate brainstem disease. Pupillary enlargement occurs early in paralysis of 3rd cranial nerve associated with aneurysm or temporal lobe herniation. (c) *Fundi* – for early papilloedema, optic atrophy, emboli in retinal arteries, subhyaloid hemorrhage.
5. *Focal neurological deficit* – Test for hemiparesis, hemianopia or hemisensory loss.

B. General

1. *Blood pressure* – for arterial hypertension. BP should be checked in both arms because of possibility of aortic arch syndrome or subclavian steal syndrome.
2. *Heart* – for cardiac arrhythmia such as atrial fibrillation, or recent myocardial infarction, atrial myxoma or valvular disease.
3. *Arterial pulses* – (a) For peripheral vascular disease. (b) In neck – for carotid artery stenosis. (c) Temporal arteries – Absent pulsation in external carotid occlusion.

Tortuous in atheroma. Tender, thickened, poorly pulsatile in cranial arteritis. Tortuous, dilated highly pulsatile temporal artery when the artery is feeding an arteriovenous malformation, or a meningioma.

4. *Bruits* – due to stenosis. Over carotid and subclavian arteries, bruit produced by stenosis in vertebral arteries. Auscultation of orbit or skull if intracranial arteriovenous malformation or arteriovenous shunt.
5. *Signs of head injury*.
6. *Ophthalmodynamometry* – for recording ophthalmic artery pressure. A difference in the pressure of the two ophthalmic arteries would suggest a disease in the internal carotid artery on the side of the low pressure.

III. Investigations

CT scan – to establish the pathological diagnosis (infarction or hemorrhage) (Figs. 20 and 21) and to exclude other conditions that may mimic stroke (e.g. subdural hematoma, intracranial tumour). All patients must undergo scanning within 24 hours. The site of infarction can be identified and may give clues to the pathogenesis (e.g. border zone infarct suggests a hemodynamic origin, multiple cortical infarcts a cardiac source of emboli). In suspected SAH, scanning may show subarachnoid blood, and the need for LP may hence be avoided.

With CT, hemorrhage can be seen within a few minutes as an area of increased attenuation, but after a few weeks the lesion becomes of low attenuation, and it may be impossible to distinguish infarct from hemorrhage, if CT is not performed within 2 weeks.

An urgent CT scan is required to exclude surgically treatable conditions (e.g. SAH, cerebellar haematoma, space-occupying lesion). **Indications** – (i) Progressive or fluctuating symptoms. (ii) Drowsiness or coma. (iii) Brainstem symptoms or signs. (iv) Papilloedema, neck stiffness or fever. (v) Severe headache. (vi) Unexpected deterioration.

Magnetic resonance techniques – MRI is more sensitive to small areas of ischemia than CT and can detect traces of old hemorrhage (hemosiderin deposits) indefinitely. New MRI sequences are sensitive to changes of cerebral ischemia and can provide information about the underlying pathophysiology.

- Diffusion weighted imaging uses a sequence of magnetic resonance pulses that are sensitive to intracellular oedema (Figs. 22 and 23). It shows areas of critically ischemic brain tissue as intensely bright increases in signal within minutes of onset ('light-bulb' sign). In acute stroke it is the investigation of choice.

Fig. 20: CT scan showing a cerebral hemorrhage (white area) in left basal ganglia region

Fig. 21: Axial CT image showing hyperdense left MCA in a case of acute infarct

Fig. 22: Acute infarct in left PCA territory showing diffusion restriction on MRI DWI

Fig. 23: Acute infarct in pons DW MRI image

- Perfusion MRI shows low cerebral blood flow by measuring the distribution and transit time of i.v. contrast.
- MR spectroscopy measures the concentration of certain chemical entities within the brain, for example it is sensitive to the presence of lactate (a marker of ischemia not found in normal brain), and can measure the concentration of N-acetyl aspartate (a marker of intact functioning neurons).
- Intracranial magnetic resonance angiography (MRA) can be used to confirm or exclude intracranial vessel occlusion.
- Combination of diffusion-weighted MRI, perfusion MRI and MRA (multimodal imaging) can be performed within 20 minutes. These techniques would

allow targeting for treatment those most likely to benefit, e.g. thrombolysis might be appropriate only in patients with both vessel occlusion on MRA and perfusion-diffusion mismatch.

Carotid ultrasonography - using duplex imaging and Doppler measurement of blood flow in patients with TIA and stroke in the carotid territories, to identify carotid artery stenosis, occlusion and dissection.

MRA - provides an alternative to ultrasound for non-invasive detection of carotid artery stenosis and occlusion or dissection. It can also be used to image distal vertebral and intracranial vessels.

Digital subtraction angiography - (a) If there is doubt after non-invasive imaging (Fig. 24). (b) To confirm occlusion or dissection. (c) In subarachnoid and intrac-

ranial hemorrhage to diagnose the source of bleeding, to detect aneurysms. (d) In suspected vasculitis occasionally. (e) In younger patients with recurrent or unexplained symptoms.

Measurement of O₂ saturation by pulse oximetry

Blood tests

- FBC, including platelet count to detect polycythemia, platelet disorders and infection.
- ESR – if raised suggests infection, systemic vasculitis or carcinoma and should lead to further investigations (e.g. autoantibody screen, CXR).
- Blood sugar, electrolytes and kidney function.
- Fasting lipids.
- Clotting screen – in intracerebral hemorrhage and SAH.

Fig. 24: Magnetic resonance angiogram showing severe left internal carotid artery stenosis in the neck

- Thrombophilia screen – for anti-cardiolipin antibodies, protein C and protein S and antithrombin III levels and factor V Leiden polymorphism, is indicated in patients under age of 30 years or in older patients with TIA or ischemic stroke.
- Syphilitic serology.
- Blood cultures – if infective endocarditis is suspected.

Cardiac investigation – to detect sources of cardiac embolism. (a) ECG – to detect atrial fibrillation. (b) Echo – in patients under age of 60 or older patients with significant cardiac abnormalities or recurrent unexplained stroke. TOE is more likely to identify an atrial abnormality or patent foramen ovale. An i.v. injection of agitated saline can be given to detect right-to-left shunting of blood by visualizing the passage of air bubbles across the patent foramen from right to left atrium during a Valsalva manoeuvre. TOE may also identify ulcerated aortic atherosclerosis or dissection.

Lumbar puncture – for CSF examination, if after CT has excluded distortion of intracranial structures in suspected meningitis or encephalitis. Also to detect blood and xanthochromia in SAH, and to detect increased white cell count and oligoclonal immunoglobulin in those with suspected vasculitis.

Table 41 gives differential diagnosis of vascular causes of stroke.

Table 42 for the localization of site of lesion in stroke.

Management

Acute Ischemic Stroke

1. **General therapy** – comprises respiratory and cardiac care, fluid and metabolic management, control of BP, prophylactic measures against DVT, aspiration pneumonia and decubitus ulcer.

Table 41: Differential diagnosis of vascular causes			
	Embolism	Thrombosis	Haemorrhage
1. Age	Young	Middle or old	Middle age or old
2. Nature of onset	Instantaneous Maximum deficit at onset	Sudden or progressive	Catastrophic Progressive
3. Premonitory symptoms	Absent	Difficulty in speaking or weakness of arm or leg may be first symptoms	Usually absent
4. Common cause	Mitral stenosis with atrial fibrillation, carotid stenosis	Arteriosclerosis with or without hypertension	Hypertension almost invariable
5. Clinical features Headache	Variable	Slight or absent	Severe in large haemorrhage

Contd...

Contd...

	<i>Embolism</i>	<i>Thrombosis</i>	<i>Haemorrhage</i>
Vomiting at onset	Rare	Rare	Common
Convulsions	Common	Rare	Common
Coma	Rarely deep	Varies with extent of thrombosis	Deep unconsciousness
Cheyne-Stokes respiration or laboured breathing	Not common	Seldom	Common
Stiff neck	Rare	Rare	Frequent
Conjugate deviation of eyes	No change	Seldom	Frequent
Reaction of pupil to light	Normal	May be impaired	Commonly impaired
Blood pressure	Rare	May be high	Usually high
Bilateral extensor plantar		May be present	Frequent
6. CSF	Usually normal Pleocytosis, if infected embolus	Clear, pressure slightly increased	Usually bloody, pressure increased
7. CT scan or MRI	Infarction may not appear for 24–48 hrs on CT	May not appear for 24–48 hrs on CT scan	Can be confirmed within minutes of onset
8. Termination	Recovery usual	Recovery often	Rapid deterioration High mortality

Note: Large infarct may present like (mimic) bleed, small bleed may present like infarct.

Table 42: Localization of site of lesion

<i>Site of lesion</i>	<i>Localizing symptoms</i>
Cortex	F1acid hemiplegia with cortical sensory loss. Aphasia common in dominant hemisphere lesions. Convulsions may occur.
Internal capsule	Commonest site. Hemiplegia. Hemianaesthesia, if lesion in posterior one-third. No loss of consciousness. Spasticity marked.
Thalamus	<i>Thalamic syndrome</i> – (i) Fleeting hemiparesis or hemiplegia on the side opposite the lesion. (ii) Impairment of superficial and loss of deep sensation on the opposite side of the body. (iii) Elevation of threshold to cutaneous, tactile, thermal, and painful stimuli, but these when perceived have an abnormal painful quality. (iv) Intolerable, spontaneous pains and hyperpathia on opposite side. (v) Ataxia, tremor and/or choreoathetoid movements on the opposite side. (vi) Conjugate internal deviation of both eyes with weakness of upward gaze, eyes deviated down and medially.
Midbrain	Upper level – Weber's syndrome – 3rd nerve palsy with crossed hemiplegia. Lower level – Benedict's syndrome (upper red nucleus syndrome) – 3rd nerve on side of lesion with tremors, hypertonia and ataxia on opposite side.
Pons (Fig. 25)	Millard-Gubler syndrome – Paralysis of lateral rectus, with or without LMN type of facial paralysis on one side with crossed hemiplegia. Foville's syndrome – Similar to Millard-Gubler syndrome except that instead of lateral rectus paralysis, there is conjugate ocular deviation to side of lesion. Avellis's syndrome – Paralysis of 10th cr. n. on one side (LMN type) with contralateral hemiplegia. Horner's syndrome – Paralysis of the ocular sympathetic may result from a lesion in the tegmentum of the pons.
Medulla	Medial medullary syndrome (Dejerine's syndrome) – Ipsilateral flaccid tongue weakness, contralateral hemiplegia and contralateral loss of position and vibration sense (from infarction of medial lemniscus), occasionally upbeat nystagmus. Lateral medullary syndrome (Wallenberg's syndrome) – Abrupt onset with vertigo (vestibular nucleus), dysphagia (N. ambiguus), ataxia (inferior cerebellar peduncle). On examination ipsilateral anaesthesia of face (descending tract of 5th nerve), and contralateral of limbs and trunk (spinothalamic tract), ipsilateral Horner's syndrome (descending sympathetic fibres), nystagmus (vestibular nerve and cerebellar fibres), ipsilateral intention tremor (inferior cerebellar peduncle).

Contd...

Contd...

Site of lesion	Localizing symptoms
Temporal lobe	Deep posterior temporal lobe – Pyramidal fibres pass in close proximity to visual fibres hence hemiplegia usually associated with homonymous hemianopia or upper quadrantic field defect.
	Anterior temporal lobe – On the dominant hemisphere the pyramidal system lies just medial to the speech fibres, hence hemiparesis associated with expressive aphasia.
Spinal cord	Unilateral lesion of the corticospinal tract below the medulla and fifth cervical segment produces spinal hemiplegia involving the limbs of the affected side but without paralysis of muscles innervated by cranial nerves.
Cerebellum (Figs. 26 and 27)	Acute cerebellar infarct is due to vertebrobasilar ischemia and presents with severe vomiting, headache, vertigo and altered sensorium. Being in the posterior fossa, it can deteriorate fast and herniate.

Fig. 25: Acute infarct in pons MRI axial view T2 image

Fig. 26: Cerebellar infarct MRI axial view T2 image

Fig. 27: Cerebellar infarct MRI DW image

(a) **Oxygen** – 2–4 litres/minute nasally helps attain adequate oxygenation of the penumbra. Intubation should be considered in case of vertebrobasilar and hemispheric infarction and also in cases of pathological respiratory pattern.

(b) **Assessment of cardiac function** includes optimal cardiac output, maintenance of high normal BP and a normal heart rate. Cerebral blood flow autoregulation depends on Mean Arterial Pressure, hence a drop in BP should be prevented to maintain optimum cerebral perfusion. As a result, BP level of 180/100 should be maintained in previously hypertensive patient. In other cases mild hypertension is desirable.

(c) **Blood sugar** – above 100 mmol/L should be managed with insulin titration.

(d) **Fever** – Temp. >37.5°C should be treated with paracetamol. Also the cause of the fever should be ascertained and treated appropriately.

(e) **Fluid and electrolytes** should be monitored.

2. **Specific therapy** – (a) Thrombolysis with recombinant-tissue plasma activator (rT-PA) 0.9 mg/kg administered within 3 hours of acute ischemic stroke with 10% as bolus and remainder of the drug by infusion over one hour. Table 43 for the eligibility criteria for iv rT-PA for acute ischemic stroke.

Table 43: Eligibility criteria for iv rT-PA for acute ischemic stroke

Inclusion criteria	
•	Onset of symptoms to drug administration time <4.5 hours.
•	Clinical diagnosis of stroke
•	No hemorrhage on CT scan or edema of > 1/3 of the MCA territory
•	Age >18 years
•	Consent by patient or surrogate
Exclusion criteria	
•	Stroke or severe head trauma in last 3 months or prior intracranial hemorrhage
•	Major surgery in last 14 days
•	Systolic BP above 185 or Diastolic >110.
•	If patient is rapidly improving or has minor symptoms
•	Symptoms suggest SAH
•	Haematuria, malena, haemoptysis or GI bleeding within last 21 days
•	Seizure at onset of stroke
•	Elevated PTT, use of heparin in last 48 hours
•	Prothrombin time >5 sec.
•	Platelet count <100,000/mm ³
•	Glucose <50 or >400 mg/dL
•	Recent myocardial infarction
•	Coma or stupor

In patient with stroke onset <8 hours with occlusion of major carotid artery (MCA), intraarterial thrombolysis can be considered after DSA. Mechanical removal of clot using devices like MERCI device or stent, retrievers can be attempted.

- Prevention of complications** – (a) Nasogastric tube significantly reduces risk of post-stroke pneumonia by preventing aspiration. (b) Treatment of urinary tract infection if any. (c) Prevention of DVT and pulmonary embolism – Physical therapy, support stockings and LMW heparin. (d) Prevention of decubitus ulcer by frequent change of position in bed. (e) Treatment of brain oedema with mannitol. (f) Decompressive surgery for MCA infarction allows extracranial expansion of the oedematous brain tissue to avoid ventricular compression and may be lifesaving at times.
- Rehabilitation** should be active, based on the degree of disability. (a) Active physiotherapy protects against DVT. Prevention of DVT and pulmonary embolism among bedridden patients is the only indication for early anticoagulation after acute ischemic stroke. (b) Aspirin given early may be considered in all patients

mainly to reduce the risk of early recurrence. (c) Treatment of aphasia – Language training of left hand in performance of voluntary movement, in right handed patients.

INTRACEREBRAL HEMORRHAGE

Blood pressure

- Mean arterial pressure <130 in those with history of hypertension
- Avoid mean arterial pressure <110, if patient is post-operative
- Prevent fall of systolic BP <90

Intracranial pressure

- No steroids are indicated
- Intracranial therapy is defined more than 20 mm Hg for > 5 min.
- Maintain cerebral perfusion pressure >70 mm Hg
- Osmotherapy – Mannitol 20% 0.25–0.5 g/kg every 4 hour, keeping sodium osmolality goal of ≤310 mOsm/decilitre
- Hyperventilation – PaCO₂ 30–35
- Muscle relaxants
- Non depolarizing neuromuscular blockade
- Maintain euvolaemia

Temperature

- Treat temp. > 38.5°C

Medical therapy

- Factor rVII given within 4 hours after intracerebral hemorrhage
- **Surgery** – Posterior fossa craniotomy in cases of cerebellar hemorrhage or infarction with acute obstructive hydrocephalus. Ventricular decompression with external ventricular drainage also can reduce intracranial pressure.

Secondary prevention

1. General measures – Stopping smoking, regular exercise. Control of hypertension, diabetes and treatment of hyperlipidemia.
2. Antiplatelet agents – Combination of Prasugrel 5 mg bd, or Ticagrelor 90 mg bd along with low dose Aspirin 25 mg bd is more effective than Aspirin alone in TIA or ischemic stroke. Combination of Aspirin and Clopidogrel 75 mg/day have been used but with increased risk of bleeding.

Fig. 28: Superior sagittal sinus thrombosis with loss of flow void (black arrow) with venous infarct (white arrow)

Fig. 29: Sinus thrombosis with venous infarct (arrow)

- Preventive neurosurgery – For recurrent subarachnoid and intracerebral bleeding from aneurysms and arterial malformations. In acute cerebellar infarction, if impending herniation, posterior fossa surgical decompression.
- Carotid artery stenosis – (i) **Carotid endarterectomy** – *Indications* – (a) Moderate degree of stenosis. (b) TIA, amaurosis fugax, stroke or retinal infarct within 6 months and with good recovery. (c) Significant stenosis in patient scheduled for major surgery such as coronary bypass.
(ii) **Percutaneous transluminal angioplasty** with stenting is an alternative treatment.
Contraindications – (a) Recent MI. (b) CHF. (c) Uncontrolled hypertension. (d) Age over 80 years.

VENOUS INFARCTION

Thrombosis of cortical veins and/or dural sinuses is less common than central arterial occlusion.

Causes – Dehydration, pyogenic middle ear or sinus infection, pregnancy and puerperium, polycythemia, hyperviscosity syndromes, septicaemia, ulcerative colitis, severe iron deficiency anaemia, head injury, extracranial malignancy, oral contraceptives.

Clinical features – Onset is sudden commonly with focal epilepsy. Raised intracranial pressure develops rapidly if obstruction of the dural sinuses. A focal neurological deficit develops which can be clinically indistinguishable from a stroke due to arterial occlusion, severe headache, papilloedema.

Table 44: Predisposing causes of cerebral aneurysms

1. Coarctation of aorta.
2. Polycystic kidney disease.
3. Renal artery stenosis (fibromuscular dysplasia).
4. Essential hypertension.
5. Ehlers-Danlos syndrome type IV.
6. PAN.
7. SLE.
8. Wegener's granulomatosis.

Investigations – An enhanced CT scan may show a clot within the superior sagittal sinus, but this is better demonstrated by MRI (Figs. 28 and 29). Angiography may be required to make a definite diagnosis.

Treatment – (a) Antibiotics – if sinus thrombosis is infective in origin. (b) IV low molecular weight dextran. (b) Anticoagulants – recommended in spite of presence of haemorrhagic component of the infarct since the underlying cause is thrombosis of the venous sinuses.

Local thrombolysis of the sinuses in case of severe sinus occlusion and raised IP and unconscious patient.

SUBARACHNOID HAEMORRHAGE (SAH)

Causes

- Intracranial aneurysm – Rupture of congenital berry aneurysm or angioma. In order of frequency the aneurysms arise from anterior cerebral arteries, internal carotid intracerebrally, middle cerebral and from the basilar system. Rarely rupture of a mycotic aneurysm (Table 44).

2. Arteriovenous malformation.
3. Cerebral or cerebellar haemorrhage leading into the ventricles or subarachnoid space.
4. Trauma.
5. No obvious cause.

Mycotic aneurysm more often causes distal bleed, not SAH.

SUBARACHNOID HEMORRHAGE

Two common sites are proximal portions of anterior communicating artery and at the origin of posterior communicating artery from the stem of the internal carotid.

SPONTANEOUS SUBARACHNOID HAEMORRHAGE

Clinical Features

1. **Before rupture** – In some cases of aneurysm. Migraine, focal symptoms like transitory attacks of blindness, monoplegia, cranial nerve palsies, or trigeminal anaesthesia.
2. **After rupture**
 - *Symptoms due to rapidly increasing intracranial pressure with meningeal irritation* – The intensity of symptoms depends on rapidity and persistence of hemorrhage. Loss of consciousness with generalized flaccidity occurs when leakage is considerable. In less severe cases the patient may remain semi-stuporose with severe headache and signs of meningeal irritation – headache, photophobia, neck stiffness and Kernig's sign.

Fever – Moderate pyrexia common. If severe and fluctuating, it may suggest ischemic hypothalamic damage.

Fundus – Unilateral or bilateral haemorrhages in some cases, may be accompanied by subhyaloid and vitreous haemorrhages.
 - *Focal symptoms* – due to compression of neighbouring cranial nerves by blood clot, or to invasion of the cerebral hemisphere by the hemorrhage – (i) Visual field defect from compression of optic nerve, chiasma or tracts. (ii) 3rd, 4th and 6th nerve involvement, if aneurysm near cavernous sinus. (iii) Mental impairment, hemiparesis, and if on left side expressive aphasia from hemorrhage from aneurysm at junction of anterior cerebral and anterior communicating arteries invading the frontal lobe. (iv) Epileptiform convulsions and monoplegia if leakage of aneurysm in cortical course of

middle cerebral. (v) Crossed homonymous hemianopia due to hemorrhage into substance of posterior lobe. (vi) Quadriplegia or crossed paralysis, if basilar artery aneurysm and leakage. (vii) Head retraction, if bleeding into posterior fossa.

- *Reactive hypertension* – Rise of BP in patients with no evidence of pre-existing hypertension may take several days to return to normal.

Complications: of Aneurysmal SAH

A. Intracranial

1. *Rebleeding* – Risk of recurrent hemorrhage reaches its peak between 10th and 14th day after initial rupture. About 30% rebleed.
2. *Cerebral ischemia* – A blood clot in subarachnoid space in vicinity of major cerebral vessels may result in development of cerebral arterial spasm after 5–10 days. Diagnostic features – (a) Gradual fall in level of consciousness. (b) Appearance or worsening of focal neurological deficits such as dysphasia or hemiplegia. (c) Repeat lumbar puncture shows no evidence of fresh hemorrhage and (d) CT scan – In patients with focal signs there are usually areas of ischemia which do not show characteristic wedge-shaped patterns of arterial infarction and are often haemorrhagic.
3. *Hydrocephalus* – may develop some weeks after SAH and should be considered in patients who fail to improve. CSF drainage may be impaired by blood clot within basal cisterns or obstruction of arachnoid villi ('communicating' hydrocephalus), or blood clot within ventricular system ('obstructive' hydrocephalus).
4. *Expanding intracerebral hematoma* – Brain swelling around the hematoma may cause progressive deterioration in level of consciousness or progression of focal signs.
5. *Seizures* – generalized or focal may occur at any stage especially if cortical damage from the hematoma.
6. *Hyponatremia* – there is natriuresis and volume depletion, seen immediately within 2 hours (cerebral salt wasting syndrome)

B. Extracranial

1. *Cardiac* – Myocardial infarction and cardiac arrhythmias due to catecholamine release following ischemic damage to hypothalamus.
2. *Pulmonary oedema* – Probably as a result of massive sympathetic discharge.
3. *Gastric hemorrhage* – from stress erosions.
4. *SIADH*.

Investigations

CSF - Pressure raised, red cells with supernatant fluid xanthochromic. Proteins increased slightly and mononuclear pleocytosis usually due to irritation of meninges by extravasated blood.

Angiography - may reveal the causal lesion in about two-third cases. It should be done unless the patient's condition contraindicates surgery because of shock, old age, atheroma of severe degree or hypertension, even if the lesion is demonstrated.

Skull radiograph - Shift of pineal gland (if calcified) when there is a large hematoma.

CT scan - (a) Confirms diagnosis of SAH. (b) Identifies other associated lesions such as hydrocephalus, intracerebral hematoma, A-V malformation. (c) Helps identification of site of aneurysm rupture.

Digital subtraction angiography - has the advantage of giving computer-enhanced images and amount of contrast material required is small (Fig. 30).

Prognosis: About one-third die in first attack; of survivors about half have recurrence within 2-4 weeks. Tendency for interval between successive haemorrhages to become shorter. Prognosis better with angioma than with aneurysm.

Management

1. Medical - (a) *General* - Bed rest with head slightly elevated. If an aneurysm has been demonstrated and patient is not suitable for surgery, a minimum of 4 weeks of complete rest in bed will probably reduce risk of recurrent hemorrhage. (b) *Reduction of BP* - towards normal unless there is evidence of progressive

Fig. 30: IV DSA image of the left carotid artery shows a large aneurysm arising from the left middle cerebral artery (arrow)

neurologic deficit due to ischemia. (c) *Nimodipine* - A calcium channel blocker reduces the incidence of cerebral ischemia. Dose 60 mg every 4 hours should be started as soon as possible and continued for 21 days after the SAH. (d) Reduction of increased intracranial pressure as indicated by headache, convulsions or stiff neck. Spinal puncture is done only for diagnostic purposes. Repeated lumbar punctures may give rise to a new leakage. (e) *Symptomatic treatment* - Analgesics and/or diazepam for headache and restlessness.

2. Surgical - for prevention of rebleeding- (a) *Direct clipping* - of the aneurysm neck - is optimal method of treatment. (b) *Trapping* - Clipping of proximal and distal vessels for giant aneurysms and intracavernous aneurysms. Prior anastomosis of superficial temporal to middle cerebral artery minimises the risk of ischemic deficit. (c) *Wrapping* - If clipping is not possible because of the width of the aneurysm or its attachment to adjacent vessels, muslin gauze can be wrapped round the fundus. (d) *Induced thrombosis* - within the aneurysm sac. Risky and rebleeding may occur. (e) *An aneurysm is localized* - Ligation of internal carotid or common carotid artery in neck. Indications - (i) Young patients with severe initial hemorrhage or early recurrences. (ii) Subdural hematoma following ruptured aneurysm. (iii) Aneurysms arising directly from carotid artery where clipping has failed or not attempted, e.g. intracavernous or giant ophthalmic artery aneurysm. (f) *Coiling* - Endovascular techniques involve placing platinum coils or other embolic material, within the aneurysm via a catheter that is passed from the femoral artery.
3. *After recovery* - Metabolic changes due to release of catecholamines produce ischemia of hypothalamus, kidneys and heart. Hence glycosuria, high blood pressure, ECG changes. Vascular spasm may produce drowsiness, confusion, hemiplegia and aphasia.

ARTERIOVENOUS MALFORMATIONS (AVMs)

AVMs are congenital abnormalities which may affect any part of the brain, including cerebellum and brainstem.

Clinical Presentation

1. Intracranial bleeding - more commonly intracerebral.
2. Epilepsy - AVMs responsible are usually large parietal lesions.
3. Progressive neurological deficits - such as slowly evolving hemiparesis.

Fig. 31: AV malformation dynamic post-contrast early filling of superior sagittal sinus

Fig. 32: AV malformation flow voids in MRI T2 image

4. Headache – may be the only presenting symptom. Migraine like headache in occipital AVM.

Investigations – CT scan can demonstrate large AVMs. Angiography for small AVMs when surgical excision is being considered (Figs. 31 and 32).

Treatment – (a) Surgery indicated if hemorrhage has occurred and the malformation is easily accessible and can be excised without neurological deficit. (b) Embolization of feeding arteries of large lesions with multiple feeders. (c) Stereotaxic radiosurgery may be used to obliterate small AVMs.

13. COMA AND BRAINSTEM DEATH

Coma is a state of total absence of awareness of self and environment. Unconsciousness may result from disturbances (functional or structural) of large areas of both cerebral hemispheres and/or upper brainstem structures. Table 45 for the causes of coma.

DIAGNOSIS OF COMA

Structural Brain Damage

A. Supratentorial mass lesions:

1. *Signs of causative lesion* – e.g. hemiparesis, papilloedema.
2. *Signs due to expanding mass lesion* – causing downward displacement of the temporal lobe over the edge of the tentorium (uncal herniation), or midline compression of the upper brainstem – (a) *Uncal herniation* – Signs of hemipare-

Table 45: Causes of coma

1. Structural brain damage (supratentorial, infratentorial):
 - Infarction
 - Haemorrhage
 - Head injury
 - Tumour
 - Haematoma
 - Infection: meningitis, cerebral malaria, encephalitis, abscess
 - Brainstem demyelination (multifocal, diffuse, metabolic disease)
2. Systemic causes:
 - *Metabolic* – Anoxia-ischemia. Respiratory, cardiac, hepatic diseases or kidney failure. Hypoglycemia. Wernicke's encephalopathy. Hypo/hyponatremia, Hypo/hypercalcaemia.
 - *Endocrine* – Diabetic coma, myxoedema, Addison's disease, pituitary apoplexy.
 - *Drug overdose and poisons* – Barbiturates, organophosphorus poisoning, alcohol, carbon monoxide poisoning, etc.
 - *Physical agents* – Hypothermia, heat stroke.
 - *Hypertensive encephalopathy*.
 - *Septicaemia*.
3. Psychogenic

sis and papilloedema, and sequential loss of 3rd nerve function. Unilateral dilatation of the pupil with impaired response to light implies temporal lobe herniation. (b) *Central herniation* – Orderly progression of brainstem dysfunction – (i) At first reactive small pupils and Cheyne-Stokes respiration are present and the patient can be roused by painful stimuli. (ii) Midbrain compression causes decerebrate rigidity, dysconjugate eye movements and fixed medium-sized pupils and the subject is

then virtually unresponsive. (iii) Finally the pupils dilate, respiration becomes grossly irregular, no eye movements can be elicited and patient is deeply comatose. Medullary involvement causes gasping, usually a terminal sign. (c) *Cerebellar herniation* (see later).

B. Brainstem (local) lesion:

1. *Rapid onset of coma* – Infarction of brainstem.
2. *Abnormalities of pupil responses and eye movements* – Present from the onset and orderly sequence of changes caused by herniation is not seen. Pupils may be fixed and counter rolling of head may reveal dysconjugate eye movements and loss of gaze in one direction. Pontine haemorrhage produces pin point pupils, loss of eye movements and hyperthermia. The eyes look toward a hemispherical lesion and away from a brainstem lesion.
3. *Cranial nerve signs.*
4. *Bilateral long tract signs.*
3. *Headache* – with vomiting, progressive mental changes, increasing weakness or unsteadiness of limbs would suggest an expanding intracranial lesion. Severe headache and vomiting at onset with immediate loss of consciousness in hypertensive patient favours diagnosis of intracerebral hemorrhage. History of fever with headache and vomiting in meningitis, meningoen- cephalitis with or without hydrocephalus.
4. *History of severe psychological disturbance* – raises possibility of self-administered drug intoxication.
5. *History of alcohol intake.*
6. *History of head injury* – (i) On admission – Diffuse shearing injury and/or intracranial hematoma. (ii) Previous head injury (e.g. 6 weeks) – Chronic subdural hematoma.
7. *History of bleeding diathesis* – Non-traumatic intracerebral hemorrhage is usually associated with systemic hypertension but may occur in patients with bleeding diathesis.
8. *Recent symptoms suggestive of a tumour* – e.g. headache, personality change or insidious hemiparesis.
9. *Symptoms of cerebellar hemorrhage* – Headache, vertigo and vomiting, with unilateral cerebellar ataxia, would suggest occurrence of hemorrhage into one cerebellar hemisphere.
10. *Past history* – Of diabetes mellitus, epilepsy (post-ictal state), kidney disease, cardiac or respiratory failure or of hypertension or malignancy (intracranial metastasis). Previous overdose attempts due to depressive illness.

Metabolic Coma

1. Absence of signs of focal lesion in CNS (except in hypoglycemia) like hemiplegia, 3rd nerve palsy.
2. Preserved pupillary responses (except in cases of anoxia and glutethimide poisoning).
3. Retained eye movements. Dolls eye movement absent.
4. Symmetrical, hypotonic limbs with depressed reflexes.
5. Depressed or Cheyne-Stokes respiration.
6. Flapping tremor, generalized myoclonus, muscle twitching, and acidotic respiration – may be seen in some metabolic causes, e.g. hepatic or respiratory failure, delirium precedes deterioration in consciousness.

INVESTIGATION OF A CASE OF COMA

History

1. *Mode of onset* – Abrupt loss of consciousness in cerebrovascular accidents and postictal, rapid and in a period of few hours in some cases of intracranial hemorrhage and some toxic states; gradual over days in expanding intracranial lesions, metabolic or infective cause.
2. *Premonitory symptoms* – Complete absence of premonitory symptoms would suggest a primary intracranial vascular accident.

General Examination

1. *General appearance* – Flushed face in alcoholic, pale yellow in uraemia, cherry red in carbon monoxide poisoning. Cold clammy skin suggests hyperinsulinism or morphine poisoning; pigmentation of skin and buccal mucosa in Addison's disease; petechiae in skin suggestive of cerebral embolism.

Fever – usually indicates a systemic infection, meningitis, cerebral malaria, encephalitis or cerebral abscess.

2. *Odour* – of alcohol, sweet smell in diabetic ketosis, ammoniacal in uraemia, and of drug like cyanide. Foetor hepaticus in hepatic coma. Pungent odour in organophosphorous poisoning.
3. *Head* – Depressed fracture of skull may be palpable.
4. *Ears* – Blood may suggest basal fracture. Middle ear infection or tenderness and swelling over mastoid may indicate an intracranial abscess.

5. *Eyes* – (a) *Jaundice* in liver failure. (b) *Soft eyeballs* in diabetic acidosis. (c) *Resistance to opening of eyes* and rolling up of eye balls in hysterical coma.
6. *Hypothermia* – following exposure to low temperatures, intoxication with alcohol or hypnotics, profound myxoedema or peripheral circulatory failure, barbiturate poisoning.
7. *Tachy or bradyarrhythmias* or evidence of valvular heart disease or peripheral emboli suggest cardiogenic cause. Bruits over carotids suggest cerebrovascular disease (Embolic stroke).
8. *Hypotension* – Possibility of shock, myocardial infarction or septicaemia or Addison's disease, barbiturate poisoning.
9. *Respiration* – Slow, shallow breathing suggests drug intoxication. Deep and rapid respirations suggest pneumonia or metabolic acidosis or diabetic ketosis. Periodic respiration suggests cardiac or brainstem lesion.
10. *Enlargement of an abdominal organ* – might indicate portal hypertension, polycystic kidneys and an associated SAH.
11. *Purpura* – suggests a bleeding diathesis, and bruising around the head possible trauma or fracture at base of skull.
12. *Rash* – may indicate an infective or inflammatory disease, meningococcal meningitis.
13. *Evidence of puncture wounds* – may identify a diabetic patient or a drug user.

Neurological Examination

Glasgow coma scale – The patient's response to certain stimuli (supraorbital pressure, rubbing the sternum with knuckles, pressing the side of a pencil on the nail-bed, and pressure on Achilles tendons) is observed (Table 46).

Brainstem Function

Pupils

- Unilateral dilatation of pupil with no light response suggests an uncal herniation; expanding supratentorial lesion it may also be seen in posterior communicating artery aneurysm or other IIIrd nerve damage.
- Mid-brain lesions typically cause loss of light reflex with pupils in mid-position, and lesions in the pons cause miosis with retained light responses.
- Fixed dilatation of pupils suggests significant brainstem damage, but must be differentiated from the fixed dilatation from earlier instillation of atropine-like agents.

Table 46: Glasgow coma scale

Maximum score = 15, minimum = 3		
		Score
<i>Eye opening:</i>	<i>Spontaneous</i>	4
	To speech	3
	To pain stimulus	2
	Nil	1
<i>Verbal response:</i>	Orientated	5
	Confused conversation	4
	Inappropriate words	3
	Incomprehensible sounds	2
	Nil	1
<i>Motor response:</i> (best limb)	Obeys commands	6
	Localizes pain	5
	Withdraws	4
	Abnormal flexion to pain	3
	Extension to pain	2
	Nil	1

- Horner's syndrome may be seen with lesions in the hypothalamus or brainstem, but can also be observed in diseases affecting the wall of the carotid artery.
- Small pupils which are reactive – metabolic coma, diencephalic lesion. Pinpoint and reacting – pontine lesions (requires magnifying lens to examine pupillary light responses). Drug intoxication tends not to affect pupillary light responses. Opiates and organophosphorus poisoning cause bilateral pinpoint pupils.
- Anaesthesia results in unreactive and slightly dilated pupils.

Corneal response – is usually retained until very deep coma. If it is absent in patient in light coma, the cause of coma may be drug intoxication. Loss of corneal reflex in absence of drug overdosage is a poor prognostic indicator. Suggests brainstem (pons) dysfunction.

Spontaneous eye movements – (a) Conjugate deviation of the eyes suggests a focal hemispheric or brainstem lesion. (b) Depression of eye movements may occur in midbrain damage at level of the tectum and occasionally in metabolic coma. (c) Skew deviation suggests a lesion at pontomedullary junction. (d) Dysconjugate eyes suggest damage to oculomotor or abducens nerve in brainstem or pathways. Repetitive conjugate horizontal ocular

deviation ('ping-pong gaze') is an indicator of brainstem lesions. Nystagmus, in which the eyes jerk backwards in the orbits, usually indicates a mid-brain lesion. Irritative or epileptic phenomenon cause deviation of eyes away from a cerebral lesion. Convergence retraction nystagmus - Dorsal brain lesion (Parinaud's syndrome). In pontine lesions eyes are deviated away from the lesion. Eyes are deviated downwards and medially in lesions due to compression on midbrain tectum. Wrong way eyes (deviation away from lesion) may be seen in medial thalamic lesions. Intermittent jerking downwards of the eyes (ocular bobbing) is seen with lesions in the low pons.

Reflex eye movements - (a) Oculocephalic response is tested by rotating the patient's head from side to side and observing the position of the eyes. With intact brainstem activity, the eyes move conjugately in a direction opposite to the head movements (*doll's eye movements*), but when the brainstem is depressed the eyes remain in the mid-position of the head. (b) Oculovestibular testing involves instilling 50 mL of ice cold water into the ear. Conscious patients, or those with psychogenic coma, will develop nystagmus with the quick phase away from the side of the stimulation. A tonic response with conjugate movements of the eyes towards the stimulated side indicates an intact pons and suggests a supratentorial cause for the coma; a dysconjugate response or absence of response, implies a lesion in the brainstem.

Respiratory pattern - Long-cycle Cheyne-Stokes respiration indicates damage at the level of the diencephalon, and short-cycle occurs with damage at medullary level. Central neurogenic hyperventilation occurs with lesions in the low mid-brain and upper pons. Reflex responses such as yawning, vomiting and hiccough may occur with brainstem disturbance. Acidotic respiration suggests diabetic ketoacidosis or uraemia.

Motor function - is assessed for the Glasgow coma scale, but lateralizing abnormalities are important. (a) Generalized or focal seizures implies hemispheric damage and may help lateralization. (b) Multifocal myoclonus favours a metabolic or anoxic cause for coma with diffuse cortical irritation. (c) Tendon reflexes - Deep tendon reflexes and plantar response may also give clues to lateralization, implying a focal cause for coma, though focal signs may be seen in hepatic encephalopathy and hypoglycemia.

Involuntary movements - (a) Asterixis, tremulousness and multiple myoclonic jerks are usually seen in patients with metabolic encephalopathies. (b) Multifocal

cal seizures may also occur in patients with uraemia and hyperglycaemic hyperosmolar state (HHS).

Spleen - may be palpable in cerebral malaria.

Pulse - Slow, full bounding pulse suggests increased intracranial pressure. Slow in morphine poisoning, brain tumour and Stokes-Adams syndrome. Irregular pulse may be found in valvular heart disease causing embolism.

Fever - in cerebral malaria, subarachnoid, intracerebral or pontine haemorrhage; sun stroke, septicaemia. May be normal in morphine poisoning and uraemia.

Sweating - strikingly absent in heat hyperpyrexia.

Blood pressure - elevated in uraemia or cerebral haemorrhage.

Fundus - Papilloedema in intracranial tumour, cerebral venous sinus thrombosis or hypertensive encephalopathy; white patches and haemorrhages in uraemia, changes of diabetic retinopathy, subhyaloid haemorrhage in SAH.

Laboratory Investigations

1. *Urine* - for sugar, albumin and acetone for toxic screening (benzodiazepines, alcohol).
2. *Blood* - Blood count, estimation of blood glucose, electrolyte values including calcium. Blood urea. Blood levels of common intoxicants. Blood ketones and osmolality in certain circumstances. Blood smear for malarial parasites. Blood culture.
3. *CSF* - for evidence of haemorrhage, meningitis or encephalitis. (Lumbar puncture may be deferred, if a mass lesion is present.)
4. *Analysis of vomit or gastric lavage.*

Radiography

1. *Of skull* - to demonstrate any fracture, to show condition of sella - erosion would suggest increased intracranial pressure; to show infection in sinuses, mastoids or petrous bones which may suggest intracranial infection; to demonstrate pineal shift which suggests a mass lesion.
2. *Of chest* - may reveal carcinoma (cerebral metastasis), bronchiectasis, abscess or empyema (cerebral abscess), tuberculosis (meningitis) or mitral stenosis (cerebral embolism).

CT Scan or MRI

- (a) Coma with focal signs or evidence of head injury, whether the focal signs indicate a brainstem or supratentorial lesion. A normal scan may be seen in patients with hypoglycemia or hepatic coma.

- (b) Coma without focal signs but with meningeal irritation - Brain imaging to identify subarachnoid blood excludes the focal collections in case of bleeding or infection. Depending on the results of the scan a lumbar puncture can be undertaken.
- (c) Coma without focal or lateralizing neurological signs without meningismus - Most of these patients have suffered diffuse anoxic or ischemic disease, e.g. following cardiac arrest. Metabolic derangement or drug insult. Imaging may be necessary, but assessment of metabolic indices and toxic metabolites in the blood will provide the diagnosis. LP may be indicated to exclude an inflammatory or infective cause. Marked depression of brainstem responses in a patient who appears to be in relatively light coma suggests drug-induced coma.

Cerebral Angiography

Useful aid in brain tumour and subdural haematoma.

EEG

(a) In comatose patients, where clinical examination has failed to localize the lesion, an EEG may localize it to one hemisphere, of particular value in cerebral abscess. (b) May provide evidence of nonconvulsive status. Triphasic waves in hepatic encephalopathy, uraemia, periodic lateralizing discharges in herpes encephalitis. Burst suppression in hypoxic - ischemic encephalopathy. Normal EEG may suggest locked-in state. Isoelectric, flat EEG (< 2 mV amplitude) suggests brain death (Electrocerebral silence, inactivity). Alpha coma waves anteriorly seen in drug-induced coma, post hypoxic. (c) An entirely normal EEG will make a supratentorial lesion unlikely. (d) It may give evidence of

a specific cause such as hepatic encephalopathy or herpes simplex encephalitis, or minor epileptic status.

Therapeutic test

IV 50% glucose can be given as a therapeutic test in any case of unexplained coma or hemiparesis where hypoglycemia is suspected (oral hypoglycaemic induced, self-medication with insulin).

DIFFERENTIAL DIAGNOSIS OF COMA

Vascular Causes

1. *Cerebral haemorrhage, thrombosis or embolism* - (Refer).
2. *Subarachnoid haemorrhage* - (i) Sudden intense headache. (ii) Meningeal signs and neck rigidity usually prominent. (iii) Focal neurological signs frequently absent but can occur and are usually due to intracerebral clot or infarction in the region of the involved territory. (iv) Subhyaloid haemorrhage may be noted on fundus examination. (v) CSF - presence of blood.
3. *Hypertensive encephalopathy* - (i) Common in patients with acute hypertension as in eclampsia, pheochromocytoma or acute GN. (ii) Convulsions, either focal or generalized. (iii) Transient cerebral symptoms like blindness, aphasia or hemiplegia. (iv) Papilloedema. (v) Lumbar puncture - CSF gushes out in a stream (raised intracranial pressure).
4. *Cerebral venous thrombosis* - Superior longitudinal sinus thrombosis (Figs. 33 and 34) occurs in relation to extra and intracranial sepsis, debilitating diseases, dehydration, pregnancy, post-partum period,

Fig. 33: CT venography shows superior sagittal sinus thrombosis empty delta sign (arrow)

Fig. 34: CT venography shows filling defect in right sigmoid sinus due to thrombosis (arrow)

polycythemia, or in women taking contraceptive pills. Common clinical features include focal seizures, loss of sensation and movement in the legs (crural dominance), and features of raised intracranial pressure – headache, vomiting and papilloedema.

5. *Adams-Stokes syndrome* – (i) History of myocardial infarction. (ii) Giddiness, faintness and convulsions precede coma. (iii) Heart rate very slow.
6. *Shock* – due to injury or loss of blood. (i) Evidence of cause. (ii) Low blood pressure. (iii) Feeble pulse. (iv) Cold and clammy skin.

Metabolic Disorders

Relative preservation of brainstem reflexes. Seizures. Symmetrical signs. No focal findings.

1. *Diabetic coma* (Hyperglycaemic ketoacidosis) – History of diabetes. Dehydration and hyperventilation (Kussmaul's respiration). Breath smells of acetone. Often hypotension, tachycardia, warm skin.
2. *Chronic kidney failure* (Uraemia) – History of renal disease. Variable rate of progress. Anaemia, hypertension. Ammoniacal odour of breath. Raised blood urea and creatinine.
3. *Hepatic coma* – (i) Preceding stage of acute hepatitis or cirrhosis. (ii) Severe jaundice. (iii) Liver may be palpable. (iv) Vomiting. (v) Headache, delirium or convulsions. (vi) Hepatic foetor usually present when collateral vessels link portal (gut) with systemic (mouth) circulation.
4. *Hypoglycaemic coma* – (i) History of taking insulin or spontaneous (insulinoma). (ii) Sudden onset. (iii) Headache common. (iv) Diplopia, apathy and confusion. (v) Muscular twitchings. (vi) Skin pale and moist. (vii) Deep reflexes brisk. (viii) Low blood sugar.

HEAD INJURIES AND THEIR COMPLICATIONS

1. *Brain trauma* – (i) History or evidence of head injury. (ii) Bleeding from nose, mouth or ears. (iii) Respiration rapid, irregular or Cheyne Stokes. (iv) Pulse rapid, later slow. (v) Pupils inactive, often unequal. (vi) Paralysis of cranial nerves. (vii) CSF – blood, with normal pressure.
2. *Chronic subdural haematoma* – (i) History of head injury followed weeks or months later by (ii) headache, nausea, vomiting and disturbances of vision. (iii) Headache of gradually increasing intensity. (iv) Mental symptoms. (v) Weakness in extremities on one or

both sides. (vi) Periods of unconsciousness. (vii) CSF – pressure increased, yellowish. (viii) CT scan of skull confirms diagnosis.

Drugs and Poisons

Depression of brainstem reflexes particularly reflex eye movements. Symmetrical signs (see Chapter 15).

INTRACRANIAL INFECTIONS AND TUMOURS

1. *Meningitis* – (i) Gradual onset. (ii) Signs of meningeal irritation. (iii) Fever. (iv) CSF changes.
2. *Brain tumour* – (i) Headache and vomiting. (ii) Visual disturbances. (iii) Neurological signs according to site of tumour. (iv) Progressive course. (v) Papilloedema.
3. *Cerebral abscess* – (i) Course usually more rapid than intracranial tumour. (ii) Evidence of infection like sinusitis, otitis media, lung abscess, etc. (iii) Fever. (iv) Leucocytosis. (v) CSF – increased cells.
4. *Cerebral malaria* – (i) History of fever with rigors. (ii) Spleen may be enlarged. (iii) Fever common; may be hyperpyrexia.
5. *Encephalitis* – (i) Acute onset seizures. (ii) Headache. (iii) Insomnia or drowsiness. (iv) Pupillary and ocular changes. (v) Involuntary movements. (vi) CSF – Normal sugar suggestive. (vii) EEG – Focal abnormalities, PNED.

POST-EPILEPTIC COMA

Diagnostic features – (a) History of GTC seizures. (b) Scars on head from previous falls. (c) Tongue may be bitten. (d) Respiration slow. (e) Pupils fixed during convulsion. (f) Evidence of involuntary defecation or micturition. (g) Recovery usually within an hour without paralytic sequelae, but status epilepticus may be followed by prolonged coma.

COMA OF ENDOCRINE ORIGIN

1. *Hypopituitarism* – Sudden onset if precipitated by infection. Usually female with changes of hypopituitarism. Low BP and low blood sugar.
2. *Myxoedema* – Characteristic appearance with slow pulse and subnormal temperature.
3. *Suprarenal cortical failure* – May occur suddenly as a result of stress, e.g. operation in a patient known to be suffering from cortical deficiency. Low BP and electrolyte disturbances.

PHYSICAL AGENTS

1. *Heat hyperpyrexia and Sun stroke* - (i) Prolonged exposure to high temperature or to heat of sun. (ii) Suffused conjunctivae with contracted pupils. (iii) Hyperpyrexia. (iv) Absence of sweating and dry skin. (v) Circulatory collapse. (vi) Convulsions.
2. *Electric shock* - (i) History of being exposed to electric current. (ii) Evidence of skin burns.
3. *Severe fevers* - e.g. typhoid, typhus - (i) Insidious onset. (ii) Fever of a few days or weeks duration. (iii) Other features or typhoid state.

Psychogenic: *Suggested by* - (i) History of psychological disturbance like hysteria, depressive state or schizophrenia. (ii) Usually occurs in presence of audience. (iii) Not true unconsciousness but severe state of stupor. (iv) Unusual attitudes. (v) Absence of physical signs. (vi) Fluttering of eyelids, resistance to opening and rolling upward of eyeballs. (vii) Normal pupillary reactions. (viii) Normal EEG.

Management of coma: ABC - Airway, Breathing, Circulation to be secured foremost.

1. *Removal or control of cause* - e.g. - Gastric lavage and diuretics in narcotic poisoning; removal of patient to uncontaminated atmosphere and inhalation of oxygen and 5% carbon dioxide in carbon monoxide poisoning; ice bath or covering the patient with ice water sheets and placing under a fan in heat stroke.
2. *Ensure proper respiration* - (i) Keep tongue forward. (ii) Oxygen inhalation. (iii) When there is deep coma, secretions and vomit if inhaled into the lungs, will soon result in death. The patient must be nursed in the semi-prone or lateral position with frequent changes from one side to the other.
3. *Ensure proper circulation* - (a) Parenteral fluids - Glucose saline, plasma, or blood transfusion. (b) Vasopressor drugs like dopamine if low blood pressure or shock.
4. *Care of bowels and bladder* - (i) Indwelling catheter. (ii) Saline or soap enema.
5. *Care of skin* - (i) Frequent change of position in bed. (ii) Alcohol or spirit rub and powdering of skin. (iii) Care of mouth.
6. *Control of secondary infection* - with antibiotics especially in presence of fever or in afebrile patients with the object of preventing pneumonia.
7. *Specific measures* - e.g. for benzodiazepines or organophosphorus poisoning, meningitis, diabetic coma, etc.
8. *Neurosurgical intervention* - if coma progression raises the possibility of herniation.

PSEUDO-COMA STATES

Locked-in syndrome - Damage to the ventral portion of the pons, below the level of IIIrd nerve nuclei, results in locked-in syndrome in which there is total paralysis of the limbs and lower cranial nerves, but consciousness is intact. Patients can open, elevate and depress their eyes but cannot move them horizontally and have no other voluntary movement or speech. The most common cause is infarction of the ventral pons, usually in hypertensive individuals. Locked-in syndrome is also seen in patients with pontine tumors or multiple sclerosis, in central pontine myelinolysis following profound hyponatremia after head injury and after snake bite. EEG is normal.

Classification

- Classic quadriplegia and anarthria with preserved consciousness and vertical eye movements.
- Incomplete: Same as classic but with remnants of voluntary movement other than vertical eye movements.
- Total: Total inability to communicate with full consciousness.

Psychogenic unresponsiveness - The term 'pseudocoma' is used in patients who appear to be unconscious and in coma, but are not. The simplest means of identifying pseudocoma is oculovestibular testing which reveals nystagmus and indicates that the patient has an intact brainstem and cortex (minimally conscious state).

Vegetative state - In the vegetative state, patient breathes spontaneously, and shows cycles of eye opening and closing, but is unaware of the self and the environment. A vegetative state may be seen transiently in recovery from coma, but it may persist to death. It is usually seen in patients with diffuse bilateral cerebral hemisphere disturbance, most commonly after head injury or as a result of hypoxic-ischemic damage following cardiac arrest. Sleep wave cycle is preserved. Some cortical functions may be preserved.

Akinetic mutism - Such patients appear awake but are mute and either fail to respond to stimuli or respond only after very long delays. It is usually caused by severe bifrontal lobe disease. Patients with akinetic mutism have flaccid tone unlike patients in the vegetative state.

BRAINSTEM DEATH

Preconditions for Diagnosis

1. Patient's condition is due to irremediable brain damage of known aetiology.

Table 47: Criteria for diagnosis of brain death

Patient should be examined to ensure that all brainstem reflexes are absent:

- Pupils are fixed in diameter and do not respond to sharp changes in the intensity of instant light.
- No corneal reflex.
- Oculovestibular reflexes absent.
- No motor responses within cranial nerve distribution can be elicited by adequate stimulation of any somatic area.
- No gag reflex or reflex response to bronchial stimulation by a suction catheter passed down the trachea.
- Apnoea confirmed by a $\text{PaCO}_2 > 6.65$ kPa measured via arterial blood gas analysis, taken 10 min. after disconnection from mechanical ventilation.
- EEG – Flat (< 2 mV amplitude).
- Absent blood flow on angio.

2. Patient should be deeply comatose, and the effects of depressant drugs, primary hypothermia or potentially reversible metabolic and endocrine disturbances as the cause of continuation of coma must be excluded.
3. Patient is being maintained on a ventilator because spontaneous respiration has become inadequate or ceased.
4. BP is maintained on ionotropes.
Table 47 gives the criteria for diagnosis of brain death.

14. NEUROSYPHILIS

Table 48 gives neurological involvement in syphilis.

ASYMPTOMATIC NEUROSYPHILIS

Diagnosis – If syphilis is untreated for 2 years after primary infection, CNS invasion by *Treponema* may occur. There are no clinical symptoms or signs. CSF shows increased cells and gives positive VDRL, FTA and TPHA tests. CSF becomes normal 6 months after adequate treatment.

Antisyphilitic therapy prevents development of symptomatic neurosyphilis in future.

MENINGOVASCULAR NEUROSYPHILIS

Cerebral

1. **Cerebral vascular** – Characterized pathologically by endarteritis with thrombosis and encephalomalacia and clinically by various focal neurological signs such as hemiplegia and aphasia.
2. **Cerebral meningeal** –

Table 48: Clinical manifestations

1. Primary – CSF lymphocytosis.
2. Secondary – Acute syphilitic meningitis.
3. Tertiary:
 - a. *Meningovascular* – (i) Cerebral or spinal endarteritis. (ii) Cerebral or spinal leptomeningitis. (iii) Meningomyelitis.
 - b. *Parenchymatous* – (i) General paresis. (ii) Tabes dorsalis. (iii) Primary optic atrophy.
4. Congenital.

(a) Diffuse cerebral meningeal neurosyphilis

Acute syphilitic meningitis – (i) Acute onset. (ii) Symptoms of increased intracranial pressure – headache, nausea and vomiting. (iii) Evidence of meningeal irritation but Kernig's sign not usually pronounced. (iv) Cranial nerve palsies. (v) Fever. (vi) CSF – 1,000 to 1,500 cells. Thirty percent or more polynuclears; positive for treponemal antibodies (VDRL and FTA - ABS).

Chronic cerebral leptomeningitis – (a) Basal meningitis – Cranial nerve involvement including optic nerves and chiasma. Hydrocephalus, hypothalamic disturbance may occur. (b) Convexity meningitis – results in headache, drowsiness and focal cortical symptoms including fits.

(b) Focal cerebral meningeal neurosyphilis (Gumma) – Signs of expanding intracranial lesion in patient with abnormalities in CSF characteristic of syphilis.

3. **Syphilitic primary optic atrophy** – due to localized syphilitic meningitis. Types – (a) Progressive diminution of vision concentrically from periphery to centre. (b) Wedge-shaped projection. (c) Central visual loss with peripheral vision intact. This is uncommon and does not respond to anti-syphilitic therapy.
4. **Syphilitic dementia or pseudo-general paralysis** – Symptoms closely resembling GPI but cranial nerve paralysis and other indications of widespread lesion.

Spinal

1. *Chronic meningomyelitis* – Initial symptoms due to meningitis – pain in the back, pain in root areas and paraesthesiae. Later symptoms due to extension to cord.
2. *Acute transverse myelitis* (Spinal vascular syphilis) – Spinal arterial thrombosis produces myelitis of sudden onset or with premonitory pains, if coexisting syphilitic meningeal involvement. Symptoms of complete or almost complete transection of the cord.

3. *Cervical hypertrophic pachymeningitis* - (i) Pain in neck, radiating down the upper limbs and between the shoulders. (ii) Progressive weakness and atrophy of muscles supplied by the corresponding anterior roots. (iii) Finally progressive spastic paraplegia with sensory loss below level of lesion. CSF - Mild or moderate lymphocytic pleocytosis, protein content greatly elevated.
4. *Erb's spastic paraparesis* - Progression of paraparesis is very slow and there is little sensory loss.
5. *Spinal gumma* - Symptoms of rapidly growing spinal tumour.
6. *Syphilitic amyotrophy* - Closely resembles idiopathic progressive muscular atrophy or amyotrophic lateral sclerosis. Sensory loss absent or minimal. Pain in the affected limb may occur at onset and is sometimes severe. Treponemal tests positive. Anti-syphilitic treatment arrests progress of the disease.
7. *Radiculitis* - Syphilis usually affects the posterior roots which gives rise to pain of segmental distribution. If anterior roots are affected, there is weakness and wasting of the segmental muscles.
8. *Pseudotabes* - Onset 18 months to 5 years after primary infection. Presents with root pains, absent deep reflexes and bladder disturbances. No AR pupils.

PARENCHYMATOUS NEUROSYPHILIS

General Paresis of the Insane (GPI)

Clinical Features: Stages

1. *Incipient stage* - Presenting symptoms often vague as in dementing illness, ill-defined personality changes with irritability and forgetfulness, poor concentration, headaches and weight loss.
2. *Period of full development of psychosis* - Multiform psychic pictures - (a) Simple demented type - Memory defect, impairment of judgement and lability of mood going on to imbecility. (b) Grandiose type - Sense of euphoria and expressions of delusions of grandeur.
3. *Terminal stage or period of decline* - Fits, sometimes with transient neurological deficits may accompany deterioration or occasionally herald it. Motor signs gradually appear.

Signs - (i) Pupillary abnormalities often of Argyll-Robertson type. (ii) Cranial nerves - Optic atrophy much less common than in tabes. Coarse tremors of facial, labial and tongue muscles. (iii) Slurred and tremulous speech, micrographia and inability to write in straight line. (iv) Exaggerated deep reflexes, plantars extensor. (v) Tabes dorsalis may co-exist (Taboparesis).

CSF - Moderate pleocytosis, 15-100 cells per cmm., increased protein and positive antibody tests.

Tabes Dorsalis

Basic lesion is in the root entry zone of the posterior nerve roots and there is ascending degeneration of the posterior columns, diagnostic features are referable to these.

Clinical Features

1. *Subjective sensory disturbances* - (a) Pains - (i) typical lightning pains; (ii) fixed pains; (iii) girdle pains; (iv) pains of tabetic crisis. (b) Feeling of walking on cotton wool.
2. *Objective sensory loss* - Butterfly area on face, inner side of arms, saddle-shaped area round anus, feet. Anaesthesia of tendo Achilles (Abadie's sign).
3. *Hypotonia* - Abnormal active and passive movements of the limbs; "double jointed" man.
4. *Ataxia*.
5. *Reflexes* - Early loss of ankle jerks; plantars always flexor unless complicated by GPI (Taboparesis).
6. *Ocular signs* - Pupils usually contracted and irregular or unequal in size, sluggish reaction to light. AR pupil in late stages. Optic atrophy may be early; ptosis, transient paralysis of external ocular muscles, diplopia.
7. *Sphincters* - Difficulty in micturition or incontinence or sometimes retention. Faecal incontinence may occur. Impotence sometimes an early symptom.
8. *Trophic changes* - (a) Perforating ulcer usually of pad of great toe. (b) Charcot's joints.
9. *Gait* - (a) Wide-based, (b) eyes fixed to the ground, (c) legs lifted unduly in air, and (d) brought down with a stamp.
10. *Crisis* - Paroxysmal painful disorders of function of various viscera - Gastric crises, the commonest may cause epigastric or, shoulder tip pain with or without vomiting or vomiting without pain.

CSF - Cells usually not above 100/cmm., mononuclear cells, excess of globulin.

CONGENITAL NEUROSYPHILIS

Clinical features - and course similar to those seen after infection in later life. (a) Meningovascular disease is seen during first few years after birth. (b) GPI may occur during school years and present as simple deterioration in performance with fits. (c) Tabes is much less common. (d) Isolated perceptive deafness may present in middle age.

LABORATORY DIAGNOSIS OF NEUROSYPHILIS

Blood serology - In active neurosyphilis VDRL positive in about 75% and TPHA test and FTA-ABS test in nearly all cases. If blood tests are positive, disease activity should be further assessed by CSF examination.

CSF - (a) *Serology* - Positive VDRL is more likely to indicate active disease than positive specific serology. (b) *Cell count and proteins* - Active neurosyphilis of any variety produces increase in mononuclear cells to about 200/mm³, mainly lymphocytes and rise in protein to about 2 g/litre. (c) *IgG* - Electrophoresis often shows elevation of cathodal IgG which may be diffuse or banded.

TREATMENT: OF NEUROSYPHILIS

1. **Prednisolone** - 40 mg daily for 3 days to prevent Herxheimer reaction (most likely to occur in GPI or when CSF cell count is raised). A longer course in optic atrophy may be helpful.
2. **Specific therapy** - Aqueous crystalline penicillin G (18-24 mU/d IV given as 3-4 mU q4h or continuous infusion) for 10-14 days or Aqueous procaine penicillin G (2.4 mU/d IM) plus oral probenecid (500 mg qid), both for 10-14 days. In case of patients allergic to Penicillin, desensitization and treatment with penicillin.

Follow-up - CSF cell count should return to normal within 3 months, protein within 6 months. This response should be checked by repeat lumbar puncture at 6 weeks and 3 months after completion of therapy and thereafter at 6 monthly intervals until cells and

proteins have been normal on two consecutive occasions. The IgG, and serology often revert but may remain abnormal for long periods.

3. **Symptomatic treatment** - may be required for confusion, ataxia, urinary retention and Charcot's joints.

15. TUBERCULOSIS OF THE CENTRAL NERVOUS SYSTEM

CLINICAL MANIFESTATIONS

1. **Tuberculous meningitis**
2. **Intracranial tuberculoma** -

Clinical features - (a) *Age* - Any but more common below 10 years. (b) *Site* - In paediatric age group it is common in posterior fossa, while in adults it is common supratentorially. (c) *Symptoms and signs* - (i) Due to raised intracranial pressure - Headache, vomiting, papilloedema. (ii) Focal abnormality depending on site of lesion (hemiparesis, ataxia).

Investigations - (a) For site of lesion - CT scan, angiography, MRI (Figs. 35 to 37). (b) For evidence of tuberculous diathesis - ESR, X-ray chest, tuberculin test. CT chest and abdomen.

Management - Antituberculous therapy, measures to relieve intracranial tension, and surgical excision of tumour mass. AKT for 1-2 years.

3. **Pott's paraplegia** -

Pathogenesis - Incidence of spinal tuberculosis is more than 50% of all bone and joint tuberculosis. It can occur at any age and sex incidence is equal. Spinal

Fig. 35: MR post-contrast showing multiple tuberculomas (arrowheads)

Fig. 36: CECT showing multiple tuberculomas (white arrows) with surrounding oedema (black arrows)

Fig. 37: CECT showing multiple tuberculomas (white arrows) with surrounding oedema (black arrow)

Fig. 38: Potts spine involving D12 and L1 vertebrae (arrows)

cord compression may be due to - (a) Fluid abscess in spinal canal. (b) Paraspinal abscess invading spinal canal. (c) Granulomatous tissue invading spinal canal. (d) Dislocated vertebra. (e) Thick transverse ridge of granulomatous tissue producing compression. (f) Spinal phlebitis resulting in venous infarction of the spinal cord and syringomyelia (secondary).

Clinical features - Subacute or chronic onset of paraparesis or paraplegia, symmetrical or asymmetrical, preceded or followed by root pains and paraesthesiae. Level of objective sensory loss. Sphincter involvement usually late. Spinal deformity (gibbus) and spinal tenderness.

Investigations - (a) For confirmation of diagnosis of extramedullary compression - X-ray spine, MRI, CT (Fig. 38). (b) For confirming aetiology - ESR, X-ray chest, histopathology of lesion.

Management - Immobilization, antituberculous chemotherapy with steroids. Laminectomy and removal of granulomatous mass or aspiration of abscess.

- Arachnoiditis** - Chronic spinal meningitides due to inflammation of all three layers of spinal theca. May be of primary spinal variety, or secondary to vertebral tuberculosis or tuberculous basal meningitis.

Clinical features - (a) Subacute form - Maximal severity is reached within 2-5 days. Symptoms of root pains, paraesthesiae, paralysis, bladder disturbance, and wasting of muscles. General symptoms of low grade fever, malaise and anorexia. The disease may present as a single-level lesion resembling spinal tumour, or multifocal radiculopathy and/or myelopathy with or without vasculopathy, or an ascending variety with affection of lumbosacral roots

Fig. 39: Arachnoiditis seen on MRI axial T2 image (arrow)

and severe sciatica followed by an areflexic hypotonic limb and bladder paralysis, and sensory loss. Soon the sensory loss, root pains and paralysis ascend to involve all four limbs (b) Chronic form - May progress slowly over months or years simulating a spinal tumour with lesion localised to a single level, or with multifocal spinal cord lesions.

Investigations - (a) *Plain X-ray of spine* - may show vertebral caries. (b) *CSF* - Typically there is lymphocytic proliferation with 50-100 cells/cmm, and marked rise in proteins even up to 2-3 gm/100 mL. (c) *MRI* - Meningeal enhancement, thickening and clumping of nerve roots (Fig. 39).

Management - Antituberculous therapy, high doses of steroids with intrathecal steroid administration, and physiotherapy.

Table 49: Classification of intracranial tumours**1. Tumors of neuro-epithelial origin**

- Astrocytic tumours

Astrocytoma (most common primary benign tumour)
Glioblastoma (Fig. 40)
Pilocytic astrocytoma
- Oligodendroglioma
- Ependymoma
- Choroid plexus papilloma/carcinoma (Fig. 41)
- Pineal cell tumours
- Ganglioglioma
- Neuroblastoma/neurocytoma
- Medulloblastoma (uncommon in adults) (Figs. 42 and 43)
- Primitive neuro-ectodermal tumours

Tumours of nerve sheath origin

- Schwannoma (Fig. 44)
- Neurofibroma

Meningeal tumours

- Meningioma
- Meningeal sarcoma

Tumours of mesenchymal origin

- Haemangiopericytoma

Primary cerebral lymphoma**Tumours of uncertain histogenesis**

- Haemangioblastoma

Tumours of germ cell origin

- Germinoma
- Teratoma

Pituitary tumours

- Pituitary adenoma

Others

- Craniopharyngioma
- Colloid cyst (Fig. 45)
- Dermoid cyst
- Epidermoid cyst

Cerebral metastasis (Fig. 46)**Local extension from head and neck tumors**

- Chordoma
- Glomus jugulare tumour

Infective granulomas

- Tuberculoma
- Gumma

Parasitic cysts

- Cysticercus
- Echinococcus

**Fig. 40:** MRI T2 image showing glioblastoma multiforme (white arrow) with hemorrhage inside (black arrow head) and surrounding oedema (black arrow)**Fig. 41:** CECT showing choroid plexus papilloma (arrows)**Fig. 42:** MRI axial Flair image showing decompensated hydrocephalus due to medulloblastoma with periventricular ooze

Fig. 43: MRI axial T2 image showing medulloblastoma (arrow) in patient in Figure 42

Fig. 44: MRI axial T2 image showing right VIth VIIIth nerve complex schwannoma (arrow)

Fig. 45: MRI axial T2 image showing hydrocephalus (black arrow) due to colloid cyst (white arrow) in third ventricle

Fig. 46: Brain metastasis from melanoma

16. INTRACRANIAL TUMOURS

Table 49 gives classification of intracranial tumours.

CLINICAL FEATURES

Symptoms

1. *Raised intracranial pressure* may be the result of – (a) the mass itself. (b) Associated cerebral oedema. (c) Obstruction of CSF pathways causing hydrocephalus as in many tumors of posterior fossa:
 - (a) *Headache* – tends to occur in early morning and is usually described as vice-like or gripping pain, aggravated by activities which increase intracranial

pressure such as coughing and straining. (b) *Vomiting* – is sudden, projectile and not preceded by nausea. (c) *Visual disturbance* – Progressive loss of visual activity usually with episodes of transient blindness in both eyes (visual obscurations) lasting only a few seconds but increasing in duration and frequency with increasing intracranial pressure. (d) *Altered consciousness level* – in the form of acute and profound deterioration, or increasing lethargy and ‘general slowing down’ of the patient noticed by the family. (e) *Intellectual deterioration*, incontinence and disequilibrium, if pressure increases over long period. (f) *Drowsiness followed by coma*, if rapidly rising intracranial pressure.

2. *Epilepsy* - is the presenting feature in up to 50% of tumours.
3. *Focal neurological deficits* - depend on the location of the tumour. Gradual onset of hemiparesis, hemianopia or dysphasia is typical of many supratentorial gliomas. Frontal lobe tumors typically cause a loss of affect with self-neglect and intellectual deterioration. Tumors in posterior fossa give rise to ataxia, dysarthria and brainstem and cranial nerve signs.

Associated features - may include:

- Signs of systemic malignancy.
- Focal effects from tumours at base of skull, e.g. proptosis, epistaxis.
- Features of a neurocutaneous syndrome associated with tumours, e.g. neurofibromatosis.
- Endocrine or developmental disturbance.

INVESTIGATIONS

1. **CT** - is more specific and sensitive with respect to diagnosis and location (Figs. 47 and 48) than radiography and isotope scans.
2. **MRI** - however provides better images of lesions in the posterior fossa, around the skull base and suprasellar regions, and in the pineal region. MRI is more sensitive in detecting low-grade gliomas and demonstrating multiple metastases. When a tumour is identified in a child, the whole spine should be imaged to look for 'drop' metastases along the neuraxis.
3. **Plain radiography of skull** - (in absence of CT or MRI): (a) Features of raised intracranial pressure - In adults erosion of pituitary fossa, especially the lamina dura and occasionally "copper beating" or "beaten brass" appearance of skull. In children

Fig. 47: CT showing hyperdense meningioma of sphenoid ridge (arrowheads)

skull sutures may be separated up to 10 years of age. (b) Displacement of calcified pineal gland by a large lesion in one hemisphere. (c) Calcification of the lesion: Astrocytoma, oligodendroglioma and craniopharyngioma. (d) Hyperostosis of overlying skull: meningioma. (e) Erosion of normal structures, e.g. acoustic neuroma widening the external auditory meatus.

4. **Chest radiograph** - to exclude primary tumours of bronchus and to help to detect secondary tumours from other sources.
5. **Cerebral angiography** - Tumours of the brain are localized by displacement of arteries and veins and by presence of abnormal vascular patterns. Of particular value in differential diagnosis of brain tumour from cerebral vascular lesions, aneurysm and angiomatous malformations.
6. **EEG** - is not a primary aid, but abnormalities consistent with hemisphere or deep central lesions, or with hydrocephalus, may be recognised.

DIFFERENTIAL DIAGNOSIS

Other Conditions Causing Increased Intracranial Pressure

I. Infection:

1. **Intracranial abscess** - Source of infection - (a) Haematogenous - SIE, congenital heart disease (e.g. right to left shunt), bronchiectasis or lung abscess. (b) Intracranial spread - Compound depressed fracture of skull, frontal sinusitis, chronic otitis media, mastoiditis, extension of infected thrombus.

Fig. 48: Meningioma showing postcontrast enhancement (arrow)

Clinical features - (a) Of toxæmia - Pyrexia, malaise. (b) Raised intracranial pressure - Headache, vomiting. (c) Focal damage - Hemiparesis, dysphasia, ataxia. At times seizures. (d) Infected site - Ear discharge, cardiac murmurs.

Investigations - (a) X-ray of sinuses and mastoid. (b) CT scan with IV contrast - Midline shift from mass effect, ring enhancement, central area of low density, and surrounding area of low density due to oedema.

2. **Tuberculoma** - Clinical features of intracranial mass. Skull X-ray - may show calcified tuberculoma (Fig. 49). CT scan - Lesion resembles astrocytoma or metastasis. Reduction in lesion after antituberculous therapy.
3. **Neurosyphilis** - (a) Meningovascular - Cranial nerve palsies, pupillary changes, positive serology and characteristic CSF changes. (b) Cerebral gumma - very rare; response to antisyphilitic therapy.

II. Vascular

1. **Cerebral infarct** - Hemiparesis, hemisensory loss and dysarthria. Hemianopia may occur. A large infarct impairs consciousness. CT scan shows the infarct.
2. **Cerebral venous and/or dural sinus thrombosis** - Secondary to intracranial suppurative disease or presence of generalised hypercoagulable state, e.g. cyanotic heart disease, pregnancy and puerperium, dehydration. Slow evolution of symptoms resembling encephalitis, or sudden onset with focal seizures. CT scan appearance of haemorrhagic infarction.

Fig. 49: Intracranial calcification due to tuberculoma

3. **Intracranial aneurysm** - (a) Before rupture - Symptoms due to pressure on surrounding structures but very slowly progressive, headache slight, no papilloedema. Angiography to confirm diagnosis. (b) After rupture - Headache, secondary optic atrophy and sometimes focal cerebral symptoms. History of acute episode.
4. **Subdural haematoma** - Symptoms and signs fall into 3 groups:
 - (a) *Due to raised ICP* - Headache, nausea, vomiting, dizziness, convulsions.
 - (b) *Due to fluctuation in volume of contents of haematoma* - State of consciousness varies from lapse of memory to aberrations of behaviour or coma. Semicomatose or mental stupor may develop in a few days or few hours.
 - (c) *Due to local pressure on adjacent structures* - Diplopia, ocular palsy, hemiparesis and generalized fits may occur.

Diagnosis - confirmed by CT scan.

5. **Malignant hypertension** - Severe headache and papilloedema with perhaps a focal cerebral lesion. B.P. high, haemorrhages and cotton wool patches in retina; enlargement of heart, progressive, and evidence of renal insufficiency.
6. **A-V malformation** - (a) Seizures generalized or partial especially, if involvement of cerebral cortex. (b) Neurological deficit - if large malformation - Slowly progressive - dementia, hemiparesis or visual field defects. (c) Headache - Well localized, unilateral, throbbing. (d) Bruit may be heard over eyeball. CT scan - AVM easily seen as area of mixed density with high density patches (calcification). After IV contrast dilated vessels seen as streaks of enhancement. Four vessel angiography confirms presence of AVM and delineates the vessels.

III. Hydrocephalus

- (a) **Congenital** - Enlargement of head, slowly progressive wide anterior fontanelle, dilatation of scalp veins. 'Cracked pot' sound on skull percussion 'Setting sun' appearance of eyes, vomiting rare, mental deficiency.
- (b) **Acquired** - (i) Raised intracranial pressure. Headaches often worse in morning. Nausea and vomiting. Occasionally blurred vision. Eventually drowsiness leading to depressed consciousness level - papilloedema conspicuous, with little headache

and vomiting. No focal signs. (ii) Due to meningitis - History of meningitis. Headache at first paroxysmal, later constant with intense exacerbations; cranial nerve palsies common. CT scan shows enormous dilatation of the ventricular system.

IV. Benign intracranial hypertension (*Pseudotumour cerebri*)

Condition of raised intracranial pressure not due to expanding mass lesion or obstruction to CSF flow. Mechanism unknown. *Possible causes* - (i) Diet - obesity, hyper/hypovitaminosis A. (ii) Endocrine - Hypoparathyroidism, Cushing's syndrome, Addison's disease, menopause. (iii) Haematological - Iron deficiency anemia, polycythemia vera. (iv) Drugs - Oral contraceptives, nalidixic acid, tetracycline, steroid administration or withdrawal. (v) Chronic respiratory insufficiency. *Clinical features* - Age - Predominantly between 10-15 years. Headache, vomiting, impaired visual acuity from papilloedema, diplopia from VI nerve palsy. *Investigations* - (i) Visual field charting - enlarged blind spot, peripheral field constriction. (b) Lumbar puncture - and pressure measurement. CT scan - Small ventricles, no mass lesion.

V. Increased intracranial pressure (ICP)

May be due to (a) intracranial causes, e.g. cerebral tumour, subdural hematoma, intracerebral hemorrhage, obstructive hydrocephalus, benign intracranial hypertension. Major sinus vein occlusion, post neurosurgery. (b) Extracranial cause - Hypoventilation, convulsions, hyperpyrexia, drug induced (e.g. tetracycline, valproate), hepatic failure, high altitude, cerebral oedema. Cl. Fs. - If acute rise in ICP - Cushing's triad (bradycardia raised BP, respiratory depression), drowsiness, papilloedema, if ICP persists for more than a few days.

VI. Cysts

Arachnoid or hydatid - may present as intracranial mass. CT scan - shows a low density, well-demarcated lesion. In cerebral cysticercosis - Epileptic fits, palpable subcuticular cysts in muscles or subcutaneous tissues, eosinophilia.

Disorders Causing Progressive or Recurrent Symptoms

1. **Cerebral atheroma** - Carotid artery stenosis may present as a slowly progressive lesion, symptoms and signs developing over weeks or months. Progressive mental deterioration, hemiplegia and headache simulate

cerebral neoplasm. Unilateral or bilateral papilloedema may be present. Carotid bruit often heard. Angiography and other investigations confirm diagnosis.

2. **Epilepsy** - Convulsions starting after age of 25 should suggest possibility of tumour. Investigations must be done to determine, if epilepsy is due to tumour (if focal seizure).

Management - Definitive treatment is based on the specific tumor type and includes surgery, radiotherapy and chemotherapy. But patient needs simultaneous symptomatic treatment

For raised intracranial tension: (a) Posture with head elevated. (b) *Mechanical hyperventilation* reduces arterial PaO₂ which in turn reduces blood volume and blood flow. Raised ICP begins to fall 10-30 seconds after hyperventilation, reaches its nadir in 10 mins and returns to its original level in less than an hour. There is thus limited time for effective ICP control with hyperventilation. (c) *Osmotic dehydration* - (i) Mannitol 0.25 g/kg infused rapidly and given 2-3 times/day. (ii) Glycerol 1.5 g/kg body wt/d in 3-4 divided doses diluted with fruit juice to mask the unpleasant taste. Serum osmolality and urine output should be measured frequently. (iii) Frusemide 20-40 mg bd for causing diuresis. BP and electrolytes to be checked. (iv) Acetazolamide 250-500 mg/day helps to restrict CSF formation. (v) 3% hypertonic saline can be used not only in cases of hyponatremia, but also sometimes as an osmotic diuretic. (d) Glucocorticoids are highly effective at reducing perilesional edema and improving neurologic function within hours of administration. Dexamethasone has been the glucocorticoid of choice, doses are typically 12-16 mg/d in divided doses given orally or IV.

Patients who present with seizures require antiepileptic drug therapy. There is no role for prophylactic antiepileptic drugs in patients who have not had a seizure.

HERNIATION SYNDROMES

Transtentorial Syndromes

- Central herniation - Expanding lesions of frontal, partial or occipital lobes or midline extracerebral tumors may produce a downward movement of midline intracranial structures into the posterior fossa. Initial focal features relating to the lobe of origin are soon

replaced by diencephalic symptoms as hernia begins. Wider fluctuations of temperature and impairment of upgaze. Later brainstem symptoms, including respiratory and hemodynamic disturbances appear.

- Uncal herniation produces deterioration of sensorium, ipsilateral dilatation of pupil, contralateral hemiparesis and decerebrate posturing.
- Cerebellar tonsillar herniation through the foramen magnum can occur due to rapidly expanding hemorrhage, infarcts or mass lesion in posterior fossa. Cerebellar symptoms and signs rapidly evolved to medullary dysfunction with coma, decerebrate posturing and respiratory impairment.
- Subfalcine or cingulate herniation may cause occlusion of anterior cerebral artery and its branches with widespread infarction.

17. DISORDERS OF THE SPINAL CORD

PARAPLEGIA

Paraplegia is paralysis confined to the lower limbs. Table 50 gives classification of causes of paraplegia.

Common causes of spastic paraplegia are – (1) Transverse myelitis. (2) Spinal cord compression including tuberculosis of spine. (3) Anterior spinal artery occlusion. (4) Trauma to spine.

Investigation of A Case of Paraplegia

A. Is the difficulty in walking due to other causes?

1. Decreased muscle power.
2. Disturbances of tone, e.g. Parkinsonism.
3. Cerebellar disorder causing ataxia, and chorea.
4. Loss of postural sense, e.g. diabetes, tabes dorsalis.
5. Hysteria.

B. Is the paraplegia hysterical or organic?

Hysterical Paraplegia

1. Plantar response never extensor.
2. No correlation between distribution of sensory loss and known anatomical distribution, or glove and stocking type of anaesthesia. Bilateral anaesthesia rare. Patient does not burn or cut the anaesthetic skin.

Table 50: Classification of causes of paraplegia

I. *Due to upper motor neuron lesion*

A. Intracranial causes

- Tumour of falx cerebri (parasagittal meningioma).
- Thrombosis of superior sagittal sinus.
- Cerebral diplegia.
- Hydrocephalus.
- Thrombosis of unpaired anterior cerebral artery.
- ACA infarcts.

B. Spinal causes

Systemic degeneration of tracts

- Subacute combined degeneration
- Multiple sclerosis
- Amyotrophic lateral sclerosis
- Syringomyelia
- Friedreich's ataxia.

Secondary affections of white matter

- *Trauma* – Fracture dislocation, Kummel's disease.
- *Infection* – Acute transverse myelitis, epidural abscess, syphilis.
- *Vascular* – (i) Haemorrhage – (a) Intrathecal (haematomyelia). (b) Intramedullary (spinal epidural haematoma). (ii) Thrombosis (myelomalacia). (iii) Spinal A-V malformations.

Compression

Acute – Common: Metastatic tumour (Fig. 50). Rare – Infection, spontaneous hematoma, cervical or thoracic disc, intrinsic tumour.

Chronic – Common: Cervical spondylosis. Rare: Neurofibroma, meningioma, intrinsic tumour, congenital cysts, thoracic disc, syringomyelia, inflammatory disease, arachnoiditis.

- *Chronic malnutrition* – Pellagra.
- *Toxins* – Lathyrism, fluorosis.
- *Radiation myelopathy*.

II. *Due to lower motor neuron lesion*

- *Anterior horn cell* – Acute anterior poliomyelitis, spinal muscular atrophies, motor neuron disease.
- *Peripheral nerve* – Peripheral neuropathy, Guillain-Barre syndrome.
- *Myoneural junction* – Myasthenia gravis, familial periodic paralysis.
- *Muscles* – Muscular dystrophies, polymyositis.

3. Motor power may be normal when recumbent, yet patient cannot stand (astasia abasia).
4. Hysterical rigidity – Rigidity shows variation from moment to moment.
5. Reflexes normal or exaggerated.
6. No sphincter disturbances.

Table 51: Differences between upper motor and lower motor neuron paralysis

UMN lesion	LMN lesion
1. Paresis of movement	1. Paralysis of individual muscles or muscle group
2. Diffuse distribution	2. Distribution confined to individual muscles
3. Spasticity	3. Hypotonia
4. No muscular wasting	4. Muscular atrophy. Fasciculations
5. Brisk reflexes	5. Hypo or areflexia
6. Extensor plantar response	6. Flexor plantar response
7. Associated involuntary movements (flexor spasms)	7. No associated involuntary movements
8. Electrical reaction normal	8. Reaction of degeneration

**Fig. 50:** MRI showing multiple metastases from carcinoma of prostate into the spine

C. Is it upper motor or lower motor neuron paralysis? (Table 51)

D. Is the paraplegia due to localized or system disease of the spinal cord?

In localized disease signs and symptoms are referable to one or two segments of the cord. In system disease symptoms and signs are referable to various systems of the nervous system. (Sensory, motor, cerebellar, extra-pyramidal).

Investigation of a Case of Spastic Paraplegia

I. History

1. Onset

- (a) *Acute* - Spinal: Acute transverse myelitis, trauma (fracture dislocation of spine), prolapsed disc, vascular disorders (infarction or haemorrhage), epidural abscess, hysteria. Cerebral - Superior sagittal

sinus thrombosis, thrombosis of unpaired anterior cerebral artery.

- (b) *Subacute* - Developing over two or three days - Acute myelitis, compression of spinal cord, e.g. tuberculous spinal osteitis or pyogenic extradural abscess or rarely secondary carcinoma of spine.
- (c) *Insidious* - Meningomyelitis, subacute combined degeneration, cervical spondylosis, amyotrophic lateral sclerosis, spinal tumour, syringomyelia, multiple sclerosis, cauda equina and conus medullaris lesions and sometimes lathyrism. General paralysis of insane, hereditary spastic paraplegia, and ischemic degeneration of spinal cord due to atherosclerosis.
- (d) *Unilateral* - onset in spinal tumour.
- ##### 2. Age
- (a) *Children* - Cerebral diplegia, hydrocephalus, meningitis, spina bifida, spinal caries and superior longitudinal sinus thrombosis.
- (b) *Adult* - Common are spinal tumour, TB spine, transverse myelitis, amyotrophic lateral sclerosis, syringomyelia, multiple sclerosis and craniovertebral anomalies.
- (c) *Middle and old* - Cervical spondylosis, subacute combined degeneration, secondary deposits, Paget's disease, progressive cervical myelopathy.
- ##### 3. Family history
- (a) In subacute combined degeneration more than one member of family may have evidence of paraplegia, neuritis or pernicious anaemia.
- (b) In lathyrism more than one member of family affected, and history of consumption of lathyrus pulse.
- (c) Familial incidence in hereditary spastic paraplegia.
- ##### 4. History of trauma
- Fracture dislocation of spine or haematomyelia.
- ##### 5. History of syphilis.

6. Recurrent paraplegia – Multiple sclerosis, periodic paralysis, recurrent spinal ischemia, A-V malformation with minor bleed or oedema, hysterical.
7. Symptoms –
 - (a) *Pain* – Constant or intermittent in extramedullary spinal tumour; may be aggravated by coughing or straining. Root pains in radicular spinal syndrome, syringomyelia.
 - (b) *Numbness and tingling* – Subacute combined degeneration, spinal tumours, disc protrusion, fluorosis.
 - (c) *Progress of symptoms* – Frequent arrests in multiple sclerosis and syringomyelia. Rapid progress in malignant deposits.
 - (d) *Psychological symptoms* – Euphoria common in multiple sclerosis. Mental symptoms in subacute combined degeneration and GPI. Mental deficiency in cerebral diplegia.
 - (e) *Fever* – may be present with tuberculosis of spine, or epidural abscess.

II. Physical examination

1. Speech – Staccato speech in multiple sclerosis; dysarthria in amyotrophic lateral sclerosis and syringomyelia.
2. Cranial nerves – Optic atrophy (Table 52). Paralysis in intracranial tumours. Nystagmus in multiple sclerosis. Pupillary changes in neurosyphilis. Inability to swallow in amyotrophic lateral sclerosis.
3. Motor system:
 - (a) *Wasting* – in presence of increased jerks suggestive of amyotrophic lateral sclerosis. Combination of upper motor paralysis in lower extremities and lower motor in upper extremities:
 - Amyotrophic lateral sclerosis
 - Syringomyelia

Table 52: Paraplegia with optic atrophy

1. Hereditary ataxias – Friedreich's, Sanger Brown.
2. Demyelinating – Multiple sclerosis.
3. Infections – TB, syphilis, arachnoiditis.
4. Deficiency – Subacute combined degeneration, pellagra.
5. Vascular – Eale's disease.
6. Toxic – Alcohol, SMON.
7. Miscellaneous – Metastasis, Paget's disease of bone.
8. Neuromyelitis optica (Aquaaporin antibodies).

- Hypertrophic cervical pachymeningitis, and
 - Compression of cervical region by tumour or cervical disc degeneration,
- (b) *Co-ordination* – Ataxia combined with spasticity in early stage of subacute combined degeneration; multiple sclerosis, Friedreich's ataxia, cervical spondylotic myelopathy, craniovertebral anomalies.
 - (c) *Involuntary movements* – Tremors in multiple sclerosis. Muscular fasciculations in amyotrophic lateral sclerosis, and syringomyelia. Choreoathetoid movements in cerebral diplegia.
4. Sensory system:
 - (a) *Dissociated anaesthesia* – A lesion in the centre of the cord, e.g. syringomyelia, haematomyelia, intramedullary tumour, anterior spinal artery thrombosis or haemorrhage (impaired pain, temperature, touch preserved).
 - (b) *Total loss of all forms of sensation* – below the segmental level in the trunk at which the transection takes place. Often there is a zone of hyperaesthesia in the skin area supplied by the segment of the spinal cord immediately above the lesion.
 - (c) *Signs of posterior column affection* – Sensory ataxia, Romberg's sign, loss of vibration and position sense with normal tactile and pain sensations in subacute combined degeneration and injury or compression of cord.
 - (d) *Only lateral column affection (Pure motor spastic paraplegia)* (Table 53).
 - (e) *Postero-lateral columns affection (Sensory motor spinal cord disorders)* – (i) Subacute combined degeneration, (ii) Multiple sclerosis, (iii) Syringomyelia, (iv) Compression myelitis, (v) Haematomyelia and myelomalacia, (vi) Radiation myelitis, (vii) Pellagra.
 - (f) *Radicular spinal syndrome* – Signs of spinal cord compression associated with root pains, segmental sensory changes or motor disturbance and spinal tenderness all occurring at level of lesion – spinal arachnoiditis.
 5. Reflexes:
 - (a) *Absent knee and ankle jerks with extensor plantar* (Table 54)
 - (b) *Inversion of the radial reflex* – long-standing cervical disc protrusion.
 - (c) *Paraplegia with loss of deep reflexes*
 1. State of spinal shock.

Table 53: Causes of pure motor spastic paraplegia

- Amyotrophic lateral sclerosis.
- Anteriorly placed extradural compression, e.g. TB spine.
- Vascular lesions like thrombosis or haemorrhage in which sensory function has recovered.
- Primary lateral sclerosis.
- Cerebral palsy.
- Lathyrism.
- Familial spastic paraplegia.

2. Spinal artery thrombosis/hemorrhage.
3. Associated radiculitis
6. Sphincters:
 - (a) *Spinal bladder* from damage to spinal cord by trauma, cord tumour or multiple sclerosis.
 - (b) *Autonomous bladder* in cauda equina lesions.
 - (c) *Sensory bladder* in subacute combined degeneration and multiple sclerosis.
7. Trophic changes – Syringomyelia.
8. Gait:
 - (a) Ataxic in SCD and MS.
 - (b) Scissor gait in cerebral diplegia.
 - (c) In lathyrism patient walks with stiff legs bent at knees and advancing limb strongly abducted and dragged forward with the toes reaching the ground first.
9. Spine – Deformity, tenderness and rigidity in TB spine. Kyphoscoliosis in syringomyelia and hereditary ataxias. Percussion tenderness in radicular spinal syndrome, TB spine.
10. Other findings:
 - *Other signs of syphilitic infection* in spinal syphilis.
 - *Anaemia and tenderness of calf muscles* in subacute combined degeneration.
 - *Constitutional symptoms* or evidence of tuberculosis elsewhere in the body in Pott's disease.
 - *Painful, stiff neck* with pain in arms with spastic weakness of legs in elderly persons should suggest cervical spondylotic myelopathy.
 - *Symptoms due to primary disease*, e.g. leukaemia (secondary deposits).
 - *Symptoms of increased intracranial pressure* in intracranial tumour.
 - *Short neck with a low hair line* and limitation of rotation of neck in chronic progressive myelopathy complicating craniovertebral anomaly.

Table 54: Paraplegias with absent ankle jerks with extensor plantar

- Subacute combined degeneration.
- Friedreich's ataxia.
- State of spinal shock.
- Meningeal carcinomatosis.
- Coexisting lumbar and cervical spondylosis.
- Conus medullaris lesion.
- Epiconus lesion.
- Spinal arachnoiditis.
- Taboparesis.

- *Lhermitte's sign* – may be positive in multiple sclerosis, craniovertebral anomaly, cervical spondylosis or cervical cord injuries, and subacute combined degeneration. The patient complains of sudden, transient, electric shock feeling spreading down the body when he flexes the head forward.
- *Pes cavus* in Friedreich's ataxia and familial spastic paraplegia.
- *Mottling of teeth* in fluorosis.

III. Investigations

1. CSF – Routine, serological tests for diagnosis of spinal syphilis. *Froin's syndrome* – In spinal block – (a) Xanthochromic fluid. (b) Increase in proteins as a result of which the fluid may coagulate spontaneously. (c) Slight or no increase of cells.
2. Imaging –
 - (a) *Plain X-ray of vertebral column* – Changes of TB spine, herniated intervertebral disc, secondary deposits, fracture dislocation. In spinal tumour increase of distance between pedicles or erosion of vertebra. X-rays of cervical spine for spondylosis and cervicovertebral junction for dislocation of atlantoaxial joints.
 - (b) *MRI* – is investigation of choice for cord compression.
 - (c) *CT scan* – for detecting bony abnormalities of vertebral column – Vertebral osteomyelitis, metastasis, myeloma, osteosclerosis.
 - (d) *Chest radiograph* – Lung carcinoma is a common primary causing metastatic spinal disease.
 - (e) *Cerebral angiography* – if suspicion of expanding mass or vascular abnormality.
3. Blood – (i) Megaloblastic anaemia in subacute combined degeneration. (ii) Treponemal antibodies in spinal syphilis. (iii) Protein electrophoresis for multiple myeloma. (iv) Prostate specific antigen for prostatic malignancy if indicated.

4. Gastric analysis - Pentagastrin-fast achlorhydria with maximum histamine stimulation in SCD.
5. Fundus - Papilloedema in intracranial tumour. Temporal pallor in multiple sclerosis. Hydrocephalus, cerebral venous sinus thrombosis with parasagittal venous haemorrhagic infarcts.
6. Urine - for fluorine estimation in endemic fluorosis.
7. Therapeutic test - If suspected cervical disc degeneration, restriction of neck movements by rest or by wearing a collar for few weeks will often produce marked improvement in walking.

D.D. of Flaccid paraplegias (Paraparesis)

1. **Poliomyelitis** - (i) Acute onset with possibly signs of meningeal irritation. (ii) Muscular weakness and flaccid paralysis of scattered muscle groups. (iii) Not bilaterally symmetrical.
2. **Peripheral neuritis** - (i) Numbness and tingling at onset. (ii) Tenderness of calf muscles. (iii) Glove and stocking type of anaesthesia. (iv) Vasomotor and trophic changes - oedema, dryness, desquamation. (v) Bilaterally symmetrical paresis.
3. **Guillain-Barre syndrome** - (i) Preceding viral illness. (ii) Weakness usually starting in lower limbs, increases in severity over next few days and then ascends up to involve trunk muscles, upper limbs and in some cases neck, face and bulbar muscles. (iii) Areflexia is the key to diagnosis.
4. **Cauda equina lesions** (Any lesion in spinal canal below T10 can cause cauda equina syndrome) - (a) Lateral cauda equina syndrome (e.g. neurofibroma) - Anterior thigh pain, weakness of quadriceps and absent knee jerk. In case of high lesion extensor plantar response. (b) Midline cauda lesion from within (Conus lesion) - (e.g. ependymoma (Fig. 51), dermoid or lipoma) - Rectal and genital pain, micturition disturbances and impotence. Saddle anaesthesia. Symmetrical findings. (c) Midline lesion from outside (e.g. disc) - Signs of bilateral lumbar and sacral root involvement.
5. **Lumbar disc syndrome** - Paraplegia rare. (i) History of trauma may be obtained. (ii) Initial phase of pain in lumbar region. (iii) Radiation of pain to buttocks and back of thigh. (iv) Pain often aggravated by coughing. (v) Impairment of spinal movements. (vi) Impairment of sensation over dorsum of foot common.
6. **Lumbar disc stenosis** - Constriction of lumbosacral spinal canal can produce symptoms due to direct compression or vascular insufficiency (syndrome of inter-

Fig. 51: Ependymoma filum terminale (arrows)

- mittent claudication of cauda equina). Presentation can be unremitting with backache and radicular radiation, or more commonly, with intermittent symptoms such as transient weakness or numbness as a result of exertion or hyperextension of lumbar spine. To ease symptoms, patient may adopt stooping posture when walking. Absent reflexes, sensory loss, weakness and impaired straight leg raising may be demonstrated only after exertion. CT scan myelography - Characteristic angular or trefoil appearance of neural canal or MRI.
7. **Tabes dorsalis** - (i) Lightning pains. (ii) Absent ankle and knee jerks. (iii) Pupillary changes. (iv) Positive Romberg's sign.
 8. **Friedreich's ataxia** - (i) Heredofamilial. (ii) Age - usually young, 10-15 years. (iii) Cerebellar signs - Nystagmus, ataxic dysarthria or scanning speech, ataxia. (iv) Pyramidal signs - Absent abdominal reflexes, extensor plantars. (v) Posterior column involvement - Loss of tendon reflexes. (vi) Deformities - Pes cavus and scoliosis.
 9. **Peroneal muscular atrophy** - (i) Usually young adults. (ii) Muscular wasting in lower limbs; muscles involved transversely (fat bottle or inverted champagne bottle appearance). (iii) High steppage gait and clubbed feet.
 10. **Hysterical** - (i) Paralysis generally preceded by pain or discomfort in the limbs. (ii) Muscular wasting may occur after some time due to disuse. (iii) Stocking type of anaesthesia common. Sharply demarcated sensory loss. (iv) Patient can often move legs normally when lying or sitting, but collapses at once when he tries to stand or walk (astasia abasia).

11. **Distal myopathy of Welander** – Very rare. Slowly progressive, predominantly distal wasting and weakness.

COMPRESSION OF THE SPINAL CORD AND ROOT COMPRESSION

Classification: There are many possible classifications of compression based on location (extradural or intradural), disease type (congenital, acquired, inflammatory, infective, neoplastic, degenerative or traumatic) or timing of onset (acute or chronic).

Location

Extradural compression – Common – disc prolapse or spondylosis, metastatic disease and spinal trauma.

Intradural compression may be situated within the cord substance (intramedullary) or on the surface (extramedullary). It is less common than extradural compression.

- Intradural extramedullary lesions are mainly tumors and almost always benign and include meningiomas and neurofibromas.
- Intradural intramedullary lesions are less common; the principal tumors are astrocytoma (Fig. 52) and ependymoma.

Table 55 lists the causes of compression of cord.

Onset – May be acute (e.g. lumbar central disc causing cauda equina syndrome, traumatic injury to the spine) or chronic (e.g. a slow-growing benign tumour such as meningioma or neurofibroma), or sometime acute-on-chronic (e.g. metastatic breast carcinoma complicated by vertebral body collapse).

Fig. 52: MRI STIR image showing astrocytoma in cervical cord (arrows)

Clinical Features

Acute cord compression syndrome is manifested by complete motor paralysis (corticospinal function) and sensory anaesthesia (spinothalamic function). Damage is primarily in the anterior two-thirds of the cord related to vascular insufficiency. Motor loss is often greater in lower legs than in arms. Marked spinal pain and tenderness.

Brown-Sequard syndrome results from hemisection of the spinal cord with unilateral damage to spinothalamic and corticospinal tracts, and resultant loss of ipsilateral motor and dorsal column function and of contralateral pain and temperature sensation. It often results from penetrating trauma or unilateral facet fracture or dislocation or demyelination.

Table 55: Causes of compression

Congenital

- Spinal dysraphism (spina bifida, diastematomyelia, tethered cord)
- Dwarfing syndromes (achondroplasia, Morquio's syndrome, spondyloepiphyseal dysplasia)
- Chiari malformation (cerebellar ectopia)
- Vertebral body malformation (hemivertebra)

Acquired

Traumatic

- Fracture dislocation

Infective – Osteomyelitis of vertebrae

- Bacterial
- Fungal
- Tuberculous

Inflammatory – Demyelinating

- Multiple sclerosis
- Sarcoid
- Rheumatoid arthritis

Neoplastic

- Benign
- Malignant (primary or secondary)

Biochemical

- Paget's disease

Endocrine

- Hyperparathyroidism (Brown's tumour)
- Osteoporosis collapse

Degenerative

- Cervical spondylosis (myelopathy or radiculopathy)
- Lumbar disc
- Spondylolisthesis
- Lumbar sacral stenosis

Central cord syndrome is often associated with extension injury to an osteoarthritic spine. This results in proportionally greater loss of motor function in the arms than in the legs, with variable sensory sparing ('man in a barrel'). Fibres responsible for lower extremity motor and sensory functions are located in the most peripheral parts of the cord, whereas fibres controlling the upper extremity and voluntary bowel and bladder function are more centrally located. Sacral tracts are located on the periphery of the cord and are usually spared from injury. Impact damage to the grey matter, produced by the 'pincer' effect of osteophytes anteriorly and infolded ligamentum flavum posteriorly, produces severe lower motor neuron paralysis of fingers, hands and arms. Bladder and bowel function may also be lost. "Dissociated sensory" loss is seen.

Cauda equina syndrome. The subarachnoid space extends in a dural arachnoid sheath around each dorsal and ventral route, roughly to the level of union of the roots. A myelomere (the segment of cord from which a nerve root arises) lies one or two levels above the same number vertebral body between C₂ and T₁₀. Below the inferior end of the cord, the dural-arachnoid sac contains a leash of nerve roots; this complex constitutes the cauda equina. When examining patients who have cauda equina syndrome, it is important to assess saddle anaesthesia, rectal tone, bulbocavernosus reflex and sacral sparing. Urinary retention, incontinence is the most common finding.

Localization of Segmental Level

1. Pyramidal system -

- Spasticity of all four limbs - lesion above C₄ cord segment.
- Spasticity of lower limbs plus flaccid weakness of scattered muscles of upper limbs - lesion of cervical enlargement (C₅-T₂).
- Spasticity of lower limbs alone - lesions of thoracic cord (T₂-L₁).
- Irregular spasticity of lower limbs plus flaccid weakness of scattered muscles of lower limbs - lesion of lumbosacral enlargement (L₂-S₂).

2. **Sensory symptoms** - Hyperaesthesia and hyperalgesia at level of lesion, analgesia and thermoanaesthesia below. Radicular pain offers a clue to specific dermatome localization early in the disease process. To localise the exact vertebral level corresponding to

the spinal compression, for upper cervical same as cords level, for the lower cervical vertebrae add 1, for dorsal 1-6 add 2 and for dorsal 7-9 add 3. The 12th dorsal arch overlies lumbar 5.

The testing of vibration sense is valuable in ascertaining the level of a lesion which affects the posterior columns. The tuning fork is applied to the bony prominences from below upwards until the level is determined at which it is felt.

3. **Reflexes** - Deep reflexes below the level of the lesion are exaggerated, and those corresponding to the level of lesion lost, e.g. lesion of C_{5/6} cervical will cause loss of biceps and supinator jerks but exaggeration of triceps (inverted radial reflex).
4. **Imaging** - (i) *Plain radiograph* - in spinal tumour may show any of the following - (a) Localised destruction of the vertebra or vertebrae. (b) Changes in contour of or separation of pedicles. (c) Distortion of paraspinal tissues by tumours (frequently neurofibroma) which extend through the inter-vertebral foramen. (d) Proliferation of bone - rare except in osteomas and sarcomas, occasionally in haemangioma. (e) Presence of calcification occasionally in meningiomas. (ii) *MRI* - is the most useful investigation and has replaced myelography. It shows the degree and source of compression of neural structures. Discs are well visualized. It readily demonstrates fractures, inflammatory changes and metastatic disease, including microdeposits. (iii) *CT* - with bone windows provides superior information about osseous integrity. CT scan can be helpful in surgical planning.
5. **Other investigations** -
 - Urine - microscopy, culture and sensitivity for infection and urinalysis for Bence-Jones protein (myeloma)
 - Full blood count, ESR (marker for infection/malignancy). Macrocytes in B₁₂ deficiency.
 - Routine biochemistry including calcium, liver and bone enzymes and tumour markers.

Relation of Source of Compression to Cord

1. Vertebral causes

Table 56 gives localization signs to various levels of cord compression.

2. Intraspinial tumours

Table 57 differentiates between extramedullary intradural and intramedullary cord lesion.

Table 56: Localization signs to various levels of cord compression

<i>Cord segment</i>	<i>Clinical features</i>	<i>Muscles paralysed</i>	<i>Reflexes</i>
C 3-4	Pain in neck and occiput. Pain, paraesthesia and weakness in upper limbs early. Relative anaesthesia of face. Quadriplegia.	Lower part of trapezius, supraspinati and infraspinati. Muscles of upper limbs. Diaphragm.	
C 5	Quadriplegia.	Deltoid, biceps, brachialis, rhomboids and supinator	Biceps (C5-6) and Supinator (C5-6) diminished or lost. Inversion of the radial reflex. Triceps ++ brisk
C 7	Paraplegia	Triceps and extensors of wrist and fingers	Triceps (C-7) lost.
C 8-D1	Spastic paralysis of trunk and lower limbs. Paralysis of ocular sympathetic sometimes.	Flexors of wrist and fingers and small muscles of hand.	Tendon reflexes in upper limbs normal, in lower limbs exaggerated.
D 6	Spastic paralysis of muscles of abdomen and lower limbs	Intercostals, upper and lower rectus abdominals, oblique abdominals	Epigastric (C-6-8) lost.
D 9-10	Spastic paraplegia.	Lower halves of rectus abdominis.	Upper abdominals present. Lower abdominals lost.
D 12-L1	Spastic paraplegia.	Lower fibres of oblique abdominis, transversalis and iliopsoas.	Abdominals present. Cremasteric (L1-2) lost.
L 3-4	Spastic paraplegia.	Paralysis of external sphincter.	Anal and bulbocavernous reflexes lost. Deep reflexes normal.
S 1-2	Flexion of hip, adduction of thigh, extension of knee and dorsiflexion of foot possible, all other movements in the lower extremities weak.	Glutei, calf muscles, anterior tibial, and peroneal, small muscles of foot	Knee jerks present. Ankle jerks lost. Plantar reflexes lost.
S 3-4	No paraplegia. Retention of urine and faeces.	Quadriceps, adductors of hip.	Knee jerks (L2-4) lost. Ankle jerks (S1-2) brisk
Cauda equina	(i) Whole cauda – Anaesthesia below the folds of the groins including genitals. Loss of control of bladder and rectum.	Paralysis of lower limbs.	Absent deep reflexes.
	(ii) Upper sacral and L5 – Sensory loss over front and posterior and outer aspect of thigh.	Paralysis of glutei, hamstrings, and all muscles below the knees.	Knee jerks present. Ankle jerks lost.
	(iii) Below S2 –Saddle shaped area of anaesthesia. Incontinence of urine and faeces.	No paralysis of lower limbs.	All reflexes in lower limbs normal.
	(iv) S 4-5 and coccygeal roots – Anaesthesia of anus and rectum.	Paralysis of levator ani.	

Table 57: Differences between extramedullary intradural and intramedullary cord lesion

<i>Extramedullary intradural</i>	<i>Intramedullary (Intrinsic lesions of spinal cord)</i>
1. Radicular pains common.	1. Radicular pains rare.
2. Paraesthesia rare until late.	2. Paraesthesia occur in all stages.
3. Muscle fasciculations rare.	3. Muscle fasciculations common.

Contd...

Contd...

Extramedullary intradural	Intramedullary (Intrinsic lesions of spinal cord)
4. No dissociated loss of sensibility.	4. Dissociation of sensations common.
5. Bladder and rectal disturbances late.	5. Bladder and rectal disturbances early.
6. Rising level of sensory disturbances as peripheral tracts more affected.	6. Descending level of sensory disturbances.
7. No sacral sparing.	7. Sacral sparing.
8. Brown-Sequard syndrome may occur.	8. Persistent Brown-Sequard syndrome very rare.
9. Spasticity and other pyramidal signs pronounced.	9. Spasticity less pronounced.
10. Little or no muscle atrophy.	10. Characterised by muscle atrophy.
11. Trophic skin changes absent.	11. Trophic skin changes common.
12. Vertebral column may be sensitive to local pressure.	12. No local tenderness of spine.
13. Spinal fluid changes frequent.	13. Spinal fluid changes rare.

CRANIOCERVICAL ANOMALIES

Clinical Features

Compression of the area of foramen magnum may present with:

1. Syringomyelia.
2. Occipital and nuchal pain and stiffness.
3. Occult hydrocephalus.
4. Nystagmus, ataxia and facial sensory loss.
5. Nuchal paraesthesiae and pseudo-athetosis in fingers.
6. Weakness and atrophy of neck and shoulder girdle.
7. Spastic tetraparesis. Evidence of pyramidal tract affection in all four limbs. Paraesthesiae either confined to upper limbs or involving all four limbs.

Clinical Entities

1. Atlantoaxial subluxation –

Causes – Separation of odontoid process of axis may be due to occipitalization or other developmental anomalies, ankylosing spondylitis, or rheumatoid arthritis or trauma. *Associated conditions* – (i) Spinal – Syringomyelia, hydromyelia, spina bifida. (ii) Cranial – Hydrocephalus. (iii) Others – Anomalies of cardiovascular, GI and genitourinary systems.

Clinical features – Dislocation with resultant ischemia in vertebrobasilar area may produce transitory attacks of loss of consciousness, blurring of vision or blindness, and pyramidal weakness, or tetraplegia. Delayed myelopathy may follow after some years. Other features include low hair line, short neck and restricted neck movements (Feil's triad). Dysplastic face, associated congenital anomalies and absence of cranial

Fig. 53: MRI showing vertebral-basilar anomaly with atlanto-occipital fusion (white arrow), basilar invagination (black arrow), C2-C3 vertebral fusion (black arrowheads) and syrinx formation (white arrowhead)

nerve palsies. *Diagnosis* – is made from radiographs of neck in flexion and extension.

Treatment – Surgical fusion of atlantoaxial joint.

2. **Basilar invagination** – Displacement of dens of axis into foramen magnum. Usually presents as picture of posterior fossa lesion. *Clinical features* – Lower cranial nerve palsies, cerebellar signs (pyramidal dysfunction), signs of increased intracranial pressure. *Radiography* – Dens of axis is seen to extend above a line drawn from the posterior end of hard palate to posterior tip of foramen magnum (Figs. 53 and 54).
3. **Occipitalization or fusion of other cervical vertebrae** (Block vertebrae) – (Klippel-Feil anomaly) – Usually asymptomatic. Signs due to other associated anomalies. Feil's triad seen.

Fig. 54: CT scan showing vertebral-basilar anomaly with atlanto-occipital fusion (white arrow), basilar invagination (black arrow) and C2-C3 vertebral fusion (black arrowheads)

4. **Arnold-Chiari malformation** – The medulla and cerebellum are elongated and extend down through the foramen magnum. Usually presents with cerebellar signs and syringomyelia or syringobulbia-like clinical picture. Spina bifida frequent.

NON-COMPRESSIVE SPINAL CORD DISORDERS

Table 58 gives causes of non-compressive myelopathy.

Transverse myelitis reflects several pathological processes, all of which present with monophasic acute cord disturbance with bilateral involvement and segmental level. It can be acute or subacute. Table 59 for the causes of transverse myelitis.

Vascular - Thrombosis of spinal arteries, spinal A-V malformation, vasculitis due to heroine.

Clinical Features

1. At or below the level of involvement – neuropathic pain in the midline or deeper aching pain or in a dermatomal distribution (radicular pain or burning sensation), this giving a clue to the anatomical level of the lesion. Numbness and tingling sensation in the legs with diminution in pain and sensation.
2. Muscle weakness, flaccid paralysis followed by spasticity.
3. Lhermitte's sign because of demyelination
4. Sphincter impairment. Loss of bladder and bowel disturbances.

Table 58: Causes of non-compressive myelopathy

Vascular

- Infarction
- Hemorrhage
- A-V malformation
- Hypercoagulable states

Heredodegenerative

- Spinal muscular atrophy
- Hereditary spastic paraparesis
- Friedreich's ataxia
- Abetalipoproteinaemia
- X-linked adrenoleukodystrophy

Transverse myelopathy

- Multiple sclerosis
- Collagen vascular disorders
- Viral infections (e.g. herpes simplex virus)
- Myelitis – Transverse myelitis

Infective

- Syphilis, HIV, HTLV-I

Nutritional

- Subacute combined degeneration
- Vitamin E deficiency, copper deficiency

Anterior horn cell disease – ALS, PLS

Tropical

- Lathyrism, konzo, tropical ataxic neuropathy

Table 59: Causes of transverse myelitis

- Viral – Herpes simplex, EB virus, cytomegalo viruses, enteroviruses, influenza, HIV, human T cell leukaemia virus
- Post-vaccine (rabies)
- Autoimmune disease - SLE, Sjogren's syndrome systemic sclerosis
- Multiple sclerosis
- Neuromyelitis optica (Devic's disease)

Diagnosis

1. CT, MRI
2. CSF – Shows monocytes increased with elevated IgG index.
3. Tests for remedial aetiology – chest X-ray, serological tests, HIV, antinuclear antibodies.

Multiple sclerosis – Spinal cord involvement in the form of transverse myelitis or a partial cord syndrome is a presenting feature in about one-third of patients, and is almost inevitable once the disease is established (Refer).

VASCULAR NON-COMPRESSIVE SPINAL CORD DISORDERS

Infarction - The anterior cord is more vulnerable than the posterior particularly in the watershed area of the artery of Adamkiewicz (T8-L2). Cord infarction is characterized by sudden onset of pain, flaccid paraparesis and urinary retention, with later spasticity and hyper-reflexia. Anterior spinal artery thrombosis.

Arteriovenous malformation (AVM) - Spinal AVM is usually congenital; it may be associated with other vascular anomalies. The most common form usually occurs below the level of T3 and comprises abnormal vessels that are partly extramedullary and are fed by durally located fistulas. Typically, a gradually evolving mixed upper and lower motor neuron defect is seen, associated with sensory disturbances and sometimes sphincter involvement.

HEREDODEGENERATIVE SPINAL CORD DISEASES

Spinal muscular atrophy (SMA) - The hallmarks are progressive weakness, hypotonia and generalized muscular atrophy secondary to degeneration of anterior horn cells or loss of bulbar motor nuclei. (a) *In acute infantile SMA*, onset of symptoms before 6 months and occasionally from birth. Motor 'milestones' are delayed and death occurs before 2 years. (b) *Late onset SMA* (Kugelberg-Welander) - Onset of symptoms is typically by 3 years. Weakness and wasting involving face, tongue and proximal musculature, including diaphragmatic weakness is seen, and scoliosis and contractures are common. It is an autosomal recessive disorder.

Hereditary spastic paresis - Symptoms may develop at any age usually manifesting as difficulty in walking. Examination shows spasticity, and hyperreflexia with extensor plantars. Weakness is usually not marked. Mild sensory impairment and pes cavus may be found. It is an autosomal dominant disorder.

Friedreich's ataxia - (Refer)

INFECTIVE NON-COMPRESSIVE SPINAL CORD DISORDERS

Syphilis - (a) In meningovascular syphilis, leptomeningeal exudation with granulomata and endarteritis produces subacute or chronic progressive spastic paraparesis. Radicular pain is common. Dorsal column sensory impairment leads to sensory ataxia. (b) *Tabes dorsalis*.

HIV - Myelitis may occur as part of seroconversion stage of infection. The most common single cause of

myelopathy in HIV is vacuolar myelopathy, a late disease marker occurring when CD4 count falls below 200/ μ l. It produces slowly progressive spastic paraparesis, extensor plantar responses, sensory ataxia and sphincter disturbance. The mechanism of myelopathy is unknown, but may involve activated microglial neurotoxicity, gp120 protein myelin toxicity or cellular vitamin B₁₂ deficiency.

Nutritional - Subacute combined degeneration.

Tropical non-progressive spinal disorders

Lathyrism is an epidemic syndrome due to increased consumption (200-300 gm/day for 3 months) of the legume *Lathyrus sativus*, which contains the excitatory neurotoxin β -N-oxalyl-amino-L-alanine. Early transient excitatory autonomic phenomena (e.g. enuresis, urinary frequency, nocturnal ejaculation) are followed by spastic paraparesis with disproportionate spasticity.

Konzo and tropical ataxic neuropathy due to inadequate preparation of Cassava root fails to remove natural cyanogenic glycosides. Clinical features are similar to those of lathyrism. In tropical ataxic neuropathy, dorsal column degeneration, sensory ataxia, hyporeflexia, optic atrophy and sensorineural deafness are seen.

LEVEL OF DISEASE

- Cervical myelitis -
 - Motor symptoms** - Paralysis of upper and lower extremities, if high cervical, death in few days.
 - Sensory** - Hyperaesthesia and root pains in the segmental areas with diminished sensations below.
 - Reflexes** - All reflexes usually lost at onset. Later tendon reflexes return in lower extremities and plantars become extensor. In complete recovery, the abdominal and cremasteric reflexes are usually lost to resume normal activity later.
 - Sphincters** - Retention of urine and faeces. After about a fortnight, automatic bladder. Sphincter function usually returns early. Priapism often present.
 - Trophic changes** - Likely to occur. Oedema and bedsores. Cystitis.
- Dorsal - Commonest form. Symptoms same as cervical but no involvement of arms. Priapism common. Girdle pain and hyperaesthetic zone between ensiform cartilage and pubes. Retention or intermittent incontinence of urine.
- Lumbar cord and conus - Paralysis of legs partly of upper and mainly of lower motor neuron; knee jerks absent (upper lumbar segment involved). Plantar reflex almost always abolished. Incontinence of urine and faeces. No priapism.

COURSE

Paraplegia in extension – In acute myelitis at the onset, all the reflexes are lost below the level of the lesion – stage of flaccidity or spinal shock. After about 3 weeks, spasticity and increased reflexes develop. Extensor muscles are spastic. Hip extended and adducted, knee extended and feet plantar flexed. At times when the stage of reflex activity supervenes, there may be spasms of the limbs, automatic bladder contraction, and excessive sweating, due to uncontrolled activity of the spinal centres in response to cutaneous stimuli (mass reflex).

Paraplegia in flexion – occurs after a complete transverse lesion as soon as the stage of spinal shock has passed; or in cases of diffuse spinal lesions, follows paraplegia-in-extension after the extrapyramidal motor tracts have also become involved. Thigh and knee flexed, feet dorsiflexed. Flexor spasms occur in the lower limbs which in severe cases become fixed in an attitude of flexion.

MANAGEMENT

General – Symptomatic and rehabilitative with the aim of preserving function and avoiding complications of contracture, pressure sores and automatic dysreflexia. Good skin care. Passive stretching exercises and physiotherapy aimed at truncal support and optimizing activity in functioning muscle groups are adjuncts to an antispasmodic (baclofen, tizanidine, dantrolene). When spasticity is severe, baclofen can be given intrathecally, or botulinum toxin can be used to weaken problematic muscle groups.

Functional independence can be maximized by occupational therapy. Detrusor instability may be helped by oxybutynin, but intermittent or permanent suprapubic catheterization may be necessary.

Specific – e.g. IV acyclovir 10 mg/kg 8-hourly in herpetic transverse myelitis. A short pulse of 3 days high-dose i.v. methyl prednisolone, 0.75-1 g/day, may reduce the time to recovery in multiple sclerosis. AVMs may be selectively embolized, and are occasionally ligated surgically. Development of vascular myelopathy in HIV may be prevented by early antiretroviral therapy.

MULTIPLE SCLEROSIS

Multiple sclerosis is an inflammatory demyelinating disease of CNS (brain and spinal cord) that is disseminated in time and space (i.e. neuroanatomical location).

Pathogenesis

An acute MS plaque develops when primed leucocytes cross the blood-brain barrier into the brain and activate macrophages. Inflammation is initiated and myelin is stripped off nearby nerve axons. Demyelinated axons lose the ability to conduct nerve impulses in normal manner, and axonal conduction is further impeded by the direct effect of soluble inflammatory mediators such as nitric oxide.

The rapid disappearance of these mediators when inflammation subsides may account for the rapid resolution of symptoms sometimes seen after an attack. It is now recognised that axons may degenerate as a secondary response to demyelination, and the axonopathy contributes to disease progression.

Autoimmune disease – The female predominance and its weak association with specific HLA types (particularly HLA DR15 and DQ6) suggests that MS may be an autoimmune disease. In 20% of patients MS affects one other family member.

Genetic predisposition – to MS is also suggested by the racial variation in prevalence and the higher concordance risk in identical compared with non-identical twins. Hence, expression of MS probably depends on the interplay of an inherited risk (from the summation of several genes) with an environmental trigger; this may be an infective agent such as human herpes virus 6 and *Chlamydia pneumoniae*.

Clinical Features

Common Symptoms

Lhermitte's symptom – Neck flexion induces an 'electric shock' sensation running down the back, caused by a plaque in the cervical cord.

Optic neuritis – Patients experience pain in one eye, particularly on eye movement, and dimming of vision in that eye, often described as looking through a dirty window or water.

Spasticity, particularly in spinal cord lesions, may lead to stiffness, flexor spasms, cramps or spontaneous clonus.

Ataxia of the limbs may be caused by a lesion of the cerebellum or its connections, or by deafferentation from a dorsal column spinal plaque.

Fatigue is often prominent.

Neuropathic pain may occur as part of a spinal cord syndrome or alone as in symptomatic trigeminal neuralgia.

Mood disturbance – Euphoria with advanced MS, but depression is more common.

Bladder dysfunction – it can be either detrusor hyper-reflexia or detrusor sphincter dyssynergia.

Table 60 gives signs of demyelinating lesions in MS according to the site of lesion.

Symptom patterns – Symptoms caused by demyelination emerge over several days, reach a plateau and then usually resolve over days or weeks. Characteristically symptoms reappear transiently or worsen with an increase in body temperature (Uhthoff phenomenon).

Depending on Clinical Course Four Subtypes

Relapsing/remitting MS (RRMS)

Secondary progressive MS (SPMS)

Table 60: Signs of demyelinating lesions in MS

Site of demyelination	Symptoms	Signs
Spinal cord	Limb weakness	Spasticity
	Lhermitte's symptom	Pyramidal weakness
	Stiff legs	Hyper-reflexia
	Sensory impairment	Absent abdominal reflexes
	Erectile dysfunction	Extensor plantars
	Urinary frequency and retention	Spinal sensory level
	Constipation	
Brainstem	Flexor spasms	
	Ataxia	Internuclear ophthalmoplegia
	Diplopia	Nystagmus
	Dysarthria	Gaze palsies
	Dysphagia	Facial sensory loss
	Facial numbness/weakness	Rubral tremor
Cerebellum	Unsteady gait and slurred speech	Gait and limb ataxia
		Dysarthria Nystagmus
Optic nerve	Unilateral visual loss and painful eye movements	Relative afferent pupillary defect
		Lost colour vision/acuity
		Optic atrophy (late sign)
Cerebrum	Poor memory	
	Personality change	Dementia (subcortical)
	Epilepsy	

Primary progressive MS (PPMS)

Progressive/relapsing MS (PRMS)

1. Relapsing/remitting MS (RRMS) - accounts for 85–90% of cases at onset, characterized by discrete attacks that generally evolve over days to weeks followed by substantial or complete recovery over the ensuing weeks to months. Between attacks, patients are neurologically stable.
2. Secondary progressive MS (SPMS) - always begins as RRMS. The clinical course changes so that the patient experiences a steady deterioration in function unassociated with acute attacks (which may continue or cease during the progressive phase). SPMS produces a greater amount of reduced neurologic disability than RRMS.
3. Primary progressive MS (PPMS) - patients do not experience attacks but only a steady functional decline from disease onset.
4. Progressive/relapsing MS (PRMS) overlaps PPMS and SPMS and accounts for 5% of MS patients

Marburg's Variant of Multiple Sclerosis

Acute MS is a rare fulminant rapidly progressive demyelinating process with multiple lesions involving central hemispheres, brainstem or optic ns. Usually there are no remissions.

Differential Diagnosis

- Structural lesion, if isolated demyelinating syndromes
- Leber's hereditary optic atrophy (Bilateral optic neuropathy to the point of blindness is rare in MS).
- Progressive cerebellar symptoms may be caused by metabolic disease or inherited cerebellar ataxia
- A complete intrinsic spinal cord lesion that develops rapidly over hours (transverse myelitis) is compatible with MS, but is also recognized as a separate monophasic entity.
- Devic's neuromyelitis optica – Optic neuritis and myelopathy occur simultaneously or sequentially.
- Acute disseminated encephalomyelitis is a post-infectious illness of monophasic but multifocal CNS demyelination involving optic nerves, brainstem and spinal cord. It is usually seen in children, but may affect adults after an infection.
- Systemic lupus erythematosus – Relapsing remitting disease may be seen, but there is presence of other systemic features.
- Marburg's variant of MS – Rare, fulminant, rapidly progressive demyelinating process with multiple lesions involving cerebral hemisphere, brainstem or optic nerves.

Fig. 55: CT showing degeneration of corpus callosum (arrows) suggestive of Marchiafava-Bignami syndrome

Fig. 56: MRI T2 Flair image showing demyelination

Fig. 57: MRI axial T2 image showing multiple demyelinating plaques in multiple sclerosis (arrows)

Fig. 58: MRI coronal Flair image showing multiple demyelinating plaques in multiple sclerosis (arrowheads)

- Tumefactive demyelination is a variant of MS in which plaques size is > 2 cm, on imaging studies it may be confused with intracranial tumour.
- Neurosarcoidosis often affects the optic nerve and spinal cord but there is also systemic involvement (particularly lung and skin).
- Isolated cerebral vasculitis more often causes seizures, encephalopathy, headache and fever.
- Leucodystrophies are a group of rare, inherited demyelinating disorders.
- Marchiafava-Bignami disease (MBD) is a rare condition characterized by demyelination of the corpus callosum. It is seen most often in patients with chronic alcoholism (Fig. 55).

Investigations

1. **To demonstrate involvement of disseminated anatomical sites** - (a) MRI most sensitively reveals asymptomatic lesions. Serial MRI demonstrates dissemination of lesions in time more rapidly than clinical events (Figs. 56 to 59). (b) Visual evoked potentials - A unilateral delay is the most sensitive index of previous subclinical optic neuritis. (c) BAER (brainstem auditory evoked responses) to demonstrate auditory pathway subclinical lesions.
2. **To demonstrate inflammatory demyelination** - (a) CSF: Presence of oligoclonal bands in CSF but not serum indicates inflammation confined to the CSF and is seen in 95% of patients with clinically definite

Fig. 59: MRI sagittal Flair image showing Dawson's fingers in multiple sclerosis (arrows)

MS. (b) Evoked potentials are usually delayed and their amplitude relatively preserved.

3. **To exclude other conditions mimicking MS** – Often structural lesions must be excluded by MRI.

Other Uses of MRI in MS

- New MRI lesions are considered 'surrogate markers' of multiple sclerosis disease activity in treatment trials.
- MRI may be used to predict the risk of MS in those who present with an isolated demyelinating event. For example, the risk of developing clinically definite MS 5 years after an episode of optic neuritis is 15% in patients with normal brain MRI, and 50% with three or more abnormal lesions on MRI at presentation.

Management

No effective curative treatment.

1. **Treatment modifying the course of the disease**

IFN β , Ia, Ib – has many potential sites of action, but probably acts mainly by inhibiting the effects of pro-inflammatory cytokines on microglial activation, thus preventing amplification of the immune response. The drug is given by s.c. or i.m. injection 1–3 times weekly, and may be useful in those who suffer frequent or disabling relapses.

Multiple sclerosis. Frequency of relapses may be reduced during pregnancy but may increase in the puerperium; overall pregnancy has little effect on the course of the illness.

Interferon- β is not recommended during pregnancy

Glatiramer acetate – is a mixture of synthetic polypeptides and may act by specifically blocking immune responses to myelin basic protein, an autoantigen in MS. Dose: 20 mg SC daily.

Natalizumab – humanized monoclonal antibody directed against the $\alpha 4$ subunit of $\alpha 4\beta 1$ integrin, a cellular adhesion molecule expressed on the surface of lymphocytes. It prevents lymphocytes from penetrating the BBB and entering the CNS. Effective in reducing the attack rate and significantly improves all measures of disease severity in MS.

Fingolimod – is a sphingosine-1-phosphate (S1P) inhibitor that prevents the egress of lymphocytes from the secondary lymphoid organs such as the lymph nodes and spleen. Its mechanism of action is the trapping of lymphocytes in the periphery and inhibiting their trafficking to the CNS. It reduces the attack rate and significantly improves all measures of disease severity in MS.

Dimethyl Fumarate (DMF) – it seems to have anti-inflammatory effects through its modulation of the expression of proinflammatory and anti-inflammatory cytokines

Teriflunomide – active metabolite of the drug leflunomide, inhibits the mitochondrial enzyme dihydroorotate dehydrogenase, which is a key part of the pathway for de novo pyrimidine biosynthesis.

Mitoxantrone received (from the FDA) the broadest indication of any current treatment for MS, indicated for use in SPMS, PRMS and in patients with worsening RRMS.

Alemtuzumab – a humanized monoclonal antibody directed against the CD52 antigen, which is expressed on both monocytes and lymphocytes. It causes lymphocyte depletion, markedly reduced the attack rate.

2. **Acute relapse** – Methylprednisolone 1 g/day for 3 days or prednisolone 60 mg p.o. for 1 week, then 40 mg for 1 week, followed by 20 mg for 1 week.
3. **Symptomatic treatment** –

Spasticity – (a) **Baclofen** 10 mg/day, increased to maximum 80–100 mg/day in divided doses. It acts on α -aminobutyric receptors to suppress reflex arcs that have been released from higher inhibitory control. (b) **Tizanidine** – 2 mg/day and increased slowly to maximum 20 mg/day. It acts through $\alpha 2$ cord receptors to moderate presynaptic release of excitatory amino acids. It is less sedating than baclofen, and associated with less muscle weakness. (c) **Dantrolene** has a direct effect on skeletal muscles and is a second line drug.

Bladder problems – If post-micturition bladder volume is more than 100 ml, failure to empty the bladder is the primary problem and clean, intermittent catheterization is recommended. If bladder empties but stores poorly Oxybutynin 5 mg t.d.s.

Fatigue – Amantadine may help.

Depression – Tricyclic antidepressant.

18. DEFICIENCY DISORDERS OF THE NERVOUS SYSTEM

VITAMIN B₁ DEFICIENCY

1. Nutritional polyneuropathy (Neuritic beriberi).
2. Wernicke-korsakoff syndrome.

Wernicke's Encephalopathy – Triad of

1. *Ophthalmoplegia* – Eye signs consist of nystagmus, VIth and IIIrd nerve palsies, gaze palsies and occasionally ptosis.
2. *Ataxia*.
3. *Confusion* – in early stages followed by disorientation, drowsiness and terminal coma. Neuropathological lesions – Petechial haemorrhages in grey matter around 3rd and 4th ventricles and aqueduct of Sylvius, including the mammillary bodies.

Korsakoff's Psychosis

Korsakoff's psychosis is the permanent sequel to Wernicke's encephalopathy and is characterized by severe, irreversible loss of short-term memory, with relative sparing of other aspects of cognitive function. Some patients may confabulate. Neuropathological features are neuronal loss and gliosis, and hemosiderin-containing macrophages in the same distribution as lesions in Wernicke's encephalopathy occurs during recovery.

Nicotinic acid deficiency – Mental confusion, sometimes fits, peripheral neuritis or spinal cord lesions occasional.

Pyridoxine deficiency – 1. *Chronic convulsions* – in infancy may be due to lack of pyridoxine. 2. *Polyneuropathy* – as a complication of isoniazid treatment of tuberculosis arises from blocking of pyridoxine by the drug. 3. *Wernicke's encephalopathy*.

Pantothenic acid deficiency – *Burning feet syndrome* – Intense discomfort in feet in absence of objective sensory alteration or of motor, or tendon reflex signs.

There are two lines of evidence for this – (i) Its reproduction in human volunteers by giving them omega-methyl-pantothenic acid, an analogue of the vitamin which acts as an antagonist. (ii) Nitrofurazone, a drug used in treating trypanosomiasis, causes an acute burning feet syndrome which responds promptly to parenteral calcium pantothenate.

VITAMIN B₁₂ DEFICIENCY

Types of Disorders

- (a) **Cerebral type** – Symptoms cover a wide range and consist of mild disorders of mood, mental slowness, memory defect which may be severe, confusion which may be persistent or relapsing, delusions and paranoid behaviour and sometimes violent mania, visual and auditory hallucinations. Faecal and urinary incontinence in the absence of overt spinal lesions. These cerebral symptoms depend on demyelinating lesion of the white matter in the brain of the same nature as occur in the posterolateral column of the spinal cord and peripheral nerves. Optic atrophy or its precursor retrobulbar neuritis is not uncommon and may be the first manifestation, occurring predominantly in males.
- (b) **Peripheral neuritis** (see Polyneuritis).
- (c) **Subacute combined degeneration.**

Aetiology – (i) Age – 40–60. (ii) Both sexes. (iii) Familial incidence known. (iv) Associated conditions – usually pernicious anaemia (Vitamin B₁₂ deficiency). Rarely as a result of carcinoma stomach, gastrectomy and gastroenterostomy, steatorrhoea or malnutrition from protein deficiency. Condition is characterized by decrease in myelin synthesis and demyelination of corticospinal tracts and posterior columns.

Clinical Features

Onset - usually gradual, sometimes rapid.

1. *Subjective sensory disturbances* – Paraesthesia – Tingling and numbness in toes, tips of fingers, rarely simultaneously in both upper and lower extremities. Sometimes burning or stabbing pains or even lightning pains like tabes.
2. *Objective sensory loss* – Sense of vibration, posture and passive movement affected first in lower, later in upper limbs. Glove and stocking type of superficial sensory loss. Tenderness of calf muscles.
3. *Motor symptoms* – Pyramidal weakness and ataxia develop at variable interval after onset of sensory disturbances.
4. *Reflexes* – Variable – Ankle jerks lost, knee jerks may be absent. Both exaggerated if lateral column lesion predominates. Plantars extensor.
5. *Sphincter disturbances* – First difficult or precipitate micturition, later retention of urine or incontinence. Impotence early.

6. *Mental changes* – not uncommon. Mild dementia, impaired memory. Confusional psychosis or irritability or depression.

7. *Bilateral primary optic atrophy* in 5%.

Diagnosis – Low haemoglobin, macrocytosis, high MCHC, megaloblastic bone marrow, gastric achlorhydria, serum vitamin B₁₂ less than 100 pg/mL, elevated homocysteine.

Management – 1,000 mcg of vitamin B₁₂ IM daily for 7–10 days, then same dose twice a week for one month, then once a fortnight to be continued for the rest of the patient's life.

Vitamin E deficiency – Impaired proprioception, sensory ataxia, areflexia.

19. EXTRAPYRAMIDAL SYNDROMES

CLINICAL MANIFESTATIONS OF LESIONS IN DIFFERENT PARTS OF EXTRAPYRAMIDAL SYSTEM

Putamen – Athetosis.

Caudate nucleus – Chorea.

Subthalamic nucleus – Hemiballismus.

Globus pallidus and substantia nigra – Parkinsonian tremor and rigidity.

PARKINSON'S DISEASE (PD)

PD is said to be present when bradykinesia and at least one of the following is present – rigidity, tremor or postural instability. Causes of parkinsonism are listed in Table 61.

Pathogenesis

The hallmark of Parkinson's disease is degeneration of melanin-containing dopaminergic neurons of the substantia nigra and typical neuronal inclusions known as Lewy bodies. The dopamine in the basal ganglia participates in a complex circuit of both excitatory and inhibitory pathways. These pathways are part of a loop that connects the cortex to the thalamus via the basal ganglia and back to the frontal cortex. This loop serves to modulate the motor system.

Parkinsonism is a common clinical presentation of different kinds of injuries to the substantia nigra.

Heredity – Twin studies have indicated a hereditary component in those in whom disease onset is before 50 years. In some families, autosomal dominant parkinsonism with features similar to Parkinson's disease occurs. In several families, a mutation has been found in the

Table 61: Causes of Parkinsonism

1. Idiopathic – Paralysis agitans (Parkinson's disease).
2. Post-encephalitic parkinsonism.
3. Symptomatic parkinsonism (Secondary Parkinsonism)
 - (a) Trauma – Head injury.
 - (b) Carbon monoxide intoxication.
 - (c) Manganese and other metallic poisoning, MPTP.
 - (d) Drug-induced – Reserpine, phenothiazines, haloperidol.
 - (e) Cerebral arteriosclerosis (Vascular Parkinsonism).
 - (f) Syphilitic mesencephalitis.
 - (g) Tumours of brainstem rarely.
 - (h) Tuberculosis (rare).

α -synuclein gene on chromosome 4. α -synuclein is found in Lewy bodies, and may participate in the abnormal precipitation of protein in a manner similar to formation of amyloid plaques in Alzheimer's disease.

Toxins – MPTP an analogue of meperidine produces a syndrome almost indistinguishable from Parkinson's disease.

Viral infections – Post-encephalitic Parkinsonism.

Clinical Features

Triad of:

1. **Tremor** – may be first symptom; usually starts in one upper limb; characteristically tremor at rest and described as 'pill rolling'. Head may be involved. Tremors disappear during sleep.
2. **Rigidity** – Plastic or lead pipe, i.e. present to equal extent in opposing muscle groups and if a limb is passively moved the rigidity gives way with a series of slight jerks, or 'cog wheel' type, if combined with tremor.
3. **Bradykinesia** – is the cardinal feature of IPD.
 - Mask-like facies – with staring eyes.
 - Infrequent blinking.
 - Impaired ocular convergence.
 - Slow and monotonous speech.
 - Micrographia.
 - Reduced swinging of arms while walking.
 - Festinant gait.
4. Other features

Postural disturbance – Difficulty in rising from chairs or rolling over in bed, stooped posture. Disturbance of balance may be seen in the 'pull' test, performed by standing behind the patient and pulling back on the shoulders. Instead of moving the arms forward and swaying the trunk, parkinsonian patient may take steps backwards (retropulsion) or even fall back into the examiner's arms, without any attempt to maintain balance.

Gait disturbance – Reduced or absent swinging of one arm while walking is an early sign of Parkinson's disease. In more advanced cases neither arm may swing; at this stage, the stride length shortens, the trunk appears stiff and the whole body moves in one mass when the patient turns (turning *en block*). In further advanced disease, patients may appear to 'freeze', their feet seem stuck to the floor, or they may take small steps on the floor, often rising on the toes and leaning forwards. A diagnostically important point is that gait in Parkinson's disease has a narrow base, regardless of how advanced the disease.

Pain – Deep cramping sensations may be a primary symptom or secondary to levodopa.

Mental disturbances – (a) Anxiety. (b) Depression. (c) Dementia may be caused by a syndrome similar to Alzheimer's disease, frontal lobe dementia with a prominent lack of motivation, or a pattern with hallucinations in absence of medication.

Postural hypotension – can be caused by antiparkinsonian drugs. It should be considered in any patient who is falling or complains of lack of energy while walking.

Dyskinesia – in the form of writing, swinging movements of limbs and trunks are typically caused by excessive levodopa, but may occur with dopamine agonists.

Nonmotor symptoms (Table 62).

Investigations

(a) MRI usually normal. In some cases accumulation in substantia nigra may be visualized as T2 hypersensitivity. (b) PET – Reduced uptake in putamen. (c) SPECT – Decreased striatal metabolism.

Differential Diagnosis of Parkinson's Disease

Essential tremor – Predominantly action tremor with symmetrical onset and response to alcohol. Positive family history may be present.

Multisystem atrophy (MSA) – Progressive neurodegenerative disorder characterized clinically by combination of parkinsonism, autonomic, cerebellar or pyramidal symp-

toms and signs. In general patients respond poorly to levodopa or have transient response and provide an important clue to differentiate from idiopathic PD. Urinary incontinence and orthostatic symptoms occurring in a Parkinsonian patient within one year history of motor syndromes suggests diagnosis of MSA with high accuracy and their absence suggests PD.

Drug-induced Parkinsonism – Neuroleptics, metoclopramide, and calcium channel blockers. Rigidity prominent but there may also be tremor, oculogyric crises, buccolingual dyspraxia and retrocollis.

Vascular Parkinsonism (VaP) – also known as lower body parkinsonism and characterized by stepwise progression, pyramidal deficits, dementia.

Alzheimer's disease – Early, prominent dementia, particularly with dysphasia and dyspraxia.

Progressive supranuclear palsy – Early falling, eye movement abnormalities.

Hydrocephalus – Urinary incontinence, greater involvement of legs than arms, early dementia.

Parkinsonism Plus

The term describes rare disorders in which there is Parkinsonism and evidence of a separate pathology, e.g. progressive supranuclear palsy. Other examples are multiple system atrophies such as olivopontocerebellar degeneration and primary autonomic failure (Shy-Drager syndrome).

Management

The mainstay of antiparkinsonian therapy is dopamine replacement. This may be achieved either directly with levodopa or indirectly with dopamine agonists or other drugs that enhance dopaminergic transmission.

Drugs for Parkinson's Disease

Drugs for Parkinson's disease are summarized in Table 63.

Plan of Treatment

Mild disease (Symptoms but no disability) – (a) Selegiline from time of diagnosis. Levodopa-sparing effect of the drug delays need for levodopa therapy. When treatment becomes necessary, a dopamine agonist is added. Anticholinergics and amantadine may also be added to ward off the need for levodopa, or (b) Levodopa 100 mg in combination with decarboxylase 25 mg t.d.s. or qds. (c) Anticholinergic initial treatment in patients with tremor, particularly if young. **With progress of the disease** – Levodopa/decarboxylase inhibitor 600–800 mg, and bromocriptine 20 mg (or lisuride 2 mg) in 3 or 4 divided doses. Dose of levodopa and dopamine agonists should be built up slowly.

Table 62: Non-motor symptoms (NMS) of Parkinson's disease

Can present at any stage of the disease

- Olfactory dysfunction
- Constipation
- RME behaviour disorder
- Depression
- Dysphagia
- Sialorrhoea
- Urinary incontinence
- Cold hands and feet

Table 63: Drugs for Parkinson's disease

Drug	Dose	Use	Side effects
Carbidopa/levodopa	25 mg + 100 mg bd or tds	Most effective drug. Improves most features	Dyskinesias (generally choreoathetoid), nausea, postural hypotension, hallucinations
Carbidopa/levodopa (sustained release)	50 + 200 mg bd		
<i>Dopamine agonists</i>			
Bromocriptine	2.5 mg b.d., increased to 20–30 mg/day	Less effective than levodopa, but less dyskinesias. Reduced motor fluctuations because of longer half-life.	Same as levodopa plus pulmonary oedema with ergoline derivatives. Confusion
Lisuride	0.2 t.d.s. to 0.6 mg qds.		
Ropinirole	1–8 mg t.d.s., max 24 mg/d		
Pramipexole	0.5–1.5 mg t.d.s., max 4–5 mg/d		
Cabergoline	0.25–4 mg o.d.		
<i>Anticholinergics</i>			
	Varies according to preparation	May help for tremor, little use for other features	Dry mouth, blurred vision, urinary retention, constipation, hallucinations
<i>Amantadine</i>			
	100 mg bd	Useful as adjuvant therapy	Headache, nausea, dizziness, sleep disturbances
	200 mg bd		Erythromelalgia
<i>MAO-B inhibitors</i>			
Selegiline	5 mg/day initial, then 5 mg bd	Inhibits metabolism of dopamine. Useful for symptoms related to dyskinesias, delays need for levodopa	Insomnia (hence given after lunch), confusion, levodopa-related side effects
Rasagiline	0.5–1 mg/d	Used for motor fluctuation	
Piribedil	50–200 mg/day with meals	Dopamine antagonist As monotherapy in forms with tremor predominant Adjuvant therapy with L-dopa	Minor GI upset
<i>Catechol-O-methyl-transferase inhibitors</i>			
Tolcapone	100–200 mg t.d.s.	Reduces predictable motor fluctuations, less 'off' time	Most common side effects result from effective increase of levodopa – diarrhoea. Tolcapone may cause liver dysfunction
Entacapone	200 mg with each dose of levodopa to max. 2000 mg/day		

Problems in drug treatment

Nausea – Start with low doses, increased by one-half of a tablet every third day, tablet to be taken after food. Domperidone if nausea continues.

COMT inhibition (e.g. Tolcapone) is an excellent means of reducing motor fluctuations, however dyskinesias may become worse and should be used with caution in these patients.

Confusion and hallucinations. Levodopa is least likely to produce these complications. Anticholinergics, amantadine and selegiline should be withdrawn. If these persist, dopamine agonists should be minimized. If still hallucinations persist, use Clozapine 12.5–50 mg/day. Quetiapine 25–50 mg/day. (WBC count should be monitored weekly). ECT is effective in treatment of antiparkinsonian drug-induced psychosis and improves the motor features of Parkinsonism.

Postural hypotension results from a combination of the disease and the medication. If antiparkinsonian drugs cannot be reduced, use fludrocortisone and midodrine. Domperidone 20 mg t.d.s. sometimes reduces medication-induced hypotension.

'On-off' phenomenon - Late deterioration in response to L-dopa therapy may occur after 3-5 years in some patients due to loss of capacity to store dopamine (narrow therapeutic index of L-dopa). Generally this manifests as fluctuations in response at different time of the day (on-off effect). More complex fluctuations may be in the form of hour to hour changes with short periods of hypokinesia, tremor and dystonia alternating with dyskinesia and agitation. These patients should be treated with smaller more frequent doses of levodopa (e.g. 50-100 mg q2-3h) or with addition of Selegiline (10 mg/day) to prolong and potentiate L-dopa doses.

Physiotherapy and Rehabilitation

In the form of massage and passive stretching of muscles; posture and gait training, speech therapy and occupational therapy.

Surgical Treatment

(a) Ablative

- Thalamotomy - used for tremor. Complications include hemiparesis and dysphonia.
- Pallidotomy - Stereotactic technique of producing destructive lesions in globus pallidus interna improves all the features of Parkinson's disease including drug-induced dyskinesia.

(b) Deep-brain stimulation

Ablative procedures such as thalamotomy are irreversible. A similar effect can be obtained by implanting electrodes in the appropriate area and delivering a high-frequency electrical discharge via an impulse generator placed beneath the clavicle in a manner similar to a cardiac pacemaker. The advantage of stimulators include a smaller lesion and the ability to adjust the pattern of the stimulus to obtain the best response. Disadvantages include limited battery life and possibility to lead shifting and infection. When successful, patients experience marked improvement and some can become medication-free.

(c) Adrenal medullary foetal tissue transplantation - Transplantation of dopamine producing cells into the striatum has been shown to restore mobility.

OTHER EXTRAPYRAMIDAL SYNDROMES

Wilson's disease (Hepatolenticular Degeneration)

A disease of copper toxicosis inherited as autosomal recessive trait.

Clinical features:

(a) Micrographia and excessive drooling of saliva, later dysarthria gives way to dysphagia and movement disorders, increases in severity with gait and postural abnormalities and pyramidal signs. (b) Cirrhosis of liver. (c) Kayser-Fleischer ring. About 97% of pts. with neurological symptoms have KF ring. The rings are visible by naked eye in some and are confirmed by slit lamp examination. Similar rings may be seen with long standing cholestasis like biliary cirrhosis, chronic active hepatitis.

Biochemical features - Low serum ceruloplasmin <20 mg/dl (Table 64), (normal 25-50 mg/dL), high urinary copper excretion (usually more than 200 mcg/24 hours), hepatic copper concentration greater than 250 µg/g dry liver.

Neuroradiology - (a) Bright caudate sign. (b) Peripheral putamen sign. (c) Ventral nucleus of thalamus sign. (d) Head of the giant panda sign. (e) CT scan may show generalized cerebral atrophy, with basal ganglia having low attenuation signals.

Treatment - (a) *Copper chelating agents* -D-penicillamine given life-long. Initially 1 g/day in 4 divided doses 45 minutes before or 2 hours after food, and Pyridoxine 25 mg/day. During first month of therapy sensitivity to penicillamine (fever, rash, granulocytopenia or thrombocytopenia) may occur. Penicillamine should be then withdrawn until the reaction has subsided. It should then be restarted at 0.25 g/day and gradually increased over 2 weeks to 1 g/day, with simultaneous administration of prednisolone 20-30 mg/day gradually tapered to zero.

Table 64: Causes of low serum ceruloplasmin level

1. New-born and infant (up to 6 months)
2. Severe malnutrition
3. Nephrotic syndrome
4. Protein-losing enteropathies
5. Congenital aceruloplasminaemia
6. Severe hepatic insufficiency
7. Acute hepatic infection

(b) Trientine if penicillamine not tolerated. It chelates copper and increases its urinary excretion. Dose 100 mg/day in 2-4 divided doses. Side effects are bone marrow suppression, proteinuria.

Drug reducing copper absorption: (a) Zinc induces metallothionein (MT) synthesis in intestinal cells and thus blocking absorption of copper. Dose - 150 mg/day. (b) Tetrathiomolybdate (TM) is the most effective anti-copper agent.

Diet - Avoid copper rich foods such as meat, shell fish, nuts, chocolates, cocoa, mushrooms.

Liver transplantation - If fulminant hepatic failure, decompensated hepatic disease with encephalopathy, coagulopathy, refractory portal hypertension.

Short term measures include haemodialysis and plasma exchange and are indicated in severely ill patients who cannot wait for 2-6 months for action of copper removing agents to become effective.

Maintenance therapy. Zinc 150 mg/day drug of choice. Alternatively penicillamine plus trientine, but these drugs are toxic and should not be used in those who are asymptomatic.

Chorea

- (a) **Sydenham's chorea** (Chorea minor) - One of the neurological manifestations of acute rheumatic fever. Associated credits and arthritis may be presents. Head and upper limbs are predominantly involved.
- (b) **Huntington's chorea** (Chronic progressive chorea) - A hereditary disorder starting in early middle age and characterised pathologically by degeneration of ganglion cells of forebrain and corpus striatum and clinically by choreiform movements and progressive dementia. The rigid form may simulate Parkinsonism (Table 65).

Treatment - Phenothiazine derivatives, e.g. pimozide may be helpful in reducing aggression and hyperac-

tivity as well as in controlling movements. *Reserpine derivatives* such as tetrabenzene, can be effective in controlling movements, but may aggravate depressive tendencies. GABA receptor antagonist, e.g. baclofen may be useful in combination with other therapy.

- (c) **Senile chorea** - Choreiform movements following vascular lesions of brain in middle or old age. Usually of sudden onset and unilateral.
- (d) **Chorea associated with systemic disease** - SLE, polycythemia rubra vera, thyrotoxicosis, encephalitis lethargica, acanthocytosis, hypocalcemia, hypernatremia.
- (e) **Drug-induced chorea** - Neuroleptics, phenytoin, amphetamines, levodopa, oral contraceptive pill.
- (f) **Hereditary non-progressive chorea.**

Multiple System Atrophy (MSA)

Three overlapping degenerative conditions:

- (a) **Progressive autonomic failure** - (Shy-Drager syndrome) - Impotence and incontinence early symptoms. Later autonomic disturbance with postural hypotension, failure of sweating and respiratory problems including sleep apnoea.
- (b) **Olivopontocerebellar degeneration** - Progressive cerebellar, limb and gait ataxia with dysarthria and nystagmus. Presence of pyramidal signs. Urinary and orthostatic symptoms in a Parkinsonian pt. within one year history of motor symptoms suggests a diagnosis of NSA-P and their absence suggests PD.
- (c) **Striatonigral degeneration** - Akinetic syndrome most likely to be confused with Parkinsonism.

Progressive Supranuclear Palsy (Table 66)

Cerebral Anoxia

Diffuse cerebral anoxia resulting usually from cardiorespiratory arrest can lead to Parkinsonism due to bilateral basal ganglia infarction. In younger people severe hypotension with hypoxia in opiate overdose and carbon monoxide poisoning are the usual causes.

Dystonia Musculorum Deformans (Torsion Spasm)

Disease of basal ganglia of unknown aetiology characterised by occurrence of slow, strong, sustained, twisting, turning and writhing movements of the somatic muscles, particularly muscles of girdle and trunk. Abnormal movements and spasm of muscles produce bizarre stepping gait and often dysarthria, facial grimacing and torticollis.

Table 65: Differences between Parkinson's disease and Huntington's chorea

	<i>Parkinson's disease</i>	<i>Huntington's chorea</i>
Site of neuronal loss	Substantia nigra	Caudate nucleus
Neurotransmitter loss	Dopamine	Acetylcholine (and GABA)
Excess of	Acetylcholine	Dopamine
Levodopa therapy	Improvement	Exacerbation of chorea
Phenothiazine	Exacerbation	Improvement of chorea

Table 66: Comparison between idiopathic Parkinson disease and progressive supranuclear palsy

Features	Idiopathic Parkinsonism	Progressive supranuclear palsy
Rigidity	Present	Present
Bradykinesia	Present	Present
Tremors	Universal	Rare
Asymmetric findings	Common	Rare
Ocular problems	Uncontrolled blinking Excessive watering of eye Diplopia	Vertical gaze palsy (Supranuclear) Eyelid apraxia, Blepharospasm (Lid freezing)
Posture	Tend to fall forwards as, if chasing centre of gravity	Tend to fall backwards due to head tilt backwards
Pseudobulbar features	Absent	Common
Cognitive deficits	Common in advanced disease	Noted in virtually all patients
Dysautonomia	Infrequent	Infrequent
Pathology	α -Synucleinopathy	Tauopathy
MRI brain	Not required with typical presentations Useful to rule out other disorders like normal pressure hydrocephalus, mass lesions and vascular disease	Midbrain atrophy "hummingbird sign"

Spasmodic Torticollis

Usually starts in adolescence or early adult life and characterized by marked tonic or clonic movements of sternomastoid, trapezius and other muscles of neck. This results in the neck being twisted to one side, the shoulder being elevated and sometimes the head tilted backwards. The movements are intermittent, aggravated by emotion and anxiety and stop during sleep. Distinction between hysterical and organic torticollis may be difficult.

20. HEREDITARY AND DEGENERATIVE DISORDERS

CEREBRAL PALSY

The term cerebral palsy refers to a variety of neurological deficits, permanent but nonprogressive, mainly affecting motor function, as a result of prenatal insult, birth injury or some illness in early infancy. In addition to motor defects, intellectual impairment is common.

Risk Factors

Prenatal – Malformations, obstructive lesions in the brain (e.g. cysts, periventricular leucomalacia), infection, exposure to toxins, genetic predisposition. *Perinatal* – Asphyxia, hemorrhage, low birth weight, prematurity, kernicterus. *Postnatal* – CNS infection and trauma.

Clinical Features

- Spastic:
 - Spastic hemiplegia* – Commonest type. May be associated hemisensory and hemianopic visual field defect, and sometimes dysphasia. Seizures may occur.
 - Spastic diplegia* – Difficulty in walking, scissor gait. Upper limbs relatively spared. Lower limbs affected more.
 - Tetraplegia* – Equal involvement of all four limbs. Seizures likely, and primitive reflexes (tonic neck, Moro, sucking, grasping) persist well-beyond normal age. Limbs may become spastic by end of first year.
- Extrapyramidal – Choreoathetosis and dystonia. Associated difficulty in articulation, drooling and emotional lability. Usually normal intelligence.
- Ataxic – Cerebellar ataxia often associated with mental retardation.
- Mixed syndrome – Combination of spastic paraplegia and ataxia.

Investigations

(a) Chromosome analysis, if features are dysmorphic or intrauterine growth is poor. (b) EEG, if seizures. (c) Brain imaging to look for maldevelopment, atrophy, periventricular leucomalacia, or migration defects.

Management

1. *Physiotherapy* – to be started early.
2. *Drugs* – (a) Spasticity – Baclofen acts peripherally, dantrolene has direct effect on muscle. (b) Dystonia – Diazepam, benzhexol, tetrabenzene.
3. *Surgery* – (a) Neurosurgical – Selective dorsal root rhizotomy. (b) Orthopaedic for contractures and other deformities.

SYRINGOMYELIA

A chronic progressive disorder in which cavitation (syrinx = pipe) develops within the spinal cord, either involving the central canal, the central grey matter of the spinal cord usually cervical and sometimes extends into the lower brainstem (syringobulbia).

Pathological Classification of Syringomyelia

Type I: With obstruction of foramen magnum and dilatation of central canal:

- (a) With type I Chiari malformation.
- (b) With other obstructive lesions of foramen magnum.

Type II: Without obstruction of foramen magnum (idiopathic).

Type III: With associated disease of spinal cord – Tumours, arachnoiditis, traumatic myelopathy.

Type IV: Pure hydromyelia with or without hydrocephalus.

Aetiology – (a) Usual age 25–40 years, more common in males. (b) Common segment affected first is 1st thoracic. (c) Associated conditions. (i) Congenital – Frequent association with Arnold-Chiari malformations. (ii) Acquired – Spinal cord tumors, basal arachnoiditis, late sequel of trauma.

Mechanism – (a) Hyperdynamic theory – Intermittent obstruction of CSF outflow from fourth ventricle increases pressure within the dilated central canal (hydromyelia) which ruptures into the substance of the cord to form a syrinx (syringomyelia). (b) In acquired type, syringomyelia probably follows intramedullary necrosis and reabsorption.

Clinical Features

1. *Onset* – (a) Wasting and weakness of small muscles of hands. (b) Loss of sensations, pain, or trophic lesions over trunk and upper extremity.
2. *Sensory symptoms* – Dissociated sensory loss, usually first on one side. Cranial extension of the syrinx cuts the trigeminal fibres, producing a typical Balaclava helmet sensory disturbance with preservation of sensation around eyes, nose and mouth.

3. *Motor symptoms* – Wasting of small muscles of hands, contractures. Leg involvement with spastic paraparesis is more insidious. Cervical lesions from C₅ upwards may produce coarse, rotating nystagmus, vertigo, Horner's syndrome and ataxia.
4. *Trophic* – Thickening of subcutaneous tissues, 'sausage fingers', Charcot's joints, ulcers, and necrosis of bones.
5. *Syringobulbia* – Earliest signs are onion-skin sensory loss over outer part of face (due to involvement of lower part of 5th nerve nucleus), dysphagia and dysphonia.
6. *Associated abnormalities* – Kyphoscoliosis, cervical rib, spina bifida, pes cavus. Associated Arnold-Chiari malformation may produce brainstem and cerebellar signs and symptoms.
7. *Bladder involvement* is late in syringomyelia.

Investigations

MRI demonstrates syrinxes clearly (Figs. 60 and 61).

Management

Surgical decompression of craniovertebral junction can often prevent further deterioration and may be combined with insertion of a syringoperitoneal shunt to prevent development of secondary hydrocephalus.

ANTERIOR HORN CELL DISEASES

1. *Inherited*:
 - *Infantile progressive muscular atrophy* (Werdnig-Hoffman disease) – Usually begins at birth or before 6 months of age. Genetically determined. Infant limp and floppy. Prognosis poor, death usually within first year.
 - *Juvenile familial benign muscular atrophy* – Usually seen later in infancy. Differs from Duchenne type of dystrophy by presence of muscle fasciculation, denervation atrophy on EMG, and normal serum creatine kinase.
 - *Juvenile muscular atrophy* (Kugelberg-Welander disease) is like infantile progressive muscular atrophy autosomal recessive disorder of lower motor neurones. It begins between 2 and 17 years of age, with a slower evolution and longer life expectancy. Walking may still be possible in middle age. Although simulating muscular dystrophy, it may be differentiated by EMG and muscle biopsy which reveal presence of neurogenic atrophy.
 - *Progressive muscular atrophy*.
2. *Infective* – Anterior poliomyelitis.

Fig. 60: MRI axial T2 image showing syrinx

Fig. 61: MRI T2 image showing syrinx in cervico-dorsal region

3. Toxic – Triorthocresyl phosphate poisoning. Tick paralysis.
4. Electric shock.

MOTOR NEURON DISEASE (MND)

MND is a progressive neurodegenerative disease. In the classical form (also termed ‘amyotrophic lateral sclerosis’) degeneration of corticospinal tract neurons in the motor cortex (upper motor neurons) and brainstem and spinal cord motor neurons (lower motor neurons) results in a unique combination of upper and lower motor neuron signs. The male: female ratio is 1.5:1. In sporadic MND, mean age of onset is 60 years, in the familial form about 50 years. Table 67 for various types of motor neuron disease.

Amyotrophic Lateral Sclerosis

Clinical Features

History – 5–10% of patients with MND have a family history, suggesting an autosomal dominant trait; 20% of such families have mutations of the Cu, Zn superoxide dismutase (SOD 1) gene on chromosome 21.

Limb weakness – Majority of patients present with progressive asymmetrical weakness of the limbs. This begins in the leg as foot drop, in the hands with difficulty of fine movements. Localized wasting is common, and fasciculations are often present. Severe cramps may precede weakness.

Bulbar symptoms – are the presenting feature in about 25% of patients. Dysarthria is either in the form of nasal speech (bulbar palsy) or, more commonly, spastic dysar-

Table 67: Clinical patterns of MND

Amyotrophic lateral sclerosis
Progressive muscular atrophy (PMA)
Progressive bulbar paralysis
Primary lateral sclerosis
Others
1. <i>Familial MND</i> – Chromosome 21.
2. <i>Variants of MND</i>
• Madras MND. Young adult, slowly progressive asymmetrical wasting and weakness of limbs along with pyramidal involvement, resulting ultimately in features of ALS. Raised serum pyruvate levels.
• Monomelic amyotrophy. Adolescents. Progressive weakness and wasting of one limb (usually upper) commonly wasted muscles are elbow flexors followed by small hand muscles.
• Hemiplegic MND
• Wasted leg syndrome
• Crural ALS
• MND with Parkinsonism
• MND with dementia

thria (pseudobulbar palsy), or a combination of two. This is followed by dysphagia with drooling of saliva.

Other presentations – A small number presents with respiratory failure. Involvement of bladder and bowels is uncommon. Dementia of frontal lobe type may be seen in about 2%.

Examination

- Muscular fasciculations
- Weakness

- Wasting
- Brisk tendon reflexes
- Extensor plantars
- Brisk jaw jerk (bulbar onset)
- Spasticity (marked in younger patients)
- Eye movements normal
- Dysarthria (involvement of bulbar muscles)
- Reduced cough and gag reflex
- Tongue shows wasting and fasciculations
- Normal sensation
- No bladder or bowel disturbance
- Tachypnoea due to ventilatory failure

Progressive Muscular Atrophy (PMA)

Most benign variety of motor neuron disease. (Pure LMN presentation).

(a) Atrophy, weakness and fasciculations. Onset usually with wasting of one hand (first dorsal interosseous muscle). Tendons become prominent as hand muscles waste, giving guttered appearance (Skeleton hand). Eventually wasting spreads to all four limbs and trunk. (b) Loss of tendon reflexes.

Progressive Bulbar Paralysis

- Dysphagia followed by dysarthria.
- Nasal regurgitation of fluids and nasal slurred voice.
- Tongue wasted and folded and fasciculations visible.
- Absent jaw jerk and gag reflex.
- Rapid progression.

Primary Lateral Sclerosis

Refers to slowly progressive spasticity and weakness of the limbs, more marked in the legs, which may be associated with pseudobulbar palsy. It has a better prognosis (Pure UMN presentation).

Pseudobulbar Palsy

Degeneration of corticobulbar pathways of V, VII, IX, XI and XII cranial nerve nuclei.

- Weakness of muscles of mastication and difficulty in chewing.
- Expressionless face
- Exaggerated jaw jerk. Brisk gag reflex
- Palatal weakness allowing food and fluid to enter nasopharynx
- Monotonous speech
- Tongue immobile and cannot be protruded
- Emotional lability – Spontaneous outbursts of laughing and crying.

Investigations

No specific test. Investigations are performed to exclude other conditions – (a) *MRI of spinal cord* – to exclude compressive lesion in neck. Cranial MRI in patients with bulbar onset to exclude brainstem lesions. On T₂-weighted images, high intensity lesions are visible in motor cortex, internal capsule and brainstem. (b) *EMG and nerve conduction studies* – reveal anterior horn cell damage but do not specify the cause. (c) Creatine phosphokinase may be slightly raised. (d) CSF is normal.

Management

MND progresses rapidly and is hence difficult to manage.

Drug treatment – (a) Riluzole, a glutamate release inhibitor used early in the evolution of the disease may prolong survival. (b) Botulinum toxin to control drooling. (c) Baclofen or Tizanidine for spasticity. (d) Antidepressant drugs. (e) Gastrostomy to reduce expiration.

Symptomatic Treatment

Depression and insomnia – Antidepressants.

Dysphagia – Food thickeners initially, but definitive procedure is percutaneous endoscopic gastrostomy.

Dysarthria – Speech and language therapy.

Ventilatory failure – Non-invasive nocturnal nasal intermittent positive pressure ventilation in some patients who have good bulbar and limb function.

Spasticity – Baclofen or dantrolene. Quinine for muscle cramps.

Dyspepsia – Antacids, H₂-blockers or omeprazole.

Excess saliva – Anticholinergics such as benzhexol or antidepressant, e.g. amitriptyline, dothiepin. Radiotherapy to parotid gland if these measures fail.

Related Disorders

1. Kennedy's syndrome (Bulbar and spinal muscular atrophy) – X-linked LMN disease. A rare form of MND with near normal life expectancy. Presents in males between ages of 20 and 50. Features: Mild dysarthria, wasted fasciculating tongue, tremor, proximal weakness with wasting and fasciculations, Gynecomastia and reduced fertility.
2. Multifocal motor neuropathy (MMN) – occurs in men under 45, with asymmetrical, progressive, mainly distal weakness with onset in the arms. Signs include fasciculations, wasting and reduced reflexes. EMG shows multifocal conduction block. High serum titres of antibodies to GM₁ ganglioside often detectable. May respond to treatment with i.v. human immunoglobulin, plasmapheresis or cyclophosphamide.

3. Spinal muscular atrophy (SMA) – Diseases that usually present in infancy or childhood and affect only lower motor neurons.
 - *Type I SMA* (Werdnig-Hoffman disease) presents at birth with hypotonia, reduced movements, proximal weakness, wasting and reduced reflexes. Death before one year of age.
 - *Type II SMA* presents at about 6 months, and has a more protracted course. Death from respiratory failure before age of 10.
 - *Type III SMA* (Kugelberg-Welander disease) presents at about 10 years with life expectancy of about 35 years. Progression tends to be slower than lower motor neuron forms of MND.
 - *Type IV SMA* has an early adult onset. Survival may be normal.

Differential Diagnosis

Table 68 for the differential diagnosis of MND.

Madras MND - Young adults, slowly progressive asymmetrical wasting and weakness of limbs along with pyramidal involvement, resulting ultimately in features of ALS. Raised serum pyruvate levels.

Table 68: Differential diagnosis of MND	
Disorder/syndrome	Main diagnostic test
<i>Cerebral and brain disorders</i>	
• Infiltrating tumors	• Cranial MRI
• Vascular disorders	• Cranial MRI, CSF, ESR, C-reactive protein, autoantibodies (e.g. multifocal infarction, vasculitis, A-V malformations)
• Syringobulbia	• Cranial MRI
• Cranial neuropathies	• CSF, ESR, CRP, autoantibodies, EMG
• Creutzfeldt-Jakob disease	• EEG, prion gene analysis
<i>Spinal cord disorders</i>	
• Cervical radiculomyelopathy	• Cervical MRI, CT, myelography
• Cervical myelopathy with lumbosacral radiculopathy	• EMG studies, MRI
• Syringomyelia	• MRI
• Intramedullary tumours	• MRI
• Infiltrations (e.g. Ca, lymphoma)	• MRI, CSF analysis
• Infections (e.g. syphilis)	• Serological tests for syphilis.
• HIV-associated syndromes	• HIV antibodies
• HTLV-1-associated myelopathy	• HTLV-1 antibodies

Contd...

SPINOCEREBELLAR DEGENERATIONS

1. Friedreich's ataxia – (Refer)
2. Familial spastic paraplegia – Family history of pure motor paraparesis in siblings or parents. Usually patient presents in the first decade. Pes cavus is often present.
3. Abetalipoproteinaemia – If untreated may produce similar neurological picture.
4. Due to unknown biochemical abnormality – Hereditary spastic ataxia (Marie), hereditary areflexic dystasia (Roussy-Levy), and olivopontocerebellar atrophy.

21. CEREBELLUM AND ITS DISORDERS

ANATOMY

The cerebellum. Situated in the posterior fossa beneath the tentorium, and attached to the brainstem by the superior, middle and inferior peduncles, comprises two lateral hemispheres and the vermis which contains afferent and efferent nerve fibres.

Afferent Connections

Functionally, the cerebellar cortex is divided into three parts:

Contd...

Disorder/syndrome	Main diagnostic test
• Vasculitis	• ESR, CRP, autoantibodies
• Spinal A-V malformations	• MRI, myelography, spinal angiography
<i>Heredofamilial disorders mimicking MND</i>	
• Kennedy's syndrome	• EMG, androgen receptor mutation
• Late-onset spinal muscular atrophy	• EMG, gene mutation analysis
• Hexosaminidase A, B deficiency	• Enzyme analysis
<i>Metabolic and toxic disorders</i>	
• Thyrotoxicosis	• TSH, T4
• Hyperparathyroidism	• PTH, calcium
• Lead poisoning	• Lead levels in serum
<i>Neuromuscular disorders that may mimic MND</i>	
• Myasthenia gravis	• Edrophonium test, acetylcholine receptor antibody, RNS
• Lambert-Eaton syndrome	• EMG, calcium channel antibodies, RNS
• Myopathy (e.g. inclusion body myositis, scapuloperoneal dystrophy)	• EMG, muscle biopsy
• Multifocal motor neuropathy	• EMG, nerve conduction studies – conduction block

1. *Vestibulocerebellum* – (lower vermis), which receives afferents from the vestibular system.
2. *Spinocerebellum* – (upper vermis and anterior parts of the hemisphere), which receives afferents from the spinal cord.
3. *Neocerebellum* – (cerebellar hemispheres), which receive afferents from the cerebral cortex.

Efferent connections: Efferent fibres originate from the Purkinje cells and pass to either the vestibular nuclei or deep cerebellar nuclei, which gives rise to a variety of ascending and descending projections. Each cerebellar subdivision sends efferents principally to that part of the nervous system from which it receives its afferents.

Afferent connections (Table 69).

Table 70 gives conditions causing cerebellar dysfunction

CLINICAL FEATURES: OF CEREBELLAR LESION

A. Localizing value

- I. Disorders of postural fixation:
 1. *Hypotonia*.
 2. *No rebound* – on displacing the out stretched arm.
 3. *Pendular knee jerk*.
- II. Disorders of movements:
 1. *Intention tremor* – Increased irregularity of movement as the finger approaches the nose in finger-nose test.
 2. *Dysmetria* – Inability to arrest movement at desired point, e.g. exaggerated splaying of fingers in grasping a small object, or lifting the leg too high when attempting to place it on a chair with eyes shut.
 3. *Dyssynergia* – Defective co-ordination of various muscles and muscle groups participating in a movement, e.g. extending the trunk backwards

Table 69: Afferent cerebellar connections

Cerebellar cortex	Afferent connection	Dysfunction
Vestibulocerebellum (lower vermis)	Vestibular system	Truncal ataxia
Spinocerebellum	From spinal cord	Unsteadiness of gait and stance (positive Rombergism)
Neocerebellum	From cerebral cortex	Ataxia of intended limb movements (past-pointing, intention tremor)

without simultaneous flexion of the knees thus losing balance.

4. *Dysdiadochokinesia* – Disturbance of rapid alternating movements, e.g. rapid pronation and supination of forearm, or tapping the thigh alternately with the palm and the back of the hand.
 5. *Scanning speech*.
 6. *Head tilt* – suggests lesion of inferior vermis. (Trochlear nerve palsy and tonsillar herniation can also produce such abnormal posture).
- III. Disorders of gait:
1. Broad based and reeling gait.
 2. Deviation to side of lesion.
 3. Truncal ataxia (unsteadiness when seated). Spinocerebellar ataxia (SCA).

B. Non-localizing

1. Static tremors due to hypotonia.
2. Eye movements – (a) Nystagmus – In unilateral disease, amplitude and rate increase when looking towards diseased side. (b) Skew deviation. (c) Ocular dysmetria – An ‘overshoot’ when the eyes voluntarily fixate.

Table 70: Causes of cerebellar dysfunction

- I. **Acute:**
 1. *Infection* – Encephalitis, abscess, Guillain Barre variant.
 2. *Vascular* – Syndrome of posterior inferior cerebellar artery, anterior inferior cerebellar artery or superior cerebellar artery. Vertebrobasilar insufficiency.
 3. *Demyelinating* – Multiple sclerosis.
 4. *Drugs* – Phenytoin, barbiturates, streptomycin, gentamicin, kanamycin, piperazine citrate.
 5. *Toxic* – Alcohol.
 6. *Hyperpyrexia*.
- II. **Chronic:**
 1. *Developmental* – Agenesis, craniovertebral anomaly, Dandy Walker syndrome, von Hippel Lindau disease.
 2. *Familial* – e.g. Refsum’s disease, lipidoses, leucodystrophies.
 3. *Degenerative* – Primary cerebellar degeneration, olivopontocerebellar degeneration, olivorubrocerebellar degeneration, delayed cerebellar degeneration. Spinal cerebellar ataxia (SCA).
 4. *Neoplastic* – CP angle tumour, pontine tumour, cerebellar tumour.
 5. *Metabolic* – Alcohol, myxoedema, inborn errors of metabolism, non-metastatic manifestation of malignancy.

3. Disturbance of speech - Scanning dysarthria with speech occasionally delivered with sudden force - explosive staccato speech.
4. Vertigo - Objects move away from the side of lesion. Sense of rotation of the body in same direction with intra-cerebellar lesion, in opposite direction with extra-cerebellar lesion.
5. Titubation - Rhythmic nodding tremor of head from side to side or to and fro usually associated with distal limb tremor.
6. Pendular knee jerk.

INVESTIGATIONS

First-line

1. CT and MRI - will usually differentiate between cerebellar tumours, cerebellar stroke and other forms of cerebellar disease such as degeneration and demyelination.
2. Presence of antineural antibodies, MRI, CSF (paraneoplastic, neurologic disorders).
3. Thyroid function tests
4. Vitamin E
5. α -fetoprotein
6. Lipid profile
7. Investigations for malignancy (CXR, abdominal ultrasound)
8. Visual evoked response

Second-line

1. CSF - to detect cerebellar inflammation
2. Antineuronal antibodies (Paraneoplastic)
3. EMG - for neuropathy
4. SCA mutations, mitochondrial gene analysis
5. DRPLA mutation - if family history
6. Fundal examination - Angiomas in cerebellar angioblastoma.

DIFFERENTIAL DIAGNOSIS

Ataxia is clumsiness of movement in absence of motor and sensory deficit.

1. Cerebellar tumours - Ataxia, symptoms of increased intracranial pressure (caused by hydrocephalus due to obstruction of fourth ventricle). Astrocytomas and

medulloblastomas occur almost exclusively in children.

2. Cerebellar stroke - (a) *Infarction* - Patients present with vertigo, headache, vomiting and ataxia. May have signs of brainstem involvement including ipsilateral Horner's syndrome, contralateral hemisensory loss and cranial nerve involvement. (b) *Hemorrhage* - Symptoms are difficult to differentiate from infarction. Hypertension and anticoagulation are risk factors.
3. Inflammatory disease of cerebellum
 - (a) *Multiple sclerosis*. (b) *Brain abscess* secondary to disease in the ear and mastoid cells. (c) *Cerebellar encephalitis* - from viral infection, e.g. varicella, less often measles, mumps and rubella. Onset of cerebellar syndrome days or weeks after infection.
4. Degenerative and symptomatic ataxias
 - (a) *Friedreich's ataxia* - (Refer)
 - (b) *Ataxia-telangiectasia* - starts in early childhood. Combination of neurological symptoms (ataxia, choreoathetosis, defective horizontal conjugate gaze), cutaneous and conjunctival telangiectasias, immunological abnormalities which predispose to recurrent infections and increased incidence of malignancies. Increased levels of serum α -fetoprotein.
 - (c) *Multiple system atrophy* - (Refer)
 - (d) *Episodic ataxias* - Autosomal dominant inherited disorders which differ from other types of ADCAs by the intermittent nature of the ataxia, which may last from minutes to a few days. Frequency of attacks is reduced by acetazolamide.
 - (e) *Idiopathic cerebellar ataxia* (IDCA) - A sporadically occurring disorder of unknown cause characterised by progressive ataxia. Onset usually at age of 50-60 years. Additional extra-cerebellar symptoms (parkinsonism, autonomic failure, spasticity, bulbar symptoms). Olivopontocerebellar atrophy is the pathological lesion.
 - (f) *Spinocerebellar ataxia* - (SCA) - Autosomal dominant. Progressive cerebellar syndrome with ataxia of stance and gait of limb movements, dysarthria and oculomotor abnormalities such as gaze paresis. Also corticospinal tract signs - spasticity, extensor plantars, diminished vibration sense, dysphagia.
 - (g) *Abetalipoproteinaemia or toxins* - anti-epileptic drugs, lithium, cyclosporine.

(h) *Immune-mediated:*

- Multiple sclerosis
- Miller Fisher syndrome
- SLE
- Paraneoplastic (small cell lung ca, breast or ovary).

(i) *Symptomatic ataxia* - Sporadically occurring ataxias due to toxic, endocrinological, paraneoplastic, nutritional or infectious causes. (i) *Ataxia due to alcoholism* - Ataxic gait, postural tremor. No major involvement of the upper extremities. Pathological changes comprise loss of Purkinje cells of vermis and anterior parts of cerebellar hemispheres resulting in a typical pattern of atrophy in imaging studies. (ii) *Due to - Antidepressants, antiepileptic drugs lithium, cyclosporine, metronidazole.* (iii) *Paraneoplastic cerebellar ataxia* - An uncommon manifestation of cancer, usually associated with ovarian, breast or small cell lung cancer or Hodgkin's disease. Patients present with subacute onset of a cerebellar syndrome, with severe ataxia, oculomotor abnormalities and dysarthria. The presence of auto-antibodies recognizing neural antigen suggests an immune-mediated disorder.

(j) *Spinocerebellar ataxia* (Table 71).

22. MYOPATHIES

The term myopathy may be used to define any disease in which the patient's symptoms and/or physical signs can be attributed to pathological, biochemical or electrical changes which are occurring in the muscle fibres or in the interstitial tissues of the voluntary musculature, and in which there is no evidence that the symptoms related to the muscles are in any way secondary to disordered function of the central or peripheral nervous system.

Table 71: Distinguishing features of cerebellar and sensory ataxia

	<i>Cerebellar ataxia</i>	<i>Sensory ataxia</i>
Muscle power	Normal	May be reduced
Deep reflexes	Pendular	Absent
Post. column signs	Absent	Present
Neuropathic features	Absent	May be present
Romberg's sign	Negative	Positive
Gait	Broad based	Stamping

Muscle disorders may be genetically determined or may result from autoimmune disorders, systemic diseases or the effects of a variety of exogenous toxins. They can be classified in terms of causative genetic mutations, by specific protein deficiencies, on the basis of histopathological changes, by pathogenic mechanisms, and by clinical phenotype.

GENETICALLY DETERMINED MYOPATHIES

There are four main groups of genetic myopathies:

1. **Muscular dystrophies** are due to abnormal muscle protein and generally characterized by fibre necrosis and replacement of muscle by fat and fibrous connective tissue. Different types of muscular dystrophy can be recognised by clinical features (e.g. muscle hypertrophy, contractures, evidence of cardiac involvement, and by the pattern of involvement of muscle groups). Three main pattern are - axial and limb girdle weakness, non-limb girdle weakness pattern with prominent involvement of cranial musculature, and distal weakness.
2. **Congenital myopathies** are classified by specific histological and ultrastructural features.
3. **Myotonias and periodic paralyses** are associated with disturbance of muscle ion channels (muscle channelopathies).
4. **Genetically determined metabolic myopathies** include disorders of glycogen and lipid metabolism, malignant hyperthermia and mitochondrial cytopathies.

Muscular dystrophies - with predominantly axial and limb girdle weakness.

Pseudo-hypertrophic muscular dystrophy - [Duchenne muscular dystrophy (DMD)].

Aetiology - Age - 5 to 10 years, rare after puberty. Sex - X-linked recessive disease is confined to males, though occasionally seen in females with Turner's syndrome. Familial - exhibited by males but transmitted by females.

Clinical Features

1. **Onset** - gradual, clumsiness and frequent falls.
2. **Attitude on standing** - Marked lordosis of lumbar spine, shoulders held far back and scapulae project. The large size of the buttocks makes the lordosis appear more accentuated than it is in reality. Abdomen protuberant.
3. **Muscles** - Usually involved symmetrically: (i) Hypertrophy of - deltoid, infra-spinal, glutei, quadriceps and calf muscles; less often supraspinati, triceps and biceps; rarely serratus anterior, muscles of forearms and masseters. Macroglossia is sometimes observed. (ii) Atrophy of - lower portion of pectoralis major,

biceps, latissimus dorsi and thigh muscles. (iii) Muscles not affected - hands and face. The weakness of the shoulder girdle muscles is easily demonstrated by picking the child up under his arms, when the arms go up and the child tends to slip through one's hands.

4. *Gait* - When walking the child waddles. The trunk and head are usually held very erect. In sitting, the lordosis, which is present on sitting passes into a kyphosis, the back being bent according to the degree of weakness of the dorsal muscles.
5. *Rising from the ground* (Gower's sign) - The child attempts to rise by 'walking up his legs'. This manoeuvre may be considered pathognomonic of the disease.
6. *Cardiomyopathy* - seen in almost all patients. Congestive heart failure seldom occurs except with severe stress such as pneumonia. Cardiac arrhythmias are rare. The typical electrocardiogram (ECG) shows an increased net RS in lead V1; deep, narrow Q waves in the precordial leads; and tall right precordial R waves in V1.
7. *Intellectual impairment* - in Duchenne dystrophy is common

Progress - Death usually occurs between ages of 18-22 years from respiratory infection and/ or cardiac failure.

Becker muscular dystrophy - Age of onset 3 to 20 years, similar clinical picture as DMD, but clinical course much more benign. Myocardial and intellectual impairment is much less common. Exertional myalgia is a common presenting symptom. Calf muscle enlargement is often striking. Death occurs between 30-60 years of age.

Pathogenesis - BMD and DMD are forms of dystrophinopathy. Dystrophin, a component of the cytoskeleton lying beneath the muscle fibre, is one of the largest proteins in the body. Dystrophin deficiency results in loss of structural integrity of the muscle surface membrane. Mutations of the encoding gene may be 'out of frame' resulting in complete absence of dystrophin, causing DMD, or 'in frame' producing partial dystrophin deficiency characteristic of BMD.

Diagnosis of dystrophinopathy may be suggested by the history and physical signs, with very high serum creatinine kinase (CK), and can usually be confirmed by standard DNA analysis which detect the common dystrophin gene deletions in 70% of patients. Most patients require muscle biopsy.

Management - Prednisolone 0.5-1.5 mg/day has been shown to improve natural history of DMD for up to 2 years. Gene therapy, using myoblasts and other cells transfected with the dystrophin mini-gene may restore muscle dys-

trophin. Otherwise physical therapy, use of orthoses and surgical correction of spinal and other deformities.

Muscular dystrophy in females - DMD and BMD have occasionally been reported in females in patients with Turner's syndrome. In about 65% of cases, the mothers are carriers of the gene. A proportion of adult females with limb-girdle myopathies will be 'manifesting' carriers of either DMD or BMD.

Limb-girdle muscular dystrophies (LGMDs) - LGMDs are a complex, genetically heterogeneous group of disorders, but can be divided into two broad clinical groups:

Milder forms usually present between 20-30 years of age, with progressive difficulty in walking followed by proximal arm weakness and loss of ambulation after 20-30 years; however age of onset and progression vary. Neck and shoulder muscles become weak. Muscles of shoulder and pelvic girdles, and proximal arm and leg muscles become weak and wasted. Distal involvement and calf hypertrophy is variable. Bilateral scapular winging is typical and often early feature.

Severe forms present in childhood. Severe childhood autosomal recessive muscular dystrophy (SCARMD) is clinically similar to DMD and is the most common cause of a DMD-like phenotype in girls. However cardiac and mental function are unaffected.

CK levels are increased by tenfold to more than 100-fold. Biopsy findings may range from mild, nonspecific dystrophic changes in milder forms to severe, often very focal fibre necrosis in SCARMD.

Emery-Dreifuss muscular dystrophy (EDMD) presents in childhood with progressive weakness and wasting of the scapulohumeral and anterior tibial and peroneal muscle groups. It accounts for most forms of 'scapuloperoneal muscular dystrophy'. Muscle contractures develop at an early stage, leading to pathognomonic posture, elbow flexion, equinovarus ankle deformities and fixed neck flexion. Cardiac involvement leads to serious conduction disorders and sometimes sudden death.

Bethlem myopathy is a relatively benign, autosomal dominant condition that progresses insidiously from infancy, causing increasing difficulty with running, then walking and standing. Significant disability develops in old age. Characteristic contractures of the fingers but not thumbs ('prayer sign') are diagnostic and associated with contractures of the elbows and equinovarus ankle deformities. The disease is caused by a deficiency of type IV collagen in the extracellular matrix of muscle fibres.

Congenital muscular dystrophies – One of the causes of ‘the floppy infant’. Myopathy manifests at birth or early life. Small, weak, hypotonic muscles, proximal usually more affected than distal. Both sexes.

NON-LIMB-GIRDLE PATTERN MUSCULAR DYSTROPHIES WITH INVOLVEMENT OF CRANIAL MUSCULATURE

Facioscapulohumeral muscular dystrophy – AD transmission. Either sex. Onset usually in adolescence. Initial involvement, sometimes symmetrical, of facial and shoulder-girdle muscles, soon followed by weakness of anterior tibial and peroneal muscles, usually with spread within 20 or 30 years to pelvic muscles. Profound facial weakness produces pouting of the lips and a transverse smile. Inability to whistle is characteristic. In later stages, dramatic scapular fixators allows ‘over-riding’ of the scapulae above the shoulders, like a pair of wings. Foot drop and later proximal weakness can occur. Diagnostic confirmation depends on demonstration of abnormally small 4q35-specific DNA fragments following digestion with restriction site enzymes.

Oculopharyngeal muscular dystrophy presents with ptosis and weakness of extraocular muscles, muscles of the pharynx and larynx (causing progressive dysphagia and dysphonia), and facial, limb-girdle and even distal muscles. Cases may be mild to severe and present typically in the sixth decade.

Muscle biopsy can show changes which may include rimmed vacuoles and ragged red fibres typical of mitochondrial myopathy.

Distal myopathies

Several neuromuscular diseases present with distal weakness and wasting of the limbs.

Welander’s, Udd’s and Markesbery-Griggs type distal myopathies are all late-onset, dominantly inherited disorders of distal limb muscles, usually beginning after age 40 years.

Laing’s distal myopathy is also a dominantly inherited disorder heralded by tibial weakness; it is distinguished by onset in childhood or early adult life.

Nonaka’s distal myopathy and Miyoshi’s myopathy are distinguished by autosomal recessive inheritance and onset in the late teens or twenties.

Congenital myopathies are classified on basis of specific histological features. Patients can present at any time from childhood to adult life, usually with distal weakness.

A long, thin face and high arched palate are common. This group of disorders includes centronuclear and myotubular myopathies, nemaline myopathy and central core disease.

Myotonic disorders – Myotonia is prolonged contraction of muscle, with subsequent slowed relaxation, following activation. It results from genetic or acquired changes in excitability of muscle surface membranes and is found in several primary muscle diseases.

DYSTROPHIC MYOTONIAS

Myotonic dystrophy is the most common inherited muscular dystrophy in adults. The characteristic phenotype includes, in addition to grip and percussion myotonia:

- Progressive muscular weakness and wasting starting distally
- Bilateral ptosis and facial muscle weakness, temporalis and masseter muscle atrophy and weakness – “hatchet face”
- Sternomastoid wasting
- Cataracts
- Endocrinopathy, notably insulin resistance
- Cardiac conduction defects, which can lead to sudden death
- Bulbar and respiratory muscle weakness
- Dysphagia and gut dysfunction
- Frontal balding and calcifying epithelioma of Malherbe
- In severe cases, mental retardation

Other features of the disease cataracts, testicular atrophy, insulin resistance, constipation, hypersomnia and cognitive defects.

Laboratory Features—The Diagnosis of Myotonic Dystrophy

Gene expression can vary from asymptomatic cases with no clinical signs, to severe congenital onset disease.

Proximal myotonic myopathy is clinically and genetically distinct from myotonic dystrophy but shares a number of phenotypic features. Weakness starts and is mainly confined to proximal muscles, and cramps are common.

Non-dystrophic myotonias and periodic paralyses – A number of familial muscle diseases have been shown to result from mutations of genes encoding muscle ion channels. The defects can lead to a phenotype in which myotonia is the major manifestation, as in myotonia congenita (chloride channelopathy), or to episodic weakness, as in

hyperkalaemic periodic paralysis (calcium channelopathy). Sodium channel mutations lead to a complex mixture of phenotypes in which myotonic stiffness or periodic weakness can occur under various conditions (e.g. exercise, exposure to cold). Periodic paralysis presents with episodic, profound muscular weakness, not involving breathing and with normal consciousness, with abnormal serum potassium. Hyperkalaemic periodic paralysis is associated with myotonia, the hyperkalaemic form is not.

GENETICALLY DETERMINED METABOLIC MYOPATHIES

Disorders of intermediary metabolism – Certain genetic disorders of intermediary metabolism can affect muscle particularly or exclusively.

Pompe's Disease – Three clinical forms of α glucosidase, or acid maltase, deficiency (type II glycogenosis) can be distinguished. The infantile form is the most common, with onset of symptoms in the first 3 months of life. Infants develop severe muscle weakness, cardiomegaly, hepatomegaly and respiratory insufficiency. Glycogen accumulation in motor neurons of the spinal cord and brainstem contributes to muscle weakness. Death usually occurs by 1 year of age.
